APPENDIX H

Assurance Statements

APPENDIX A-1: DESIGN ENGINEER'S SITE CHARACTERIZATION ASSURANCE STATEMENT

To: The Owner(s) Date: 18 September 2023

Name: Mount Polley Mining Corporation

Address: PO Box 12, Likely, BC, V0L 1N0

For the dam:

UTM (Location): Zone IOU; Easting 595,768; Northing 5,818,548

Located at (Description): near Likely, BC

Name of dam or description: Mount Polley Tailings Storage Facility

Provincial dam number: Permit M-200

Dam function: Tailings Storage

Current *project stage* is:

Check one

☐ Feasibility design
☐ Detailed design
▪ Construction/operations

The undersigned hereby gives assurance that he/she is a qualified APEGBC-registered professional and is a professional engineer and is the **Design Engineer** for the dam project identified above.

I have signed, sealed, and dated the attached dam site characterization report in accordance with the *APEGBC Professional Practice Guidelines – Site Characterization for Dam Foundations in BC*. The report must be read in conjunction with this Assurance Statement.

In preparing the dam site characterization report, I have completed the following activities:

(Check the applicable items)

Completed by the Design Engineer	Activity
X	Collected and reviewed available and relevant background information, documentation, and data
X	Visited the site and reviewed the conditions in the field that may be relevant for site characterization
X	Developed and executed a site characterization program that provides information to support the design of the dam, subject to the qualifications noted
X	Reviewed previous site characterization studies and data and updated the dam site characterization assessment report to include all data and, where appropriate, revised interpretations of data
X	Assessed potential areas of risk identified during site characterization programs to date and, as far as is practical, addressed the risks
X	Evaluated the level of complexity of the site and documented how it was assessed and supported by the site characterization program(s)
X	Reviewed and accepted all assurance statements submitted by the supporting registered professionals (SRPs)
X	Prepared a data record report
X	Prepared the dam site characterization report, which interprets the site conditions

In preparing the dam site characterization report, I have completed the following activities or reviewed and accepted such activities completed by a supporting registered professional (SRP):

(Check the applicable items)

Completed by the Design Engineer	Completed by the SRP, and reviewed and accepted by the Design Engineer	Activity
	X	Assessed the surficial and bedrock geological models to confirm that they adequately support the understanding of the spatial variability of the geotechnical properties of the foundation materials
X		Carried out sufficient in situ and laboratory testing to quantify the geotechnical properties of the foundation materials
X		Assessed the strength properties of the foundation materials with consideration of stress state and response to loadings
	X	Assessed the hydrogeological properties of the foundation materials with consideration of potential hydraulic gradients, artesian pressures, and seepage flow paths
	X	Assessed the seismotectonic conditions to provide a basis for the seismic hazard analysis of the dam
X	X	Evaluated the level of complexity of the site and documented how it was assessed and supported by the site characterization program(s)
X		Reviewed and accepted all assurance statements submitted by the supporting registered professionals (SRPs)
X	X	Prepared a data record report
X	X	Prepared the dam site characterization report, which interprets the site conditions

I hereby give my assurance that based on the attached dam site characterization report, at this point in time:

Check one

- [x] The dam site characterization report is reasonably comprehensive and supports the design of the dam.
- [ ] The dam site characterization report is not sufficiently comprehensive to support the design of the dam, in that the dam site characterization report identifies areas of potential concern that require additional investigation as set out in section(s) _____ of the attached dam site characterization report

To: The Design Engineer Date: 5 September 2023

Name: Germán Pizarro-Sala

Address: WSP Canada Inc

840 Howe Street, #1000, Vancouver BC, V6Z 2M1, Canada

For the dam:

UTM (Location): Zone: IOU; Easting 595768.72 m; Northing 5818548.36 m

Located at (Description): near Likely, British Columbia

Name of dam or description: TSF Embankment

Dam function: tailings storage

Owned by: Mount Polley Mining Corporation (MPMC)

Current project stage is:

Check one

☐ Feasibility design
☐ Detailed design
☒ Construction/operations

This is to advise that the undersigned is a **supporting registered professional** (SRP) retained by MPMC to carry out supporting professional services for the dam.

I undertook supporting professional services in the following:

(Check applicable sections)

☐ Bedrock/structural geology
☐ Surficial geology
☐ Geotechnical investigations
☒ Hydrogeology
☐ Seismotectonic investigations
☐ Other

The undersigned hereby gives assurance that the

hydrogeological and geochemical assessment

and the documents prepared by this supporting registered professional for the project have been carried out in a manner that meets the intent of the applicable APEGBC guidelines and good professional practice.

These professional services are described, and the results of them reported on in the documents prepared by me, or under my direct supervision, which bear my professional seal.

(With respect to field reviews, initial the following statements, as applicable. Leave blank those that are not applicable.)

_____ Field review(s) are not applicable

CR Field review(s) are applicable:

CR I have performed field review(s) for the services identified above. (field review: 30 May 2022 to 1 June 2022)

_____ Field review(s) have been performed by _____.

I confirm that I have communicated and liaised as required with the appropriate APEGBC professionals for the purposes of my services.

I hereby give my assurance that I am an APEGBC-registered professional.

APPENDIX 1-5: Author Statements

BRITISH COLUMBIA | Ministry of Environment and Climate Change Strategy

Declaration of Competency

The Ministry of Environment and Climate Change Strategy relies on the work, advice, recommendations and in some cases decision making of qualified professionals[1], under government's professional reliance regime. With this comes an assumption that professionals who undertake work in relation to ministry legislation, regulations and codes of practice have the knowledge, experience and objectivity necessary to fulfill this role.

1. Name of Qualified Professional Chris Dodd

   Title Registered Professional Consulting Archaeologist

2. Are you a registered member of a professional association in B.C.? ☒ Yes ☐ No

   Name of Association: BC Association of Professional Archaeologists Registration # n/a

3. Brief description of professional services:

   Archaeological input for Section 2.12-Archaeology and Section 9.11-Archaeological Management and Impact Mitigation for the Springer Pit Expansion Joint Application

This declaration of competency is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. By signing and submitting this statement you consent to its publication and its disclosure outside of Canada. This consent is valid from the date submitted and cannot be revoked. If you have any questions about the collection, use or disclosure of your personal information please contact the Ministry of Environment and Climate Change Strategy Headquarters Office at 1-800-663-7867.

Declaration

I am a qualified professional with the knowledge, skills and experience to provide expert information, advice and/or recommendations in relation to the specific work described above.

Signature:

X

Print Name: Chris Dodd

Witnessed by:

X

Print Name: Konain Sajid

Date signed: Nov 28, 2023

[1] *Qualified Professional, in relation to a duty or function under ministry legislation, means an individual who*

a) *is registered in British Columbia with a professional association, is acting under that organization's code of ethics, and is subject to disciplinary action by that association, and*

b) *through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.*

BRITISH COLUMBIA | Ministry of Environment and Climate Change Strategy

Conflict of Interest Disclosure Statement

A qualified professional [1] providing services to either the Ministry of Environment and Climate Change Strategy ("ministry"), or to a regulated person for the purpose of obtaining an authorization from the ministry, or pursuant to a requirement imposed under the *Environmental Management Act*, the *Integrated Pest Management Act* or the *Park Act* has a real or perceived conflict of interest when the qualified professional, or their relatives, close associates or personal friends have a financial or other interest in the outcome of the work being performed.

A real or perceived conflict of interest occurs when a qualified professional has

a) an ownership interest in the regulated person's business;

b) an opportunity to influence a decision that leads to financial benefits from the regulated person or their business other than a standard fee for service (e.g. bonuses, stock options, other profit sharing arrangements);

c) a personal or professional interest in a specific outcome;

d) the promise of a long term or ongoing business relationship with the regulated person, that is contingent upon a specific outcome of work;

e) a spouse or other family member who will benefit from a specific outcome; or

f) any other interest that could be perceived as a threat to the independence or objectivity of the qualified professional in performing a duty or function.

Qualified professionals who work under ministry legislation must take care in the conduct of their work that potential conflicts of interest within their control are avoided or mitigated. Precise rules in conflict of interest are not possible and professionals must rely on guidance of their professional associations, their common sense, conscience and sense of personal integrity.

Declaration

I Chris Dodd (Print Name), as a member of BC Association of Professional Archaeologists declare

Select one of the following:

☒ Absence from conflict of interest

Other than the standard fee I will receive for my professional services, I have no financial or other interest in the outcome of this Springer Pit Expansion Joint Application (Name of Application/Project/Work).
I further declare that should a conflict of interest arise in the future during the course of this work, I will fully disclose the circumstances in writing and without delay to Luc LaChance (Name of Contact), erring on the side of caution.

BRITISH COLUMBIA | Ministry of Environment and Climate Change Strategy

☐ Real or perceived conflict of interest

Description and nature of conflict(s):

_____

_____

_____

I will maintain my objectivity, conducting my work in accordance with my Code of Ethics and standards of practice.

In addition, I will take the following steps to mitigate the real or perceived conflict(s) I have disclosed, to ensure the public interest remains paramount:

_____

_____

_____

Further, I acknowledge that this disclosure may be interpreted as a threat to my independence and will be considered by the statutory decision maker accordingly.

This conflict of interest disclosure statement is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. By signing and submitting this statement you consent to its publication and its disclosure outside of Canada. This consent is valid from the date submitted and cannot be revoked. If you have any questions about the collection, use or disclosure of your personal information please contact the Ministry of Environment and Climate Change Strategy Headquarters Office at 1-800-663-7867.

Declaration of Competency

The Ministry of Environment and Climate Change Strategy relies on the work, advice, recommendations and in some cases decision making of qualified professionals[1], under government's professional reliance regime. With this comes an assumption that professionals who undertake work in relation to ministry legislation, regulations and codes of practice have the knowledge, experience and objectivity necessary to fulfill this role.

1. Name of Qualified Professional Jacqueline Foley

   Title Senior Principal Hydrogeologist

2. Are you a registered member of a professional association in B.C.? ☒ Yes ☐ No

   Name of Association: Engineers and Geoscientists BC Registration # 130626

3. Brief description of professional services:

   Provided hydrogeological support and technical oversite in support of the permit application.

This declaration of competency is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. By signing and submitting this statement you consent to its publication and its disclosure outside of Canada. This consent is valid from the date submitted and cannot be revoked. If you have any questions about the collection, use or disclosure of your personal information please contact the Ministry of Environment and Climate Change Strategy Headquarters Office at 1-800-663-7867.

Declaration

I am a qualified professional with the knowledge, skills and experience to provide expert information, advice and/or recommendations in relation to the specific work described above.

[1] *Qualified Professional, in relation to a duty or function under ministry legislation, means an individual who*

a) is registered in British Columbia with a professional association, is acting under that organization's code of ethics, and is subject to disciplinary action by that association, and

b) *through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.*

Ministry of Environment and Climate Change Strategy

Conflict of Interest Disclosure Statement

A qualified professional [1] providing services to either the Ministry of Environment and Climate Change Strategy ("ministry"), or to a regulated person for the purpose of obtaining an authorization from the ministry, or pursuant to a requirement imposed under the *Environmental Management Act,* the *Integrated Pest Management Act* or the *Park Act* has a real or perceived conflict of interest when the qualified professional, or their relatives, close associates or personal friends have a financial or other interest in the outcome of the work being performed.

A real or perceived conflict of interest occurs when a qualified professional has

a) an ownership interest in the regulated person's business;

b) an opportunity to influence a decision that leads to financial benefits from the regulated person or their business other than a standard fee for service (e.g. bonuses, stock options, other profit sharing arrangements);

c) a personal or professional interest in a specific outcome;

d) the promise of a long term or ongoing business relationship with the regulated person, that is contingent upon a specific outcome of work;

e) a spouse or other family member who will benefit from a specific outcome; or

f) any other interest that could be perceived as a threat to the independence or objectivity of the qualified professional in performing a duty or function.

Qualified professionals who work under ministry legislation must take care in the conduct of their work that potential conflicts of interest within their control are avoided or mitigated. Precise rules in conflict of interest are not possible and professionals must rely on guidance of their professional associations, their common sense, conscience and sense of personal integrity.

Declaration

I Jacqueline Foley (Print First and Last Name), as a member of Engineers and Geoscientists of BC (Print Name of Professional Association) declare

Select one of the following:

☑ Absence from conflict of interest

Other than the standard fee I will receive for my professional services, I have no financial or other interest in the outcome of this application/assessment (application/project/work/etc.).
I further declare that should a conflict of interest arise in the future during the course of this work, I will fully disclose the circumstances in writing and without delay to Ministry of Environment and Climate Change Strategy (Ministry/Crown Agency), erring on the side of caution.

☐ Real or perceived conflict of interest

Description and nature of conflict(s):

I will maintain my objectivity, conducting my work in accordance with my Code of Ethics and standards of practice.

In addition, I will take the following steps to mitigate the real or perceived conflict(s) I have disclosed, to ensure the public interest remains paramount:

Further, I acknowledge that this disclosure may be interpreted as a threat to my independence and will be considered by the statutory decision maker accordingly.

This conflict of interest disclosure statement is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. By signing and submitting this statement you consent to its publication and its disclosure outside of Canada. This consent is valid from the date submitted and cannot be revoked. If you have any questions about the collection, use or disclosure of your personal information please contact the Ministry of Environment and Climate Change Strategy Headquarters Office at 1-800-663-7867.

[1]*Qualified Professional, in relation to a duty or function under ministry legislation, means an individual who*

a) is registered in British Columbia with a professional association, is acting under that organization's code of ethics, and is subject to disciplinary action by that association, and

b) *through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.*

Ministry of Environment and Climate Change Strategy

Declaration of Competency

The Ministry of Environment and Climate Change Strategy relies on the work, advice, recommendations and in some cases decision making of qualified professionals[1], under government's professional reliance regime. With this comes an assumption that professionals who undertake work in relation to ministry legislation, regulations and codes of practice have the knowledge, experience and objectivity necessary to fulfill this role.

1. Name of Qualified Professional Andrew McIntosh

Title Certified Erosion and Sediment Control Lead

2. Are you a registered member of a professional association in B.C.? ☒ Yes ☐ No

Name of Association: ESCA-BC Registration # 210306

3. Brief description of professional services:

Review and update of site Erosion and Sediment Control Management Plan

This declaration of competency is collected under section 26(c) of the *Freedom of Information and Protection of Privacy Act* for the purposes of increasing government transparency and ensuring professional ethics and accountability. By signing and submitting this statement you consent to its publication and its disclosure outside of Canada. This consent is valid from the date submitted and cannot be revoked. [1] *Qualified Professional, in relation to a duty or function under ministry legislation, means an individual who*

a) is registered in British Columbia with a professional association, is acting under that organization's code of ethics, and is subject to disciplinary action by that association, and

b) *through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.*

Ministry of Environment and Climate Change Strategy

Conflict of Interest Disclosure Statement

A qualified professional [1] providing services to either the Ministry of Environment and Climate Change Strategy ("ministry"), or to a regulated person for the purpose of obtaining an authorization from the ministry, or pursuant to a requirement imposed under the *Environmental Management Act,* the *Integrated Pest Management Act* or the *Park Act* has a real or perceived conflict of interest when the qualified professional, or their relatives, close associates or personal friends have a financial or other interest in the outcome of the work being performed.

A real or perceived conflict of interest occurs when a qualified professional has

a) an ownership interest in the regulated person's business;

b) an opportunity to influence a decision that leads to financial benefits from the regulated person or their business other than a standard fee for service (e.g. bonuses, stock options, other profit sharing arrangements);

c) a personal or professional interest in a specific outcome;

d) the promise of a long term or ongoing business relationship with the regulated person, that is contingent upon a specific outcome of work;

e) a spouse or other family member who will benefit from a specific outcome; or

f) any other interest that could be perceived as a threat to the independence or objectivity of the qualified professional in performing a duty or function.

Qualified professionals who work under ministry legislation must take care in the conduct of their work that potential conflicts of interest within their control are avoided or mitigated. Precise rules in conflict of interest are not possible and professionals must rely on guidance of their professional associations, their common sense, conscience and sense of personal integrity.

Declaration

I Andrew McIntosh (Insert First and Last Name), as a member of ESCA-BC (Insert Professional Association) declare

Select one of the following:

☒ Absence from conflict of interest

Other than the standard fee I will receive for my professional services, I have no financial or other interest in the outcome of this Application (application/project/work/etc.).
I further declare that should a conflict of interest arise in the future during the course of this work, I will fully disclose the circumstances in writing and without delay to EMLI (Insert Ministry Contact Name), erring on the side of caution.

☐ Real or perceived conflict of interest

Description and nature of conflict(s):

_____

_____

_____

I will maintain my objectivity, conducting my work in accordance with my Code of Ethics and standards of practice.

In addition, I will take the following steps to mitigate the real or perceived conflict(s) I have disclosed, to ensure the public interest remains paramount:

_____

_____

_____

Further, I acknowledge that this disclosure may be interpreted as a threat to my independence and will be considered by the statutory decision maker accordingly.

Executive Summary

This report provides a five-year update of climate baseline at Mount Polley Mine site (the Site) owned and operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. Updated baseline statistics are presented for precipitation (total precipitation, rainfall), air temperature, relative humidity, solar radiation, evaporation, snow depths, wind speed and directions. Updated climate change projections for the Site are also provided.

The 1974 to 1993 climate records from the nearby Environment and Climate Change Canada (ECCC) Likely climate station and 1995 to 2021 climate records from the local MPMC climate stations served as the basis for developing statistics for describing precipitation and temperature conditions for the Site. Records from regional and MPMC climate stations were reviewed to assist in characterizing climate parameters, such as relative humidity and solar radiation, and to support the identification of spatial trends. Local and regional climate station data were interrogated for inconsistencies or gaps, and then infilled using regional data and translation factors.

A summary of the updated baseline climate parameters developed in this study is provided in Table 1. The trends in climate parameters at the Site are similar to those at the ECCC regional stations considered in the study. An evaluation of future climate change projections indicates future climate at the Site will likely be warmer and wetter, with larger variations throughout the months.

Table 1: Summary of Key Mount Polley Climate Parameters

Parameter	Value
Mean annual total precipitation (mm)	612
1:2-year 24-hour rainfall (mm)	33
1:200-year 24-hour rainfall (mm)	69
Projected annual total precipitation anomaly from baseline for 2050's (%)	+5
Projected annual total precipitation anomaly from baseline for 2080's (%)	+8
Mean annual temperature (°C)	3.9
Average winter season (sub-zero mean monthly temperatures)	November to March
Projected annual air temperature anomaly from baseline for 2050's (°C)	+1.8
Projected annual air temperature anomaly from baseline for 2080's (°C)	+2.7
Mean annual relative humidity (%)	68.1
Mean annual solar radiation (W/m^2)	135
Mean annual shallow lake evaporation (mm)	673
Mean annual potential evapotranspiration (mm)	863
Mean snow water equivalent for the month of March (mm)	185

Note: Statistics are based on reviewed historical records from multiple climate stations and measured and derived data (where applicable).
mm = millimetre; ˚C = degrees Celsius; W/m^2 = watts per square metre.

Study Limitations

Golder Associates Ltd., a member of WSP (WSP Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings, and other documents contained herein, has been prepared by WSP Golder for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents WSP Golder's professional judgement based on the knowledge and information available at the time of completion. WSP Golder is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations, and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to WSP Golder by MPMC, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations, and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings, and other documents contained herein, as well as all electronic media prepared by WSP Golder are considered its professional work product and shall remain the copyright property of WSP Golder. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration, and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

1.0 INTRODUCTION

1.1 Overview

Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation, owns and operates the Mount Polley Mine (the Mine). The Mine is a copper-gold mine located 56 km northeast of Williams Lake, British Columbia (BC).

1.2 Purpose

Guidance from the Global Industry Standard on Tailings Management (GISTM) published by the International Council on Mining & Metals (ICMM) (2020) stipulates under Requirement 2.1 that the environmental knowledge base including climate parameters should be updated every five years to capture uncertainties due to climate change.

The last climate baseline for the Mine site (the Site) was carried out by Golder Associates Ltd., a member of WSP (WSP Golder) in 2016, and MPMC has retained WSP Golder to prepare an update. The purpose of the update is to extend the existing long-term climate dataset for the Site using local and regional data collected in the last 5 years in support of design activities.

This report provides a climate baseline update for precipitation, air temperature, relative humidity, solar radiation, evaporation, wind speed and direction, and snow depths, and includes updated climate change projections for the Site.

1.3 Scope

The scope of work for this climate study included:

- Literature review of previous descriptions of climate conditions near the Site study area.
- Statistical analysis of historical climate records at different locations near the Site study area to develop statistics for climate variables, including precipitation (total precipitation, rainfall), air temperature, relative humidity, solar radiation, wind speed and direction, and snow cover properties.
- Mathematical modelling to calculate evaporation and potential evapotranspiration statistics for the Site study area.
- Statistical analysis of point climate data from downscaled circulation models using Shared Socioeconomic Pathways scenarios (ECCC 2022c) for future climate projections for the Site study area.

2.0 STUDY AREAS

The Site is located 56 km northwest of Williams Lake, British Columbia (BC) near the eastern edge of the Fraser Plateau physiographic subdivision, approximately 10 km west of its boundary with the Quesnel Highland subdivision, as defined by Holland (1976).

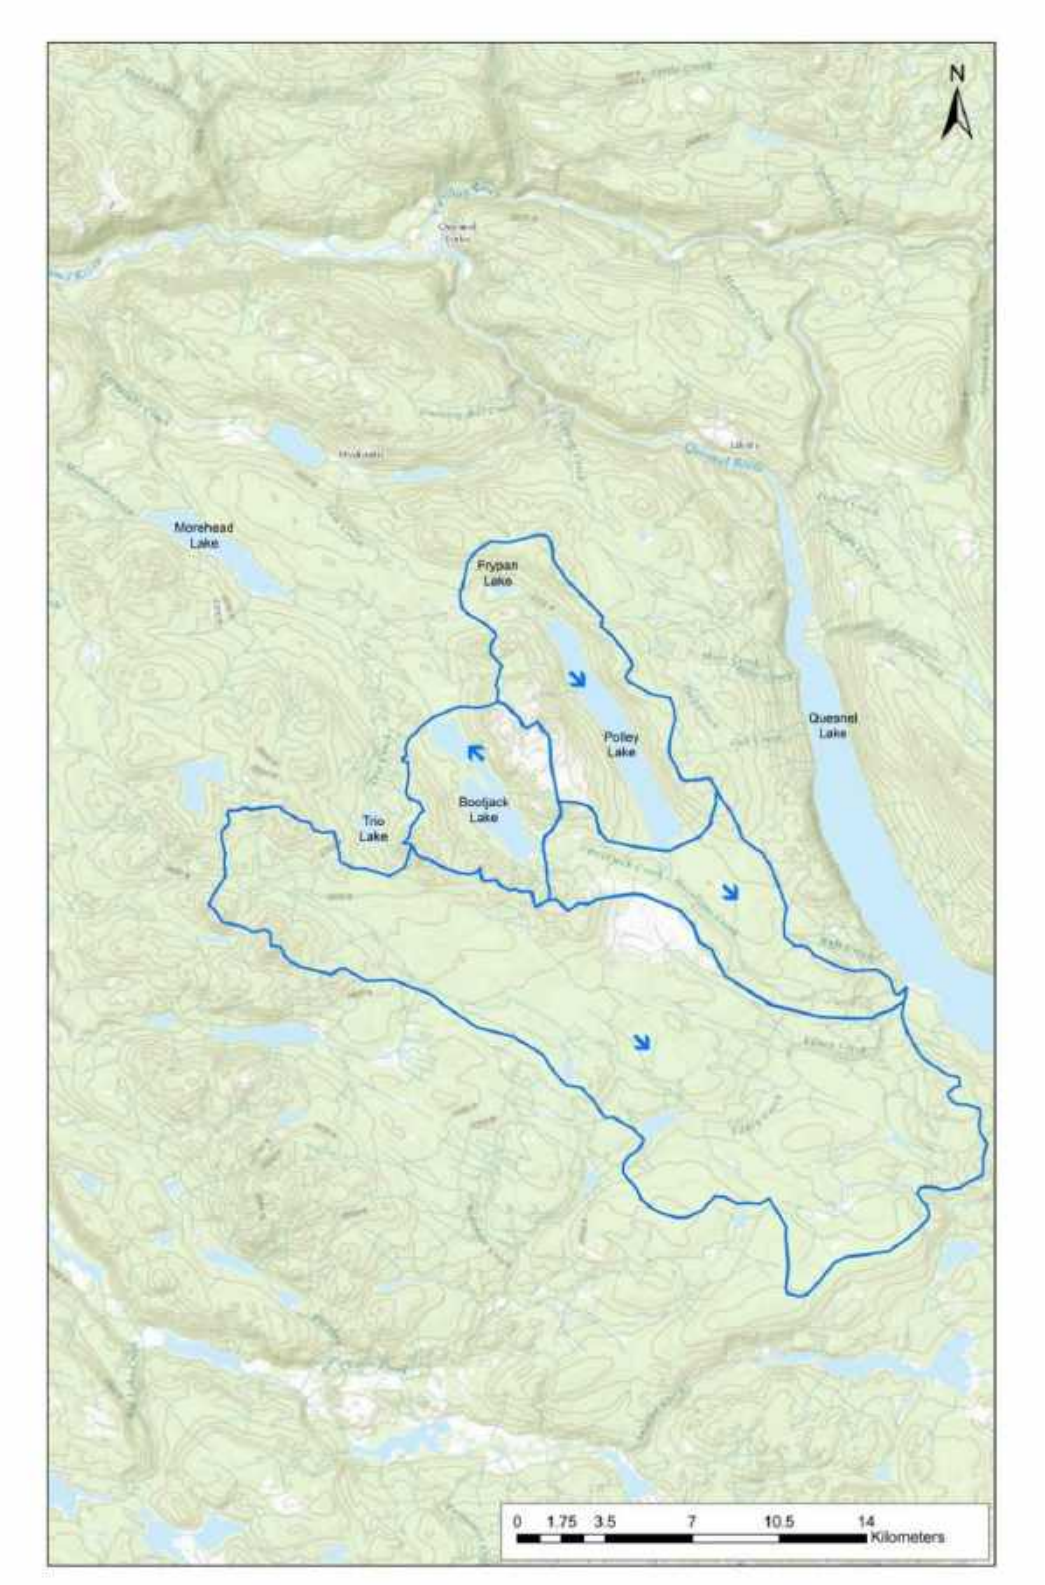
2.1 Local Study Area

Within the area of the Mine, the plateau has somewhat higher relief, with the Mine rising approximately 300 metres (m) above the surrounding terrain. Topographically, the Site area consists of north–south trending ridges of moderate elevation and relief. Local elevations range from 922 metres above sea level (masl) at Polley Lake to 1,266 masl at the top of Polley Mountain with an average elevation of 1,038 masl. The total surface area of the Site is 17.8 square kilometers (km^2).

The Site is located on the divide of two sub-watersheds within the Quesnel Lake watershed. The western watershed, which includes drainage from Bootjack Lake, discharges to the Quesnel River via Morehead Creek and drained approximately 60% of the Mount Polley area prior to Mine construction. The eastern watershed includes Polley Lake, which discharges to the east via Hazeltine Creek, Edney Creek, and the West Arm of Quesnel Lake. The Hazeltine Creek and Edney Creek watershed areas at Quesnel Lake are approximately 30.2 km^2 and 87.4 km^2, respectively. Approximately 10.5 km^2 that historically reported to this watershed is now within the Site contact water runoff collection system catchment.

Bootjack Creek is a small tributary of Hazeltine Creek downstream of Polley Lake. Historically, Bootjack Lake discharged into Hazeltine Creek via Bootjack Creek, but in 1913 a dam was constructed at the south end of Bootjack Lake and the flow direction was reversed in order to direct water into Morehead Lake for hydropower production. This resulted in 14 km^2 being diverted from the Hazeltine Creek catchment. The old Bootjack Lake Dam was upgraded by MPMC in 1997 as fulfillment of a Fish Habitat Compensation Agreement signed between MPMC and the regulating federal and provincial agencies. The Bootjack Lake watershed area is 11.2 km^2; approximately 2.3 km^2 that historically reported to this watershed is now within the Site contact water runoff collection system catchment. Currently, Bootjack Creek reports to Polley Lake.

The regional topography, water bodies, and pre-mining watersheds are shown in Figure 1. Mine Site water collection systems and catchment areas are not included in the scope of this report.



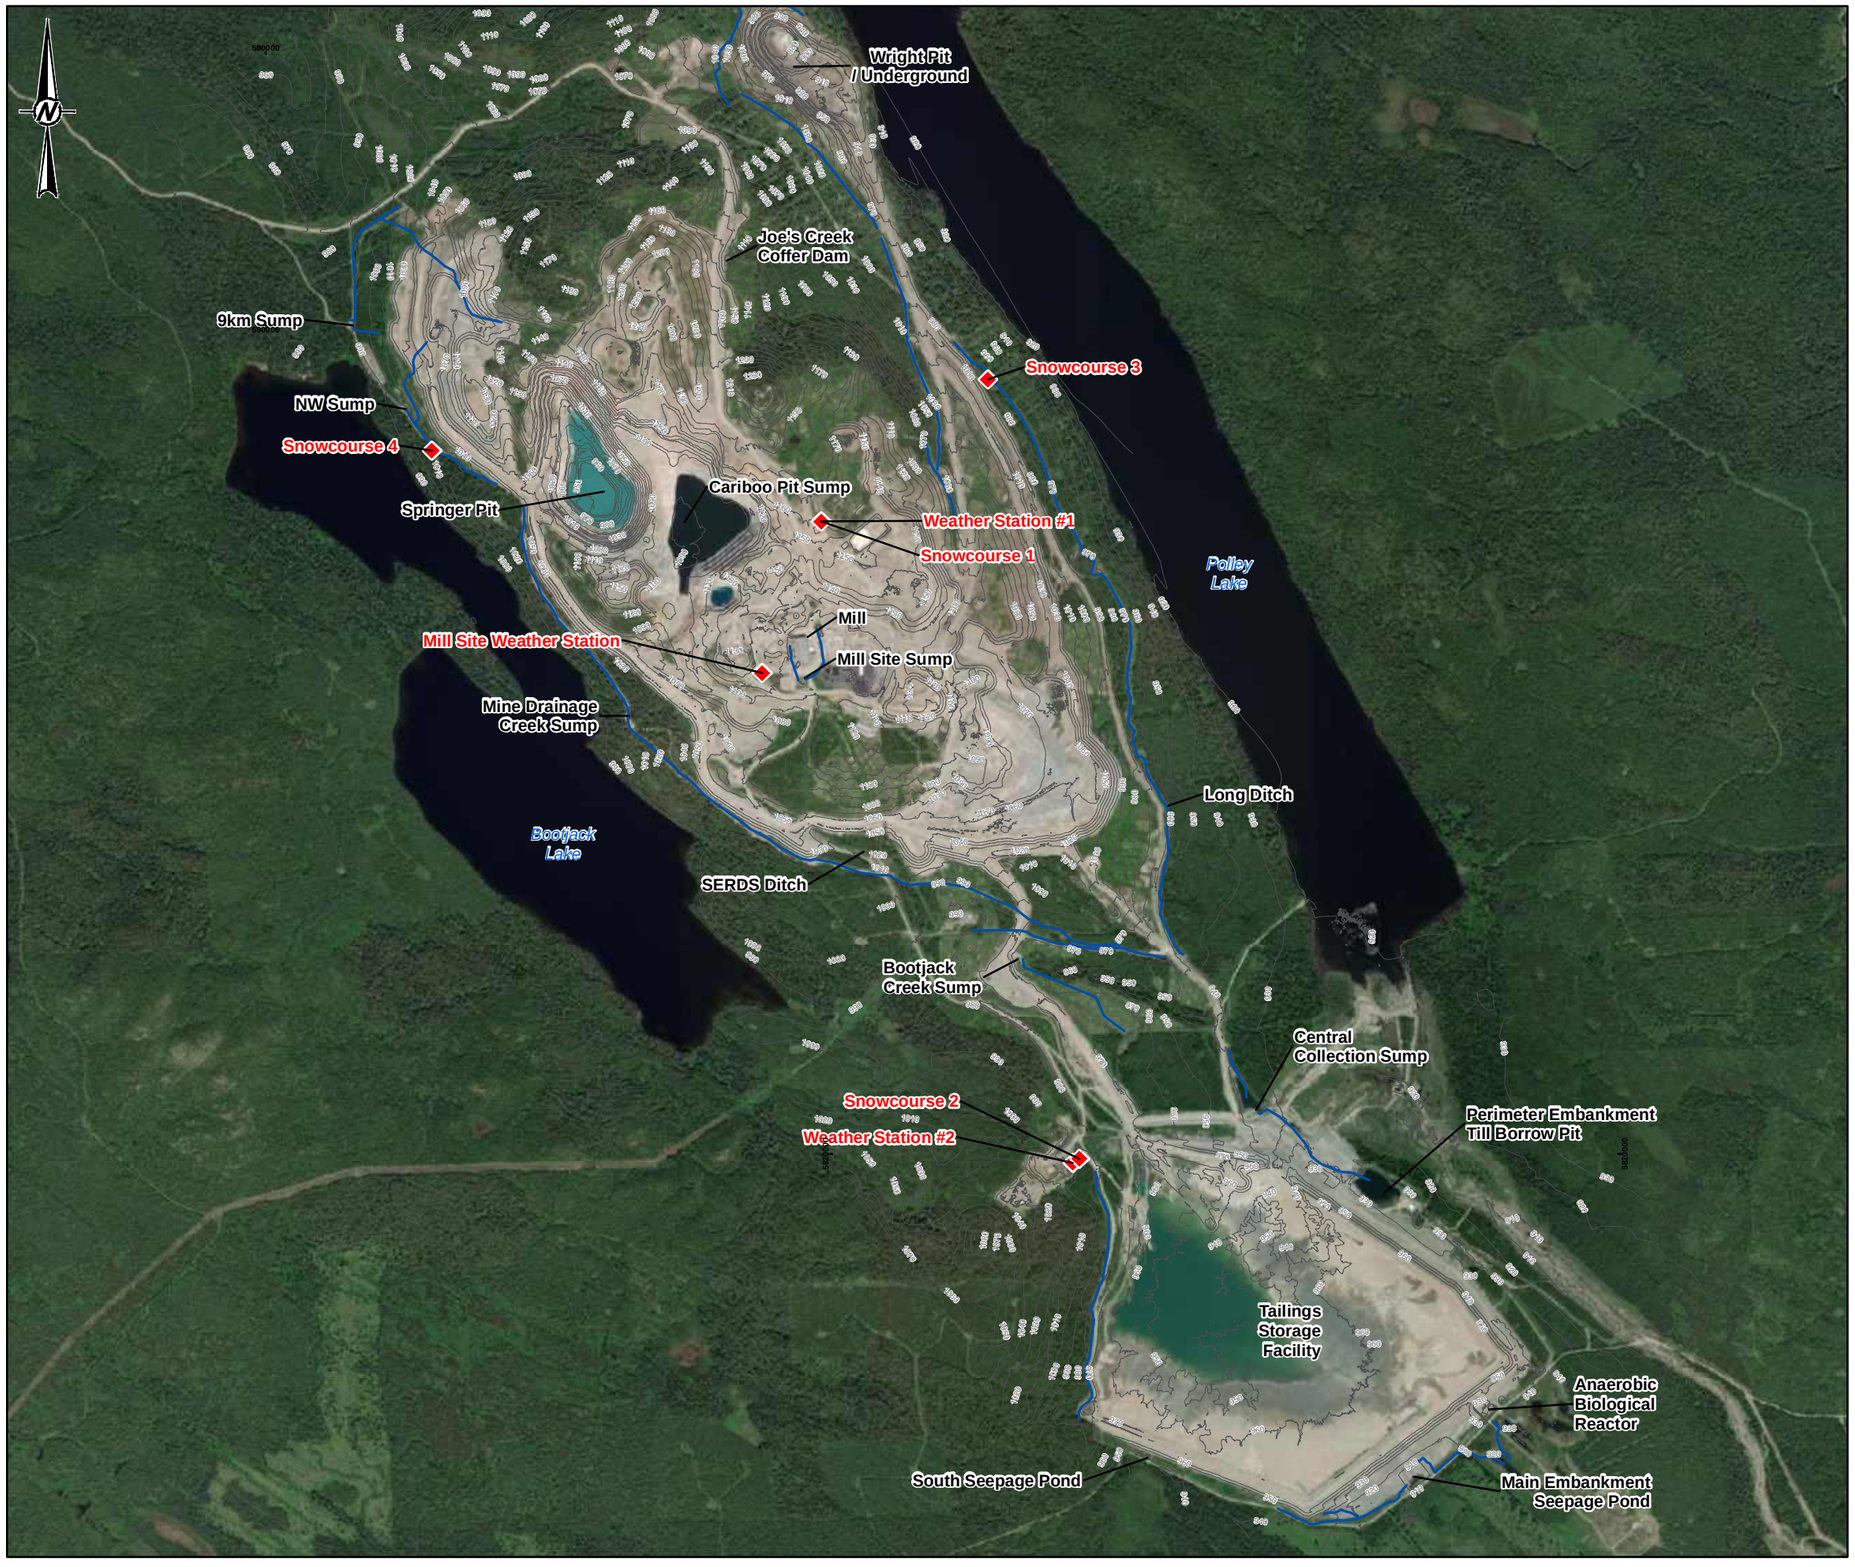


Figure 1: Mount Polley Mine Site and Surrounding Area Water Bodies and Topography Pre-Mining Activities

The Site study area is presented in Figure 2 The Site study area comprises the footprint of the physical infrastructure of the Mine and the tailings storage facility (TSF).

2.2 Regional Study Area

The regional study area (RSA) is comprised of the nearest Environment and Climate Change Canada (ECCC) climate stations (Figure 3). The RSA ECCC climate stations have elevations ranging from 1,283 m to 545 m with a mean elevation of 908 m, 130 m below the mean elevation of the Site study area.

3.0 METHODS

3.1 Study Design

Climate parameters (e.g., precipitation, temperature, and evaporation) vary both spatially and temporally. They vary spatially in response to changes in elevation and/or overall circulation patterns, and temporally, across the seasons, and from year to year. Describing the climate conditions for a certain area means presenting the climate statistics that capture the variation, including both the average expected values and the extent of the variation around the average.

The summary statistics for precipitation, temperature, evaporation, relative humidity, solar radiation, wind speed and directions, and snow depths presented herein were prepared from historical measurements recorded at local climate stations, supported by data collected from nearby regional climate stations. Raw station data were interrogated for inconsistencies or gaps then infilled using regional data and translation factors to generate short duration (daily and sub-daily) and long-duration (Annual) estimates for a range of return periods (precipitation only) or percentiles (temperature, evaporation, relative humidity, and solar radiation only). Except for wind and snow cover, the datasets were extended using historical regional data and translation factors to include a range of possible weather events and climatic trends.

Future climate projections come from publicly available statistical downscaled future climate projections on a daily scale. Recognizing the inherent uncertainty with projections, multiple projections from multiple models and scenarios were included in the analysis. Therefore, the future projections are provided in terms of percentiles or exceedance probabilities. The following sections provide a summary of the climate stations used in this report.

3.2 Review of Existing Information

Climate conditions for the Site were estimated based on data from several meteorological stations in the region and at the Site (Figure 3). The meteorological stations are listed in Table 2 and Table 4.

3.2.1 Local Climate Stations

MPMC has operated climate stations on site since 1995, although the station data records are not continuous. From 1995 through 2012, MPMC maintained one climate station at the Mill Site that measured and recorded rainfall (1997 to 2012), temperature (1995 to 2012) and wind velocity and directions (1997 to 2003). In 2012, this station was replaced with two stations: one near the mill site (WS1) and one adjacent to the TSF (WS2). These new stations measure and record wind speed, relative humidity, solar radiation, temperature, and rainfall.

Rainfall was measured using a manual rain gauge from 1997 to present at each climate station, and in 2019 automated tipping rain gauges were added at WS1 and WS2. For this study, rainfall for the Site was averaged across all instruments that recorded rainfall on a given day. Relative humidity and solar radiation were recorded at WS1 and WS2 from 2019 to 2021, although records are not continuous. In addition, solar radiation was recorded at the Mill Site station from 2001 to 2003.

Details of these stations are provided in Table 2 and their locations are shown in Figure 2.

Table 2: Local Climate Stations for the Mount Polley Mine

Station Name	Northing (m N)[1]	Easting (m E)[1]	Elevation (masl)[2]	Data Type	Period of Record
Mill Site Weather Station	5822420	592495	1,118	R, T, WS, WD	1995-2012
Weather Station #1 (WS1) [near mill]	5822420	592792	1,171	R, T, RH, SR, E, WS	2012-2021[3]
Weather Station #2 (WS2) [TSF]	5819955	594059	964	R, T, RH, SR, E, WS	2012-2021[3]

1) UTM Coordinate system – Zone 10U.

2) Elevation for on-site climate stations measured with handheld GPS device.

3) Station still in operation.

TSF = tailings storage facility; masl = metres above sea level.

R = Rainfall; S = Snowfall; T = Temperature; RH = Relative Humidity; SR = Solar Radiation; E = Evaporation; WS = Wind Speed; WD = Wind Direction.

During the winter, snowpack is measured at four snow course sites at a minimum frequency of once per month, with more frequent measurements typically taken during the melt phase. The details of these snow course stations are provided in Table 3 and their locations are shown in Figure 2.

Table 3: Local Snow Course Sites at the Mount Polley Mine

Station Name	ID	Northing (m N)[1]	Easting (m E)[1]	Approximate Elevation (masl)[2]	Period of Record
Snow Course # 1 (near mill)	N/A	5823182	592792	1,171	1997–2010, 2015–current
Snow Course # 2 (near TSF)	N/A	5819976	594092	964	1997–current
Snow Course # 3	N/A	5823895	593632	976	2012–current
Snow Course # 4	N/A	5823537	590835	1,112	2015–current

1) UTM Coordinate system - Zone 10U.

2) Elevation for on-site climate stations measured with handheld GPS device.

masl = metres above sea level; N/A = not applicable; TSF = Tailings Storage Facility.

3.2.2 Regional Climate Stations

Five Environment and Climate Change Canada (ECCC) climate stations: Likely, Spokin Lake, Williams Lake, Barkerville, and Quesnel, were selected for the update due to their proximity to the Site, length of record, elevation range, and concurrent period of record with the local climate stations at the Site. In addition, the ECCC Prince George climate station was added to include an additional station with solar radiation data. Historical records were retrieved from ECCC's Historical Climate Data web server (ECCC 2022a). More recent records were compiled through e-mail correspondence with ECCC staff (ECCC 2022b). The regional climate station details are provided in Table 4, and their respective locations are shown in Figure 3.

Table 4: Regional Climate Stations for the Mount Polley Mine

Station Name (ID)	Northing (m N)[1]	Easting (m E)[1]	Elevation (masl)	Approximate Distance to Site (km)	Data Type	Period of Record[2]
Likely (1094616)	5828785	599332	724	9	P, R, S, T	1974-1993
Williams Lake A (1098940)	5781820	564666	940	50	P, R, S, T, RH, SR	1961-2021[4]
Spokin Lake 4E (1097646)	5782274	589827	1,033	40	P, R, S, T	1983-2021[4]
Barkerville (1090660)	5880996	599515	1,283	59	P, R, S, T	1888-2021[3, 4]
Quesnel A[5] (1096630)	5873987	546720	545	80	P, R, S, T, RH	1946-2021[4]
Prince George A (1096450)	5971423	521103	691	163	P, R, S, T, RH, SR	1973-1995

1) UTM Coordinate system – Zone 10U.
2) Length of record from start year to end year may not reflect the number of complete years of data.
3) Provisional data for the period January 2016 to December 2021 were provided by ECCC.
4) Station still in operation.
5) Combined record from Quesnel A and Quesnel Airport Auto stations. Stations are located at the same location.

ID = Identification; masl = metres above sea level; km = kilometre.
P = Precipitation; R = Rainfall; S = Snowfall; T = Temperature; RH = Relative Humidity; SR = Solar Radiation.

3.3 Data Processing

Climate parameter statistics for the Site were prepared using data from the three on-site climate stations operated by MPMC, and the five regional climate stations operated by ECCC (Sections 3.2.1 and 3.2.2). Data were interrogated for gaps and errors, and where appropriate, extended and filled with data from regional stations using translation factors derived from the available periods of record as described in Section 3.4. Local data were screened for outliers in the time series that may be indicative of errors or equipment malfunction. Potential high outliers were identified in the Mount Polley rainfall record in April 2009 but were not removed from the time series as there was insufficient evidence to support removal. In addition, climate parameter records were checked using the World Meteorological Organization (WMO) guidelines (WMO 2018) as reference. Monthly records were removed if there were more than five days missing, or more than 3 consecutive days missing. Annual records were only calculated using years with a complete dataset (twelve months).

3.4 Data Analysis

3.4.1 Precipitation

The MPMC precipitation dataset was extended and infilled using the available data record from the five regional stations as described below to derive a daily and 24-hour long-term synthetic precipitation dataset for the Site.

Extended MPMC Precipitation Data Record

The Likely ECCC Station data were considered to extend the precipitation record for the Site given the station's length of record and proximity to the Site. As the Likely ECCC station and MPMC climate stations do not have concurrent data sets, the mean monthly April-to-November rainfall distribution for the available data records were compared to evaluate the suitability of using the Likely station data to represent precipitation conditions at the Site. As shown in Figure 4, the Likely and Site station monthly precipitation distributions show a similar trend overall, with MPMC recording notably greater rainfall in April, and notably less rainfall in June and August relative to Likely. The notable differences in monthly rainfall between the MPMC and Likely datasets for the months of April, June, and August were investigated with the following observations:

- April: the length of record for MPMC is relatively short and is not continuous, and outliers have potential to bias mean monthly rainfall. As previously mentioned, potential high outliers were identified in the Mount Polley rainfall record in April 2009 but were not removed from the time series as there was insufficient evidence to support removal. However, if the potential high outlier data were to be removed, the mean monthly April values would be more aligned between the data sets (48.8 mm for MPMC versus of 33.1 mm for Likely).
- June: review of the MPMC and concurrent regional June monthly rainfall records for Barkerville, Spokin Lake, and Williams Lake indicate that relatively low June rainfall totals (compared to average values for the complete available data set from the regional stations) were recorded in several years during the 1997 to 2021 period of record (2002, 2003, 2006, 2009, 2014, 2019, and 2021). These years represent approximately 40% of the available June records for MPMC, suggesting the MPMC mean June rainfall may be biased low (i.e., due to shorter period of record used in computing the mean) compared to Likely.
- August: review of regional rainfall records for Barkerville, Spokin Lake, and Williams Lake from 1997 to 2021 (i.e., concurrent with the MPMC precipitation data set), indicate that regional mean August monthly rainfall records were 84%, 87%, and 85% of the mean of the full period of record, respectively, indicating that there has been reduction (compared to the longer-term mean) in August rainfall regionally in more recent years. In other words, the differences between MPMC and Likely mean August rainfall values may be attributed to differing precipitation trends in the respective reporting periods.

Based on above, the historical Likely ECCC Station record was considered acceptable for extending the historical precipitation record for the Site. Owing to the elevation difference between the Site and Likely ECCC Station, a precipitation-elevation orographic factor was applied to adjust the raw precipitation data from the Likely ECCC climate station to the Site. The adjustment was based on the April-to-November rainfall ranking factor of the raw Likely ECCC climate station and Site rainfall records.

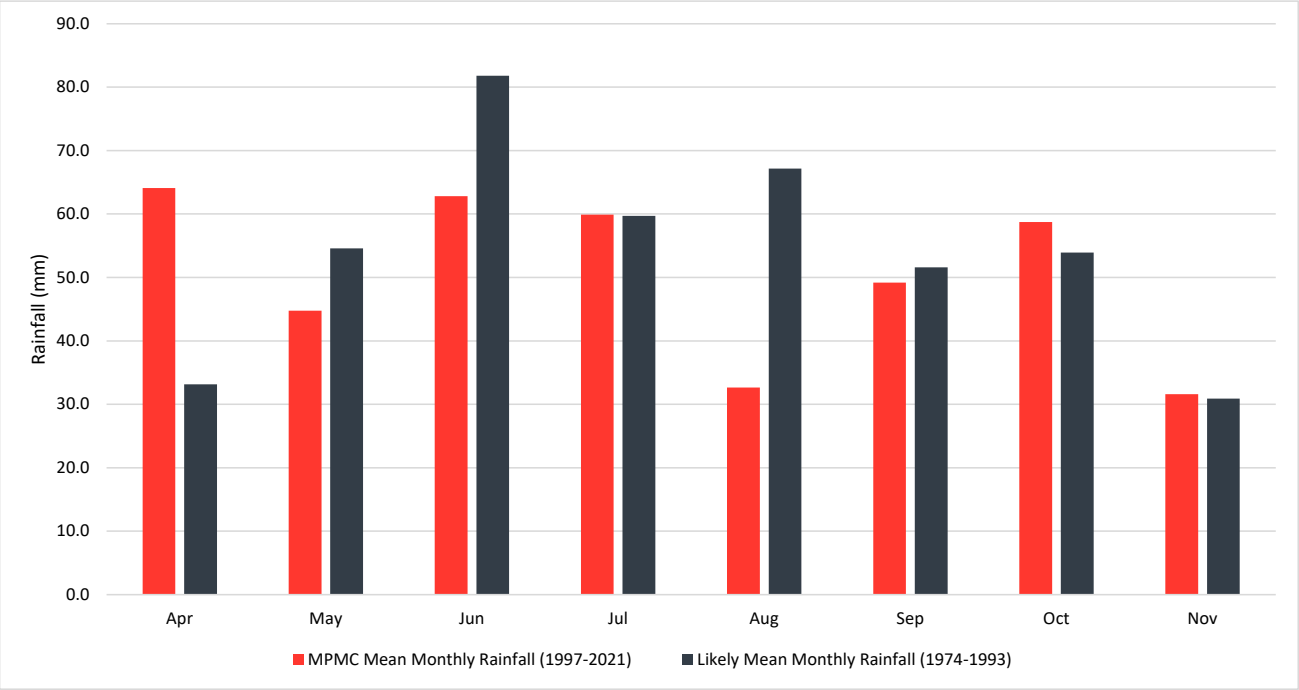

Figure 4: April-to-November Rainfall Distributions at Mount Polley Mine and ECCC Likely Climate Stations

MPMC Precipitation Data Gap Infilling

The priority sequence of concurrent regional climate station data used to infill gaps in the extended Site precipitation record was determined by analyzing measured daily rainfall from April to November for all climate stations; it was assumed that precipitation occurring between December and March occurred as snowfall. The regional climate station priority sequence considered the best-fit measured concurrent daily rainfall correlation (Rainfall Correlation), rainfall ranking correlation (Rainfall Rank), and percentage of time rain was recorded on the same day (Concurrent Daily Rain) between the raw data collected at the MPMC climate stations and each ECCC climate station (Table 5). Regional climate station precipitation data replaced missing rainfall data in the extended Site data record following the priority sequence, and all precipitation data from December to March as it was assumed precipitation during this period occurs as snowfall and daily snowfall is not recorded at the Site.

Table 5: Regional Climate Stations Priority Sequence for Precipitation Data Gap Infilling in Extended Record for MPMC

Priority	Station	Rainfall Correlation (R^2)	Rainfall Rank (R^2)	Concurrent Daily Rain (%)	Period of Record	Currently Active	Distance from site (km)
1	Williams Lake A	0.1950	0.9872	61.8	1960-2021	Yes	50
2	Spokin Lake 4E	0.1829	0.9747	65.8	1983-2021	Yes	40
3	Barkerville	0.1579	0.9216	66.4	1888-2021	Yes	59
4	Quesnel A	0.0502	0.9556	23.3	1946-2021	Yes	80

A precipitation-elevation orographic factor was applied to adjust the raw precipitation data from the ECCC climate stations used to infill gaps. The adjustment was based on the April-to-November rainfall ranking factor of the raw ECCC climate station and Site rainfall records.

Daily to 24-Hour, 3-day, and 10-day Precipitation

The daily long-term synthetic precipitation dataset was converted to 24-hour, 3-day, and 10-day precipitation by applying a factor of 1.13 (WMO 2009), 1.03, and 1.01 (Miller 1964), respectively.

3.4.2 Temperature

Similar to precipitation analysis above, the MPMC temperature dataset was extended and infilled using the available data record from the five regional stations to derive a long-term synthetic temperature dataset for the Site.

Extended MPMC Temperature Data Record

The Likely ECCC Station data were considered to extend the temperature record for the Site given the station's length of record and proximity to the Site. As the Likely ECCC station and MPMC climate stations do not have concurrent data sets, the mean monthly air temperature distributions for the Site and Likely climate stations were compared to evaluate the suitability of using the Likely station data to represent temperature conditions at the Site. As shown in Figure 5, the monthly distributions show similar trend with MPMC and the historical Likely ECCC Station record was considered acceptable for extending the historical temperature record for the Site. Owing to the elevation difference between the Site and Likely ECCC Station, a temperature-elevation orographic factor was applied to adjust the raw precipitation data from the Likely ECCC climate station used to extend the historical record. The adjustment was based on monthly regional lapse-rates as discussed below.

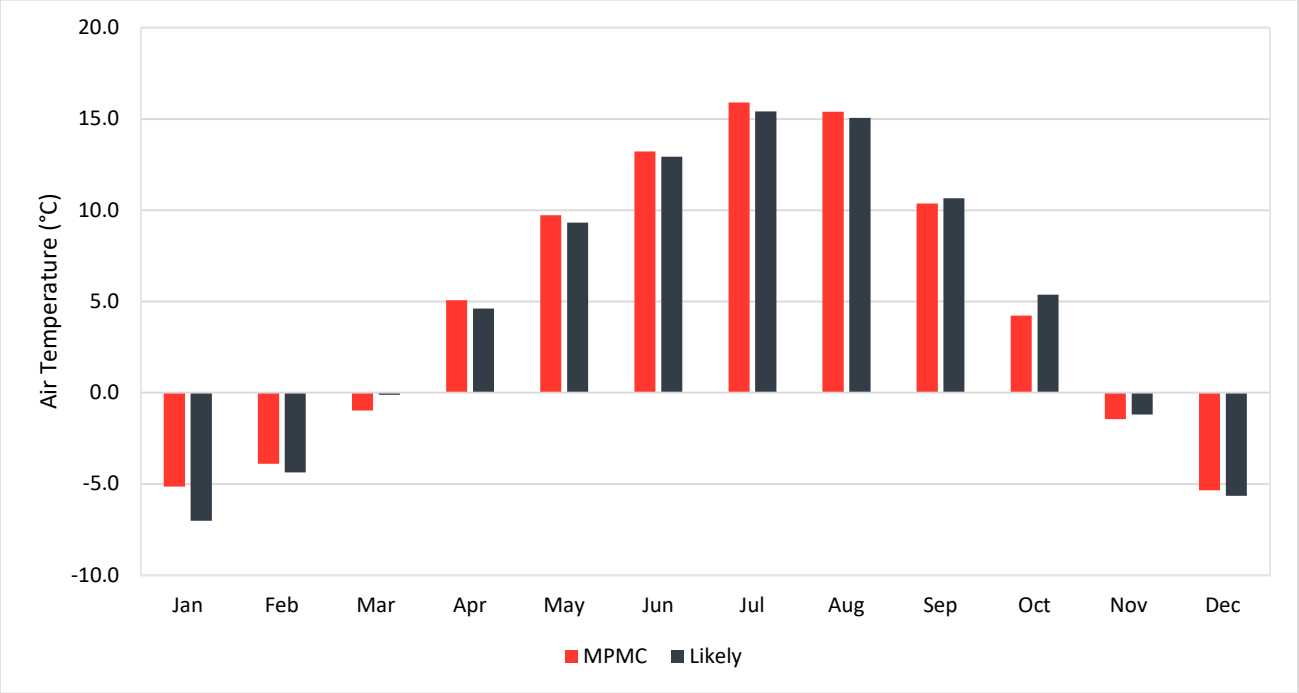

Figure 5: Mean Monthly Air Temperature Distributions for the Site and Likely ECCC Climate Station

ECCC Climate Normals for the regional climate stations were reviewed and are summarized in Table 6 and mean monthly air temperatures are presented in Figure 6. Comparing the Normals for the five regional ECCC Climate stations, there is an evident trend (the temperature lapse rate) of decreasing mean annual temperature with increasing elevation. The annual temperature lapse rate for the region is -0.47 °C / 100 m elevation increase. The lapse rate is larger for warmer months (April to October -0.55 °C / 100 m) and smaller for colder months (November to March -0.33 °C / 100 m). When analysed at a monthly level, the lapse rate is lowest for January (-0.09°C / 100 m) and highest for April, May, June, and July (-0.61°C / 100 m, -0.61°C / 100 m, -0.60°C / 100 m, and -0.59°C / 100 m, respectively). The R^2 of the linear trend is markedly lower for January (0.43) than for all the other months of the year (0.79 to 0.92), which suggests that temperature inversion may occur in the region in January. Lapse rates are presented in Table 7 and Figure 7.

Table 6: Monthly and Annual Air Temperature Climate Normals for Regional ECCC Climate Stations

Station Name	Quesnel A (545 masl)	Williams Lake A (940 masl)	Spokin Lake 4E (1,033 masl)	Barkerville (1,283 masl)	Likely (740 masl)
Time period for EC Climate Normals	1981-2010	1981-2010	1981-2010	1981-2010	1971-2000
Month	**Temperature (°C)**				
January	-6.9	-6.7	-7.6	-7.5	-7.0
February	-3.6	-4.1	-5.4	-5.9	-4.4

December	-0.32	0.82
Annual	-0.47	0.91

MPMC Temperature Data Gap Infilling

The priority sequence of regional climate station data used to infill gaps in the extended Site air temperature record was based on the best-fit daily air temperature correlation (Temperature Correlation), air temperature ranking (Temperature Ranking), and concurrent daily temperature recordings between the MPMC climate stations and each ECCC climate station (Table 8).

Table 8: Regional Climate Stations Priority Sequence for Temperature Data Gap Infilling in Extended Record for MPMC

Priority	Station	Temperature Correlation (R^2)	Temperature Rank (R^2)	Concurrent Daily Temperature (%)	Period of Record	Currently Active	Distance from site (km)
1	Williams Lake A	0.8917	0.9942	93.5	1960-2021	Yes	50
2	Barkerville	0.8834	0.9951	99.0	1888-2021	Yes	59
3	Quesnel A	0.8628	0.9861	97.5	1946-2021	Yes	80
4	Spokin Lake 4E	0.8525	0.9810	99.5	1983-2021	Yes	40

Regional ECCC climate station daily air temperature data were adjusted using the monthly air temperature lapse-rate presented in Table 7 to derive representative air temperature at the Site.

3.4.3 Relative Humidity

Relative humidity data are available for the Site from 2019 to 2021 and for ECCC climate stations Quesnel (1953 to 2021) and Williams Lake (1961 to 2021). The MPMC WS1 relative humidity record is more complete than WS2's record; therefore, WS1 data were used for the analysis and infilled with WS2 data where necessary and if available. However, relative humidity data for the Site are insufficient for characterizing long-term climatic conditions of the Site due to the short period of record. Therefore, data from Quesnel and Williams Lake stations were reviewed and analyzed to define a representative relative humidity estimate for the Site. Comparisons between the Site data and each ECCC climate station data were made to determine which station best represents the potential relative humidity at the Site.

Figure 8 and Figure 9 present the comparison between concurrent daily relative humidity values at the ECCC Quesnel and MPMC climate stations (January 2019 to December 2021). The 15-day moving average indicates that the relative humidity is generally higher at the Site than at the ECCC Quesnel climate station. The two datasets are well correlated (R^2=0.96).

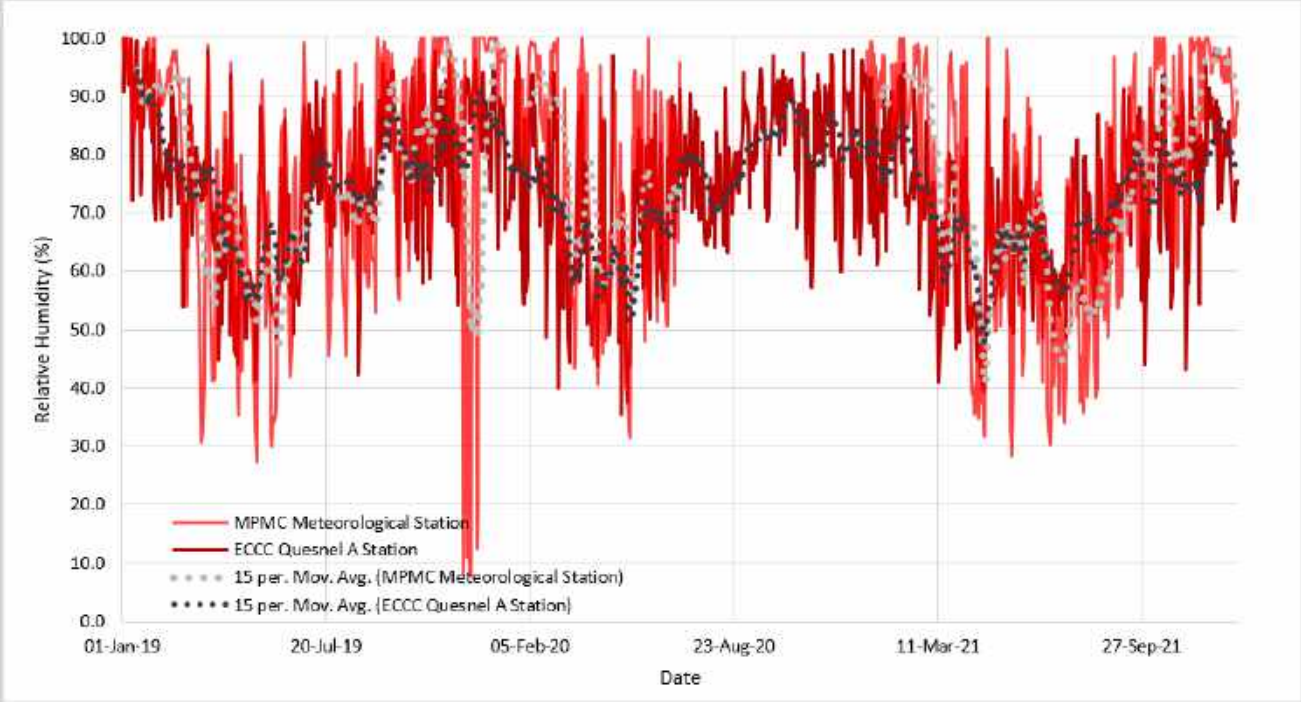

Figure 8: Concurrent Daily Relative Humidity Values at the MPMC and ECCC Quesnel Climate Stations (2019-2021)

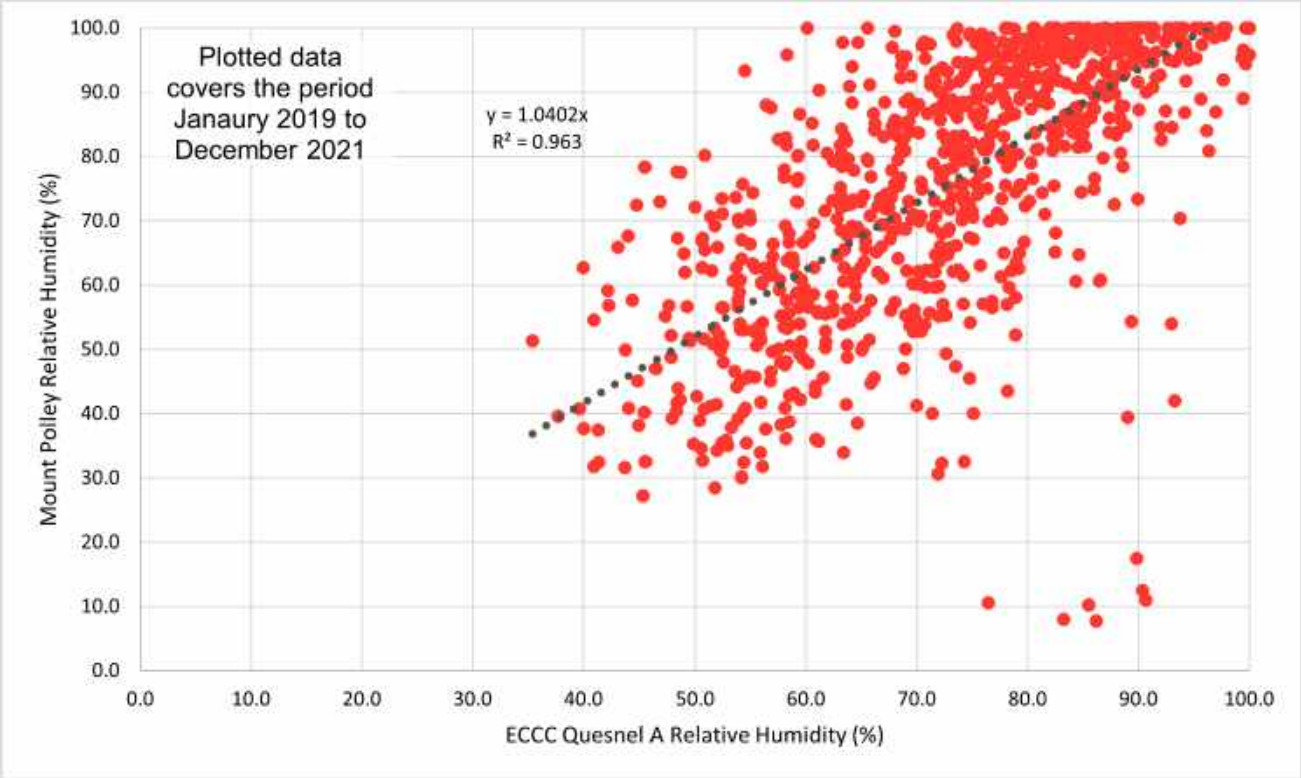

Figure 9: Correlation Relationship of Daily Relative Humidity Values at MPMC and ECCC Quesnel Climate Stations (2019-2021)

Figure 10 and Figure 11 present the comparison between concurrent daily relative humidity values at the ECCC Williams Lake and MPMC climate stations (January 2019 to December 2021). The 15-day moving average indicates that the relative humidity is generally higher at the Site than at ECCC Williams Lake climate station. The two datasets are very well correlated (R^2=0.98).

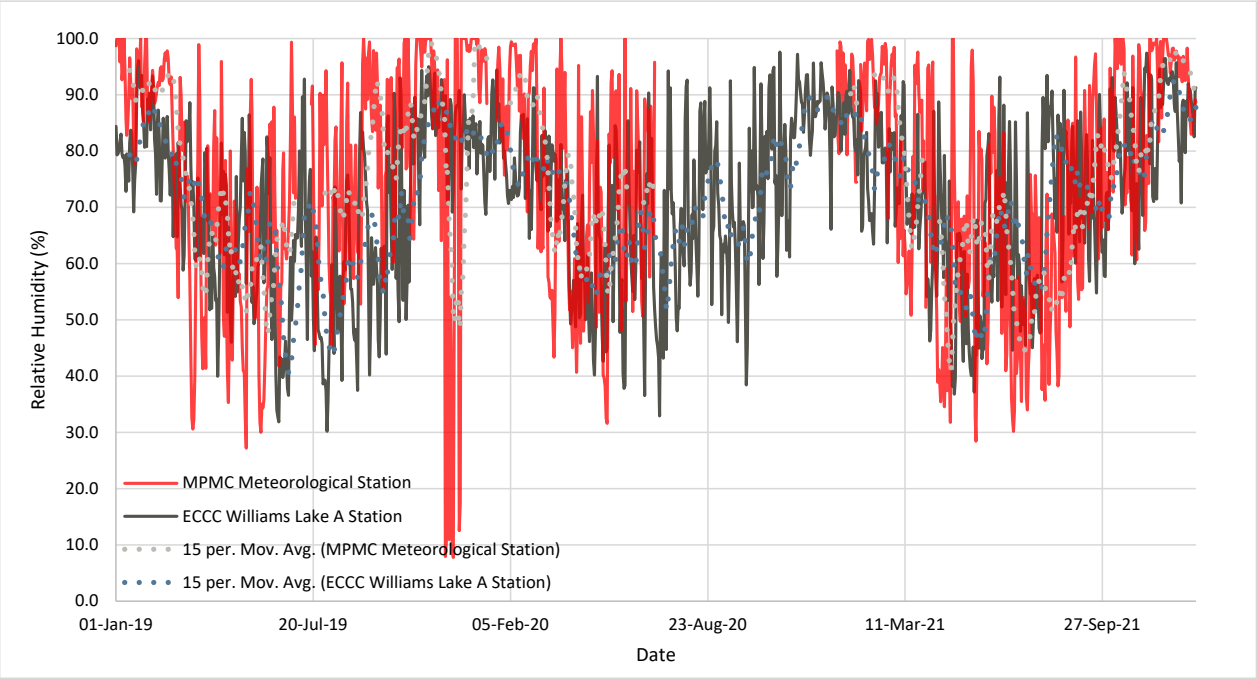

Figure 10 : Concurrent Daily Relative Humidity Values at MPMC and ECCC Williams Lake Climate Stations (2019-2021)

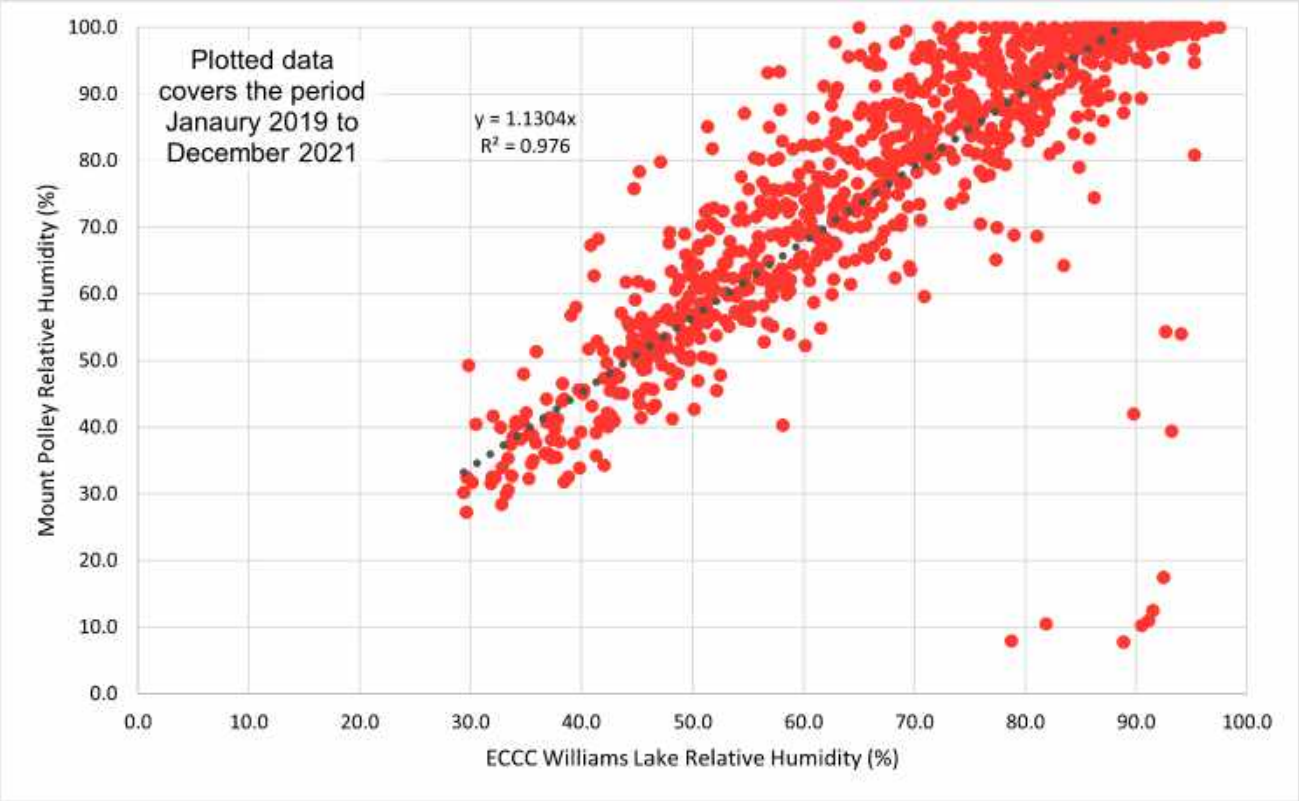

Figure 11 : Correlation Relationship of Daily Relative Humidity Values at MPMC and ECCC Williams Lake Climate Stations (2019-2021)

A long-term relative humidity time series for the Site was developed using ECCC Williams Lake A data infilled with ECCC Quesnel A data with an adjustment factor of 1.13 and 1.04 based on the relationships presented in Figure 11 and Figure 9, respectively.

3.4.4 Solar Radiation

Solar radiation data are available for the Site from 2001 to 2003 and 2019 to 2021, and for ECCC climate stations Williams Lake (1961 to 2001) and Prince George (1973 to 1995). Solar radiation data for the Site are insufficient for characterizing climatic conditions of the Site due to the short period of record, and as the data recorded in 2001 is incomplete and not concurrent with either ECCC climate station. However, as presented in Figure 12, a discernible trend in mean monthly solar radiation is apparent for MPMC solar radiation (2019 to 2021) and in data from the ECCC Williams Lake and Prince George climate stations. Figure 13 presents ECCC Williams Lake and Prince George mean monthly solar radiation correlation (R^2 = 0.98) from 1973 to 1995.

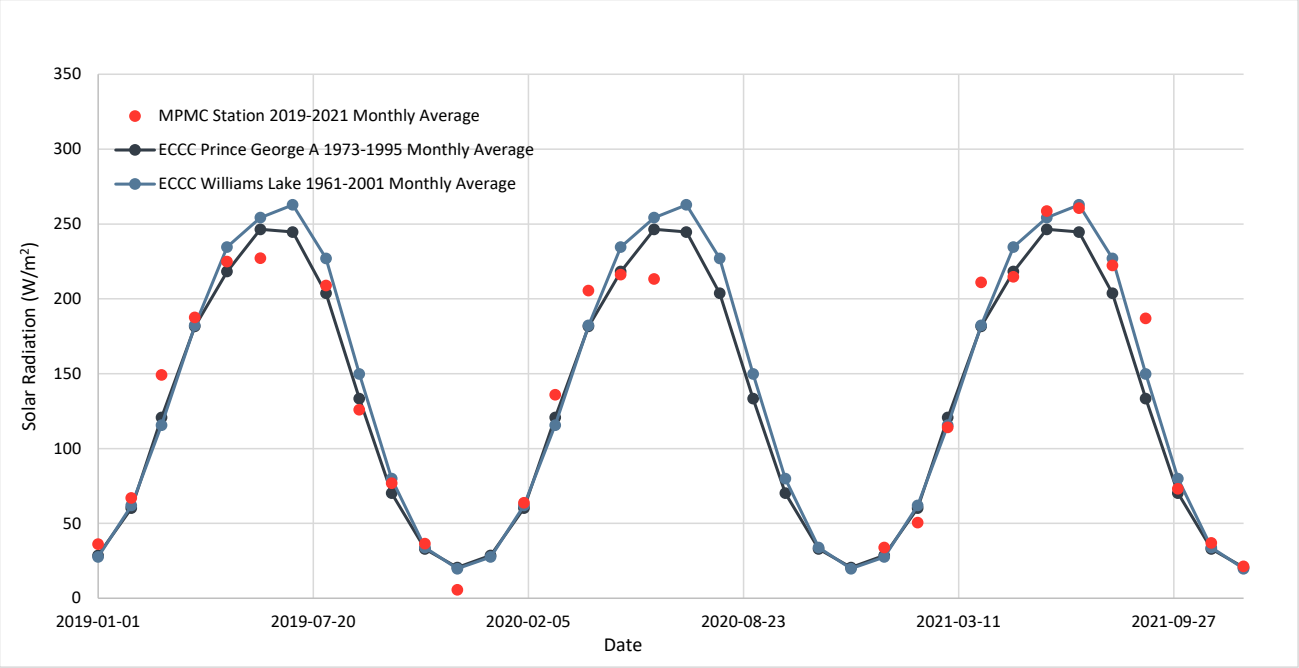

Figure 12 : Mean Monthly Solar Radiation for MPMC and ECCC Regional Climate Stations

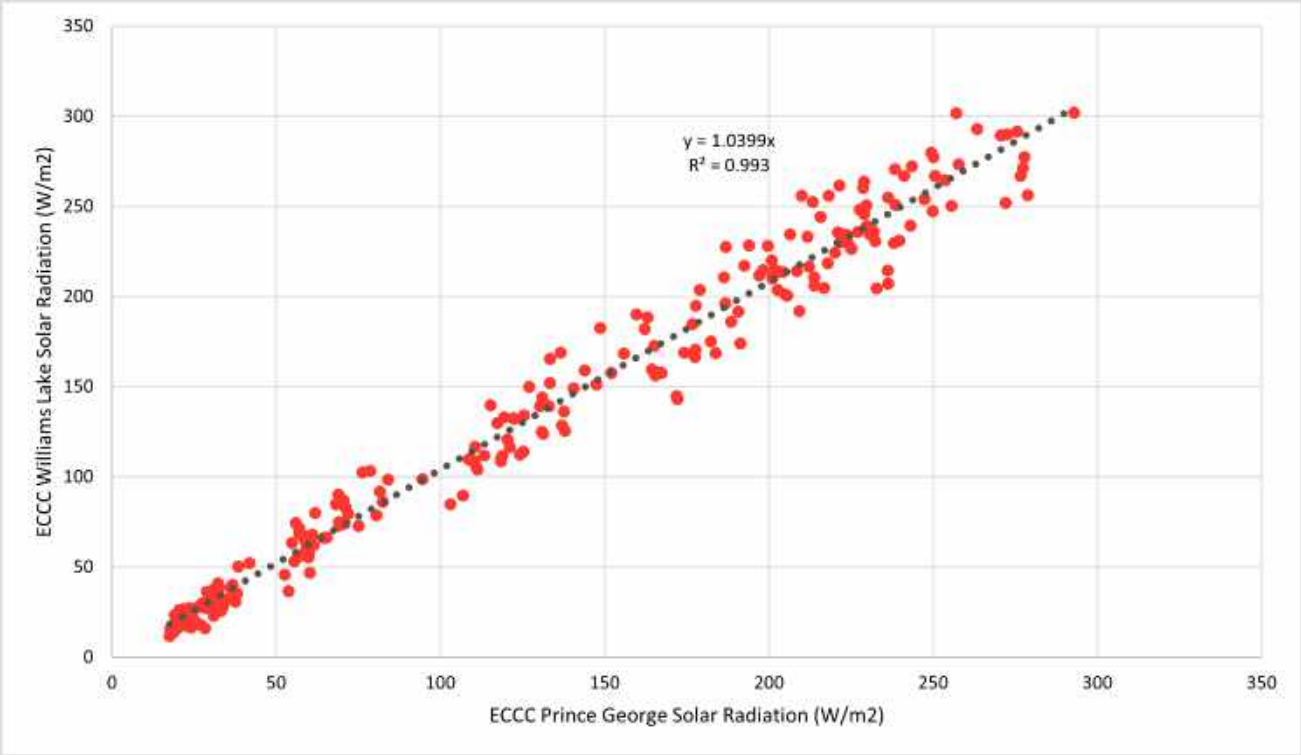

Figure 13 : Daily Solar Radiation Correlation Between ECCC Williams Lake and Prince George Climate Stations (1973-1995)

The strong correlation between ECCC Williams Lake and Prince George climate stations suggest there is little variation in solar radiation across the region. Based on the comparison of mean monthly solar radiation records and the proximity in distance to the Site, solar radiation statistics for the Site were determined from the ECCC Williams Lake data. Missing values were infilled by adjusting the Prince George records by a factor of 1.04 based on the relationship presented in Figure 13.

3.4.5 Evaporation and Evapotranspiration

Evaporation monitoring data are available for the Site from 2019 to 2021; however, the data are not continuous, and the length of record is not sufficient for characterizing the evaporation conditions at the Site. Therefore, a mathematical model (Morton 1983) was used to calculate evaporation and evapotranspiration (actual and potential) for the Site based on the long-term synthetic records for air temperature, relative humidity, and solar radiation. Evaporation in this study is defined as free water evaporation, or the amount of evaporation from open/free water surfaces (i.e., the water is returned to the atmosphere from lakes, ponds, and watercourses). Potential evapotranspiration is the water loss that occurs from a vegetated natural surface if there is no deficiency of water in the soil for use by vegetation (Thornthwaite 1948).

3.4.6 Wind Speed and Direction

Hourly wind speed and direction data are available for the Site from 1997 to 2003, and daily wind speed data are available from 2019 to 2021; however, the data are not continuous. The hourly wind speed and direction data available from 1997 to 2003 were used to develop wind rose plots. A wind rose depicts the relative frequency of wind from a given direction on a 16-point compass. Each ring on the wind rose represents a frequency of 2% of the data period. The length of the shaded bars on each wind rose petal represents the frequency of wind recorded from a given direction within a defined wind speed range. A wind rose is provided for the period of August 1997 to November 2003, and seasonal wind roses are presented to display seasonal variability in wind patterns, where the seasons have been defined as follows:

- Winter – December to February
- Spring – March to May
- Summer – June to August
- Autumn – September to November

Daily wind data recorded from 2019 to 2021 from WS1 and WS2 were wind speed only, no direction. The period of record for WS2 and 2020 are incomplete and are not included in the analysis. The relative frequency (%) of the magnitude of the daily wind speed data recorded at WS1 for 2019 and 2021 were compared in this study to the relative frequency (%) of wind speed magnitude of the data from 1997 to 2003.

3.4.7 Snow Cover Properties

Snow cover is an important climatic variable as it influences the spring freshet flow volume and distribution. Snow cover data at the Site are available monthly from manual measurements from 1997 to 2022, recorded as snow-water-equivalent (SWE). Measurements, although not continuous, are typically recorded at the beginning and end of a month, with the latter being representative of the monthly SWE.

4.0 RESULTS

The following section summarizes the precipitation, air temperature, relative humidity, solar radiation, evaporation and evapotranspiration, wind speed and direction, and snow cover baseline conditions at the Site.

4.1 Annual Precipitation

The Site experiences high summer precipitation due to summer storms, with the lowest monthly precipitation occurring in February. Precipitation typically occurs as snowfall starting in November and accumulates until March. Average annual precipitation at the Site is estimated to be 612 mm with a standard deviation of 118 mm. Frequency analyses of the derived long-term precipitation time series for the Site were undertaken to generate the variability in monthly and annual precipitation of the Site. Estimated annual wet and dry precipitation depths for a range of return periods are shown in Table 9, Figure 14, and Figure 15.

Table 9: Annual Precipitation Depths for the Site (1974-2021)

Return Period (yr)	Wet (mm)[1]	Dry (mm)[1]
5	714	508
10	768	459
25	825	412
50	861	386
100	893	366
200	922	349
Average	612	

1) Weibull distribution was selected based on the statistical distribution goodness-of-fit-test.

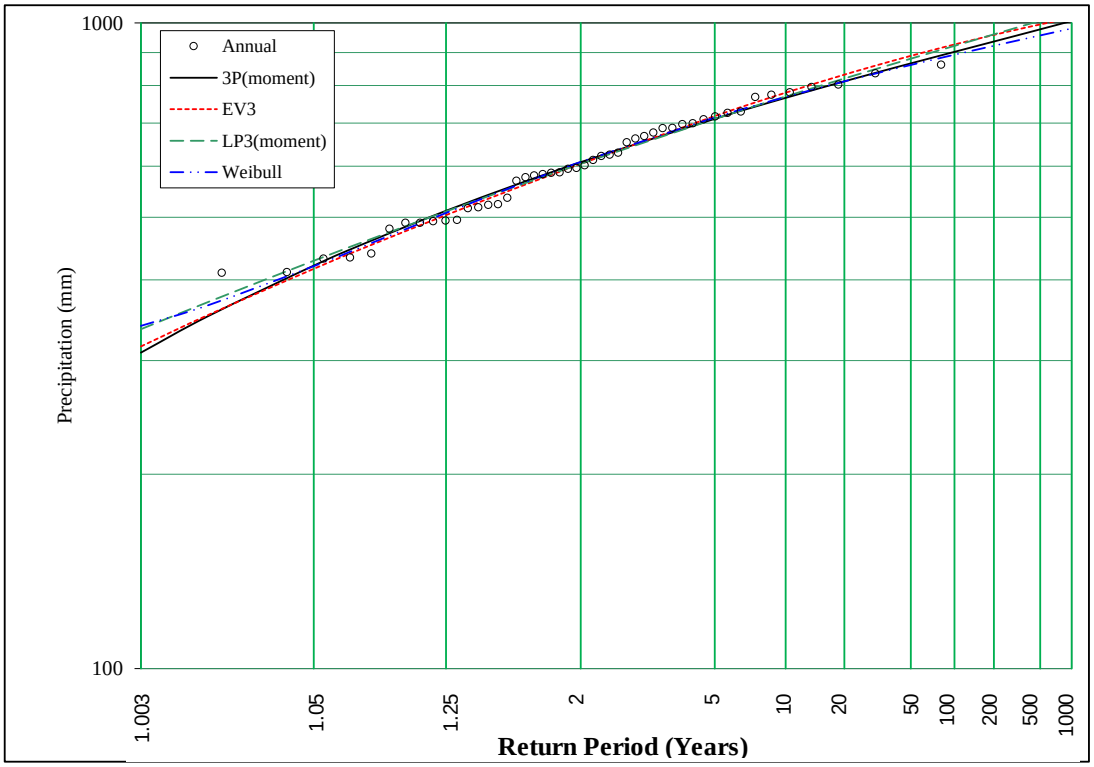

Figure 14 : Annual Precipitation Frequency Analysis – Wet Results

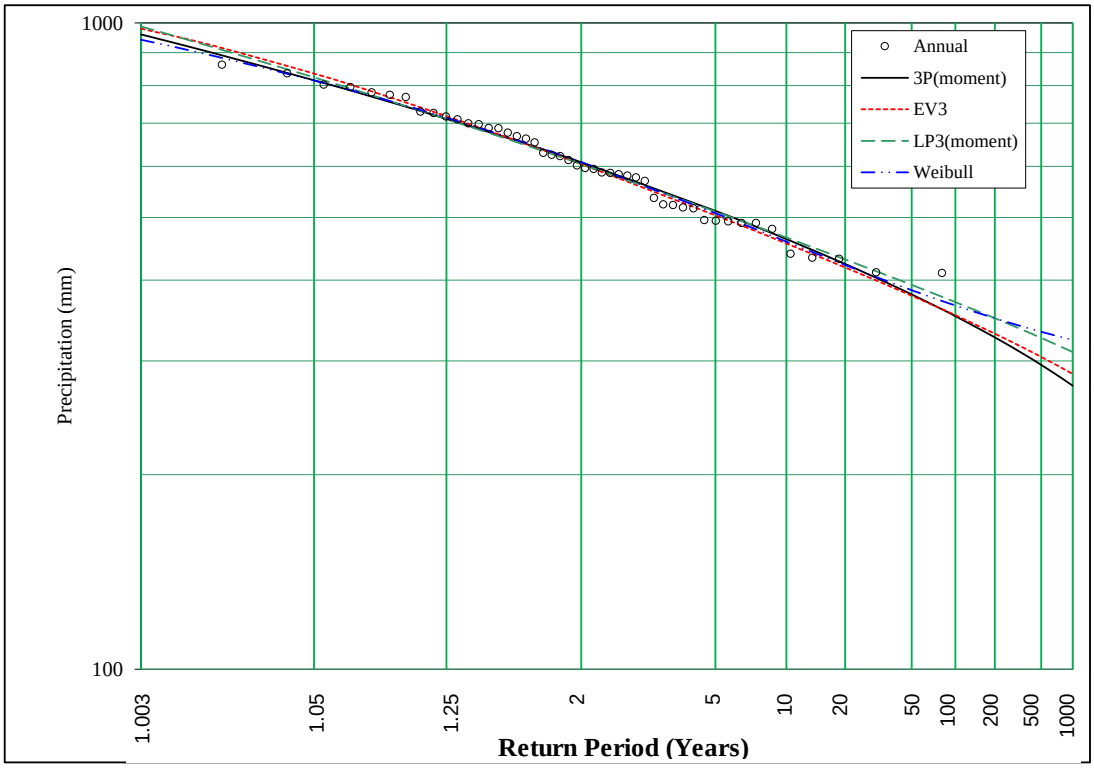

Figure 15 : Annual Precipitation Frequency Analysis - Dry Results

Monthly values for the 25- and 200-year return periods for wet and dry precipitation depths are presented in Table 10. Monthly values for the 1:25 year dry and wet precipitation for the 1:200 year dry and wet precipitation were assumed to follow the same monthly distribution as the average precipitation.

Table 10: Monthly Precipitation Depths for the Site (1974-2021)

Month[1]	Precipitation (mm)				
	Average	1:200 Year Wet	1:25 Year Wet	1:25 Year Dry	1:200 Year Dry
January	49.4	74.3	66.5	33.2	28.2
February	35.8	54.0	48.3	24.1	20.5
March	29.7	44.7	40.0	20.0	16.9
April	44.7	67.3	60.2	30.1	25.5
May	49.9	75.2	67.2	33.6	28.5
June	70.8	107	95.4	47.7	40.4
July	63.6	95.8	85.7	42.9	36.3
August	50.6	76.2	68.1	34.1	28.8
September	52.3	78.8	70.5	35.2	29.9
October	58.1	87.5	78.2	39.1	33.1
November	49.8	75.0	67.1	33.5	28.4
December	57.6	86.8	77.7	38.8	32.9
Annual Total[2]	**612**	**922**	**825**	**412**	**349**

1) Wet and Dry Monthly values assumed to follow the same monthly distribution as the Average.

2) Annual total precipitation depths were rounded to the nearest mm for presentation purposes; therefore, it may appear the sum of the monthly values do not equal the annual total.

4.2 Rainfall

Annual maximum series for 24-hour precipitation from the derived historical data set was used to undertake a frequency analysis to provide rainfall design values. Results are shown in Table 10. The 24-hour, 3-day, and 10-day annual, spring, and summer probable maximum precipitation (PMP) depths were estimated using the Hershfield method (WMO 2009).

Table 11: 24-hour Precipitation Depths for the Site (1974-2021)

Return Period (yr)	Depth (mm) [1, 2]
2	**33**
10	**47**
25	**54**
100	**64**
200	**69**
1000	**80**

1) Log Pearson III distribution was selected based on the statistical distribution goodness-of-fit test.

2) Values rounded up to the nearest mm.

Table 12: Annual, Spring, and Summer PMP Depths for the Site (1974-2021)

Period	Annual PMP[1] (mm)	Spring PMP[1, 2] (mm)	Summer PMP[1, 3] (mm)
24-Hour	224	192	191
3-Day[4]	339	272	294
10-Day[5]	562	295	486

1) The PMP does not have a return period.
2) Spring = March, April, May.
3) Summer = June, July, August.
4) Adjusted from fixed-time interval by a factor of 1.03 (Miller 1964).
5) Adjusted from fixed time interval by a factor of 1.01 (Miller 1964).

4.3 Air Temperature

Air temperature statistics for the Site were developed using historical data from the nearby ECCC climate station in Likely approximately 9 km northeast of the Site. The historical Likely data set was adjusted to the average elevation of the Mount Polley mine by applying the regional monthly lapse rate presented in Table 7. Data gaps were infilled using data from the four regional ECCC climate stations in a prioritized sequence and applying the monthly temperature lapse rate to adjust for elevation.

Monthly and annual air temperature statistics for the Site (1974-2021) are presented in Table 13 and Figure 16. The estimated mean annual temperature varies between 1.7°C and 6.3°C, with a long-term mean of 3.9°C. Mean monthly temperatures vary between –6.7°C in January and 15.1°C in July. The historical daily maximum and minimum air temperature from the derived long-term data set was 38.1°C in June 2021 (measured at the Site) and -39.8°C in December 1996, respectively. Mean monthly air temperatures generally turn positive in April and negative in November. The percentiles presented in Table 13 indicate the probability of the air temperature to be less than the calculated value for each period, i.e. the 25th percentile for the month of March indicates the monthly air temperature for March is 25% probable to be less than -2.2°C, or 75% probable to exceed -2.2°C. Larger variation between the 25th and 75th percentiles indicate greater variation in air temperature from the median during the month with the largest variations occurring in the winter months (December, January, and February).

Table 13: Derived Air Temperature (°C) Statistics for Mount Polley Mine, 1974 to 2021

Month	Temperature (°C)							
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile	Daily Maximum	Daily Minimum
January	-16.0	-6.7	-0.3	-8.7	-6.3	-4.0	11.2	-39.4
February	-13.0	-4.8	0.7	-7.7	-4.3	-2.1	13.6	-35.4

Annual	**1.7**	**3.9**	**6.3**	**3.2**	**3.9**	**4.5**	**38.1**	**-39.8**

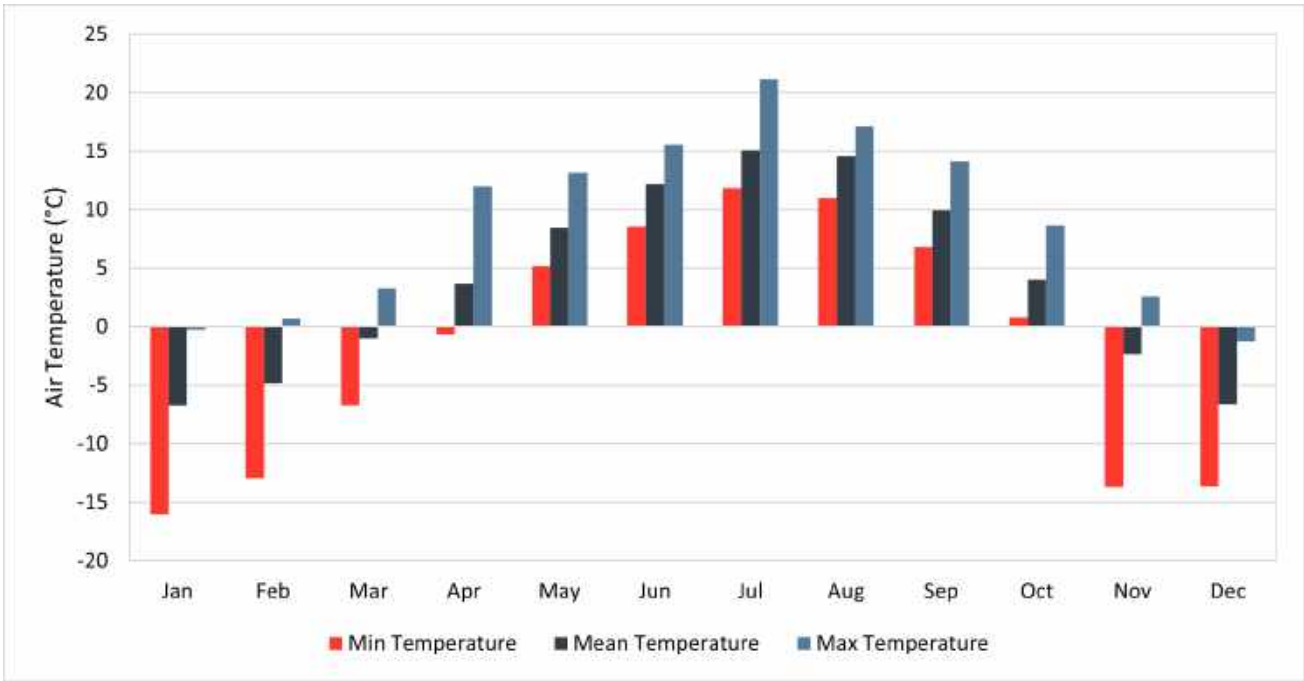

Figure 16 : Derived Monthly Air Temperature Statistics for Mount Polley Mine (1974-2021)

4.4 Relative Humidity

Statistics for relative humidity are presented in Table 14 and Figure 17. Mean annual relative humidity is 68.1%. Monthly mean values vary between 57.7% in April to 82.2% in December. The 25th and 75th percentiles for monthly relative humidity show little variation from the median indicating the Site experiences relatively constant relative humidity on a monthly basis from year to year.

Table 14: Derived Monthly and Annual Relative Humidity Statistics for the Site (1974-2021)

Month	Relative Humidity (%)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	69.2	81.3	90.1	78.9	81.7	84.0
February	65.5	75.0	84.8	72.0	75.6	77.8

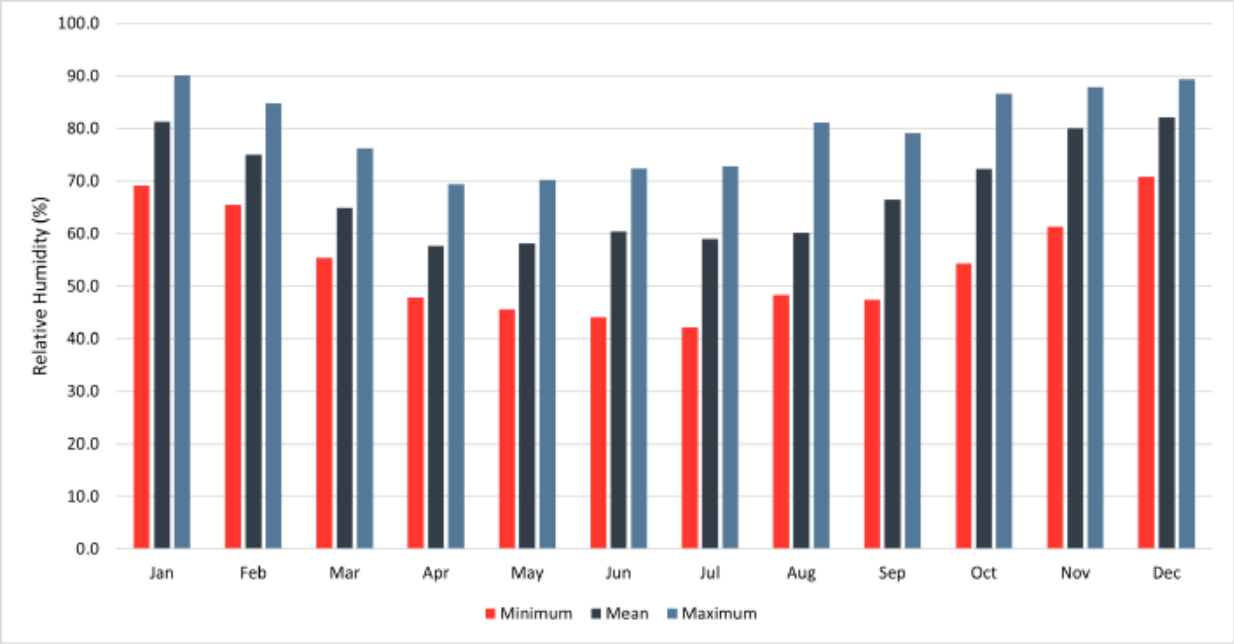

Figure 17 : Derived Monthly Relative Humidity for the Site (1974-2021)

4.5 Solar Radiation

Table 15 and Figure 16 present solar radiation statistics for the Site. Mean annual solar radiation is 135 W/m^2, with a minimum of 127 W/m^2 and maximum of 148 W/m^2. Mean monthly solar radiation varies between 20 W/m^2 in December to 257 W/m^2 in July following the same seasonal pattern for monthly air temperature. The 25th and 75th percentiles show greatest variation in solar radiation occurs in the summer months when solar radiation is greatest during the year, and less variation in winter months when solar radiation is lowest.

Table 15: Estimated Solar Radiation Statistics for the Site (1974-2001)

Month	Solar Radiation (W/m^2)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile

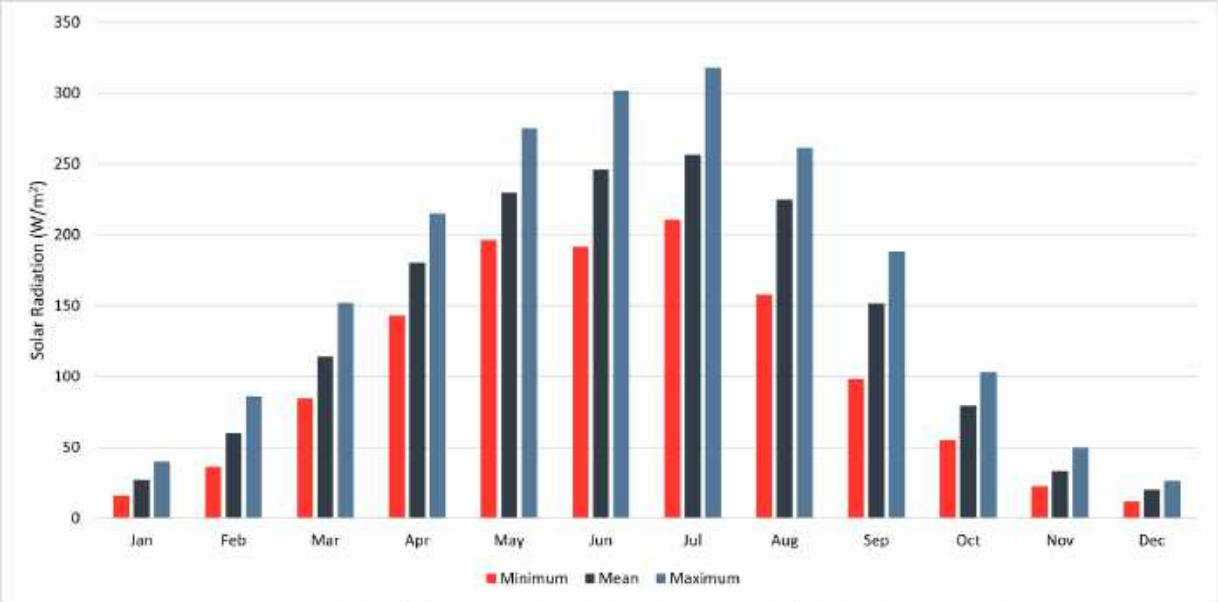

Figure 18 : Estimated Monthly Solar Radiation for the Site (1974-2001)

4.6 Evaporation and Evapotranspiration

The Morton model (Morton 1983) was applied to calculate monthly evaporation, potential evapotranspiration (PET), and actual evapotranspiration (AET) for the Site based on the air temperature, relative humidity, and solar radiation data presented in Sections 4.3, 4.4, and 4.5, respectively. The calculated evaporation rates are considered reflective of potential shallow lake evaporation rates; that is, there is no thermal impact of deeper water levels.

4.6.1 Shallow Lake Evaporation

Table 16 and Figure 19 present monthly statistics for shallow lake evaporation using the Morton Model. The mean annual evaporation rate is estimated to be 673 mm, varying between 606 mm and 762 mm. Mean monthly evaporation rates vary between 0 mm in December to 138 mm in July. The 25th and 75th percentiles indicate that greatest variation in monthly evaporation occurs in July when evaporation is greatest, and lowest variation occurs in January and December when evaporation is lowest.

Table 16 : Estimated Monthly and Annual Shallow Lake Evaporation Statistics for the Site (1974-2001)

Month	Shallow Lake Evaporation (mm)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	0	1	4	0	0	1
February	1	7	12	4	7	10
March	24	32	43	29	32	34
April	52	66	79	59	67	72

Annual	**606**	**673**	**762**	**648**	**670**	**699**

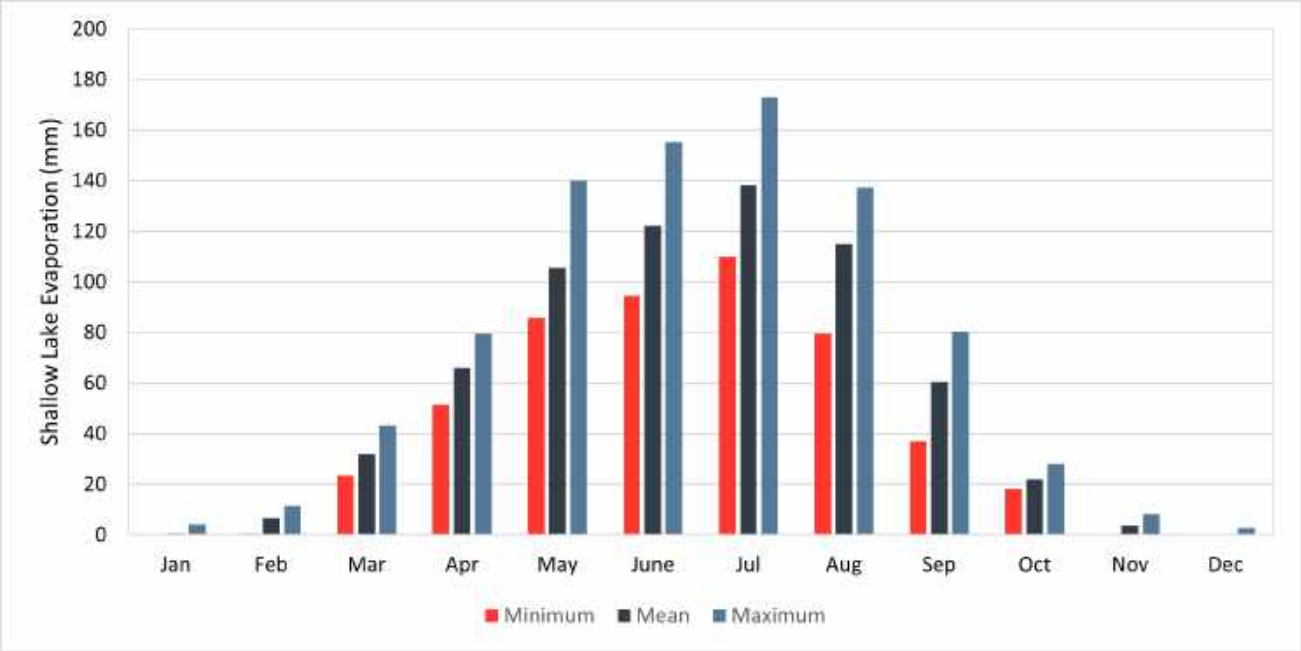

Figure 19 : Estimated Shallow Lake Evaporation Statistics for the Site (1974-2001)

4.6.2 Potential Evapotranspiration

Table 17 and Figure 20 present monthly statistics for PET using the Morton Model. The mean annual PET rate is estimated to be 863 mm, varying between 744 mm and 1022 mm. Mean monthly PET rates vary between 1 mm in December and January to 171 mm in July. The 25th and 75th percentiles indicate that greatest variation in monthly PET occurs in July when PET is greatest, and lowest variation occurs in January and December when PET is lowest. On an annual basis, PET rates are greater than shallow lake evaporation and AET since PET is not limited by the availability of water.

Table 17 : Estimated Monthly and Annual Potential Evapotranspiration Statistics for the Site (1974-2001)

Month	Potential Evapotranspiration (mm)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	0	1	5	0	0	2
February	1	7	11	4	7	10
March	24	41	59	34	42	45
April	68	92	112	83	93	102

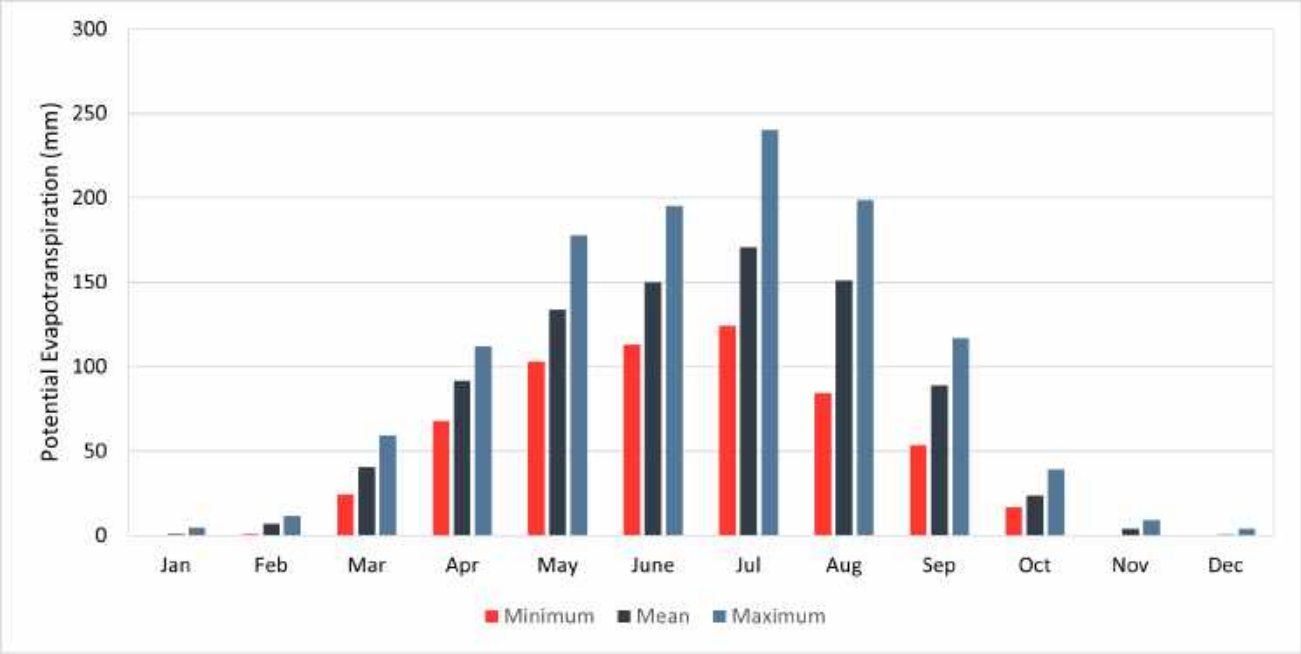

Figure 20 : Estimated Potential Evapotranspiration Statistics for the Site (1974-2001)

4.6.3 Actual Evapotranspiration

Table 18 and Figure 21 present monthly statistics for AET as calculated using the Morton Model. The mean annual AET rate is estimated to be 399 mm, varying between 319 mm and 449 mm. Mean monthly AET rates vary between 1 mm in December and January to 89 mm in July. The 25th and 75th percentiles indicate that greatest variation in monthly AET occurs in July when AET is greatest, and lowest variation occurs in January and December when AET is lowest. On an annual basis, AET at the Site is less than shallow lake evaporation and PET rates because AET is limited by the availability of water, particularly during the summer months when the air temperature is highest.

Table 18 : Estimated Monthly and Annual Actual Evapotranspiration Statistics for the Site (1974-2001)

Month	Actual Evapotranspiration (mm)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile

4.7 Wind Speed and Direction

A wind rose plot for the Site depicting the relative frequency of mean hourly wind speed and direction, and the seasonal distribution, between 29 August 1997 and 27 November 2003 is shown in Figure 22.

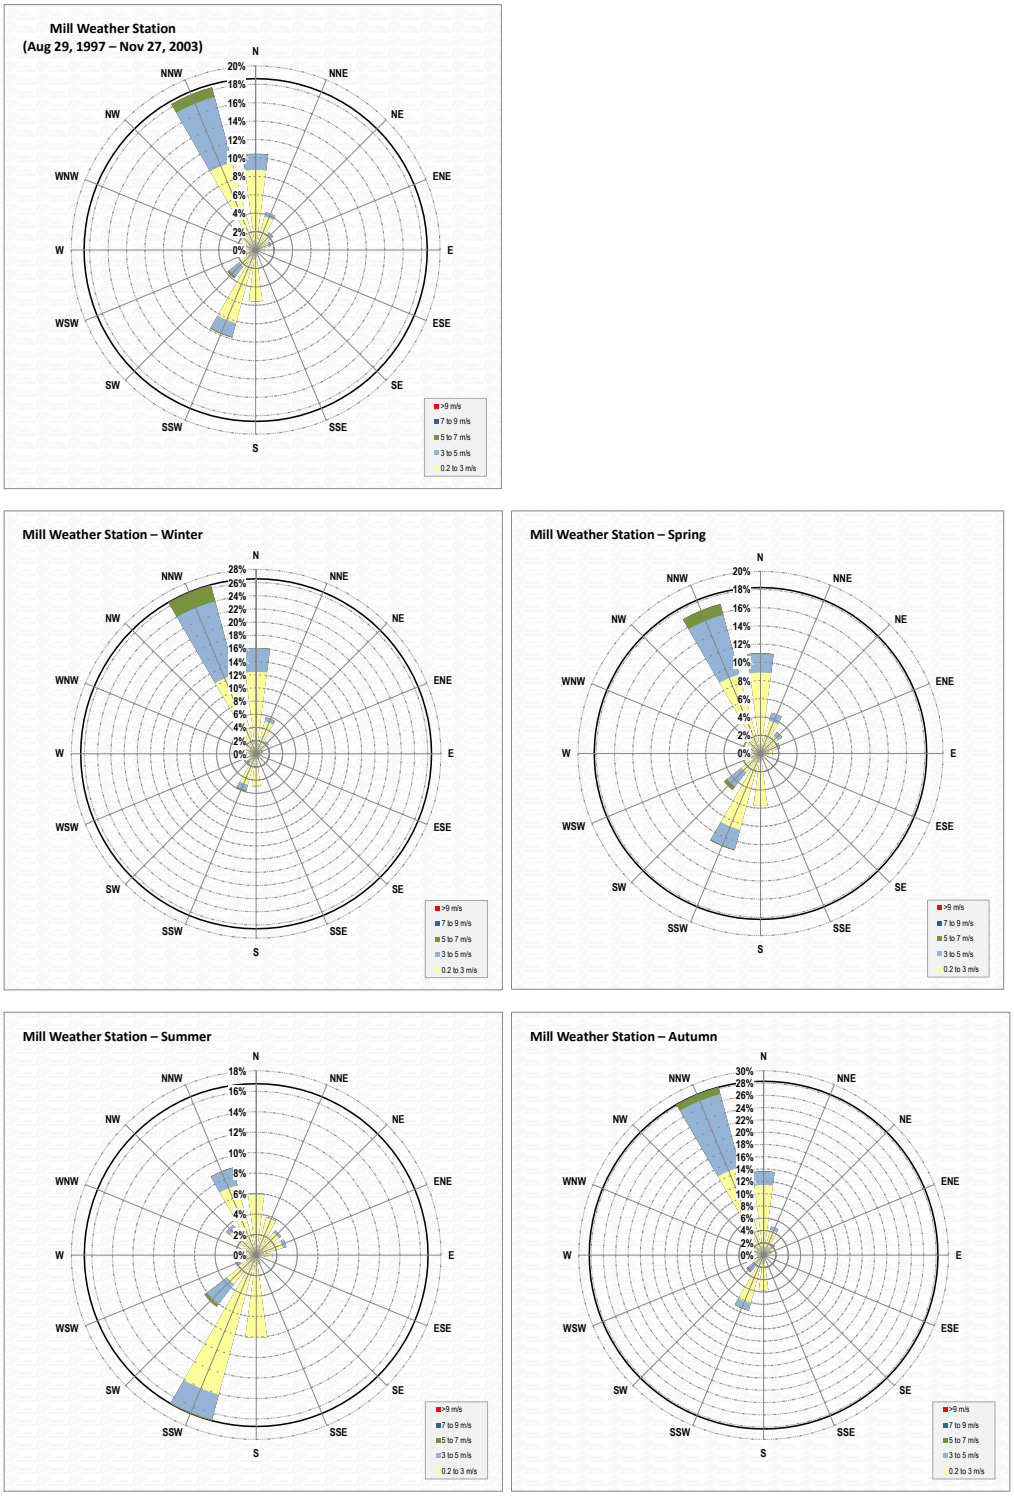

Figure 22: MPMC Station Monitoring Period and Seasonal Wind Roses - 29 August 1997 to 27 November 2003

Spring = March, April, May; Summer = June, July, August; Autumn = September, October, November; Winter = December, January, February.

Winds measured at the Site typically blew from the north-northwest, north, and south-southwest directions, with minimal winds from the east and the west. The spring, autumn, and winter seasonal wind roses were consistent with the wind rose pattern for the entire monitoring period; however, during the summer months, the majority of winds were from the south-southwest. Similarly, wind speeds in spring, autumn, and winter were generally consistent with the wind rose for the entire monitoring period, while wind speeds in summer were generally lower.

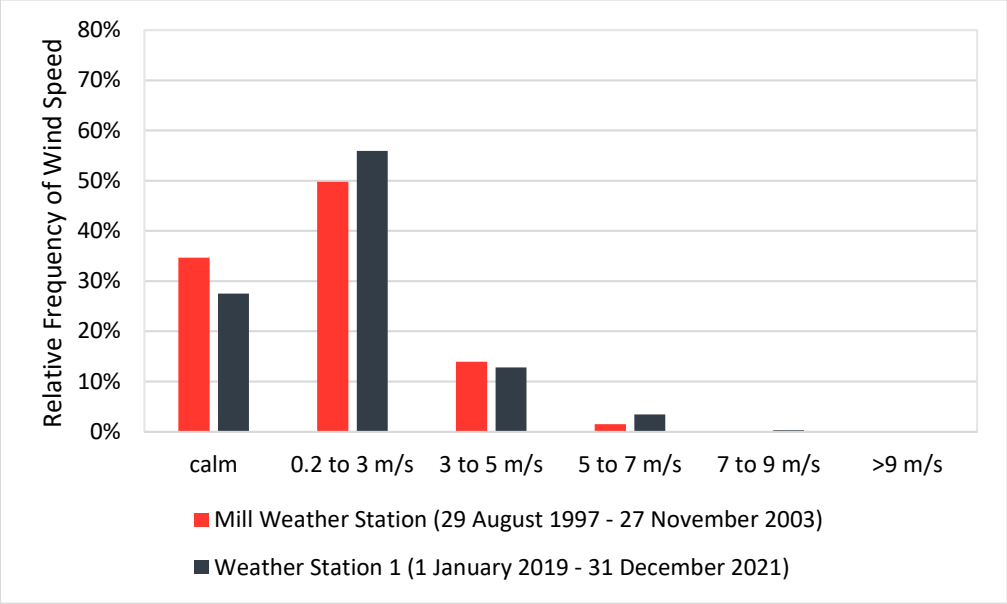
Wind speed measured and seasonal distributions at the Site from 2019 to 2021 were consistent with the relative frequency of wind speed magnitudes and the seasonal distributions recorded between 29 August 1997 and 27 November 2003 (Table 19 and Figure 23). A similar seasonal pattern in wind speed is identifiable with lower wind speeds in the summer months and higher wind speeds in the spring, autumn, and winter months (Table 20 and Figure 24). It is noted that the data from 2019 and 2021 are daily wind speed rather than hourly wind speed and only the relative frequency (%) of wind speed magnitude was compared.

Table 19: Comparison of Relative Frequency of Wind Speed from Mill Weather Station and Weather Station 1 for the Site

Wind Speed (m/s)	Mill Weather Station 29 August 1997 to 27 November 2003[1]	Weather Station 1 1 January 2019 to 31 December 2021[2]
calm	35%	28%
0.2 to 3 m/s	50%	56%
3 to 5 m/s	14%	13%
5 to 7 m/s	2%	3%
7 to 9 m/s	0%	0%
>9 m/s	0%	0%

1) Recorded as hourly wind speed.

2) Recorded as daily wind speed.



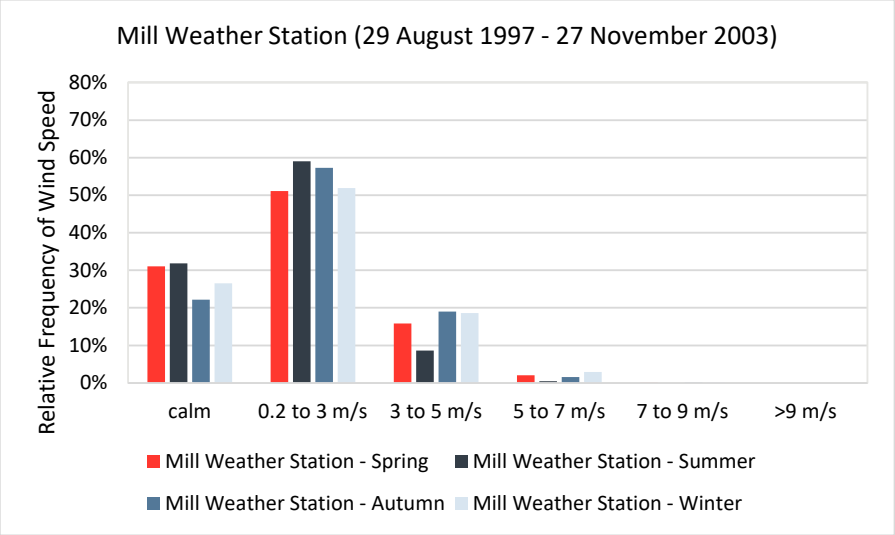


Figure 23: Comparison of Relative Frequency of Wind Speed from Mill Weather Station and Weather Station 1 for the Site

Table 20: Comparison of Relative Frequency of Wind Speed Seasonal Distributions from Mill Weather Station and Weather Station 1 for the Site

Wind Speed (m/s)	Mill Weather Station 29 August 1997 to 27 November 2003[1]				Weather Station 1 1 January 2019 to 31 December 2021[2]			
	Spring	Summer	Autumn	Winter	Spring	Summer	Autumn	Winter
calm	31%	32%	22%	27%	23%	18%	31%	37%

1) Recorded as hourly wind speed.

2) Recorded as daily wind speed.

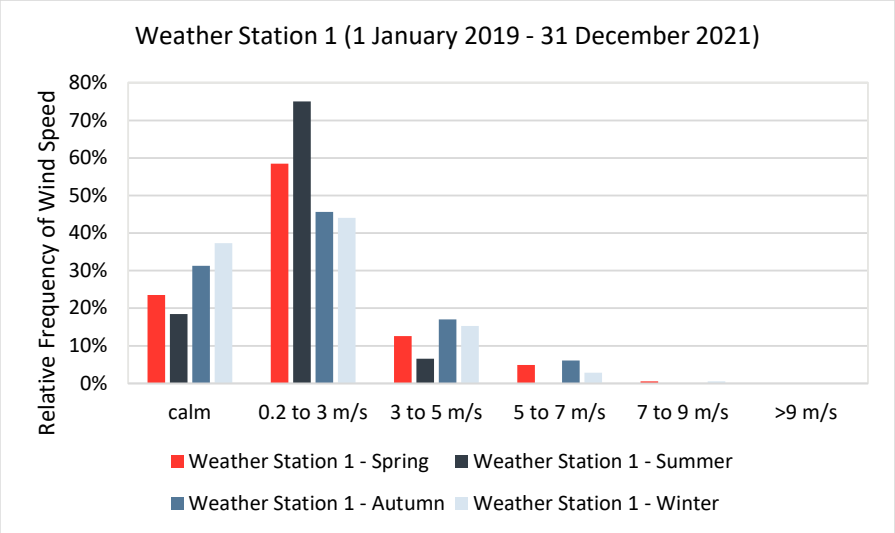

Figure 24: Comparison of Relative Frequency of Wind Speed Seasonal Distribution from Mill Weather Station and Weather Station 1 for the Site

4.8 Snow Cover Properties

Snow cover monthly statistics, reported as SWE, are presented in Table 21. At 50% exceedance, snow begins accumulating in November and achieves its maximum in March, reducing to 0 mm in April. The 5th and 95th percentiles and standard deviation values demonstrate the variability in the amount of SWE at the Site, with March having the greatest variability from year to year.

Table 21: Snow Water Equivalent for the Site (1997-2021)

Month	Number of Measurements	Mean (mm)	Minimum (mm)	Percentile					Maximum (mm)	Standard Deviation (mm)
				5%	25%	50%	75%	95%		
January	22	147	76	88	120	139	164	327	339	56

5.0 CLIMATE CHANGE PROJECTIONS

Future climate projections are important for understanding how climate is projected to change at the Site from the climate baseline. Future climate projections come from publicly available statistical downscaled future climate projections on a daily scale. Recognizing the inherent uncertainty with projections, multiple projections from multiple models and scenarios were included in the analysis presented herein, and the future projections are presented in terms of percentiles or exceedance probabilities. Changes to climate may influence how representative the statistics estimated based on historical data are for future time periods.

5.1 Data Sources for Future Climate

The Intergovernmental Panel on Climate Change (IPCC) is generally considered to be the definitive source of information related to past and future climate change as well as climate science. As an international body, the IPCC provides a common source of information relating to emission scenarios, provides third party reviews of models, and recommends approaches to document future climate projections. Periodically, the IPCC issues assessment reports summarizing the current state of climate science. The Sixth Assessment Report (AR6) (IPCC 2021) represents the most currently available complete synthesis of information regarding climate change.

5.2 Global Climate Change Projections

Future climate is typically projected using global circulation models (GCMs) that involve the mathematical representation of global land, sea, and atmosphere interactions over a long period of time. These GCMs have been developed by various government agencies, but they share a number of common elements as described by the IPCC (2021). The IPCC does not run the models but acts as a clearinghouse for the distribution and sharing of the model forecasts.

Global climate models require extensive inputs to characterize the physical processes and social development paths that could alter climate in the future. To represent the wide range of the possible inputs to global climate models, the IPCC has established a series of Shared Socioeconomic Pathways (SSPs) that help define the future levels of radiative forcing terms. Future climate projection data are available from approximately 30 GCMs and four main SSPs (SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5) in AR6 (ECCC 2022c).

The primary differentiating aspect of each model are the SSPs developed by the IPCC and presented in AR6 to quantify potential emission output scenarios (ECCC 2022c). The SSPs were created with varying assumptions about human developments and are designed to work in combination with an updated version of the Representative Concentration Pathways (RCPs) from the previous IPCC Fifth Assessment Report (AR5) (ECCC 2022c). The SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5 scenarios are the four common greenhouse gas concentration profiles that are widely used; SSP5-8.5 represents the most extreme scenario with the highest volume of greenhouse gases emitted (ECCC 2022c).

5.3 Regional Climate Change Projections

The climate change projection data available from ClimateData.ca portal provided by ECCC uses GCMs with RCP pathways from IPCC AR5 rather than the latest SSPs from AR6. Therefore, the data used in this study will be obtained from ClimateBC.ca provided by the University of British Columbia (UBC). This tool downscales PRISM (Daly et al. 2008) 1971-2000 gridded monthly climate normal data (800 x 800 m) to scale-free point locations and uses the scale-free data as a baseline to downscale more than 200 future climate variables for individual years and periods between 1901 and 2100 (Wang et al. 2016).

The ClimateBC (UBC 2022) tool that is currently managed by UBC uses the same data management framework as Coupled Model Intercomparison Project Number 6 (CMIP6) where the SSP emission profiles are coupled with GCMs. ClimateBC selected a subset of eight GCMs from the models contributing to the CMIP6 ScenarioMIP project based on the following criteria (UBC 2022):

- Minimum of three historical runs available.
- Minimum temperature and maximum temperature available for all runs.
- At least one run for each of the four main SSP marker scenarios.
- One model per institution.
- No closely related models based on Figure 5 in *Reduced global warming from CMIP6 projections when weighting models by performance and independence* (Brunner et al. 2020).
- No large biases over BC.
- Are within IPCCs transient climate response "likely[1]" range and Earth's equilibrium climate sensitivity "very likely[2]" range.

The eight GCMs presented in this report are ACCESS-ESM1-5, BC-CSM2-MR, CNRM-ESM2-1, GFDL-ESM4, GISS-E2-1-G, MIROC6, MPI-ESM1-2-HR, and MRI-ESM2-0.

Table 22: Inventory of Global Climate Models Referenced in this Study

Model	Source / Institution
ACCESS-ESM1-5	Commonwealth Scientific and Industrial Research Organisation
BC-CSM2-MR	Beijing Climate Center
CNRM-ESM2-1	CNRM (Centre National de Recherches Meteorologiques) and CERFACS (Centre Européen de Recherche et de Formation Avancée en Calcul Scientifique)
GFDL-ESM4	National Oceanic and Atmospheric Administration, Geophysical Fluid Dynamics Laboratory
GISS-E2-1-G	Goddard Institute for Space Studies
MIROC6	JAMSTEC (Japan Agency for Marine-Earth Science and Technology), AORI (Atmosphere and Ocean Research Institute), NIES (National Institute for Environmental Studies), and R-CCS (RIKEN Center for Computational Science)
MPI-ESM1-2-HR	Max Planck Institute for Meteorology
MRI-ESM2-0	Meteorological Research Institute

The Site coordinates and elevation were entered into ClimateBC to extract site-specific model outputs (i.e., projections) for precipitation, air temperature, solar radiation, relative humidity, and precipitation as snowfall.

[1] Transient climate response metric in the range 1.4 to 2.2°C (66% likelihood) deemed as "likely" in AR6 (Hausfather et al. 2022).

[2] Equilibrium climate sensitivity metric in the range 2 to 5°C deemed as "very likely" in AR6 (Hausfather et al. 2022).

5.4 Climate Change Projections Results

The following sections build on the current climate baseline by providing the projected changes under future climate conditions for two future time horizons (2041-2070; 2050s, and 2071-2100; 2080s). Time horizons used for the available projections are by periods. Section 5.4.1 provides a description of future projected conditions for temperature and precipitation. Sections 5.4.2 through 5.4.5 provide the projected changes in relative humidity, solar radiation, evaporation, and snow cover. In all sections, projections are provided in terms of exceedance probability measured over the 32-member multi-model ensemble (i.e., 8 models and 4 SSPs). The focus of the results discussion is on the 50th percentile (median), while additional exceedance probabilities are available in the tables presented, including the maximum and minimum. Using the median, or 50th percentile, provides an indication of the middle of the projected changes from the multi-model ensemble.

5.4.1 Future Temperature and Precipitation Projections

This section provides the projected future mean temperature and total precipitation for the Site. The future climate projections are benchmarked against a modelled baseline (e.g., ClimateBC output of the baseline information available for the 32-member multi-model ensemble for the normal period of 1991-2020) and are described in terms of “anomaly” or change from the baseline.

Annual Temperature and Precipitation Projections

Comparisons of the future climate projections of temperature and precipitation for the Site for the 2050s (2041-2070) and 2080s (2071-2100) projection periods are shown as a scatter plot in Figure 25. The plots illustrate the projected change in temperature (vertical axis) and precipitation (horizontal axis) from the current climate baseline (1991 through 2020 normal period) for each of the models and the four SSPs considered in the IPCC’s AR6 (IPCC 2021). For reference, the current climate is shown as a solid circle where the axes intersect. The model projections are generally in the upper right quadrant of the plots, suggesting a future climate that will likely be warmer and wetter. There is a larger spread of future projected precipitation, with a majority of model runs projecting a wetter future climate. Precipitation projections typically have larger uncertainty than temperature projections due to the challenge of capturing precipitation in the climate models (temperature is better understood) (Araya-Osses et al. 2020).

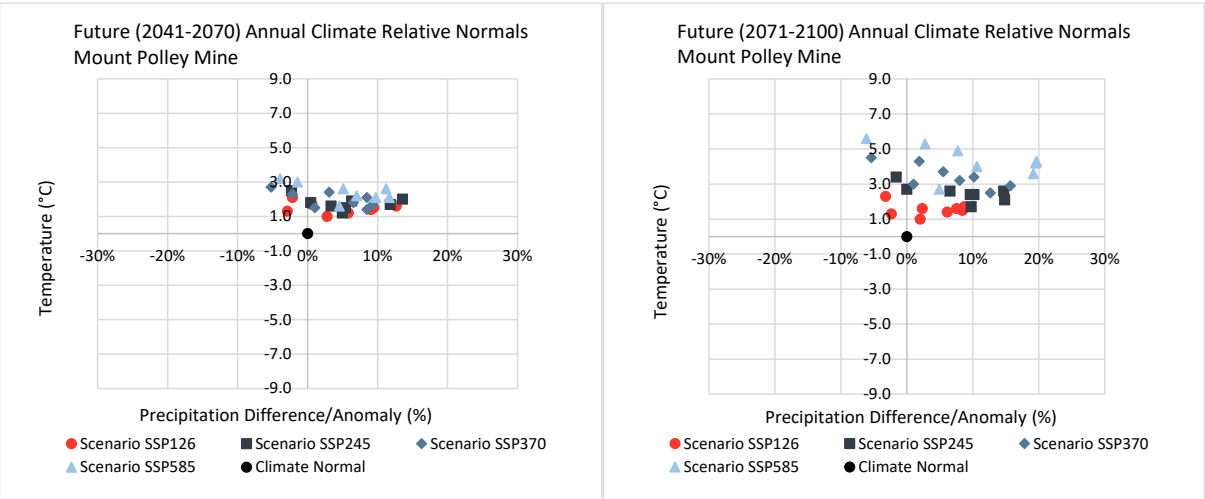

Figure 25: Scatter Plots Presenting Annual Temperature and Precipitation Projections for the 2050s and the 2080s for the Mount Polley Mine Area

Monthly Temperature and Precipitation Projections

Figure 26 and Figure 27 depict the projected anomalies in monthly temperatures for the Site for the 2050s and 2080s, respectively. The figures also show a dashed line which represents the median of all the modelled projections. The dotted lines in the figures represents the spread between the 5th percentile and the 95th percentile of the ensemble. The figures show projected increases in temperature for all months for the 2050s and the 2080s. For the 2050s (Figure 26) the projected increase in the median temperature (dashed line) is less in winter months and greater in the summer months, with an annual average increase of 1.8ºC. The 5th and 95th percentiles of the 2050s ensembles range from an increase of 1.2ºC to around 2.9ºC. The 95th percentile shows a larger variation throughout the months of the year compared to the 5th percentile, and a seasonal pattern arises for the summer months, with larger projected increases of 4.3°C.

The projected increase in the median temperature for the 2080s (Figure 27) is less in winter months and greater in the summer months, with an annual average increase of 2.7ºC. The 5th and 95th percentiles of the 2080s ensemble range from an increase of approximately 1.4ºC to 5.1ºC on average. The 95th percentile shows a larger variation throughout the months of the year and greatest variation in the summer months, with projected increases of 7ºC.

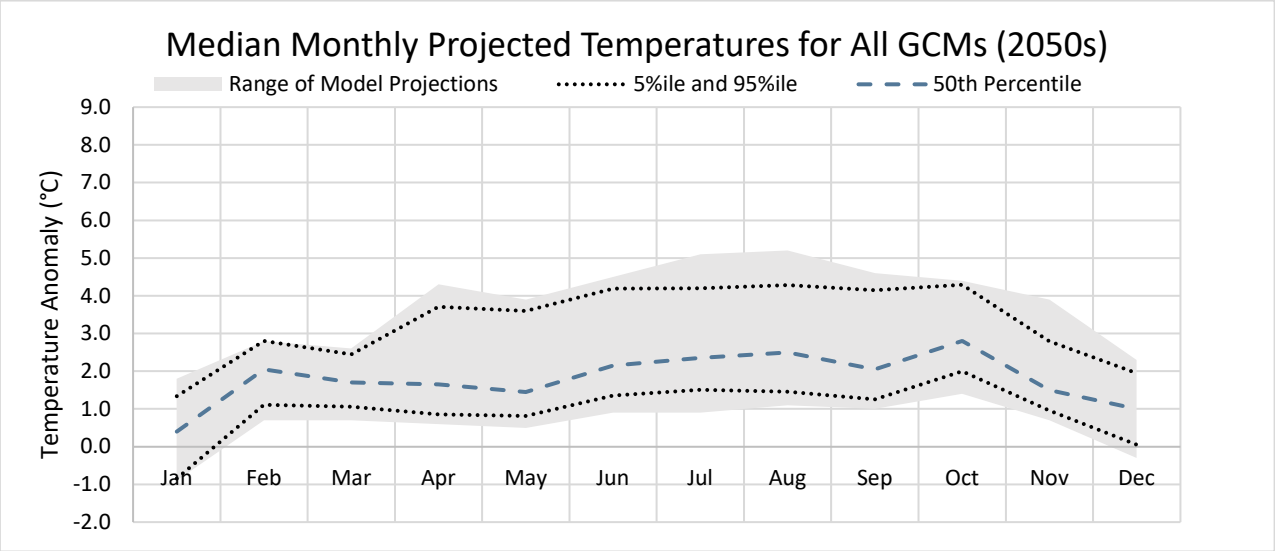

Figure 26: Monthly Projected Temperature Anomalies for the Mount Polley Mine Area (2050s)

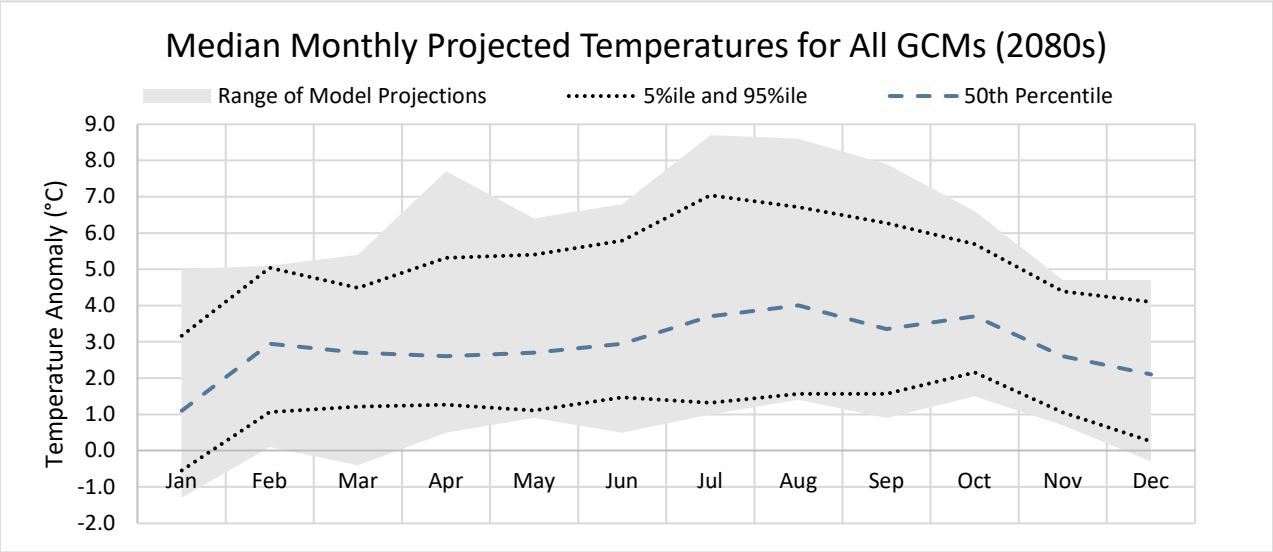

Figure 27: Monthly Projected Temperature Anomalies for the Mount Polley Mine Area (2080s)

Figure 28 and Figure 29 present the monthly projected precipitation anomalies for the Site for the 2050s and 2080s, respectively. For the 2050s (Figure 28) the projected median anomaly (dashed line) indicates changes in the seasonal distribution throughout the year, with an annual average increase of 5%, except for the summer where a slight decrease is projected for the months of June and July. The summer and fall months also present a larger spread in projections from the ensemble (shaded area on the graph), indicating less agreement between the projections. The 2080s (Figure 29) present similar behaviour to the 2050s except for an overall higher projected increase (around 8%), except for the months of June and July, where a decrease in precipitation is projected.

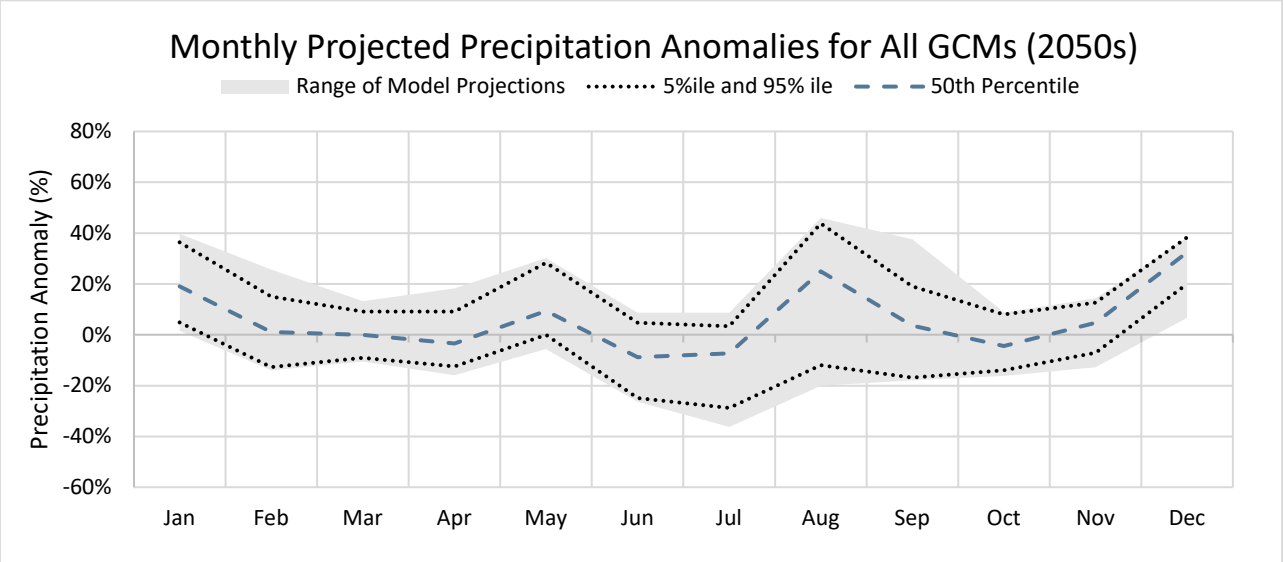

Figure 28: Monthly Projected Precipitation Anomalies for the Mount Polley Mine Area (2050s)

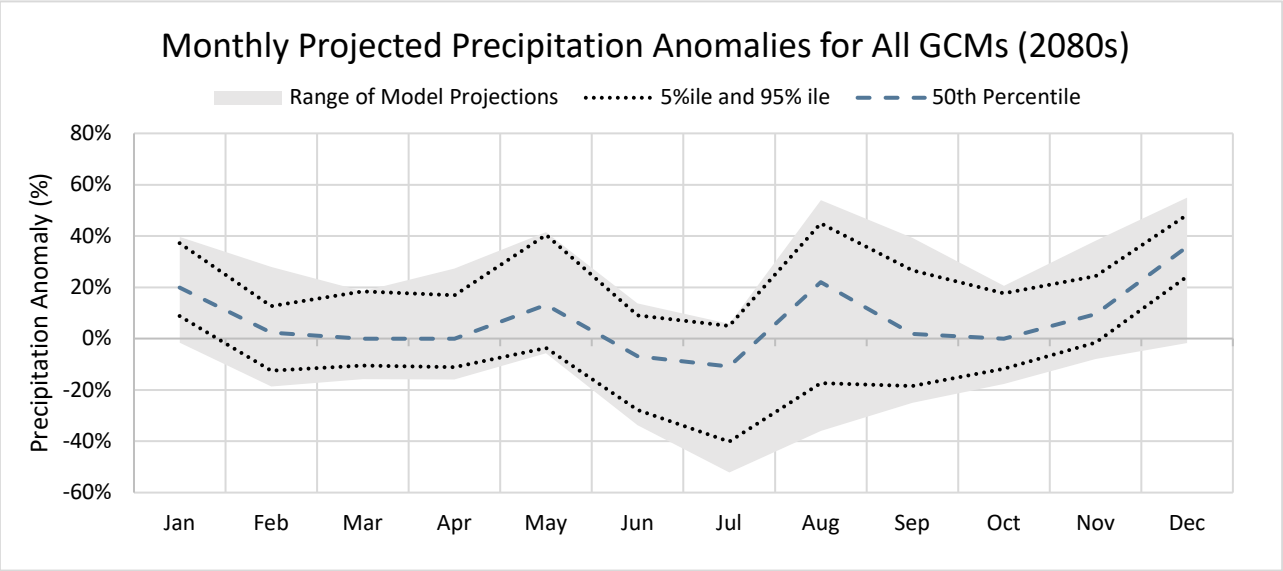

Figure 29: Monthly Projected Precipitation Anomalies for the Mount Polley Mine Area (2080s)

Overall, there is less variability and uncertainty (measured as the agreement within the ensemble or range of projected anomalies) during the 2050s. However, variability increases for both the precipitation and temperature anomalies during the 2080s.

Annual and Monthly Temperature and Precipitation Projections Summary

The projected future changes in the 2050s and 2080s from the baseline period (1991 through 2020) in monthly and annual temperatures are summarized in Table 23 and Table 24. In the 2050s, at 50% exceedance probability, the annual temperature is projected to increase by 1.8°C, with the biggest monthly increase of 2.8°C in October, and smallest monthly increase of 0.4°C in January. In the 2080s, at 50% exceedance probability, the annual temperature is projected to increase by 2.7°C, with the biggest monthly increase of 4.0°C in August, and smallest monthly increase of 1.1°C in January.

Table 23: Projected Anomalies in Monthly and Annual Temperature in the 2050s from Baseline

The projected future changes in the 2050s and 2080s from the baseline period (1991 through 2020) in monthly and annual precipitation are summarized in Table 25 and Table 26. The annual precipitation in the 2050s is projected to increase by 5% from the baseline at the 50% exceedance probability. The projected highest monthly increases in the 2050s occur in the winter and August while small and negative changes are expected in June and July. The 2080s annual precipitation is projected to increase by 8% from the baseline, with the largest increases occurring in winter and August, and a small decrease in the summer months of June and July.

Table 25: Projected Anomalies in Monthly and Annual Precipitation in the 2050s from Baseline

Comparison to Regional Projections

Within Canada there are two major sources of regional projections available: the ClimateData.ca portal (ClimateData 2022) and Canada's Changing Climate Report (Bush and Lemmen 2019). The ClimataData.ca portal provides summarized information about selected locations within Canada using a multi-model ensemble across multiple emission scenarios following IPCC AR5 RCPs (IPCC 2013). Canada's Changing Climate Report (Bush and Lemmen 2019) looks at changing climate trends across Canada and how regional changes fit within the national and global context of climate change. Both resources are used to provide context for the analysis of projections presented in Section 5.4.1 above.

Under a high emissions scenario (RCP 8.5), the ClimateData.ca portal projects a mean annual average temperature increase of 1.6ºC for the 2021 to 2050 period at the Site, 3.6ºC for the 2051 to 2080 period, and 5.1ºC for the end of the century relative to the climate normal period from 1981 to 2010 (ClimateData.ca 2022). This is consistent with the ensemble projections presented above that show increases of 1.8ºC for the 2050s (2041-2070) and 2.7ºC for the 2080s (2071-2100) relative to the modelled climate normal period from 1991 to 2020. Similarly, average annual precipitation is projected by ClimateData.ca to increase by 5% for the 2021 to 2050 period, 12% for the 2051 to 2080 period, and by 15% for the end of the century relative to climate normal period from 1951 to 1980 (ClimateData.ca 2022). These projected changes are consistent with the projections presented above considering the difference in the projection and normal periods (i.e., projection of 5% increase for the 2041 to 2070 period above compared to the 7% increase for the 2051 to 2080 period relative to normal period from 1991 to 2020).

Bush and Lemmen (2019) (Canada's Change Climate Report) does not include trends specifically for the Mine area; however, projections indicate an increase in both mean annual temperature and precipitation, with northern Canada expected to experience larger increases. Under a low emissions scenario (RCP 2.6) temperature is projected to increase by 1.8°C and by more than 6°C under a high emissions scenario (RCP 8.5) by the end of the century. Annual mean precipitation is projected to increase by 7% under a low emissions scenario (RCP 2.6) and by 24% under a high emissions scenario (RCP 8.5) by the end of the century (Bush and Lemmen 2019).

5.4.2 Future Relative Humidity Projections

Annual Projections

Comparison of the future mean annual relative humidity projections from all GCMs for the Mine area and 2050s and 2080s projection periods are shown in Table 27 and Figure 30, and Table 28 and Figure 31, respectively. Projections for the 2050s period shows little variation compared to the baseline period (1991 to 2020) for all climate models and all SSPs with an anomaly range of -2% to 2%. Projections for the 2080s period shows similar pattern to the 2050s period (-1% to 2% anomaly range) for SSP1-2.6 and SSP2-4.5, and greater variation for higher emissions scenarios SSP3-7.0 and SSP5-8.5 (-2% to 5% anomaly range).

Table 27: Projected Mean Annual Relative Humidity for all GCMs (2050s)

Climate Model	Relative Humidity Anomaly (%)			
	Scenario SSP1-2.6	Scenario SSP2-4.5	Scenario SSP3-7.0	Scenario SSP5-8.5

Anomaly Range	-1 to 2	-1 to 2	-2 to 4	-1 to 5

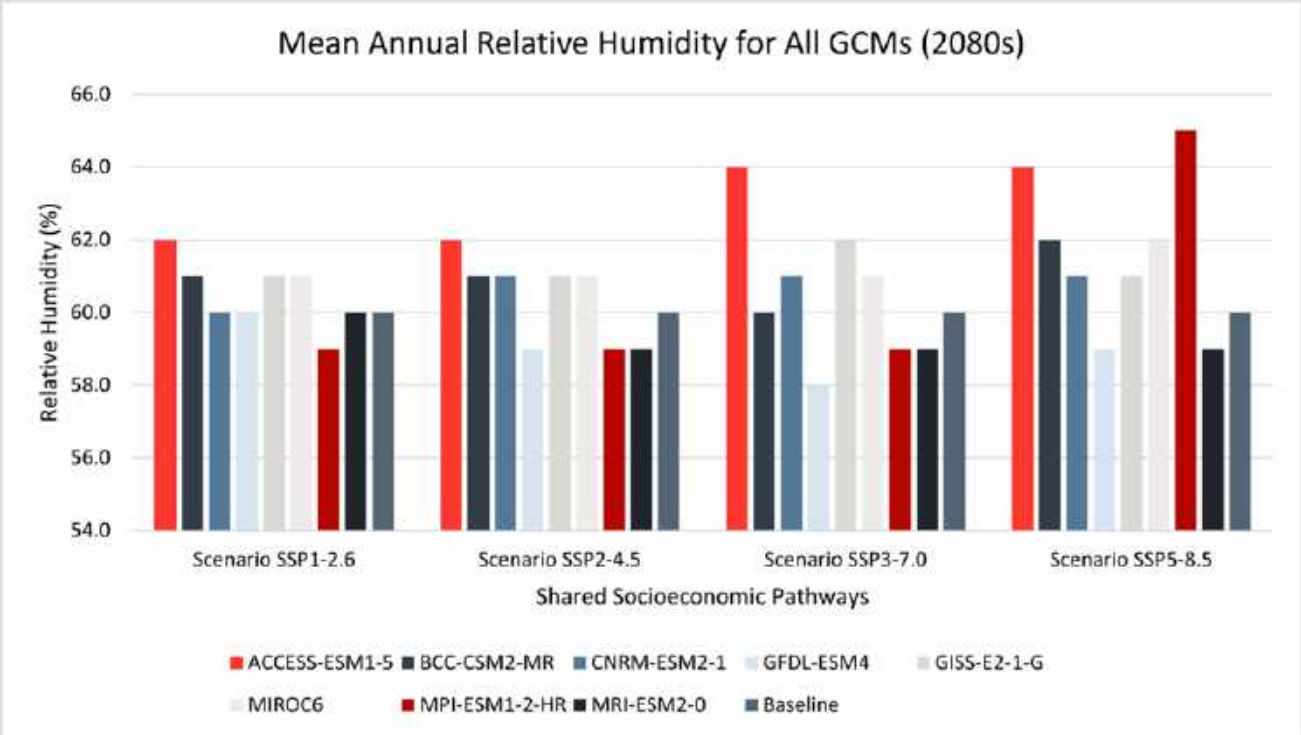

Figure 31: Projected Mean Annual Relative Humidity for all GCMs (2080s)

Monthly Projections

Figure 32 and Figure 33 depict the projected anomalies in monthly median relative humidity at the Site for the 2050s and 2080s, respectively. The figures also show a dashed line which represents the median of all the modelled projections. The dotted lines in the figures represent the spread between the 5th percentile and the 95th percentile of the ensemble. The figures show the projected seasonal pattern with increases in relative humidity for spring and summer months and decreases in relative humidity for winter months, with no change to the annual average. The 5th and 95th percentiles of the 2050s ensembles range from a decrease of -1.0% to an increase of 2.2% on average. The 5th and 95th percentile variations follow the projected median throughout the months of the year, with no discernible seasonal pattern. The 5th and 95th percentiles of the 2080s ensemble, range from a decrease of -1.0% to an increase of 4.0% on average. The 5th and 95th percentile variations are similar throughout the winter months of the year with larger projected uncertainty in the spring and summer months.

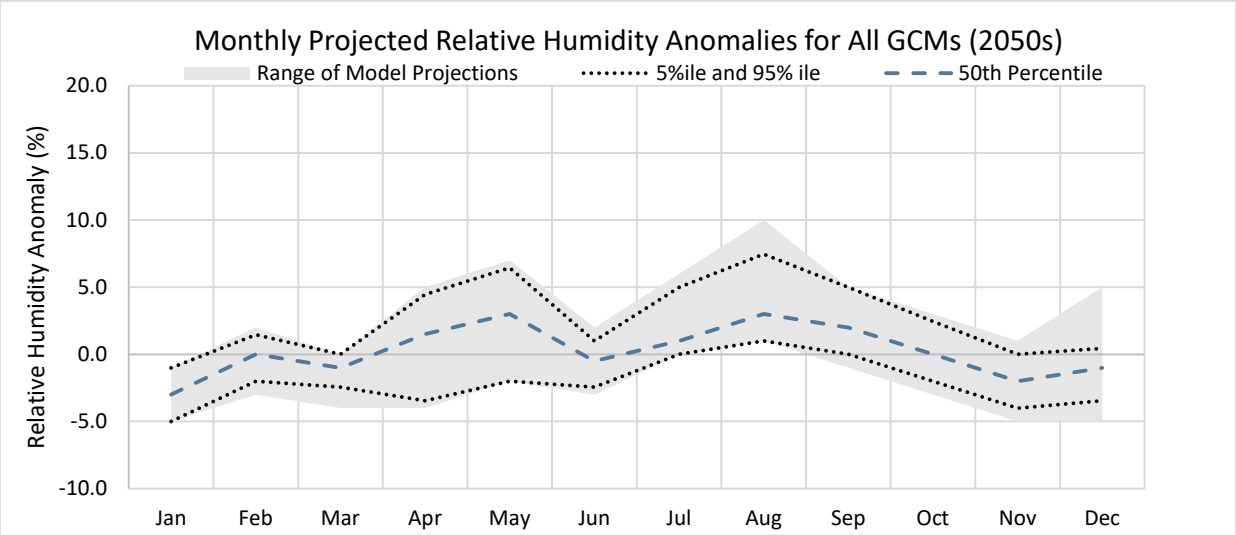

Figure 32: Monthly Projected Relative Humidity Anomalies for Mount Polley Mine Area (2050s)

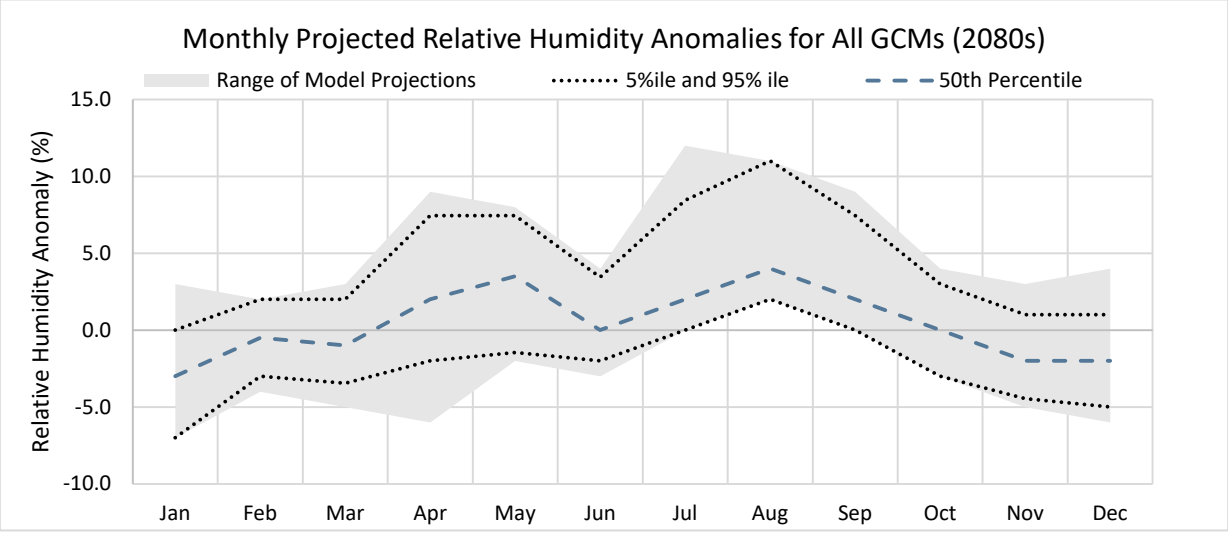

Figure 33: Monthly Projected Relative Humidity Anomalies for Mount Polley Mine Area (2080s)

Summary of Annual and Monthly Projections

The projected future changes in the 2050s and 2080s from the baseline period (1991 through 2020) in monthly and annual relative humidity are summarized in Table 29 and Table 30. In the 2050s, at 50% exceedance probability, the annual relative humidity is projected to remain the same as baseline conditions with monthly relative humidity increasing in spring and summer months (up to 3% absolute increase in May and August) and decreasing in fall and winter months (up to -3% absolute decrease in January). In the 2080s, at 50% exceedance probability, the annual relative humidity is projected to remain the same as baseline conditions with monthly relative humidity increasing in spring and summer months (up to 4% absolute increase in August) and decreasing in fall and winter months (up to -3% in January). There is greater variability in the range of relative humidity in the summer months (Figure 33).

5.4.3 Future Solar Radiation Projections

Annual Projections

Comparison of the future mean annual solar radiation projections for the Mine area for the 2050s and 2080s projection periods are shown in Table 31 and Figure 34, and Table 32 and Figure 35, respectively. Baseline solar radiation for the Site is from ECCC Williams Lake climate station for the period from 1961 through 2001 as modelled baseline solar radiation for the Site is not available. Projections for the 2050s period shows a mean annual solar radiation increase of 4.3% from baseline, with a range of 2.1% to 11.3% increase from baseline across all climate models and SSPs. Projections for the 2080s period shows a mean annual solar radiation increase of 5% from baseline, with a range of 1.2% to 12.2% increase from baseline across all climate models and SSPs.

Table 31: Projected Mean Annual Solar Radiation for all GCMs (2050s)

Climate Model	Solar Radiation Anomaly			
	Scenario SSP1-2.6	Scenario SSP2-4.5	Scenario SSP3-7.0	Scenario SSP5-8.5

a) Baseline solar radiation for the Site is from ECCC Williams Lake climate station for a period from 1961 through 2001.

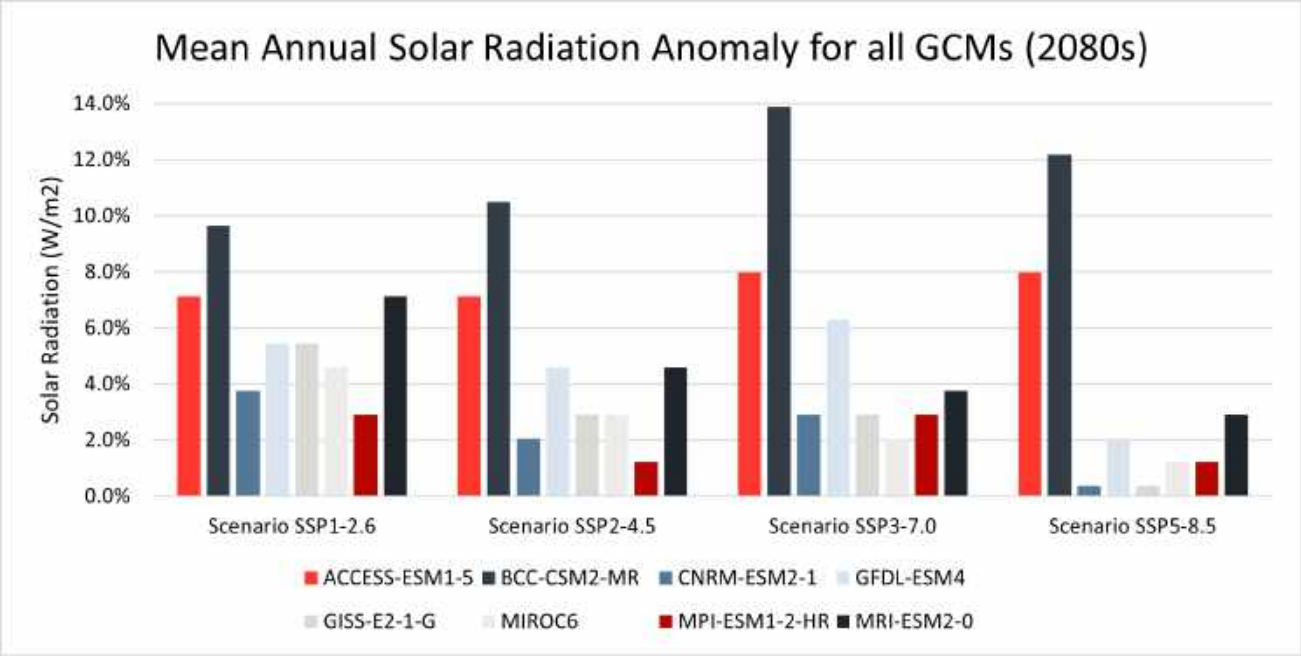

Figure 35: Projected Mean Annual Solar Radiation Anomaly for all GCMs (2080s)

Monthly Projections

Figure 36 and Figure 37 depict the projected anomalies in monthly solar radiation at the Site for the 2050s and 2080s, respectively. The figures also show a dashed line which represents the median of all the modelled projections. The dotted lines in the figures represents the spread between the 5th percentile and 95th percentile of the ensemble. The figures show projected increases in solar radiation for all months for the 2050s and the 2080s except for April, May, and October. For the 2050s (Figure 36) the projected increase in the solar radiation (dashed line) is greater in winter months and less in the summer months, with an annual average increase of 5.1 W/m^2. The 5th and 95th percentiles of the 2050s ensembles range from 2.8 W/m^2 to 11.3 W/m^2 on average with the largest variation occurring in the summer months. The 95th percentile shows a larger variation during the summer months, with projected increases of nearly 21.7 W/m^2.

The projected increase in the mean solar radiation for the 2080s (Figure 37) show a similar pattern to the 2050s period. The projected increase (dotted line) is greater in winter months and less in summer months, with an average annual increase of 5.1 W/m^2. The 5th and 95th percentiles of the 2080s ensemble range from 1.2 W/m^2 to 15.4 W/m2 on average. The 95th percentile shows a larger variation throughout the summer months, with projected increases of nearly 41.2 W/m^2. There is greater uncertainty in the projected solar radiation in July and August.

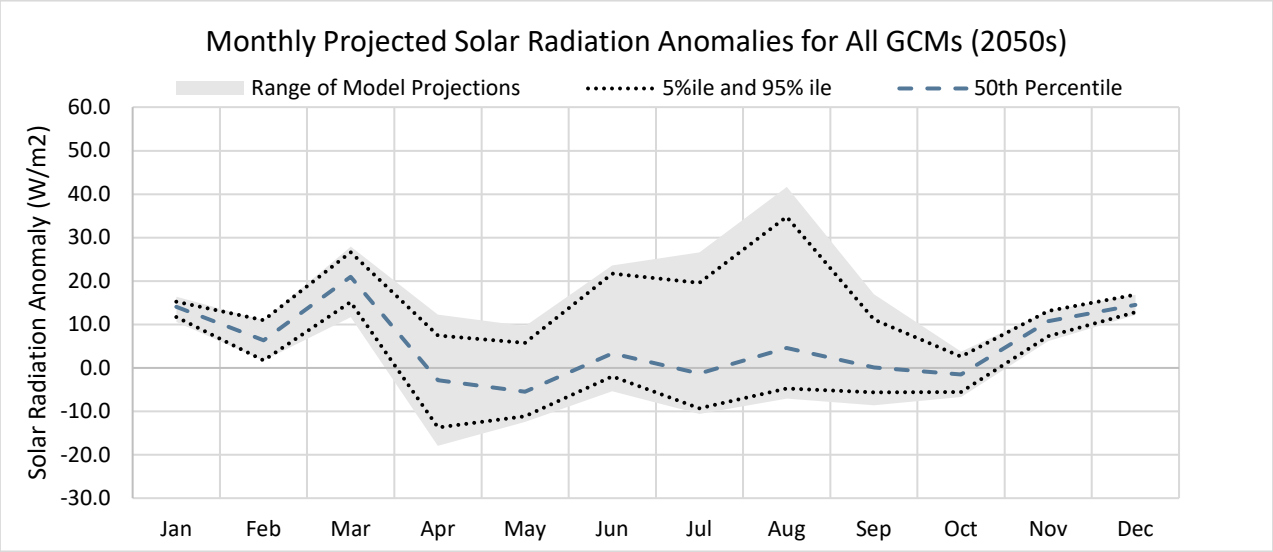

Figure 36: Projected Monthly Solar Radiation Anomalies for Mount Polley Mine Area (2050s)

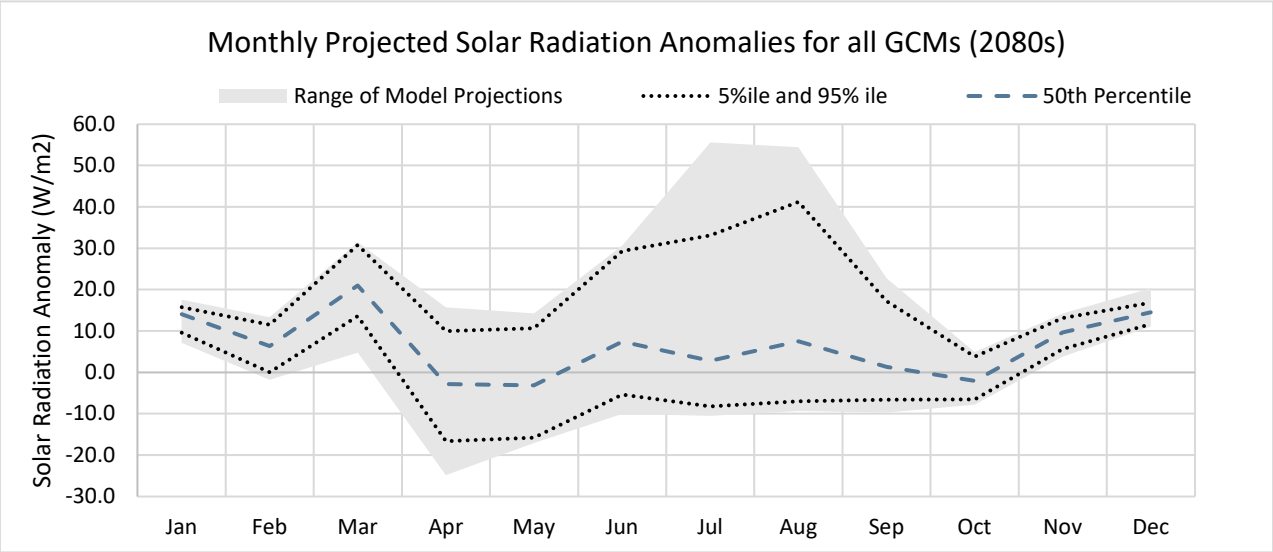

Figure 37: Projected Monthly Solar Radiation Anomalies for Mount Polley Mine Area (2080s)

Summary of Annual and Monthly Projections

The projected future changes in the 2050s and 2080s from the baseline period (Williams Lake 1961 through 2001) in monthly and annual solar radiation are summarized in Table 33 and Table 34. In the 2050s and 2080s, at 50% exceedance probability, the median annual solar radiation is projected to increase by 5.1 W/m^2. Monthly solar radiation is projected to increase for all months except April, May, and October.

Table 33: Projected Anomalies in Monthly and Annual Solar Radiation in the 2050s from Baseline

Month	Min	Percentiles								Max	Mean	Std. Dev.
		5%	10%	25%	50%	75%	90%	95%	99%			
January	10.6	11.8	12.9	13.8	14.1	15.2	15.2	15.2	16.0	16.4	14.0	1.2

5.4.4 Future Evaporation Projections

Evaporation and evapotranspiration projections are not available from ClimateBC or ClimateData.ca. However, evaporation and evapotranspiration are likely to change as dependent variables change, in particular air temperature. The extent of the change will depend on the climate change scenario.

5.4.5 Snow Cover Properties Projections

Potential changes in winter air temperature will likely lead to changes in snow cover properties and the annual SWE available for freshet. ClimateBC does not project snow cover and instead projects precipitation-as-snow (PAS) for future climate periods. PAS projections are indicative of the trends in total snow cover and SWE available to contribute to freshet flows, with less PAS resulting in less SWE. Table 35 summarizes ClimateBC projected PAS for future normal periods relative to the modelled baseline period (1991 through 2020) and indicates an overall decrease in PAS in the future. At 50% exceedance probability, the annual PAS is projected to decrease by 30 mm and 59 mm on average for the 2050s and 2080s, respectively.

Climate change model data published for the province of BC by ECCC (2019) project snow depth reduction relative to the 1986 to 2005 reference normal period using CMIP5 RCP (Table 36). At 50% exceedance, the snow cover depth is projected to decrease by 83 mm and 117 mm on average for the 2046-2065 and 2081-2100 normal periods, respectively.

Table 35: Projected Annual Precipitation-As-Snow Anomaly for the Mount Polley Mine Area

Shared Socioeconomic Pathway	Normal Period	Precipitation-as-Snow Anomaly Percentiles (mm)		
		25%	50%	75%
SSP1-2.6	2011-2040	-7	-4	2
	2041-2070	-23	-17	-13
	2071-2100	-25	-21	-18
SSP2-4.5	2011-2040	-11	-5	2

6.0 CONCLUSION AND RECOMMENDATIONS

This report provides the five-year update of climate baseline at Mount Polley Mine Site as per Requirement 2.1 of the Global Industry Standards on Tailings Management (GISTM). The purpose of the update is to extend the existing long-term climate data for the Site using local and regional data collected in the last five years. The last climate baseline update was carried out by WSP Golder in 2016.

This report provides an updated climate baseline for precipitation, air temperature, relative humidity, solar radiation, evaporation, wind speed and direction, and snow depths, and includes updated climate change projections for the Site. Overall, trends in these climate parameters at Mount Polley are similar to those at Environment and Climate Change Canada (ECCC) regional stations. Future climate projections for Mount Polley show that the future climate at the Site would likely be warmer and wetter, with larger variations throughout the months. The greatest variation would likely be in summer months with a projected summer temperature increase of 7°C and less summer precipitation by the year 2100. Annual temperature is projected to increase by 2.7^{o}C and annual precipitation is projected to increase by 8% from the baseline by 2100.

The updated climate parameters and extended long-term climate dataset are deemed to be representative of the climate at the Site and are suitable for support of design and modelling activities. It is recommended that MPMC continue to monitor and record climate data, and that the climate parameters be updated a minimum of every five years to encompass local and regional data collected, and to reflect uncertainties due to climate change.

SFE	Shake Flask Extraction
TC	Total Carbon
TIC	Total Inorganic Carbon
TSF	Tailings Storage Facility

Executive Summary

Mount Polley Mining Corporation is preparing a Joint Mines Act and Environmental Management Act Permit Amendment Application to support the Springer Pit Expansion Project. The scope of the application includes an extension of the South East Rock Disposal Site (SERDS), an expansion of the Springer Pit, an extension to the duration of treated water discharge to Quesnel Lake to be throughout mining operations, and an extension of the Northwest Potentially Acid Generating (PAG) Stockpile disposal date. This application involves modelling of water quality at the site and in the receiving environment. Inputs to this model are geochemical source terms which are estimations of the chemistry of water in contact with materials and surfaces exposed by mining activity. Source terms mainly consider the potential for metal leaching and acid rock drainage (ML/ARD).

The purpose of this report is to characterize the materials that will be mined as part of the Project, including an assessment outlining the estimated time to onset of acid rock drainage and how it relates to the proposed timeline of the Project, and to describe the derivation and use of the source terms.

The Mount Polley deposit is classified as an alkalic porphyry copper gold deposit. The deposit has been mined from several mineralized zones (Springer, Cariboo, Bell, Southeast, Northeast, Boundary). The proposed extension of the existing Springer and Cariboo pits includes mining in three new zones: Springer Deep Zone, WX Zone, and C2 Zone). With the exception of the distinctive small Pond Zone skarn deposit, all other zones have common geological features including mainly a monzonitic plutonic host rock, association with breccia bodies in the intrusion, dominantly potassic hydrothermal alteration, lack of pronounced pyrite haloes, enrichment in copper and selenium relative to global norms, pervasive calcite, and natural oxide alteration. As a result, geochemical characteristics are consistent between zones, allowing a site-wide approach to geochemical characterization.

PAG and non-PAG waste rock materials occur locally as pyrite zones but non-PAG dominates. ARD potential was used to segregate waste rock, with non-PAG waste rock being placed in several waste rock dumps and PAG waste rock either deposited in completed pits that are projected to flood at the closure of the mine (in accordance with the management practice of subaqueous disposal) or placed in a temporary stockpile for final disposal in the Springer-Cariboo Pit. Based on review of operational processes and data, non-PAG waste rock is expected to be non-acidic in perpetuity.

Tailings are classified as non-PAG based on operational monitoring and testing of tailings spilled into Hazeltine Creek in August 2014.

Major geochemical sources were identified as waste rock stockpiles and the tailings. Other sources include backfilled waste rock, ore processing, pit walls, ore stockpiles, and magnetite stockpiles. Source terms were mainly developed from conceptual geochemical models then interpretation of rock geochemical characteristics and seepage data rather than scale-up of laboratory kinetic test data. Pit wall source terms (including PAG walls) were obtained by scaling of kinetic test data. Source terms were not specifically developed for the magnetite stockpiles because they are small sources.

1 Introduction

Mount Polley Mining Corporation (MPMC), a wholly owned subsidiary of Imperial Metals Corporation, has been operating the Mount Polley Mine (MPM), located approximately 56 km northeast of Williams Lake and approximately 15 km southwest of the community of Likely in British Columbia, Canada, since 1996. MPMC recovers copper and gold from porphyry-style mineralization by open pit and underground mining. The plant is capable of processing 22,000 t/d of ore using standard mineral flotation technology.

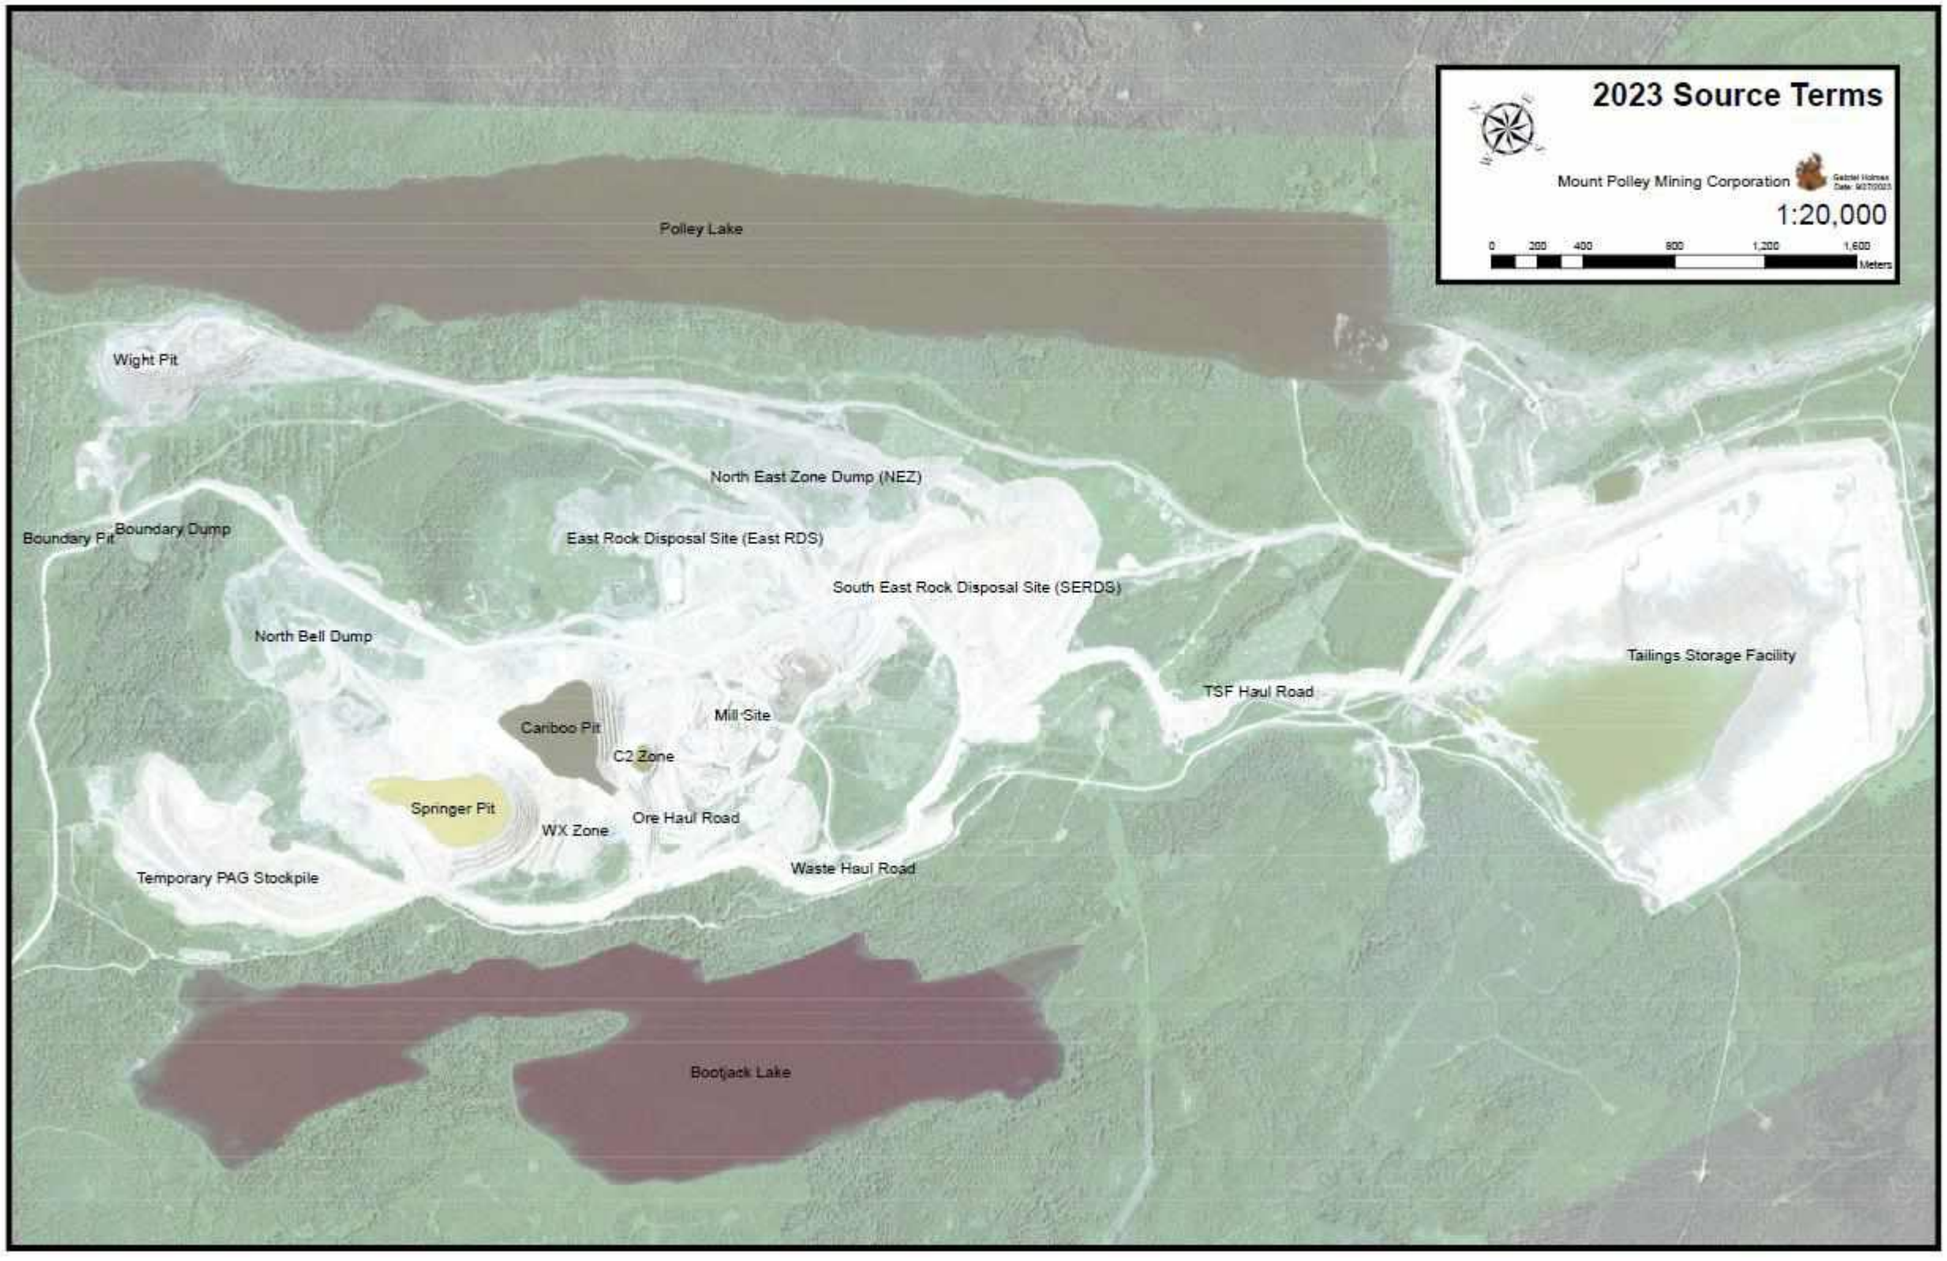
MPMC is preparing a Joint Mines Act and Environmental Management Act Permit Amendment Application to support the Springer Pit Expansion Project (the Project). The scope of the application includes an extension of the South East Rock Disposal Site (SERDS), an expansion of the Springer Pit, an extension to the duration of treated water discharge to Quesnel Lake to be throughout mining operations, and an extension of the Northwest Potentially Acid Generating (PAG) Stockpile disposal date. This application involves modelling of water quality at the site and in the receiving environment. Inputs to this model are geochemical source terms which are estimations of the chemistry of water in contact with materials and surfaces exposed by mining activity. Source terms mainly consider the potential for metal leaching and acid rock drainage (ML/ARD).

The purpose of this report is to characterize the materials that will be mined as part of the Project, including an assessment outlining the estimated time to onset of acid rock drainage and how it relates to the proposed timeline of the Project, and to describe the derivation and use of the source terms.

2 Background

2.1 Site Overview and Closure

Figure 1 shows the locations of the open pits at MPM. Full scale mining began in the Cariboo Pit by mining high oxide and high gold parts of the ore body then transitioning to the Bell Pit in 1999. Mining was suspended in 2001 due to unfavorable market conditions. The mine re-opened in 2005 after a three-and-a-half-year care-and-maintenance period. The following zones have been mined since 2005:



- Completed mining and backfilling of the Bell Pit.
- Completed mining and backfilling of the small Southeast Zone and Pond Zone Pits.
- Completed mining and flooding of the Wight Pit (Northeast Zone).
- Completed mining of the Boundary Pit.
- Completed permitted mining and flooding of Northeast Zone underground (access from the Wight Pit).

In August 2014, mining was suspended due to the breach of the tailings dam. Mining restarted in 2015 with tailings being deposited in the Springer Pit. In 2016, tailings were deposited in the Tailings Storage Facility (TSF) following reconstruction of the dam.

In May 2019, mining was again suspended due to unfavourable market conditions, but mining operations restarted in November 2021 and milling operations resumed in June 2022. Active mining is currently focussed on the Cariboo and Springer Pits (which will merge to a single pit).

Upon completion of mining, the Springer-Cariboo Pit will be backfilled by rock from the Temporary Northwest (NW) PAG Stockpile (the NAG/PAG Pad) and allowed to flood. The TSF will be decommissioned with a minimal water cover.

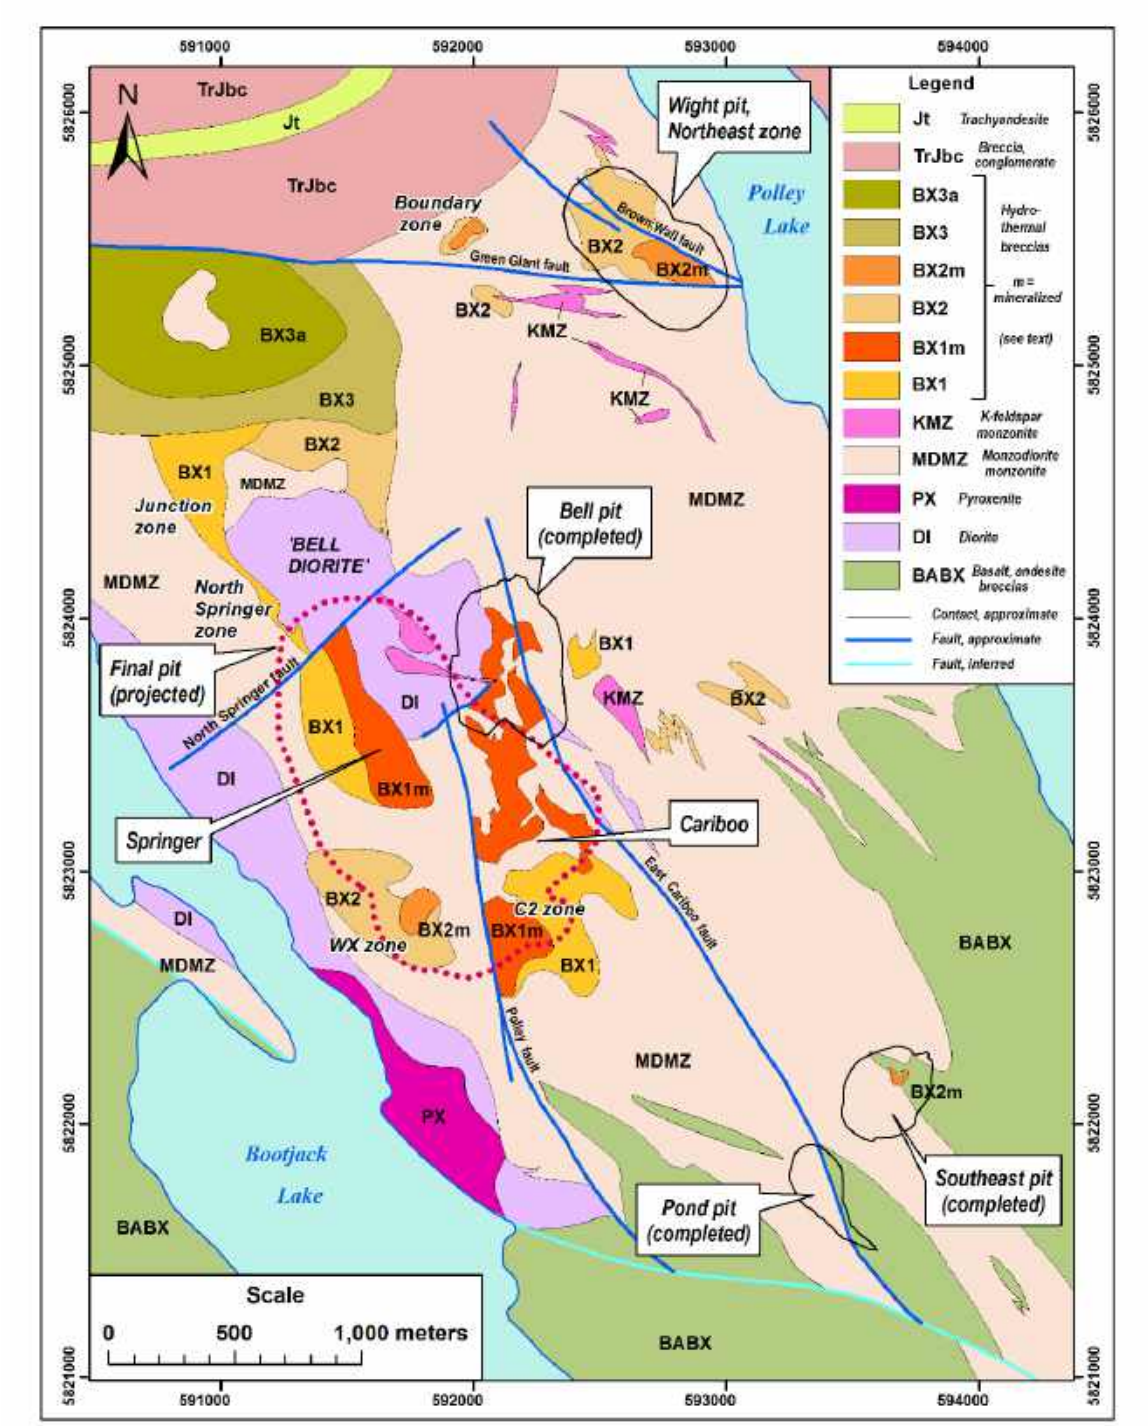
2.2 Geological Setting

The Mount Polley deposit is classified as an alkalic porphyry copper gold deposit (BC MINFILE No. 093A 008). With the exception of the distinctive small Pond Zone, it has been mined from several mineralized zones which have the following common features:

- The host rock for porphyry mineralization is the Mount Polley Intrusive Complex (MPIC) which intruded into Nicola Group Volcanics (Figure 2). The intrusion is primarily monzonite to monzo-diorite in composition. Smaller phases vary in composition from diorite to syenite.
- Mineralization is associated with magmatic-hydrothermal breccias. Alteration and mineralization occurs in the matrix of the breccias, and in veins and swarms distributed around the breccias. BX1 is the main host for the bulk of the mineralization at MPM which is mined in the Cariboo and Springer Pits (Figure 2). BX1 is characterized by alteration which resulted in the strongest destruction of both primary and breccia textures. Breccia bodies BX2 host satellite mineralization in the Southeast Zone, Wight Pit, and Boundary Zone. BX2 is less intensively altered and original textures are more apparent. BX3 is unmineralized and has not been mined.
- Alteration at MPM is classified as potassic (sodic and calcic) with salmon-pink potassium feldspar as the main alteration mineral. Biotite is less common. Sodic alteration is defined by albite and calcic alteration (actinolite, diopside, epidote, clinozoisite, and sporadic andraditic garnet). Calcite is pervasive. Alteration is zoned with the strongest calcic-potassic alteration in the core associated with BX1. Nicola Group rocks and fringing MPIC rocks are propylitically-altered and characterized by stronger epidote and pyrite.
- Like other alkalic porphyry deposits (e.g., Copper Mountain, Brenda), MPM lacks the strong hydrothermal alteration zoning that is commonly observed in calc-alkalic porphyry deposits (e.g., Highland Valley Copper, Island Copper, Gibraltar). In particular, phyllic alteration is absent at MPM. A common feature of calc-alkalic porphyry deposits is often a pronounced pyritic halo that surrounds the copper mineralization and is associated with phyllic and propylitic alteration. At MPM, discontinuous pyritic zones are present but do not appear to be mineralization halos. MPM geological staff identified a pyritic zone in the south wall of the Springer Pit which extends into the adjacent Cariboo Pit. Samples from Bell Pit blast holes collected in the early years of operations were identified as being from a Pyrite Zone but the location of this feature is not known.
- Sulphide mineralization consists mainly of chalcopyrite ($CuFeS_2$) and pyrite (FeS_2), with lesser bornite (Cu_5FeS_4), covellite (CuS), and digenite (Cu_9S_5). Bornite is relatively more abundant in the Northeast and Boundary Zones.
- Carbonate mineralization is principally calcite, with occurrences of malachite ($Cu_2CO_3(OH)_2$) formed as a natural weathering product. Iron carbonates have not been reported.
- A significant portion of the copper at the MPM is not associated with sulphides (upwards of 50% in the upper portions of each pit). This fraction has been termed ‘copper oxide’ by MPM personnel and is associated primarily with chrysocolla ($(Cu,Al)_2H_2Si_2O_5(OH)_4 \cdot nH_2O$) and malachite ($Cu_2CO_3(OH)_2$) in equal proportions (Henry 2009). SRK (2015b) has shown that chlorite is a significant host for copper. It is assumed that chlorite formed hydrothermally and incorporated



copper as part of the mineralizing event rather than due to weathering. Suarez et al. (2009) found that the form of copper in chlorite at the Aguablanca Ni-Cu-PGE Sulfide Deposit was native copper between silicate layers rather than as a substitution in the crystal lattice. The mineral is suspected to have formed during hydrothermal alteration rather than by natural weathering processes. It is not known whether this same form of copper is also present at MPM.

The small Pond Zone is andradite-clinopyroxene-magnetite skarn mineralization occurring at the contact between a diorite to monzodiorite intrusion and Nicola Group volcanic rocks of andesite to basalt composition. It appears to be linked to the presence of a limestone unit in the Nicola Group.

From an ML/ARD perspective, a significant feature of the Mount Polley mineralization is the lack of reported arsenic, lead, and zinc minerals which are commonly associated with porphyry deposits elsewhere in British Columbia and globally. Since arsenic, zinc, and associated cadmium are relatively mobile under non-acidic conditions, the lack of the minerals hosting these elements indicates that potential for leaching concerns is lower than other porphyries. Based on the copper sulphide and copper oxide dominated mineralogy, the primary metal leaching concern is expected to be for copper.

In addition, the lack of a distinctive pyrite halo means that pyrite abundance is lower than other porphyry deposits and ARD potential is expected to be lower.

2.3 ML/ARD Management

2.3.1 Classification of Mine Waste

According to the *Mines Act* Permit M-200 (referred to as the M-200 Permit in this document), potentially acid generating (PAG) and ML materials are defined as:

- Neutralization potential (NP) is calculated using total inorganic carbon (TIC).
- Acid potential (AP) is calculated using total sulphur.
- All waste rock, quarry rock, borrow materials, and tailings are classified as PAG if they have an NP/AP ratio of less than 2.0.
- Borrow material or waste rock containing soluble metal levels (as determined by the shake flask test) higher than the receiving water objectives are defined as having potential for metal leaching.

2.3.2 Mine Waste Rock and Tailings Management

The M-200 Permit specifies the following requirements for waste management:

- Waste Rock
  - PAG waste rock can only be disposed in the Cariboo, combined Cariboo/Springer, Wight, and Southeast Zone pits, where it is submerged permanently beneath a water cover.
  - A maximum of 62 million tonnes of PAG waste rock can be stored in the Temporary NW PAG Stockpile.
  - Isolated pockets of PAG materials (less than 1,000 tonnes) may be blended with non-PAG materials within the waste rock dumps, at a minimum non-PAG:PAG ratio of 20:1.
- Quarry Rock
  - Quarry rock can be used as construction material in the TSF if the NP/AP is greater than 2.0 and the total copper solid concentration is less than 180 mg/kg.
- Tailings
  - PAG tailings may not be cycloned for use in dam construction.
  - Cyclone tailings must have an NP/AP ratio greater than 2.0.
  - Cycloned tailings may be used for construction of the following TSF components:
    - The upstream and downstream faces of the Perimeter Embankment.
    - The upstream side of the Main Embankment.
    - The maintenance of a till core in the Perimeter and Main Embankments.

The procedure used by MPMC to identify and segregate PAG waste rock is attached in Appendix A.

2.3.3 Waste Rock Inventory

Table 1 summarizes major waste rock disposal locations as of September 30, 2023, which are shown in Figure 1. The primary NAG rock disposal locations are the North Bell Dump, which includes backfill in the Bell Pit, the South East Rock Disposal Site (SERDS), which also includes the backfilled Southeast Zone and Pond Zone Pits, and the Northeast Zone (NEZ) Dump. NAG rock has been used for construction purposes (Waste Haul Road and the TSF). NAG rock from the open pits has been disposed at a variety of different locations resulting in waste rock dumps containing non-unique source materials. The exception is that the NEZ Dump received waste primarily from the Wight Pit.

As described in SRK (2016), prior to 2005 (i.e., before operations were re-started), limited PAG waste rock was mined and was dumped into the bottom of the Bell Pit. A small amount was dumped over the north end of the Cariboo Pit, but it was re-handled to the bottom of the Cariboo Pit. Acid-base accounting (ABA) analyses were performed by an external lab.

Since 2005, PAG waste rock has primarily been disposed in the Temporary NW PAG Stockpile (which includes the NAG/PAG Pad and called Ex-pit PAG in this report) which is planned to be backhauled to the Springer-Cariboo Pit at closure for subaqueous disposal. PAG rock has also been disposed sub-aqueously in the Cariboo Pit backfill and Southeast Zone Pit. PAG rock mainly originates from the Cariboo Pit and Springer Pit. The PAG waste rock in the North Bell Dump originated from the Southeast Zone Pit which was dominated by PAG waste rock.

An amendment to Mines Act Permit M-200 on July 8, 2009 allowed the placement of low sulphur (less than 0.3%) waste (LSW) as 2 m layers with Springer Zone NAG waste rock to create a NAG waste rock blend. The quantity of PAG rock mined from the Pond Zone was 6,615 t, which was disposed in a portion of the Northeast Zone Dump referred to as the Sandwich Dump.

2.3.4 Stockpiled Ore

Stockpiled ore is not classified by ARD potential, but the quantities are insignificant relative to waste rock. The current quantity of stockpiled ore is summarized in Table 2.

Table 1: Waste Rock Disposal Locations as of September 30, 2023

Placement Location	NAG		PAG	
	Mass (kt)	Percent of NAG	Mass (kt)	Percent of PAG
Bell Pit Rock Disposal	74,891	30%	530[1]	1%
Boundary Pit Rock Disposal	821	0.3%	-	0%
Temporary NW PAG Stockpile	7,461	3.0%	34,560	78%
East Rock Disposal Site	28,502	11%	-	0%
South East Rock Disposal Site	66,617	26%	-	0%
SERDS Co-Disposal	3,146	1.2%	-	0%
Northeast Zone Dump	34,590	14%	-	0%
Sandwich Dump	275[2]	0.1%	-	0%
Southeast Pit Backfill	36	0.01%	1,017[1]	2%
Wight Pit Backfill	363	0.1%	8,089	18%
Crusher Haul Road	4,116	1.6%	-	0%
SERD Lower Haul Road	6,953	2.8%	-	0%
TSF Access and Haul Roads	6,624	2.6%	-	0%
TSF Dam	15,230	6.0%	-	0%
Other (Minor Road Construction and Maintenance)	2,999	1.2%	-	0%
Total Tonnes	**252,625**		**44,197**	

Sources: MPMC, https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/Compiled_Geochem_Data_CAPR002434_Rev02_SJL_KWJ.xlsx

Notes:

[1] Submerged.

[2] Includes 6,615 t of low sulphur waste from the Pond Zone.

Table 2: Stockpiled Ore Inventory

Stockpile	Mass (kt)
#1 Stockpile	70
Upper Super High Grade & High Oxide	12
Low Grade Stockpiles[1]	800
Springer Ore Muck (in pit)	162
#3 Stockpile	1,538
High Oxide	2,564
Total	**5,147**

Notes:

[3] Total of two low grade stockpiles.

2.4 Springer Pit Expansion

MPM is proposing to extend the LOM to 2032 by mining approximately 65 million tonnes of additional ore from an extension of MPM Site's existing pit infrastructure. The project will include the following modifications:

- **Pit and waste rock dump extensions:** extension of the existing Springer and Cariboo pits (i.e., into Springer Deep Zone, WX Zone, and C2 Zone) and associated waste rock dumps (SERDS and Temporary NW PAG Stockpile).
- **PAG waste rock disposal date:** To allow for mining to continue in the Springer Pit for the proposed LOM, the date in which the Springer-Cariboo Pit will be backfilled by PAG rock from the Temporary NW PAG Stockpile will need to be extended to December 31, 2034. This accounts for three years of rehandling PAG material (2032 to 2034).
- **Tailings storage expansion:** incremental expansion of the existing TSF to accommodate additional tailings form the extended mine life.

3 Geochemical Characteristics

3.1 Rock

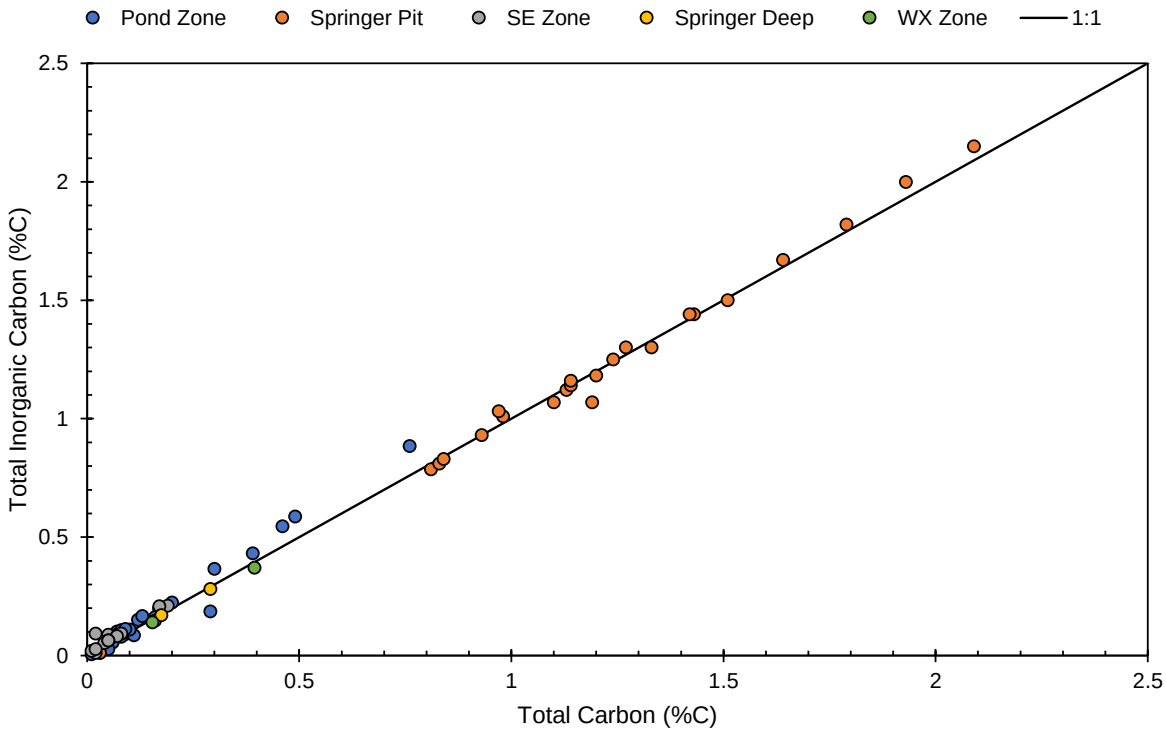
3.1.1 Overview

Understanding of waste rock geochemical characteristics has been accumulated from a variety of sources including diamond drill core tested prior to mining, blast hole cuttings to inform waste rock management operations in the pit during operations, and post-depositional monitoring (Table 3). The database is dominated by the data gathered to operationally characterize waste rock in the Springer Pit, including the Springer Deep Zone. However, the database is incomplete because some of the earlier data were lost, and blast hole data are lacking for Cariboo Pit and Bell Pit. For Cariboo Pit and Wight Pit, confirmatory post-depositional data partly address this gap. For Cariboo Pit, data gathered to operationally characterize waste rock during more recent mining operations in the pit from 2016 – 2019 also addresses this gap.

Table 3: Static Test Inventory for Rock Samples with Known Source as of the End of 2022

Source	Drill Core	Blast Hole	Confirmatory[1]	Total
Boundary Zone	16	123	0	139
Bell Pit	0	78	25	103
Wight Zone	102	0	0	102
SE Zone	52	132	0	184
Pond Zone	27	174	0	201
Springer Pit	131	4,929	9	5,069
Cariboo Pit	1,004	2,877	60	3,941
C2 Pit	604	0	0	604
Springer Deep	16,391	0	0	16,391
WX Zone	5,267	0	0	5,267
Total	23,594	8,313	94	32,001

Source: https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/[Compiled_Geochem_Data_CAPR002434_Rev02_SJL_KWJ.xlsm]



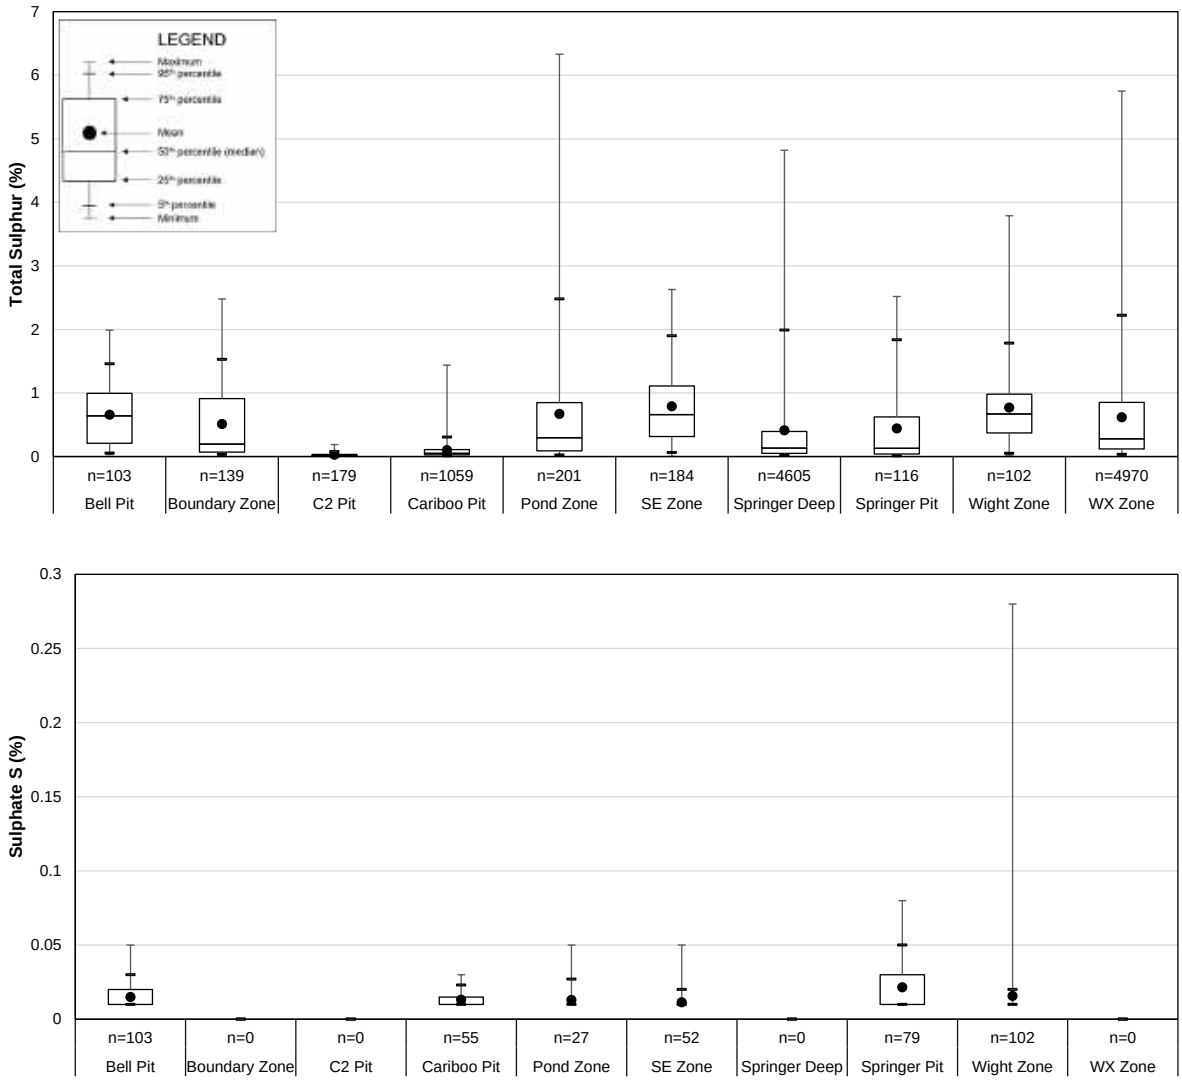
Notes:

[1] Includes blast muck and post-depositional samples where source of rock is known.

The inventory primarily contains static ARD potential data, though trace element scans are also available for all zones except the Boundary Pit. Drill core analyses were primarily performed by off-site laboratories and included total sulphur, sulphate, sulphide by difference, total carbonate, neutralization potential (NP by Sobek method), and paste pH. For some samples, a trace element scan was performed. On-site tests were total sulphur and total carbon. The former is assumed to be a proxy for sulphide sulphur because other forms of sulphur (including sulphate) are not common at MPM. The

latter is assumed to be a proxy for reactive carbonate minerals. The assumption is supported by the observed dominance of calcite, the lack of reported iron carbonate and the strong correlation and equivalence of total carbon and total inorganic carbon (TIC) (Figure 3). The dominant plutonic geological setting supports the lack of non-carbonate carbon. As TC equals TIC, NP is represented by carbonate content as represented by TC (NP*).

Figure 3: Comparison of Total Carbon and Total Inorganic Carbon



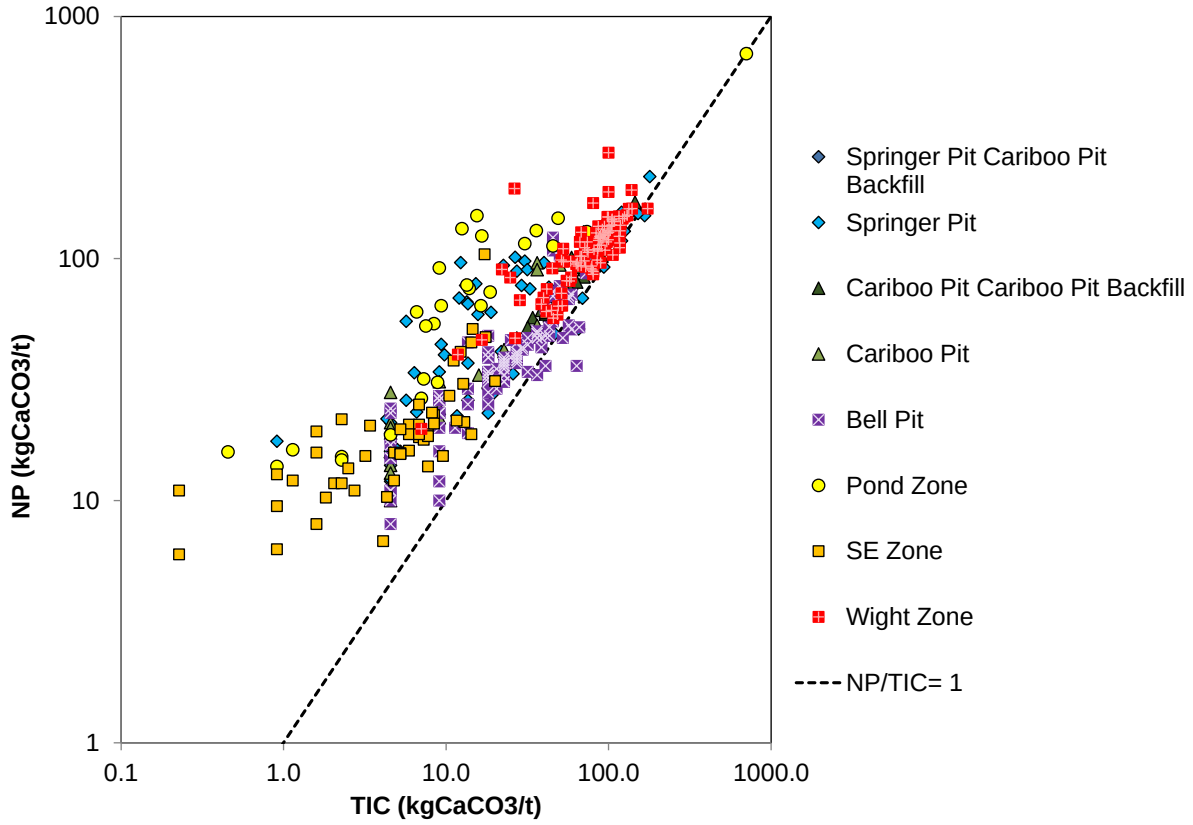
Source: https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/[Compiled_Geochem_Data_CAPR002434_Rev02_SJL_KWJ.xlsm]

3.1.2 ARD Potential

Figure 4 shows the distribution of total sulphur and sulphate by zone. Sulphate concentrations are uniformly low (averages near the detection limit of 0.01%) with no substantial differences between zones. Total sulphur, which therefore provides an approximation of sulphide content, shows some differences by zone as there is variability in higher end concentration values (95th percentiles range from 0.08% to 2.5%). The Southeast Zone and Wight Zone have the highest mean total sulphur concentrations at 0.79% and 0.77%, respectively, whereas C2 Pit and Cariboo Pit have the lowest at 0.029% and 0.098%. No sulphate data were available for the Boundary Zone, C2, Springer Deep, and WX Zone.

Figure 4: Total Sulphur (Top) and Sulphate (Bottom) Distributions by Zone

Sources: https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/[Compiled_Geochem_Data_CAPR002434_Rev02_SJL_KWJ.xlsm]



Comparison of carbonate content with NP shows that, except for few samples, Sobek NP exceeds TIC (Figure 5). This reflects the digestion of silicates during the NP determination. The difference between NP and TIC varies by zone. The skarn mineralization of the Pond Zone shows the greatest NP relative to TIC reflecting the presence of epidote that digests more readily in acid than feldspars which dominate in the other rock types. The Springer Pit (including Cariboo Pit backfill samples), the Southeast Zone and the Cariboo Pit show the next greatest difference followed by the Wight Zone, and the Bell Pit.

The difference between NP and TIC at MPM led to the adoption of total carbon as a proxy for TIC content rather than relying on NP (see Figure 6). Comparison of AP and TIC for drill core samples

shows that the Southeast Zone is dominantly PAG whereas the Wight Zone, the Cariboo Pit, and the C2 Pit are dominantly NAG (Figure 6). Other zones show characteristics overlapping the NAG and PAG, including the Springer Deep and WX zones, which were plotted individually due to a large number of data points for these localities (Figure 6).

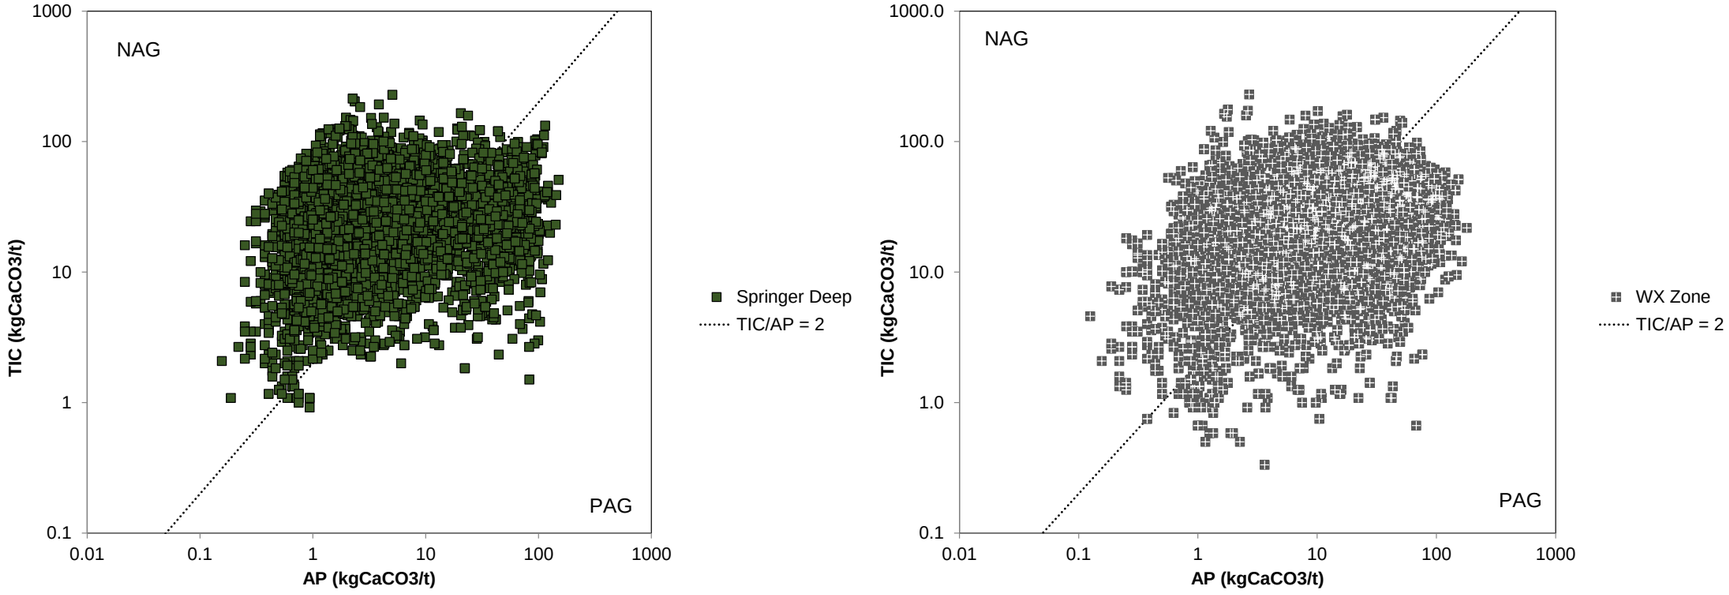


Figure 7 shows results of blast hole sampling for comparison. Bell Pit blast hole data are presented as part of the above descriptions because pre-mining ABA data were not available. The presence of PAG rock in all zones is apparent and resulted in segregation. This figure illustrates that for the most part, PAG rock has higher sulphide content than NAG rock because TIC-NP is relatively consistent regardless of sulphide content.

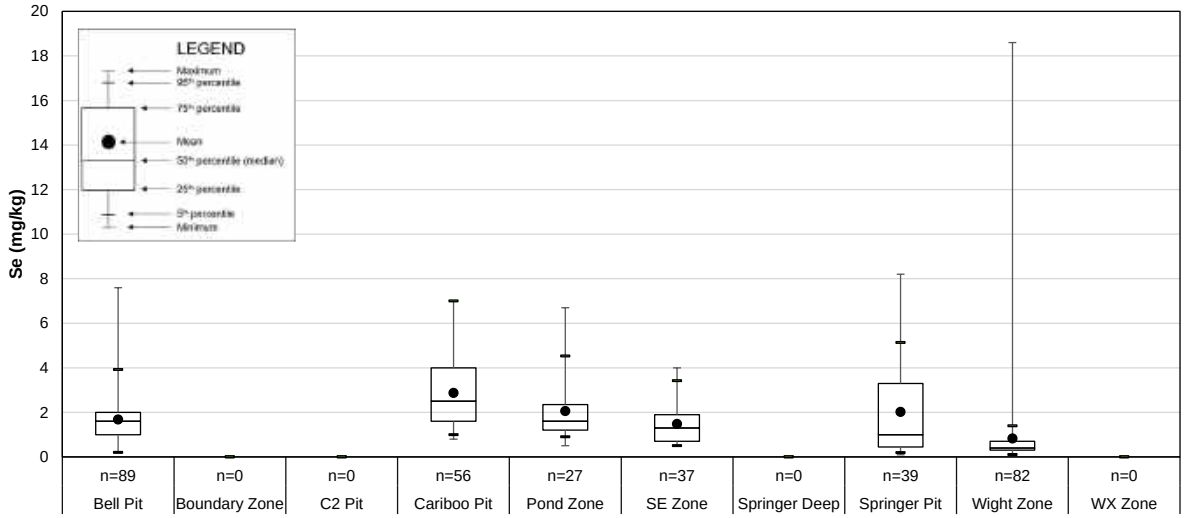
3.1.3 Trace Element Content

When compared to the global average for igneous rocks (Price 1997), some of the rocks (greater than 75% of samples) at MPM have concentrations an order of magnitude higher for antimony, arsenic, copper, molybdenum, selenium, and silver. Median copper concentrations exceed this threshold in the Bell Pit, Cariboo Pit, Pond Zone, Springer Pit, and Wight Zone. Median selenium concentrations exceeded this threshold in the Bell Pit, Cariboo Pit, Pond Zone, and Southeast Zone. Trace element data were not collected for the Boundary Zone and C2 Pit, and copper and selenium concentrations were not available for Springer Deep or WX Zone. Copper concentrations correlate with selenium concentrations (Figure 8).



Within the site, selenium concentrations were elevated in the Cariboo Pit and Springer Pit rocks and lowest at the Wight Pit (Figure 9). Selenium-to-sulphur ratios were examined because selenium is typically released by oxidation of sulphide and the ratios can be indicative of differences in selenium release. The ratio is notably higher for the Cariboo Pit and Springer Pit, intermediate for the Bell Pit and Pond Zone and lowest for the Southeast Zone and Wight Zone (Figure 10). The distributions imply spatial zoning of selenium relative to sulphide. Selenium data were not collected for Boundary Zone, C2 Pit, Springer Deep, and WX Zone.

3.1.4 Extraction Tests

The Mines Act Permit M-200 amended on August 2, 2000 required that “oxidized” samples be tested for solubility using the Shake Flask Extraction (SFE) method of Price (2009). The definition of oxidized was not provided in the permit. Nine samples of the -2 mm fraction of blasted rock were submitted for the procedure in 2001. Eight samples of ore stockpile rock were also tested in 2015 as part of a Mines Act Permit M-200 requirement to evaluate closure requirements for the stockpiles (SRK 2015b).

Leachates from all extraction tests were non-acidic with leachate chemistry dominated by sulphate, alkalinity, and calcium. The 2015 tests were more useful than the 2001 tests for understanding trace element leachability due to the use of lower detection limits and testing of stockpiled waste rock. Average arsenic, copper, molybdenum and selenium concentrations were 4, 5, 29 and 15 µg/L, respectively. A number of trace elements were not detected or yielded concentrations close to detection limits including cadmium (0.05 µg/L), chromium (0.5 µg/L), cobalt (0.1 µg/L), lead (0.1 µg/L), mercury (0.05 µg/L), nickel (0.5 µg/L) and zinc (10 µg/L).

3.1.5 Kinetic Testing

Laboratory kinetic (humidity cell) tests were performed on nineteen samples in support of geochemical characterization for permitting of mining of the Wight Pit (Northeast Zone), Southeast Zone, Boundary Zone, Pond Zone, an earlier expansion of the Springer Pit, Springer Deep, and WX Zone (Table 4). Results have been reported annually as part of Mines Act Permit M-200 requirements. The samples were generally selected to evaluate oxidation rates for typical and elevated sulphide concentrations.

Samples from the Pond Zone were submitted for an acid-leaching procedure to remove carbonate and evaluate the reactivity of silicate minerals.

Notes:

[1] Rock types for some humidity cells were not recorded. PPp = Plagioclase porphyry, Bx = Breccia, DI = Diorite, Monz = Monzonite, FBXm = Monzonite breccia.

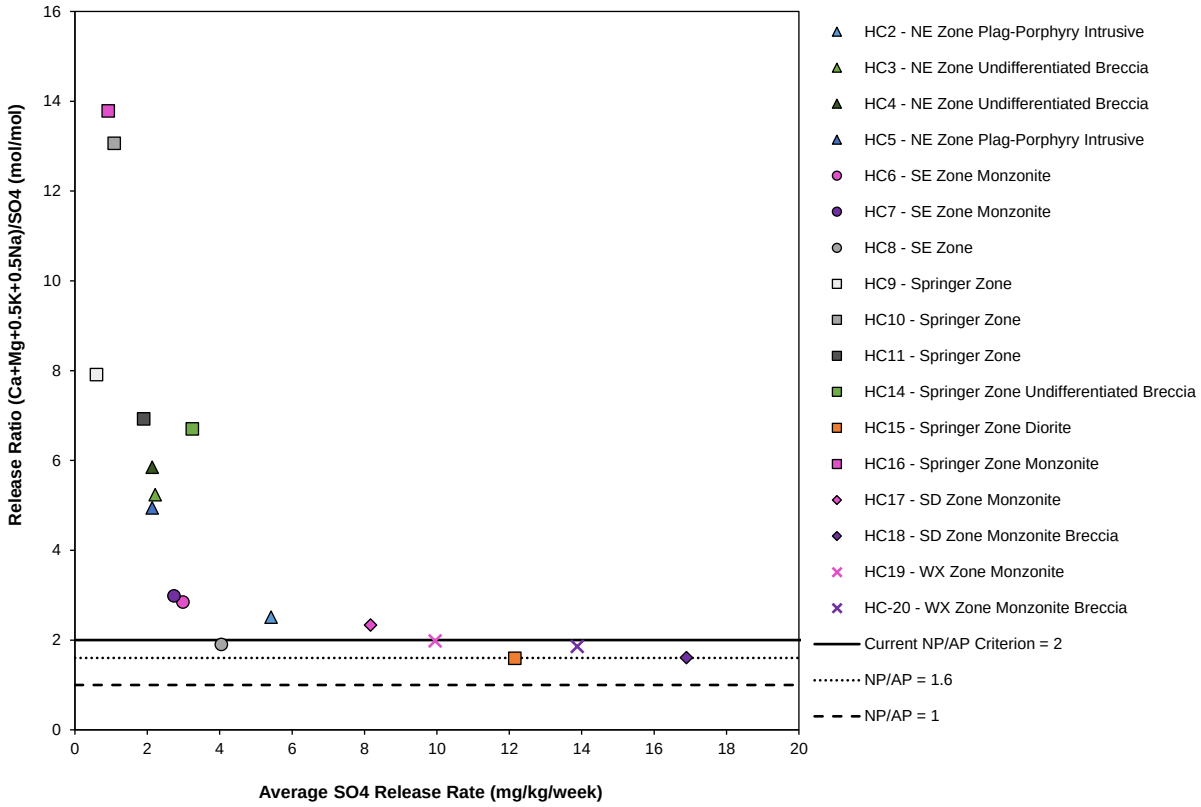
One Pond Zone test is continuing. Two Springer Deep tests and two WX Zone tests were initiated in August 2022 and are continuing. The other tests ran for 1 to 9 years. General findings were as follows:

- Except for the Pond Zone tests which were artificially depleted of carbonate to induce acidification, no other tests generated acid. Six samples were classified as PAG from ABA but carbonate content prevented acid generation for the duration of the test. Preliminary tests of Springer Deep and WX Zone rock classified as PAG have not generated acid as of 44 weeks.
- Sulphate release was strongly correlated with sulphur content regardless of zone (Figure 11).
- There was a lack of correlation between trace element content and trace element release rates, and sulphide content and trace element content.
- Comparison of relative utilization of carbonate minerals to oxidation rates indicated that an NP/AP ratio of 2 or lower is appropriate for classification of ARD potential.

Figure 11: Correlation of Sulphur Content with Oxidation Rate for Waste Rock Humidity Cells

Sources: https://srk.sharepoint.com/sites/NA1CM017.011/Internal/!020_Project_Data/030_Lab Data/Kinetic Data/Calculations/[Mt_Polley_HCT_WR_Outcomes_1CM017.011_rtc_rev00.xlsx]

Determination of Critical NP/AP



The current operational NP*/AP for classifying waste rock as NAG (or non-PAG) is specified in the Permit as 2. However, the critical NP/AP ratio (NP/AP_{crit}) can be developed using data from humidity cell tests. NP/AP_{crit} was derived from the comparison of cation release ratios and sulphate release rates (Figure 12).

Cation release ratios reflect carbonate dissolution, while sulphate release rates reflect sulphide oxidation. The trend of these data approaches a cation release ratio value between 1 and 2 and none of these cells have generated acid thus far. Relative rates expressed as the molar ratio of the stable release rates of the four cations to sulphate [$(Ca+Mg+0.5Na+0.5K)/SO_4$] mol/mol were used directly to estimate the NP/AP_{crit} for the waste rock. These ratios were compared to sulphate release rates from the HCTs to differentiate between dissolution of carbonates by sulphuric acid (from pyrite oxidation) and by carbonic acid (formed by carbon dioxide dissolved in the deionized water). The consideration of Na and K reflects the potential for Ca and Mg liberated by carbonate dissolution to exchange with Na and K in phyllosilicates. The release rate for Na and K are halved to account for their lower charge. Inclusion of Na and K also limits the possibility of under-stating carbonate mineral utilization thereby resulting in a lower NP/AP_{crit}.

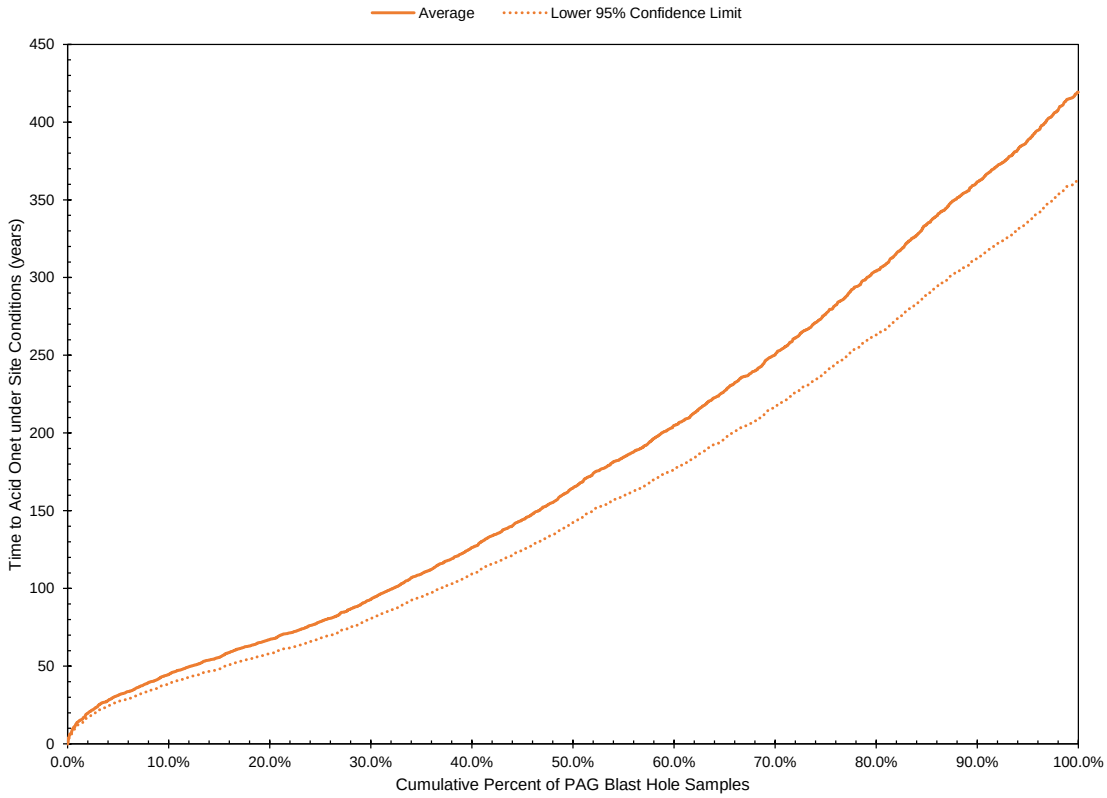
At low oxidation rates (lower sulphate release), the dominant process in the test is assumed to be dissolution of carbonates by carbonic acid and the $(Ca+Mg+0.5Na+0.5K)/SO_4$ ratio is high. As the influence of sulphide oxidation increases (shown by increase in sulphate release), the $(Ca+Mg+0.5Na+0.5K)/SO_4$ ratio greater reflects the interaction of sulphuric acid with carbonates which is the expected dominant process at full scale in waste rock dumps.

A lack of testing on samples with high oxidation rates hampered previous estimations of NP/AP_{crit} (SRK 2016). The initiation of the four HCTs in 2022, which have run for 48 weeks thus far, all have higher oxidation rates than previous HCTs and were used to define $NP/AP_{crit.}$ SRK recommends defining NP/AP_{crit} of 1.6 based on the new HCTs.

Figure 12: Cation Release Ratio versus Oxidation Rate

Sources: https://srk.sharepoint.com/sites/NA1CM017.011/Internal/!020_Project_Data/030_Lab Data/Kinetic Data/Calculations/[Mt_Polley_HCT_WR_Outcomes_1CM017.011_rtc_rev00.xlsx]

Delay to Onset of Acid Generation



Following the same method used in SRK (2016) and SRK (2010), the straight-line average of the correlation between initial NP/AP (i.e., at time = 0, NP/AP_0) and calculated time for the onset of acidification (t_{onset}, in years) for all humidity cells from MPM was updated using NP/AP_{crit} of 1.6:

$$t_{onset} = 63 \times \left(\frac{NP}{AP}\right)_0$$

The equation indicates that a sample with NP/AP of 1 might be expected to generate acid in 63 years. The calculated lower 95% confidence on the 63 years coefficient was 55 years.

To estimate the exposure time PAG waste rock can be stored sub-aerially before the onset of acidification, t_{onset} (average and lower 95% confidence limit) was calculated for samples classified as PAG from the MPM blast hole database. A temperature correction of 0.3 to reflect slower reaction rates under cooler site conditions was included in the calculation.

Figure 13: Distribution of t_{onset} for PAG Waste Rock at Mount Polley Mine

Sources: https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/TimeOnset_CAPR002434_Rev00_SJL.xlsx

The distribution for faster-reacting components represented by the lower dashed line indicates that about 2% of the rock might become acidic in 20 years, and 10% after 40 years. The majority of the rock with higher NP/AP might take over 100 years to become acidic A number of factors complicate the actual estimate for higher NP/AP materials. Increasing acidification along with heating would result in accelerated oxidation and NP depletion though decreasing oxidation rates due to sulphide depletion and formation of secondary mineral coatings would result in lower oxidation rates and greater time to onset of acidic conditions.

The general finding from the kinetic testing is that acidification of PAG materials at MPM will take on the order of decades to centuries to develop. This is consistent with the widespread pH neutral weathering conditions at MPM in both natural and mined materials. Initial mining at Mount Polley was 25 years ago but waste rock has not acidified.

The Temporary NW PAG Stockpile contains less than 0.1% of rehandled PAG waste rock that was mined between 2001 – 2007 and initial construction of the NAG/PAG Pad began in 2011 (12 years ago). The Springer Pit Expansion Project proposes to rehandle PAG waste rock stored in the Temporary NW PAG Stockpile starting in 2032 and finishing by the end of 2034. Based on the assessment above, the risk of developing widespread acidic conditions within this timeframe is low (24 years after initial construction of the Temporary NW PAG Stockpile).

3.2 Tailings

3.2.1 Overview

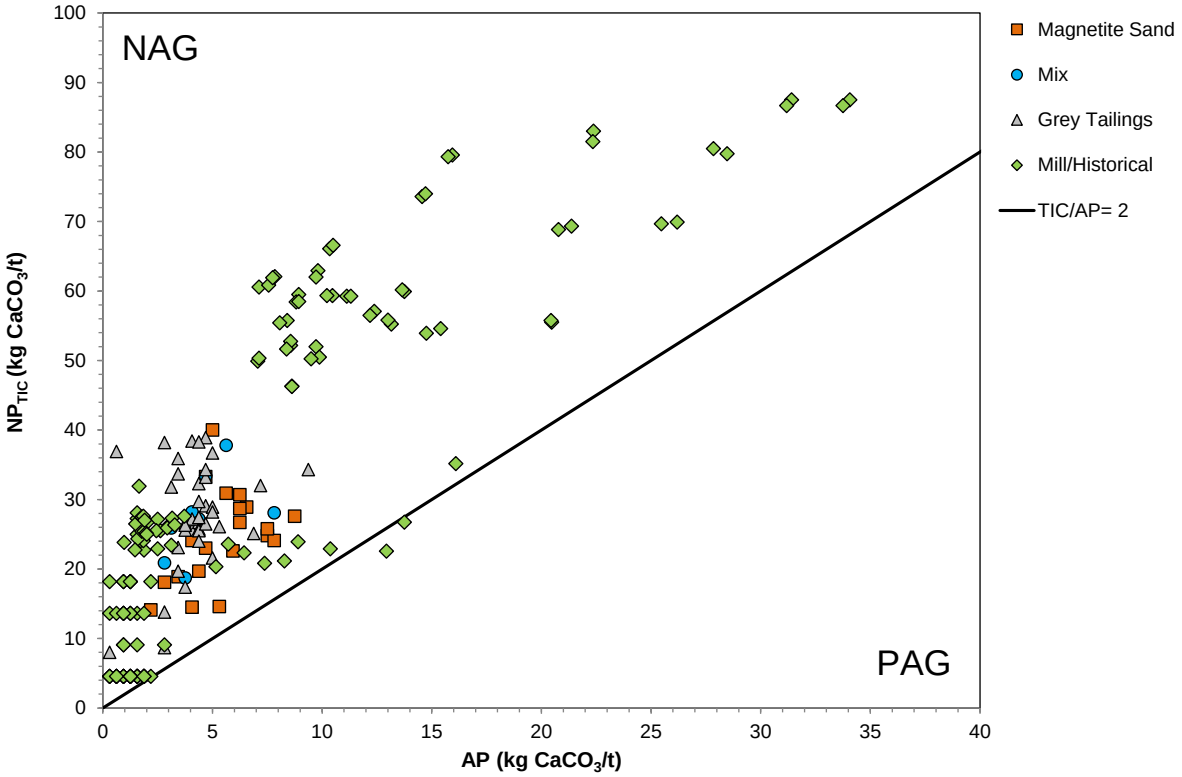
A summary of available data is presented in Table 5. Monthly composite samples of tailings have been collected in the mill when processing since 1997. Tailings samples were also collected from the banks of Hazeltine Creek in 2014 after the TSF breach ("spilled tailings") along eighteen parallel transects oriented perpendicular to the course of Hazeltine Creek, as described in SRK (2015a). Two types of tailings-bearing samples were observed along Hazeltine Creek. They were classified in the field as 'grey tailings' and 'magnetite sands'. This classification was based on physical and mineralogical characteristics as follows:

- Grey tailings were dominantly grey in colour and had a finer texture (silty sand) than the magnetite sands. They had a strong reaction (referred to as "fizz") with 10% HCl and did not contain sulphide minerals that were visible by examination with a hand lens. Mineral identification was difficult due to small grain size, but the dominant minerals included potassium feldspar and plagioclase, with minor biotite mica and quartz.
- Magnetite sands were speckled pinkish-orange and black. They were strongly magnetic and coarser (sand) than the grey tailings. They had weak fizz and trace (less than 1%) sulphide minerals were infrequently noted. The dominant minerals identified included plagioclase feldspar and magnetite. Biotite mica and quartz appeared more abundant than in the grey tailings.

Similar to waste rock, total sulphur is assumed to be a proxy for sulphide sulphur because other forms of sulphur are not common in Mount Polley tailings (SRK 2015a).

Table 5: Static Test Inventory for Tailings

Tailings Type	Number of Samples
Monthly Composite – Final Tailings	166
Grey Tailings	40
Magnetite Sand	20
Grey Tailings/Magnetite Sand Mix	8



Source: https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/Compiled_Geochem_Data_CAPR002434_Rev02_SJL_KWJ.xlsm

3.2.2 ARD Potential

ARD potential of tailings is assessed based on sulphide content (approximated from total sulphur) and NP derived from TIC. The resulting TIC/AP is used to classify Mount Polley tailings as PAG (TIC/AP ≤ 2) or NAG (TIC/AP< 2).

Sulphur concentrations in Mount Polley tailings are uniformly low, with total sulphur ranging from 0.01% to 1.1% (median concentration of 0.10%). The majority of tailings samples (99%) were found to be NAG based on their TIC/AP values (Figure 14).

Figure 14: Total Inorganic Carbon versus Acid Potential of Mount Polley Mine Tailings

Sources: https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/Compiled_Geochem_Data_CAPR002434_Rev02_SJL_KWJ.xlsm

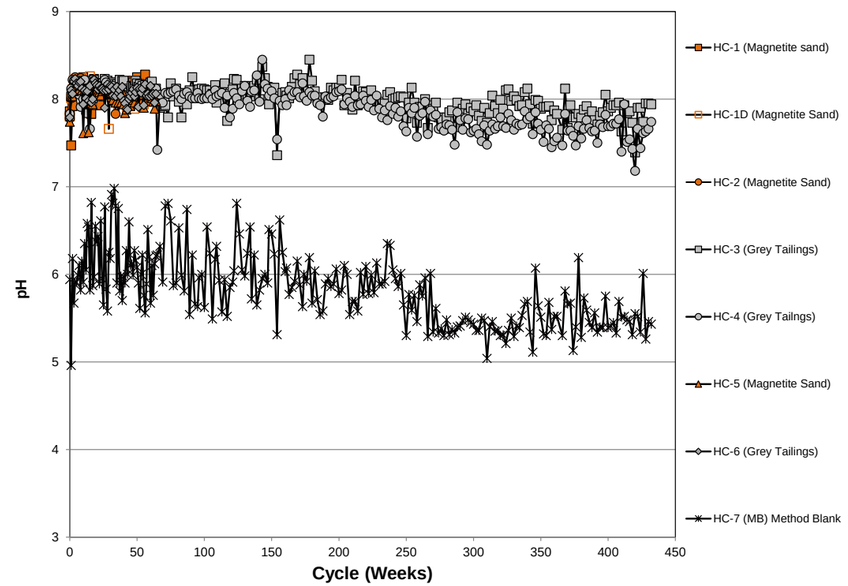
3.2.3 Trace Element Content

Median concentrations of copper and selenium were present in the tailings at an order of magnitude higher concentrations compared to average crustal concentrations for igneous rocks. Copper is partially deported as silicate minerals. Selenium is associated with the sulphide component of the tailings and is also correlated with copper content. Kinetic testing on tailings samples has to-date confirmed they are non-acid generating.

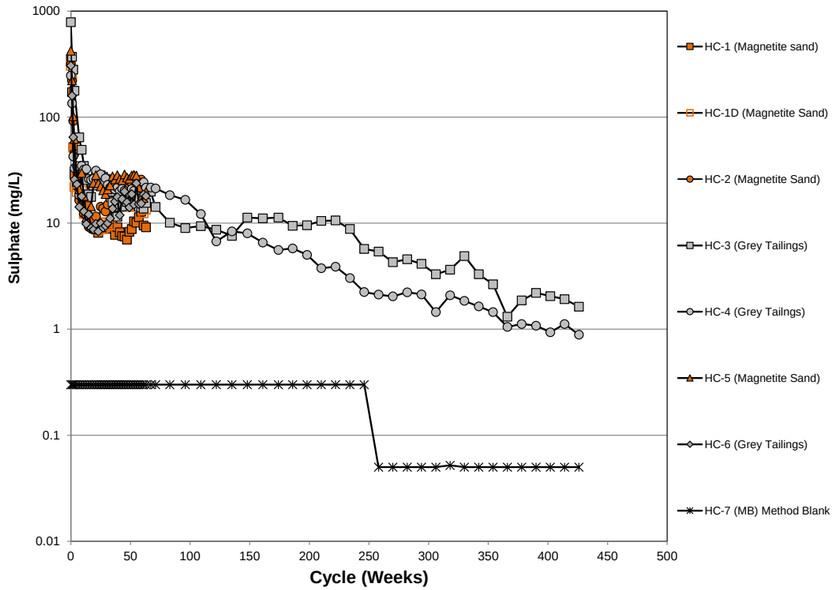
3.2.4 Kinetic Testing

Six samples of tailings collected from Hazeltine Creek following the dam failure were tested in humidity cells starting in 2015. Currently, two of these tests (HC-3 and HC-4) are continuing, while the rest were terminated after 64 weeks (Figure 15). HC-3 has relatively high sulphide content (0.33% pyrite) and elevated copper and selenium concentrations. HC-4 has lower copper and selenium concentrations, but copper is leaching at higher concentrations than in HC-3, which is thought to be attributed to higher dissolved organic carbon (DOC) leaching from HC-4 (2 mg/L) compared to HC-3 (1 mg/L) which may

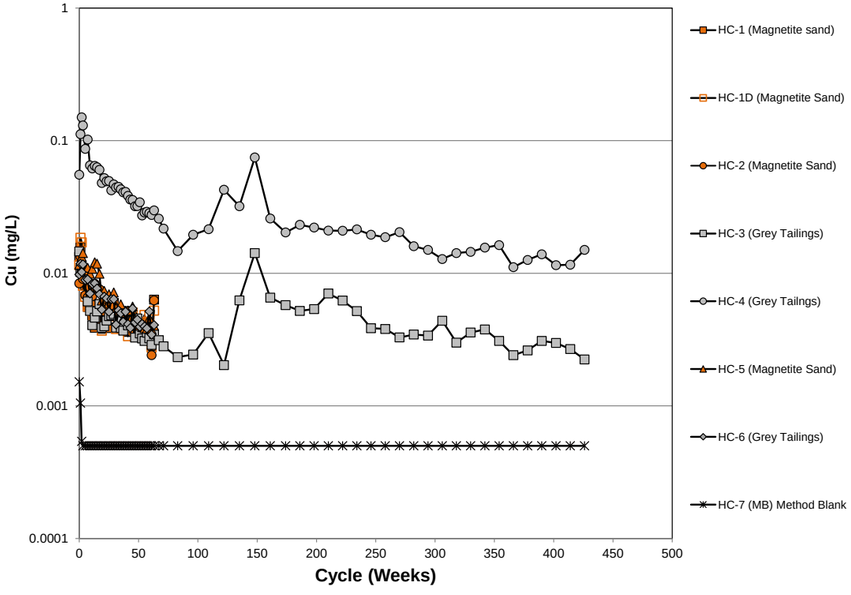
form humic complexes with copper increasing it solubility. The tests are continuing with the purpose of evaluating the role of breakdown of organic matter on metal mobility (SRK 2023).



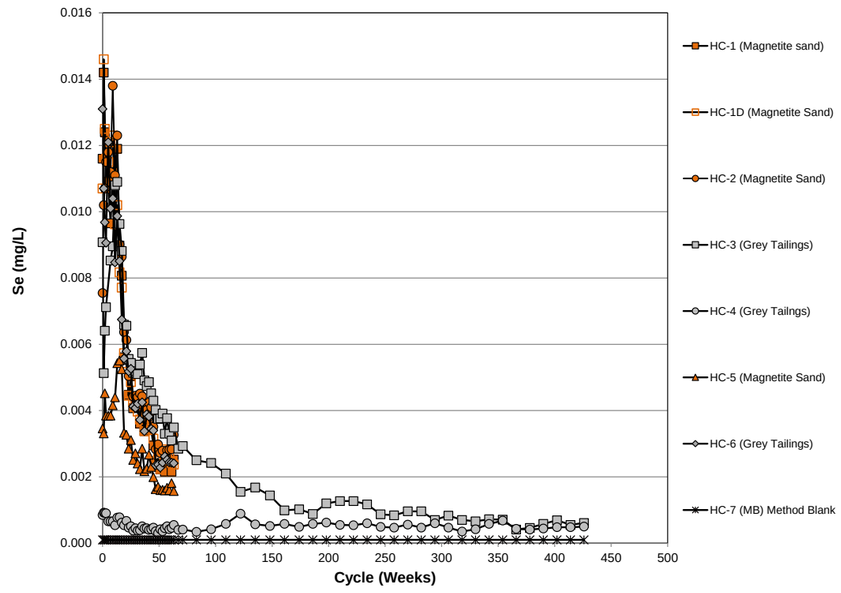
Three of the samples are also being tested in columns using a trickle leach applied at less than 0.1 L/kg/week (compared to flood leach of 0.5 L/kg/week for humidity cells). The samples were selected to represent visually distinctive tailings materials (magnetite sand and grey tailings). The samples are dominated by tailings solids but also contained native materials (mineral and organic soils, and glacial sediments entrained in the debris flow). The samples characterize weathering behaviour for a range of sulphur concentrations which align with typical characteristics of tailings in the impoundment. The columns have operated for over 400 weeks and SRK have requested them be terminated as copper release rates, which were initially unstable, have now stabilized at low levels (Figure 15).



All tests have yielded leachate pHs typically between 7.7 and 8.3. Sulphate concentrations were initially near 1000 mg/L for humidity cells and above 1000 mg/L for columns. Both types of tests showed decreasing sulphate concentrations which have stabilized at lower concentrations. They have also showed decreasing metals concentrations, including those originally enriched (copper and selenium), which have stabilized at low concentrations. Maximum copper and selenium concentrations in both tests were as follows:



- The highest copper concentration in one HCT was 0.15 mg/L, but typical maximum copper concentrations were 0.02 mg/L in HCT leachates and 0.05 mg/L in column test leachates.
- The highest selenium concentrations were 0.01 mg/L in HCT leachates and 0.06 mg/L in column test leachates.



For other parameters, notable results were initial molybdenum concentrations between 2 and 3 mg/L in column leachates. These have since stabilized to concentrations between 0.01 and 0.02 mg/L.

3.3 Other Sources

Two other sources were identified as potentially requiring geochemical source terms.

Magnetite is recovered from MPM tailings to generate a concentrate for use as a dense medium in coal processing. The magnetite stockpiles are located adjacent to the ore processing plant. No geochemical data are available for the magnetite.

Sulphur was imported in 2004 as part of evaluations of recovery of copper present as oxide. Excess sulphur was stored in a nearby stockpile, first in the Cariboo Pit (2006-2009) and then moved to a crushed rock pad beside the heap leach pad (2009-2018) when mining resumed in the Cariboo Pit. SRK (2022) found the elemental sulphur was composed of about 90% sulphur, and assumed the material had no neutralization potential. Oxidation of the sulphur generated sulphuric acid, which markedly increased the solubility of metals in the surrounding materials that would not otherwise be leachable at neutral pH. In 2018, the excess sulphur was relocated on top of the lined leach pad after evidence showed that water quality on the mine may be affected by contaminated drainage from below the sulphur stockpile (Litke et al. 2019). The affected drainage is seepage from the NEZ Dump, located east of the Test Heap Leach Facility.

4 Conceptual Geochemical Models

4.1 Purpose

The purpose of conceptual geochemical models (CGMs) is to describe the anticipated geochemical performance of each source at MPM which is then implemented as a numerical model to generate source terms. CGMs consider the current understanding of geochemical characteristics (as described in Sections 3.1 and 3.2).

The following sources were evaluated and CGMs for each are described below:

- NAG waste rock and construction fills.
- NAG waste rock influenced by the sulphur stockpile.
- PAG waste rock.
- Ore stockpiles.
- Pit backfills.
- Pit walls.
- Ore processing.
- Tailings.

4.2 Ex-Pit NAG Waste Rock and Construction Fills

Processes in NAG waste rock under non-acidic conditions include:

- Oxidation of sulphides (pyrite, chalcopyrite, and bornite) to release iron, acidity, sulphate, and trace elements contained in the sulphides. Copper is expected to be primarily released by oxidation of chalcopyrite and bornite. Iron released by oxidation of sulphides replaces pyrite and other sulphides as solid iron (III) oxyhydroxides. Iron concentrations in the drainage are expected to be at or near detection limits.
- The oxidation reaction is exothermic (releases heat) and is expected to result in average internal temperatures that are higher than ambient average temperatures. During winter, internal temperatures will be higher than ambient temperatures.
- Due to the temperature difference in winter, air will move by advection through the waste rock by convection. Cold air will be drawn in through coarser materials at the base formed by end-dumping. The heated air will exit the dump at a higher elevation. This process is expected to result in deep penetration of oxygen and generally an over-supply of oxygen for oxidation of sulphides.
- Neutralization of acidity produced by the oxidation reaction will be by reaction with calcium carbonate minerals or mixing with alkaline waters resulting in neutral to basic pHs. The pH of contact waters will be determined by the partial pressure of carbon dioxide in pore gases (lower pH with higher CO_2).

- For non-PAG waste rock the neutral pH weathering environment will result in precipitation of metals as various secondary minerals, including gypsum ($CaSO_4 \cdot 2H_2O$), metal oxides (tenorite - CuO), metal carbonates (malachite – $Cu_2CO_3(OH)_2$), and metal silicates (e.g., chrysocolla). Adsorption to secondary oxides will also occur. The resulting concentrations of metals (principally copper) in contact waters will be controlled by the relatively low solubility of the secondary minerals and the tendency to be adsorbed at these pHs.
- Selenium and molybdenum originate from oxidation of pyrite, but form oxyanions that are mobile at the expected pH. The concentrations of these trace elements are expected to increase.
- There is a hydraulic lag between when waste is placed, and its signature appears at monitoring locations.

Due to the solubility control exerted by secondary minerals, contact water chemistry is expected to be constrained so that chemical loadings are directly proportional to infiltrating water volume. Sulphate is expected to increase as new waste is added but will be constrained by gypsum solubility.

4.3 NAG Waste Rock Influenced by the Sulphur Stockpile

Elevated sulphate and metal concentrations at NEZ Seep 1 and NEZ Seep 2 since 2014 are believed to be influenced by elemental sulphur stockpile oxidation and leaching. The stockpile was stored on the East RDS near the leach pad until its removal in 2018. For context, monitoring of the drainage from the leach pad containing ore, waste rock, and elemental sulphur showed average pH, sulphate, and copper of 3.3, 15 g/L, and 750 mg/L, respectively. There was a risk that depletion of acid neutralizing minerals from the waste rock could have triggered acidification of the waste rock on the infiltrating water flowpath but this does not seem to have occurred based on sampling of the foundation materials (Litke et al. 2019). It is expected that the seeps influenced by the sulphur stockpile will show a downward trend in parameters such as sulphate and copper now that the elemental sulphur was removed.

The seeps from the NEZ Dump that are influenced by the sulphur stockpile leachate (NEZ Seep 1 and NEZ Seep 2) are collected and managed separately from the other waste rock seepages.

4.4 Ex-Pit PAG Waste Rock

Segregated and exposed ex-pit PAG waste rock is present in the Temporary NW PAG Stockpile located adjacent to the Springer Pit. PAG rock at MPM is not defined by a particular rock type but is associated with pyrite halos formed by hydrothermal alteration. Sulphide content is higher than NAG waste rock.

Due to the higher sulphide content of PAG waste rock, the overall oxidation rate of PAG waste rock is expected to be greater than NAG waste rock. However, before acidification occurs, PAG and NAG weathering conditions are expected to be similar with secondary minerals exerting solubility controls. For example, the solubility of sulphate is expected to be controlled by gypsum which will be similar regardless of the sulphide oxidation rate.

Acidification is expected to take decades to progress with early contact waters remaining basic and having metal concentrations controlled by the solubility of secondary minerals. The timeframe for acidification effects is expected to be on the order of decades.

4.5 Ore Stockpiles

Ore stockpiles will perform the same as NAG and PAG waste rock depending on composition. The presence of more copper sulphides than waste rock will result in more leachable copper being generated but similar solubility controls are expected for the elements of interest.

4.6 Pit Backfill

Existing backfilled pits are the Bell Pit (completely full), the Southeast Zone Pit (completely full), the Pond Zone Pit (completely full), the Wight Pit (partially full), and Cariboo Pit (partially full). PAG rock from Temporary NW PAG Stockpile will be backfilled into the Springer-Cariboo Pit at completion of mining. Backfilling of currently filled pits occurred during operation so that run-of mine waste rock was directed immediately to a backfill location. The water level has risen in most of these pits resulting in complete submergence of PAG rock and partial submergence of NAG rock. PAG rock in the Cariboo Pit remains unsubmerged due to drawdown of the water table as operations continue in these pits.

4.7 Pit Walls

Exposed pit walls will remain in the Springer-Cariboo Pit, Wight Pit and Boundary Pit. All other pits have been backfilled resulting in pit wall reactive surfaces becoming part of the backfill.

Pit walls are composed of fractured walls and rubble resulting from over-blast and physical weathering. Localized wall failures will contribute additional talus. Reactive surface area for pit walls is contained primarily in the broken rock rather than fractured walls.

For source terms, pit walls are assumed to perform the same as waste rock dumps composed of PAG and NAG waste but flow paths are much shorter.

During flooding of pit walls, accumulated soluble weathering products will be flushed into pit walls. Following submergence, oxidation of walls will effectively be stopped due to reduction in availability of oxygen. Highwalls above final flood levels will continue to weather.

4.8 Ore Processing

Ore processing results in crushing and grinding of ore in contact water. Soluble components of the ore are dissolved and become part of the process water. Modification of process water chemistry may occur in the cleaner circuit where lime is added to increase pH. The change in pH may cause copper to precipitate.

The ore source term is expressed as mass leached per mass of ore. Except for the possible effects of pH adjustment described above, process water concentrations are expected to be too low to be controlled by secondary minerals.

The ore processing terms will depend on the degree of oxidation of the ore. Freshly blasted ore will contribute less load than ore re-handled from stockpiles, and deep fresh ore will contribute less load than near surface ore that has been naturally oxidized.

4.9 Tailings Solids

During operations, tailings are deposited by spigotting from the TSF embankments, resulting in tailings beaches and slimes migrating to the centre of TSF. Cycloned tailings were also used for dam construction.

Under normal operational conditions, slimes in the centre would be fully saturated and below the process pond. Due to the finger drains in the dam, the water table drops from surface at the edge of the pond in the centre of the facility to the finger drains. As a result, tailings near the embankments are partially saturated. Oxygen enters the unsaturated tailings in the beaches and embankments by diffusion resulting in near surface tailings oxidizing most rapidly and consuming oxygen. An oxygen concentration profile will be present in the tailings which decreases most rapidly near surface and eventually results in negligible oxygen concentrations at depth. For tailings containing sulphur concentrations near 0.1%, the expectation is that oxidation of tailings will occur to tens of metres in depth.

Due to the acid-consuming characteristics of the tailings, the weathering environment is pH-basic and overall processes are comparable to NAG waste rock (Section 4.2). Pore water chemistry during operations is dominated by process water with less effect from weathering processes because tailings are continually deposited, resulting in re-setting of the oxidation profile.

Process water contains low levels of dissolved organic carbon from flotation process reagents (e.g., methyl isobutyl carbinol). These compounds may act as a source of reduced carbon to facilitate reductive dissolution processes in the saturated components of the tailings such as dissolution of iron oxides and release of contained trace elements. SRK (2015a) assessed this susceptibility and concluded the tailings were stable under chemically-reducing conditions.

Following the tailings dam failure in August 2014, the water table dropped, allowing more of the tailings to become unsaturated than under operational conditions. Draindown of pore waters will have occurred allowing oxidation processes to influence pore water chemistry. Reactivation of the tailings pond resulted in the water table rising again into the tailings. As the water table rose, oxidation products formed following partial draindown were dissolved by process waters. Pore waters were therefore expected to reflect a mixture of process water effects and flushing of oxidation products in the years following the reactivation of the pond. However, with the return to operational conditions in 2022, process water will be dominate.

After operations cease, the process pond will decrease and the water table will again drop resulting in more tailings becoming unsaturated. Draindown of the tailings will result in a transition from process

water dominated chemistry to oxidation effects becoming dominant. Eventual pore water chemistry will be controlled by equilibration of water chemistry with tailings weathering products which will include oxides and sulphates.

4.10 Nitrogen Leaching

Nitrogen leaching is covered separately from the foregoing conceptual models because it originates from explosives residuals rather than mineral weathering. Since the rock does not generate leachable nitrogen, the leaching of residuals provides a flush of nitrogen which occurs with water contact. It is expected that the load of nitrogen flushed is greatest initially then decaying in proportion to the remaining soluble nitrogen. In terms of cumulative leaching, a newly constructed waste rock dump would be expected to show increasing loads for several years then stable loads as the volume of rock added each year becomes small relative to the total volume. “Tailing off” at closure will occur. Delays and lag effects may be expected due to hydrological factors.

For a mature site such as MPM, active and long closed waste rock dumps indicate nitrogen release under operational and closed conditions. Sump waters from open pits indicate leaching from pit walls.

Leaching of explosive residual from ore will occur due to flushing in the milling process. Tailings solids themselves will not leach nitrogen because flushing during processing is very efficient. Nitrogen leaching from the TSF will reflect the influence of process water.

5 Source Terms

5.1 General Approach

MPM operations started in 1997, resulting in generation of waste rock and tailings. These full-scale waste facilities provide a more appropriate basis for predicting current and future water chemistry than scaling laboratory tests to full-scale conditions, provided that near source monitoring locations are available and appropriate allowance for local dilution effects at monitoring locations are included. The general approach for MPM has been to use interpreted full scale monitoring data to develop source terms supplemented by laboratory data where needed. This approach removes most of the uncertainty related to predicting source term chemistry.

The approach for each term described below follow the same methods outlined in SRK (2016). The update incorporates recent monitoring and testing data.

5.2 Incorporating Uncertainty

The CGMs described in Section 4 indicate that geochemical processes reflected in source terms consist of weathering of primary minerals, which is determined by rates of mineral conversions, and dissolution processes which combine rates and solubility constraints. The latter consists of the rate at which minerals dissolve and the eventual concentrations achieved when equilibrium with the contact water is reached. For example, chalcopyrite oxidizes at some rate to produce copper sulphate. The copper sulphate then dissolves at a rate adding copper and sulphate to the water until copper and sulphate concentrations in the water are in equilibrium with the solid copper sulphate.

As described in Section 5.1, the general methodology used to develop the source terms relies mainly on-site monitoring data which reflects the end product of weathering and dissolution of weathering products. The assumption is that the monitoring data contain indications of the endpoint solubility of the weathering products with the proviso that dilution needs to be considered. Higher end concentrations in the dataset are used as the starting point to develop source terms because these are most likely to be closest to a solubility limit. To represent uncertainty in the underlying solubility limits, the statistics from water chemistry databases used are the 95th and 99th percentile concentrations. Maximum concentrations are not used to eliminate the bias caused by spurious concentrations resulting from sampling and analytical errors. The two high end percentiles are used because concentrations constrained by the solubility of minerals are not fixed but dependent on total solution chemistry including, particularly, pH.

Other approaches to incorporating uncertainty are described in the following sections.

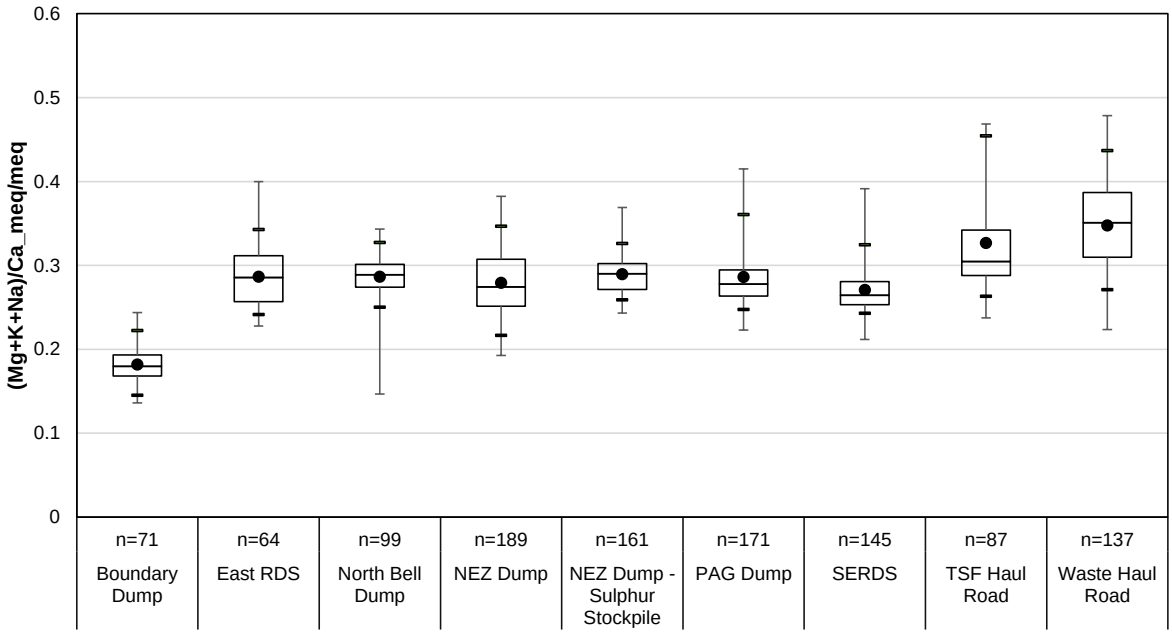
5.3 NAG Waste Rock and Construction Fills

5.3.1 Method

The method for the NAG waste rock source terms is similar to the method in SRK (2016) and is as follows:

- Evaluate partitioning of reactive minerals during blasting.
- Evaluate potential for acidification due to included PAG rock.
- Evaluate seepage chemistry for geochemical controls.
- Prepare statistical summaries for seeps from major rock dumps.
- Scale-up maximum concentrations to account for dilution effects to yield source terms.

The basis for the latter step is that seepage chemistry may be diluted from true contact water and therefore needs to be scaled to remove dilution effects. Scaling was approached by assuming that gypsum is likely to exert a strong solubility control on major ion chemistry due to the interaction between oxidizing sulphides (yielding sulphate) and dissolving carbonates (yielding calcium). It also has well-defined behaviour in which chemistry matches thermodynamic models and is expected to be one of the most soluble secondary minerals in this setting. The high solubility indicates that it will likely be the last to reach equilibrium with contact water compared to other major primary minerals.



Scaling is therefore achieved using the following equation:

$$[M]_{corrected} = \left(\frac{[SO_4]_{theoretical}}{[SO_4]_{observed}}\right) \cdot [M]_{observed}$$

Where $[M]_{corrected}$ is the scaled element concentration, $[SO_{4,\ theoretical}]$ is the maximum sulphate concentration indicated by the solubility of gypsum, $[SO_{4,\ observed}]$ is the observed sulphate concentration, and $[M]_{observed}$ is the observed element concentration. The $[SO_{4,\ observed}]$ values are the 95th and 99th percentile seep concentrations selected to be at the upper end of the distribution so that the need for correction is minimized.

$[SO_{4,\ theoretical}]$ depends on bulk chemistry being lowest for waters containing only calcium as the balancing cation. As other major ions (K, Mg, and Na) increase in significance, $[SO_{4,\ theoretical}]$ increases. The ratio (Mg+K+Na)/Ca shows variation within MPM (Figure 17), with the lowest ratio for the Boundary Dump and highest for seeps from the two haul roads. For the purpose of determining a range of $[SO_{4,\ theoretical}]$, the 50th and 95th percentiles for each dump group were used. The 50th percentile indicates median predicted sulphate whereas the 95th percentile is a conservative limit. The actual range of the ratio is fairly narrow. For the Boundary Dump, the resulting range is 1510 mg/L to 1550 mg/L whereas for the Waste Haul Road, the range is 1670 mg/L to 1750 mg/L.

5.3.2 Inputs

Mineral Partitioning During Blasting

Mineral partitioning during blasting was evaluated using blast hole cuttings because this can have an effect on the classification of waste for ARD potential (Day et al. 2015). If carbonate minerals preferentially partition into the blast fines, the use of a bulk NP/AP classification factor can lead to misclassification of rock that will probably not generate acid as PAG. The reverse can also occur if sulphide minerals preferentially classify into the fines.

In 2001, blast muck samples from the Bell and Cariboo Pits were collected and the +2 mm and -2 mm fractions were tested separately for acid-base accounts. SRK (2016) describes the interpretation for mineral partitioning for these samples. Both sulphur and carbonate preferentially partitioned into the -2 mm fraction but the effect was much stronger for carbonate. For the Cariboo Pit, there was no correlation between the fractions so the observed partitioning was qualitative only, but for the Bell Pit, a regression was derived. The finding from this assessment was that the classification of PAG using TIC/AP of 2 in blast hole cuttings has probably led to misclassification of some NAG rock as PAG. This finding was not used directly but primarily to confirm that under-classification of PAG rock (i.e., increased likelihood of PAG rock in NAG rock) is not a concern for MPM.

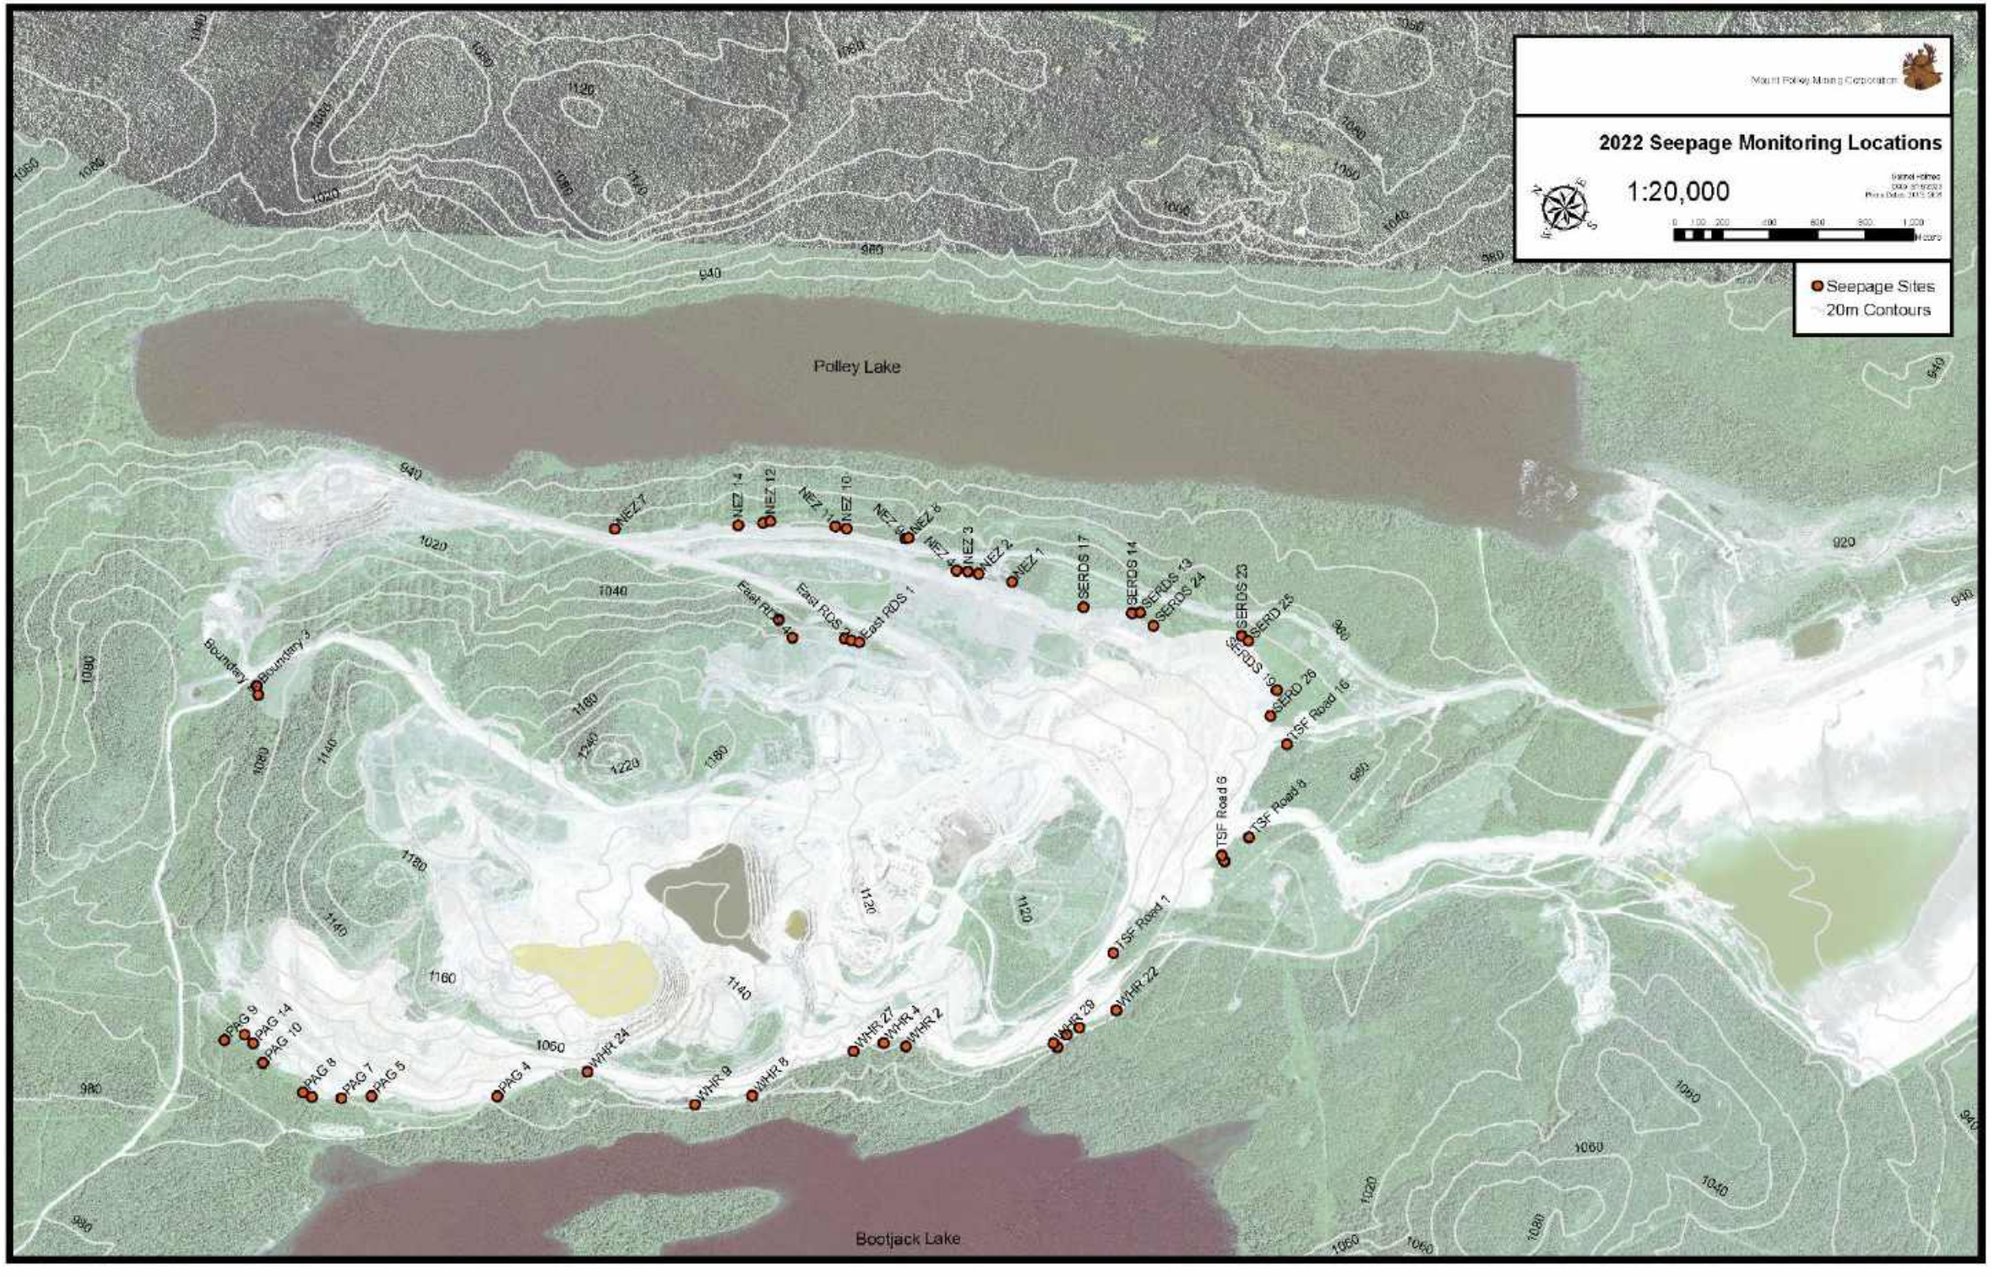
Potential for Acidification

The potential for acidification of NAG rock is described in SRK (2016) and considered:

- The likelihood that misclassified PAG waste rock occurs as large, segregated volumes (resulting in hotspots).
- The mass balance ABA resulting from misclassified PAG rock.

SRK (2016) concluded acidification of NAG waste rock at more than a very local scale is not expected because the percentage of PAG rock that could have been inadvertently included in the NAG waste risk is likely no more than a few percent. As there is a good understanding of the occurrence of PAG rock based on geological controls, it is expected that unaccounted for PAG rock is probably not more than a few percent. Therefore, NAG rock can be expected to remain permanently non-acidic and that long term changes in the NAG rock source term do not need to be considered.

Waste Rock Seepage Database



The seepage database was interpreted to understand what mineralogical controls may be constraining water chemistry, determine if seasonal variations are apparent, and derive statistics for the input into source term derivation.

As a general interpretation effort, relationships between rock composition and seepage chemistry were evaluated. However, except for the Wight Pit (Northeast Zone Dump) and Boundary Pit waste rock dumps, waste rock from all pits has been placed in several different locations limiting the opportunity to link rock composition to seepage chemistry.

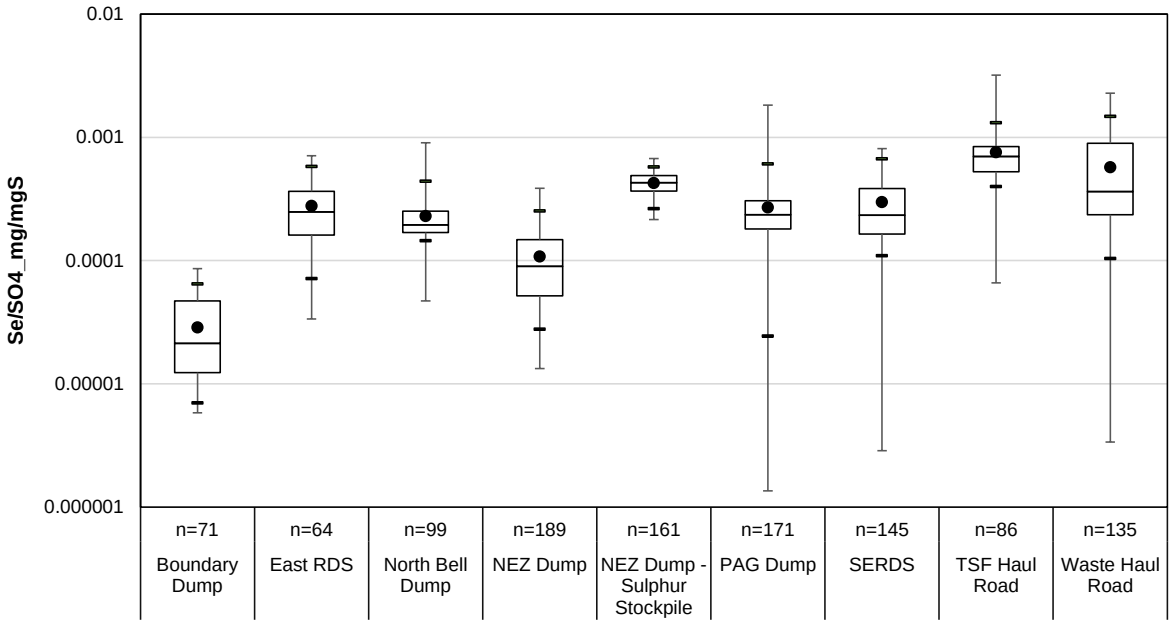
Description of the Database

The current database as of the end of 2022 contains 1124 water analyses for seeps located as shown in Figure 18. Seeps have been sampled biannually since 2013. Filtering of samples has occurred in the field since 2014. Samples are analyzed for a full range of major and trace ions.

Figure 18: Seep Sampling Locations

Sources: MPMC

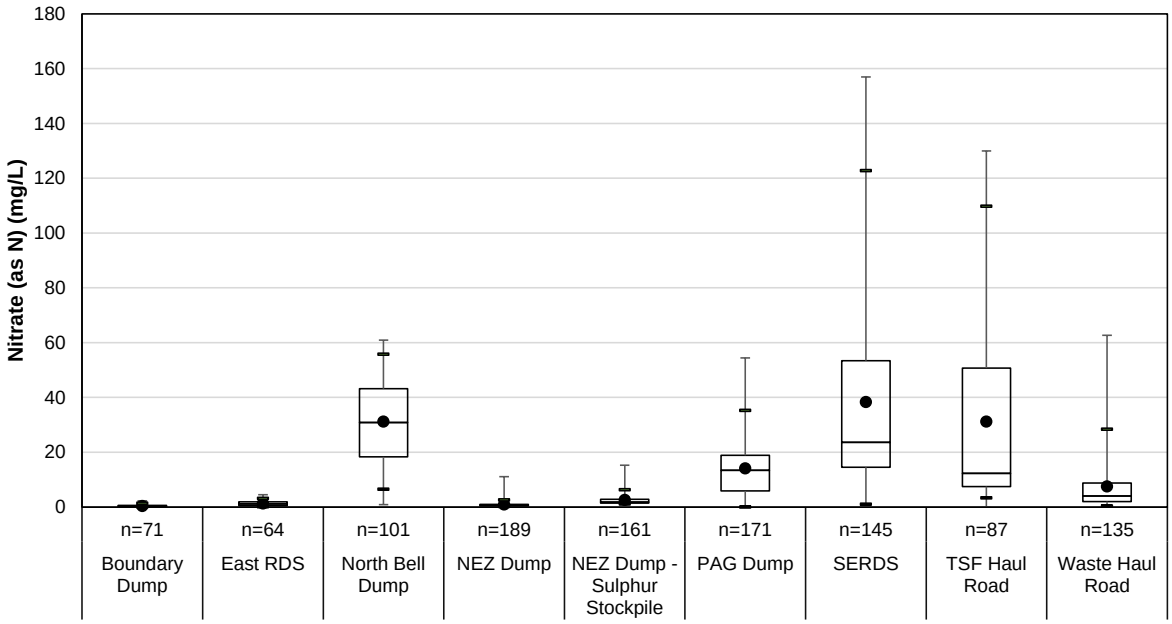
General Description of Water Chemistry



Water chemistry statistics are grouped according to the areas indicated in Table 6.

All seeps are non-acidic with medians above 7 and more typically nearer 8. The major anion is sulphate followed by bicarbonate (indicated by alkalinity) which is balanced mainly by calcium and magnesium. As discussed with reference to Figure 17, some differences in major ion chemistry were reflected in the cation ratio but differences in seepage chemistry were generally absent, except for NEZ Dump seeps influenced by the sulphur stockpile, reflecting consistencies with the geological setting and placement of waste rock from the pits at multiple locations for all other waste rock dumps.

Selenium to sulphate ratios were examined for comparison with ratios in the rocks. Rock chemistry showed some distinctive variations in the ratio with typical ratios between 0.0001 and 0.001 mg Se/mg S. Likewise, the ratio was in the same range for seeps (Figure 19). Wight Pit extended to lower ratios in both rock and seeps. SRK concluded that selenium leaching is due to oxidation of sulphides and that leaching effects are similar throughout the site.



Nitrate concentrations varied considerably by source area (Figure 20). Distinctively higher concentrations were found for the Southeast Dump, the Temporary NW PAG Stockpile, TSF Haul Road, and the North Bell Dump. The differences are linked to placement activity with lowest concentrations for dumps less recently active. Notably, nitrate concentrations in the North Bell Dump have decreased in recent years (Figure 20).

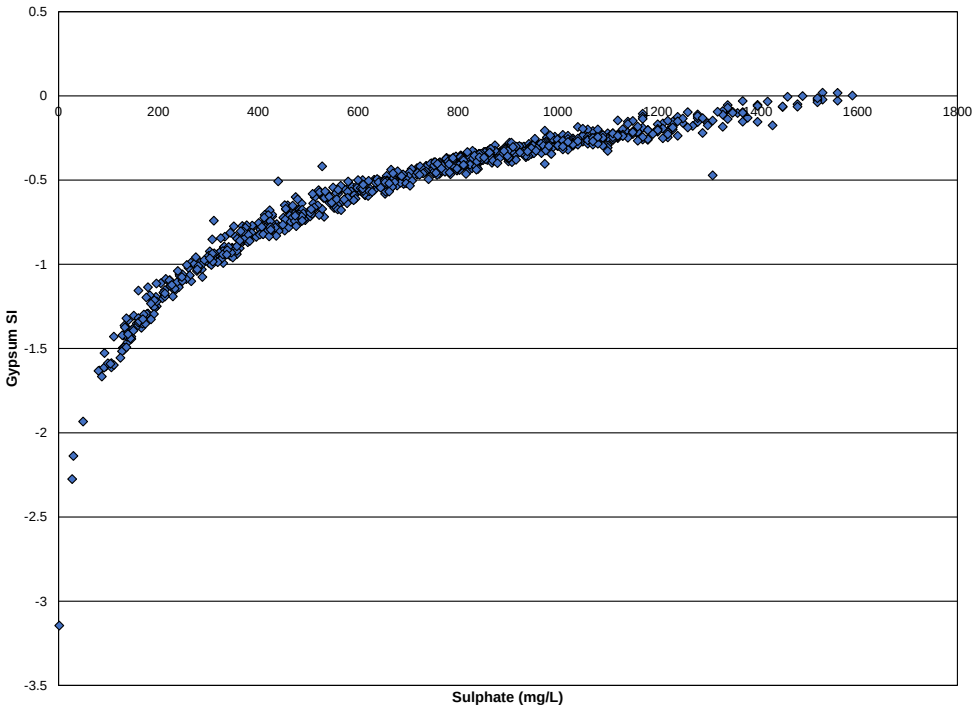
Notes:

[1] Statistics reported for pH and alkalinity are 5th percentile (for P95) and 1st percentile (for P99).

Interpretation of Water Chemistry

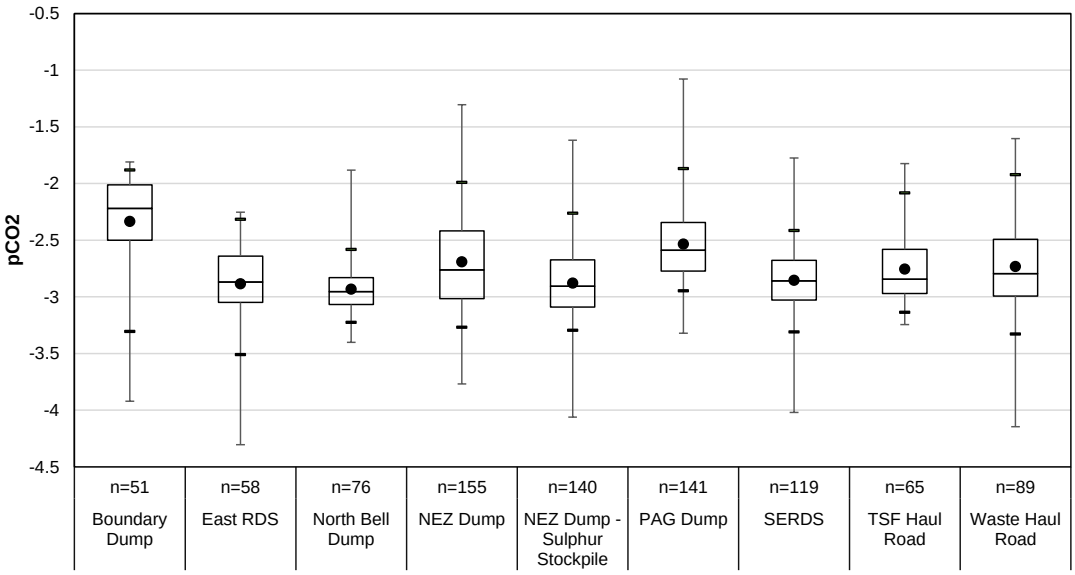
Water chemistry was interpreted by using PHREEQC and the minteq.v4 database to calculate mineral saturation indices thereby providing an indication of possible constraining minerals.



Saturation indices for sulphate were consistent with gypsum as a strong solubility control (Figure 22). At higher sulphate concentrations, gypsum saturation indices approached 0. Most seeps had sulphate concentrations well below those required to be at gypsum saturation indicating possible dilution effects, lack of gypsum, or incomplete equilibration. Regardless, the general observation is gypsum likely controls major ion (calcium and sulphate) chemistry with pH control by carbonate. Saturation indices greater than 0 for calcite were consistent with its dissolution and partial pressures for CO_2 were above -3.4 (Figure 23).

Saturation indices for malachite were well above 0 showing that copper concentrations were higher than would be predicted if malachite is controlling copper (Figure 24). Tenorite saturations indices were between 0 and 1 at higher copper concentrations indicating that it is more likely that a copper oxide is controlling copper concentrations. The finding that malachite does not appear to be controlling copper concentration is not consistent with the observed presence of malachite which formed by natural oxidation of the orebody. The likely controls on copper concentrations are secondary minerals resulting from oxidation of the waste rock following mining.

Other indications that higher end concentrations indicate mineral saturation included molybdenum which may be controlled by calcium molybdate (Figure 25). Trace elements occurring at concentrations well below saturation in indices of 0 for their discrete minerals are probably adsorbed or co-precipitated with major secondary minerals (for example, iron oxyhydroxides).



Like the majority of trace elements, saturation indices for selenium minerals were well below 0, reflecting that discrete selenium minerals are not likely to be forming. Relationships between selenium concentrations and saturation indices for major ions that do appear to be controlling solution chemistry were examined (Figure 26). The relationship with tenorite saturation indices showed that selenium concentrations appear to be constrained as copper concentrations were constrained. This may indicate that selenium is co-precipitating or adsorbing with an oxide or that the conditions resulting in copper oxide precipitation also result in selenium removal from solution. These interpretations do not provide a conclusive mechanism for constraining selenium concentrations but suggest that higher selenium concentrations in the dataset may be constrained. On this basis, seepage concentrations were used as the basis to calculate source terms.

5.3.3 Results

Source terms for NAG waste rock are provided in Appendix B.

5.4 NAG Waste Rock Influenced by the Sulphur Stockpile

Because acidification of the waste rock on the infiltrating water flowpath from the sulphur stockpile does not seem to have occurred based on sampling of the foundation materials and the sulphur stockpile has been relocated, no separate waste rock term was derived. Because the stockpile has been removed, the influence from the sulphur stockpile on these seeps may dimmish with time. The waste rock term for the seeps influenced by the sulphur stockpile is that shown as “NEZ Dump - Sulphur Stockpile” in Appendix B.

5.5 PAG Waste Rock

Since ex-pit PAG waste rock will be re-handled to the Springer-Cariboo Pit at closure before acidification is predicted to occur, and the same solubility controls are expected as NAG, no separate PAG waste rock term was generated. The PAG waste rock term is that shown as “All-PAG Pre-acid” in Appendix B.

Acidification of PAG walls is discussed subsequently in Section 5.8.

5.6 Ore Stockpiles

Ore stockpiles are composed of rock with similar composition to waste rock with the exception of higher copper concentrations. Overall controls on water chemistry are expected to be similar to NAG waste rock and no separate term was developed. The effects of processing oxidized ore are considered separately in Section 5.9.

5.7 Pit Backfill

Exposed components of pit backfill are assigned the same source term as NAG waste rock. Following submergence, the same source term is assigned to the pore water chemistry assuming that pore waters equilibrate with the same previously formed secondary minerals. Over time, leaching of these minerals will result in decreasing concentrations; however, this process has not been quantified and it is conservatively assumed that constant pore water chemistry will be maintained in perpetuity.

5.8 Pit Walls

5.8.1 Method

Similar to the approach outlined in SRK (2016), pit wall source terms prior to flooding consider the loading from weathering of rubble in exposed walls. Walls covered by waste rock backfill are not assigned a loading because the reactive surface area in waste rock far exceeds that in the rubble on pit walls.

The process of flushing walls by rising water levels was not considered because the relative volume water involved and flushing of pit walls weathering under non-acidic conditions will be small relative to ongoing flushing of exposed walls and flushing of backfilled waste rock.

Pit walls covered by water are also assumed to yield negligible loading because oxidation processes are effectively altered by a water cover. Ongoing leaching may occur (as described for waste rock backfill) but the volume involved is relatively small.

The load of parameter *i* released by weathering of rubble on pit benches (W_i) is calculated from:

$$W_i = M \cdot R_i \cdot k_O \cdot k_T \cdot k_p$$

Where R_i is the rate of release indicated by HCTs scaled to allow for oxygen availability (k_O), differences in temperature (k_T), and differences in reactive surface area (k_p), and applied to as mass M. Mass is calculated on a per m^2 planar wall basis, using a rock density (ρ) and an assumed reacting thickness (h):

$$M = 1 \cdot h \cdot \rho$$

The load leached (L_i) is calculated from:

$$L_i = W_i \cdot k_c$$

k_c is a factor to account for incomplete leaching of weathering products.

The resulting concentration [M_i] in wall area runoff over infiltration area, I, is obtained:

$$[M_i] = \frac{L_i}{I}$$

Concentrations obtained for non-acidic walls are constrained to the NAG waste rock if concentrations greater than for NAG waste rock are obtained. For PAG walls, concentrations were not constrained assuming that low pHs will result in high solubility of secondary minerals.

5.8.2 Inputs

R_is for non-acidic conditions were estimated from three humidity cells (HC14, HC15, and HC16) performed on Springer Pit rock and two humidity cells (HC (3) and HC (4)) performed on WX Zone rock (Table 4). The average of the five tests was used to estimate R. Scaling factors used for k_O, k_T, k_p, and

k_C were 1, 0.3, 0.1, and 1, respectively, and assume that oxygen is not limited, temperatures are lower under site conditions, rock is coarser than humidity cells, and weathering products are completely leached.

No naturally progressing humidity cells have yielded acidic leachate for MPM but rates obtained from HCTs on Pond Zone rock forced to generate acid by stripping of carbonate (HC12 and HC13 in Table 4) were used to estimate an acidic source term. Since these samples were selected to evaluate oxidation rates following carbonate depletion for samples containing lower sulphide in the Pond Zone, the HCT weathering rates $R_{i,HCT}$ were scaled to sulphide concentrations in the acidic Springer Pit walls ($S_{i,Wall}$) using:

$$R_{i,acid}=R_{i,HCT}\left(\frac{S_{acid,wall}}{S_{HCT}}\right)$$

$S_{acid,wall}$ was estimated from the blast hole cuttings database from the Springer Pit. For each PAG sample in the database, the sulphur remaining following depletion of all NP was calculated from the measured sulphide content (S_0) and carbonate content ($NP_{TIC,0}$) and the rate ratio for depletion of carbonate (R_{ratio}):

$$S_{acid,wall}=S_0-\left(\frac{NP_{TIC,0}}{R_{ratio}\cdot 31.25}\right)$$

R_{ratio} is equivalent to the PAG/NAG segregation criterion of 2. The 95th percentile of the resulting distribution of $S_{acid,wall}$ was calculated to be 2.3% compared to the 95th percentile of measured values of 2.8%. The resulting rates are shown in Table 7.

The weathering thickness (h) was set to 2 m to be equivalent to typical over-blast thickness. The bulk density, ρ, was used as 2.65 t/m^3.

Total annual precipitation of 620 mm/year (MPMC 2022) was used to estimate infiltration of 560 mm/year assuming that 90% of precipitation contacts wall rocks.

5.8.3 Results

Pit wall source terms of non-acidic and acidic walls are shown in Appendix C.

5.9 Ore Processing

5.9.1 Method

The method and resulting source terms are the same as presented in SRK (2016). The mass leached from ore as it is processed was calculated from shake flask extraction test data. Concentrations in the shake flask tests (in mg/L) were converted to mass leached as (mg/t) by multiplying by factors of 3 L/kg which is the leach ratio in the test, and 1000 kg/t. The mass leached is used to determine the load added to the process water from each tonne of rock processed.

5.9.2 Inputs

Shake flask data from characterization of eight samples from four ore stockpiles were used (SRK 2015b). The data were used to calculate 5th, 50th and 95th percentile of the loads leached. Since the rock in the stockpiles varied in age from one to nine years, they were not representative of freshly blasted ore. To account for this, the 5th percentile was used to indicate leaching of freshly blasted ore and the 95th percentile was used for processing of the stockpiles.

5.9.3 Results

The resulting source terms are provided in Appendix D.

5.10 Tailings

5.10.1 Method

Tailings source terms were developed for operating conditions (i.e., when tailings are being discharged) and closure conditions when contact waters are assumed to represent oxidation of tailings following draindown of process waters. Re-flooding resulting from reactivation of the impoundment would result in seepage chemistry intermediate between these conditions.

For operational conditions, observed seepage chemistry from tailings dam drains was assumed to be representative of future tailings contact water. Seepage chemistry is assumed to reflect mainly the influence of entrained process water with less influence from oxidation of tailings. Since localized influence from groundwater and non-contact surface can be expected, the range of concentrations assumed was the 95th and 99th percentiles.

For closure conditions, the preferred approach was to obtain direct chemistry from contact waters in the current unsaturated zone because these would likely represent the conditions when the tailings are

fully drained down. No suitable monitoring locations were identified with likely contact water chemistry, so data from the tailings columns were used, similar to the approach outlined in SRK (2016).

Interpretation of leach column data (see below) indicated that early chemistry provided a good indication of contact water chemistry reflecting the influence of oxidation processes. The following method was used to estimate contact water chemistry for drained down tailings:

- The 95th and 99th percentile concentrations of column data were calculated (for alkalinity, the 5th and 1st percentile, respectively, were used).
- For the majority of parameters, drain down chemistry was characterized by the column data percentiles.
- For selenium, interpretation of the column data resulted in the conclusion that attenuation of selenium may be occurring in the early stages of testing as a result of reductive process converting selenate to selenite. To address this possible effect, selenium concentrations were calculated using the sulphate statistics and the range of Se/SO_4 ratios indicated by later data:

$$[Se] = \left(\frac{Se}{SO_4}\right)_{ratio} \times [SO_4]$$

- The equivalent dam drain percentile was used for ammonia because it was not measured in column leachates.
- Manganese concentrations were markedly lower in column leachates compared to seepage. This difference may reflect that conditions in desaturated tailings favour lower mobility of manganese, but the seepage data were selected.

5.10.2 Inputs

Seepage data statistics were calculated for all seepage collection points collected between 1998 and 2022 (Table 8).

Seepage and column data were evaluated for solubility controls using the same approach as waste rock (Section 5.3). Sulphate concentrations in the early column data were close to 2000 mg/L and found to yield gypsum saturation indices near 0, and therefore consistent with solubility control by gypsum (Figure 27). Seepage saturation indices tended to be well below 0. Other parameters showing possible secondary mineral controls were copper (tenorite) and molybdenum (calcium molybdate). Based on similar reasoning as waste rock, the early column data appear to indicate secondary mineral solubility controls for these elements and provide a good indication of the solubility of other elements.

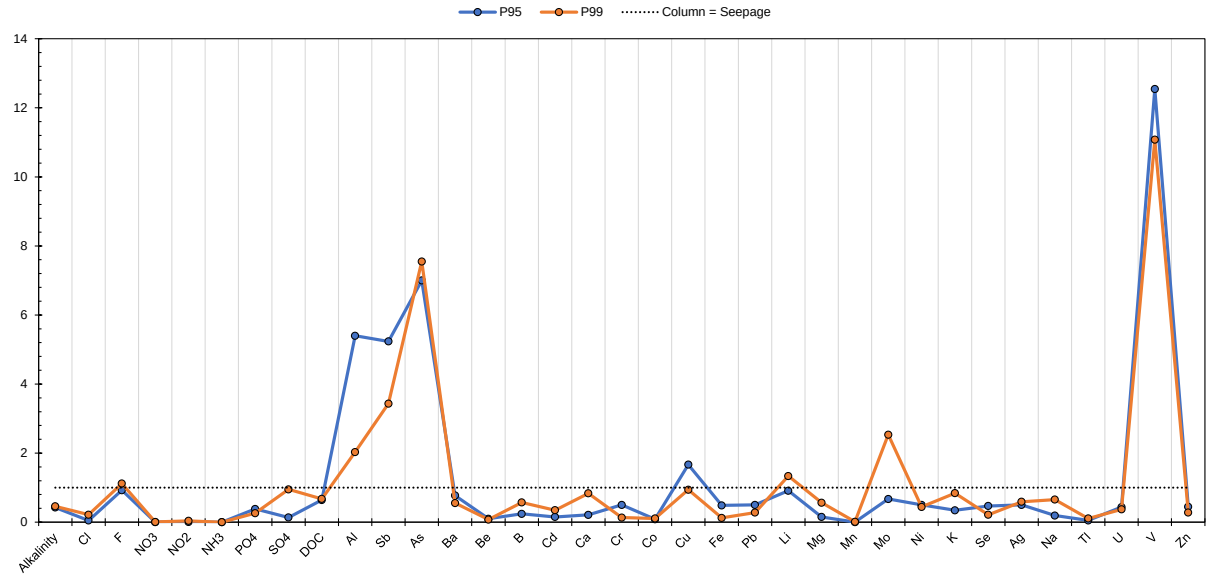
Notes:

[1] Statistics reported for pH and alkalinity are 5th percentile (for P95) and 1st percentile (for P99).

Figure 27: Gypsum Saturation Indices for Tailings Seepage and Column Data



Sources: https://srk.sharepoint.com/sites/NACAPR002434/Internal/!020_Project_Data/010_SRK/Source_Terms/Source_Terms_CAPR002434_Rev00_SJL.xlsx

Figure 28 shows the ratio of Column to Seepage for the two statistics. The columns showed higher concentrations than seepage for some elements (Al, As, Sb, V), but were within an order of magnitude for all except arsenic. The high concentrations of arsenic (> 0.01 mg/L) in the column leachates were not associated with an initial flush and may be evidence of some desorption during testing. Concentrations have been < 0.01 mg/L since cycle 233.

Most parameters linked to acid generation and neutralization processes (SO_4, Ca, Mg) and related elements (Cu, Mo, Se) are now similar to or lower in the columns compared to what was reported in SRK (2016), reflecting depletion as the tests proceeded. Those lower in column data also include nitrogen forms (which would be introduced by leaching in the process plant), and manganese and iron. Manganese and iron may be higher in seepage due to reducing conditions in drains.

Figure 28: Comparison of P95 and P99 Statistics for Ratio of Column/Seepage

5.10.3 Results

Tailings source terms are provided in Appendix E.

5.11 Magnetite Stockpiles

No separate source term was developed for the magnetite stockpiles. Relative to other sources, these stockpiles are not expected to be significant sources.

5.12 Nitrogen Leaching

Nitrogen leaching was included for each source term as follows:

- **Waste Rock:** Nitrogen sources terms were developed from existing seepage by grouping waste rock dumps into active (PAG Ex-Pit and SERDS), and inactive (Boundary Dump and NEZ Dump). For each group, mean concentrations and 95% confidence limits on the means were calculated to consider uncertainty (Table 9).
- **Pit Walls:** Pit walls were assumed to have zero contribution due to the small mass involved and expected results of meteoric leaching which is expected to result in any leaching effects having short duration and being insignificant relative to waste rock reporting to pit water sumps.
- **Backfill:** Backfill source terms are the same as those for waste rock (Table 9).

- **Ore Processing:** Leaching of nitrogen forms by processing were based on the shake flask extraction data (Appendix D).
- **Tailings:** Tailings source terms are based on the observed seepage for operational conditions and column data for draindown conditions (Appendix E).

Table 9: Waste Rock Nitrogen Source Terms

Phase	Statistic	Ammonia	Nitrate	Nitrite
		mg-N/L	mg-N/L	mg-N/L
Inactive	Low 95% Confidence Limit	0.013	0.84	0.0065
	Mean	0.027	1.6	0.0078
	Upper 95% Confidence Limit	0.04	2.4	0.0092
Active	Low 95% Confidence Limit	0.017	19	0
	Mean	0.057	26	0.38
	Upper 95% Confidence Limit	0.098	33	1.0

6 Conclusions

This report presents source term geochemical predictions that are inputs into the site wide water quality model. The main conclusions that provided input into the source terms are:

- While several ore zones at MPM have been mined since 1997, all except the relatively small Pond Zone are alkalic porphyry mineralization centred on magmatic-hydrothermal breccia bodies with similar geological characteristics. The host rock for the mineralization is the MPIC which is mainly monzonite. The similarities of the mineralized zones, including their host rocks, indicate that source terms can appropriately be developed on a site-wide basis rather than considering significant differences between the zones.
- As a result of geochemical segregation of waste rock based on ARD potential through the mine life, PAG waste rock has been or will be placed in open pits where it will be permanently flooded thereby preventing ARD from developing.
- It is expected that operational inefficiencies will have resulted in PAG waste being incorporated into the NAG waste rock but the segregation approach was conservative and mass balance excess of acid neutralizing minerals over acid generating minerals means that future development of ARD is unlikely. Weathering conditions are predicted to be pH-basic in perpetuity.
- Tailings are non-PAG.
- As a result of the pH-basic weathering conditions, chemistry of seepage from the existing full-scale facilities reflects solubility limits for weathering minerals. Chemistry is affected by dilution which was corrected using the solubility limit of gypsum.

Closure

ML/ARD MANAGEMENT PROCEDURE MANUAL

OBJECTIVE

The objective of this Metal Leaching/Acid Rock Drainage (ML/ARD) Management Procedure Manual is to provide detail on how ML/ARD potential is considered in material management at the Mount Polley Mine (MPM). This document summarizes all the various procedures and considerations related to ML/ARD potential through mine life processes.

DOCUMENT REVISION HISTORY

This document replaces earlier versions of similar documents that directed ML/ARD Management at MPM in response to *Mines Act* Permit M-200 issued on August 3, 1995. The procedures as described have been in the place since that date.

Document Update Summary

Revision Date	Author	Comment
June 30, 2016	Chad Cameron Ben Harding Katie McMahen Luke Moger Ryan Brown Stephen Day (SRK)	Original Document
August 04, 2022	Mathieu O'Leary Gabriel Holmes Aaron Zwiebel (DWB) Shauna Litke (SRK)	Added contacts, water treatment plant waste ML/ARD characterization, QA/QC sampling, and PAG misplacement action plan.

KEY CONTACTS AND QUALIFIED PROFESSIONALS

Numerous personnel at Mount Polley are responsible for carrying out the procedures written in this plan. Key mine personnel and their contact information are as follows.

Name	Role	Phone	Email
Don Parson	General Manager	604-488-2652	don.parsons@imperialmetals.com

BACKGROUND

Metal leaching and acid generation are naturally occurring chemical processes which may have negative impacts on the receiving environment. The potential environmental impact of ML/ARD will depend on their magnitude, the sensitivity of the receiving environment, dilution and/or attenuation, as well as any mitigation measures that are in place.

Metal leaching occurs as a result of: weathering of metal-containing minerals (i.e., exposure to water and oxygen), drainage conditions that increase solubility, and flow of water through source materials. Acid generation occurs when minerals containing reduced sulphur (e.g. sulphide and elemental sulphur) are exposed to the weathering effects of oxygen and water. In iron sulphide minerals (e.g. pyrite) acidity is also generated when ferric iron precipitates. Other minerals in the source rock, primarily calcium and magnesium carbonates can neutralize the acid. ARD occurs when the amount of acid-generation exceeds the ability of the source rock to neutralize this acid. Any surplus acid is entrained in water and can create acidic and metal-containing run-off.

Pre-mining and operational geochemical characterization has shown that ARD potential at MPM is restricted due to the abundance of acid-consuming carbonate minerals compared to acid generating sulphide minerals. In addition, the presence of natural carbonate and oxide copper minerals in the pre-mining weathering zone reinforce the expectation that weathering conditions are dominantly basic. However, due

to the potential consequences of acid generation for long term management of the site, Mount Polley Mining Corporation (MPMC) actively manages waste rock based on its ARD potential as described in the following sections.

MPMC has focused on managing potential for ARD due to the link between acid generation and enhanced solubility of copper which is expected to be the primary concern for ML. Selenium leaching has also been identified as occurring at MPM. Selenium is released by oxidation of sulphide minerals but leaching is not necessarily associated with pH depression. Selenium leaching occurs regardless of whether waste rock is classified as potentially ARD generating (PAG) or non-PAG (referred to as NAG at MPM).

UNDERSTANDING OF THE DISTRIBUTION OF ARD POTENTIAL

Like other alkalic porphyry deposits (e.g. Copper Mountain, Brenda), MPM lacks the strong hydrothermal alteration zoning that is commonly observed in calc-alkalic porphyry deposits (e.g. Highland Valley Copper, Island Copper, Gibraltar). In particular, phyllic alteration is absent at MPM. A common feature of calc-alkalic porphyry deposits is often a pronounced pyritic halo that surrounds the copper mineralization and is associated with phyllic and propylitic alteration. At MPM, discontinuous pyritic zones are present but do not appear to be mineralization halos. MPMC geological staff identified a pyritic zone in the south wall of the Springer Pit which extends into the adjacent Cariboo Pit.

This ML/ARD Management Procedure Manual applies to waste rock and ore stockpiles. Tailings are consistently NAG due to removal of copper sulphides by ore processing.

MANAGEMENT OF PAG ROCK

Best practice for management of PAG rock is subaqueous disposal in a configuration that provides permanent and low maintenance containment. At MPM, this has been implemented by disposing of waste rock in completed open pits that will subsequently fill with water. Mine planning is carried out at MPM such that the open pits have sufficient capacity that PAG material can be re-handled into the open pits and stored subaqueously at closure. The following pits are available for subaqueous disposal (in sequence):

- Cariboo Pit
- Bell Pit
- Pond Zone Pit
- Southeast Zone Pit
- Wight Pit
- Cariboo-Springer Pit.

For the Springer Pit, backfill locations are not currently available. The PAG rock is therefore stockpiled adjacent to the open pit in the Temporary Northwest PAG Stockpile for backhauling to the Cariboo-Springer Pit upon completion of mining.

For the small Pond Zone Pit, low sulfur PAG waste rock is layered with NAG waste rock.

Onset of acidic conditions in waste rock at MPM takes at least decades as shown by humidity cells, and the lack of acidification in the natural exposure of the deposit indicates that flooding of PAG waste rock does not need to be immediate. The current approaches of backfilling into dry pits and stockpiling following by backfilling allows PAG rock to be submerged before it acidifies.

DETERMINATION OF ML/ARD POTENTIAL

Waste rock on site is separated into two categories, NAG and PAG, using Neutralizing Potential Ratio (NPR) defined as:

NPR = NP/AP.

Acid Potential (AP) (in kg $CaCO_3$/t) is measured from:

- Total sulphur (%) x 31.25

Neutralizing Potential (NP) (in kg $CaCO_3$/t) is measured from total carbonate NP determined from:

- Total carbon (%C) x 83.33.

Due to the dominantly intrusive rock host at MPM, total carbon is an appropriate proxy for carbonate.

As required by *Mines Act* Permit M-200, PAG is defined as:

- NPR≤2 and total S>0.1%.

This *Mines Act* Permit M-200 requirement was specified in terms of NP determined by a whole-rock acid extraction and titration method; however, MPMC chose to use total carbonate which yields lower NP than the titration methods.

MATERIAL CHARACTERIZATION OVERVIEW

This section provides an overview of characterization procedures.

The MPM program characterizes all material types that will be handled during the mine life. Analysis is completed on site by Mount Polley's LECO™ instrument , allowing MPMC to best manage mine waste by directing it to suitable storage sites, or to construction usage when required (and if deemed suitable).

On each bench, a sample of cuttings is collected from each blast hole and analyzed for total copper, non-sulphide copper, iron, and gold. Areas of ore and waste are identified by interpolation of these assay results and the economic analysis of the resulting metal grades. Ore/waste boundaries are then established based on the calculated mill head values.

In areas which have proven to be consistently NAG on previous adjacent benches in blasthole samples, the waste tonnage in each blast is divided by 40,000 in order to determine the number of ABA samples to be

submitted (i.e., one per 40,000 tonnes (t) of waste). However, in areas where PAG has been modelled through either exploration sampling, or results of previous blasthole sampling on other benches, (or where NAG and PAG may coincide), the sample density is doubled to one per 20,000 t. This approach results in greater sampling density in areas of suspected NAG/PAG boundaries, and increases the certainty of defining PAG. Typically structures at MPM are vertically oriented, and relatively continuous. This provides some assurance that blasthole samples from previously mined benches have relevance for determining where additional samples should be taken on new benches.

Any ore that will be stockpiled rather than processed immediately is sampled at a frequency of one (1) per 20,000 t to determine if it is classified as PAG or NAG. Millfeed ore areas are excluded from ABA analysis, as this material is processed through the Mill.

Composite tailings samples are collected and analyzed every month when processing of ore occurs to represent the tonnage of tailings deposited.

Water treatment wastes are quantified monthly and sampled quarterly, with material characterization performed to assess ML/ARD potential and contribute to a material inventory.

As a confirmatory sampling measure, the Environmental Department takes random weekly grab samples from the NAG waste dump when NAG is being dumped and/or used for construction, to verify that material is being appropriately characterized and handled.

In the event that a confirmatory sample or other activities result in the discovery of PAG material in a NAG-designated area, a QP is to be informed without delay, who will dictate the response actions in coordination with site contacts. Mount Polley is permitted to blend pockets of less than 1,000 t of PAG materials with non-PAG materials at a ratio of 20:1, as described in *Mines Act* Permit M-200 Section D.3.(c)(i)(d). If these conditions cannot be met, it may be necessary to remove PAG material from NAG areas.

Water chemistry monitoring of seepage from rock dumps, water treatment plant wastes, and contact water from the site water collection systems is also conducted by the Environmental Department to inform development of geochemical source terms and long-term water quality predictions. Similarly, tailings composites and monthly random drill pulp samples are sent to a third-party laboratory for metals analysis as an additional source of data for site geochemical models.

IN-PIT SEGREGATION

Blasthole Samples:

1. After the production drill has completed and moved away from the hole, the sample may be taken.
2. Using a tube sampler, the Driller will take a representative sample of the cuttings pile.
3. Samples are to be collected in a clean plastic sample bag.
4. The Driller is to complete a Blasthole Sample Tag, tearing off the tag once completed and inserting it into sample bag.
5. The sample bag is to be tied off using ribbon.

6. In the case where multiple composite samples are to be taken from a single hole, the remaining cuttings after the sample are to be removed by the Driller so a clean new pile of cuttings can be formed.
7. Completed samples are to be left on the drill by the Driller. At the end of shift, the Mine Operations Pit Supervisor (or designate) will collect all samples and deliver them to the Bucking Room.

Bucking Room:

1. Each sample is to be transferred from the sample bag to a clean metal tray. The Blasthole Sample Tag is to be kept with the sample.
2. The sample is to be dried at 105°C.
3. The sample is then to be crushed in the Primary Crusher.
4. The sample is then to be crushed in the Fine Crusher.
5. The sample is to be split until the sample size is approximately 200 g.
    a. Reject from the sample is to be wasted.
6. The sample is then to be pulverized for 75 seconds.
7. The sample is to be placed in a pouch with the Blasthole Sample Tag stapled to the pouch.
8. If the pouch is a pit sample, it is to be sent to Assay Lab 1. If the sample is an ABA sample, it is to be sent to Assay Lab 2.

Assay Lab 1:

1. The Assay Lab is to run the sample through the atomic absorption analyzer which automatically transfers the copper (CU), non-sulphide copper (CUNS) and iron (FE) values into the LIMS database.
2. The samples for gold analysis are to be fire assayed and analyzed by atomic absorption which automatically transfers the gold (AU) value into the LIMS database.
3. The sample is then to be placed into storage. Pit samples are to be stored for 21 days.

Ore Control Technician 1:

1. Once assays have been entered into the LIMS database, the Ore Control Technician will review the data and roughly determine where in the blast any Mill Feed Ore will be located.
2. Once the Ore Control Technician drafts the Mill Feed Ore locations, the Ore Control Technician will evenly select holes in the non-Mill Feed Ore areas (including materials designated for ore stockpiles) at a ratio of one (1) sample per 20,000 t of rock. This equates to about one for every nine blast holes. Additional samples can be requested whenever additional data is desired for improving understanding of the geological conditions. An example of a sample layout is included as Figure 1.

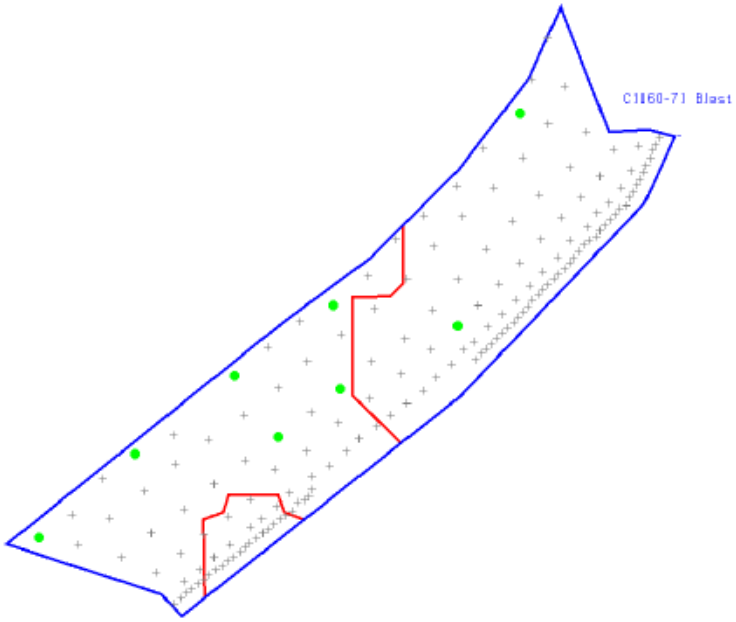

Figure 1: Location of ABA samples (green dots) within a blast. Red polygons denote mill feed ore, remainder is waste. The Ore Control Technician focuses sampling on areas which are designated waste and/or stockpile ore by the blasthole model. Reference blast = 149,173 t.

3. The Ore Control Technician is to then make an Analysis Request with the holes selected to the Assay Lab.

Assay Lab 2:

1. If the Assay Lab receives an Analysis Request, they will retrieve the sample pouch from storage, otherwise the sample will be delivered to the Bucking Room.
2. The Assay Lab will run the sample through the LECO CS230 Carbon Sulphur Analyzer.
3. Once analyzed, the machine transfers the carbon percentage (C%) and the sulphur percentage (S%) to a spreadsheet where NPR, NP and AP are calculated.
4. The NPR, NP, AP, C% and S% are transferred automatically to the LIMS database.
5. The sample is then to be placed into storage. ABA samples are to be stored for 14 days.

Ore Control Technician 2:

1. Once all the assays and ABAs have been entered into the LIMS database, the Ore Control Technician is to review the data and model the blast.
2. Modeling the blast
    a. The software used is MineSight.
    b. The model is based on a 5 metre (m) x 5 m x 12 m block system.
    c. The block closest to the ABA sample will closely match the sample.
    d. The blocks between the samples receive a weighted average of the sample carbon and sulfur grades.

e. Once each block gets the weighted C% and S%, then the AP, NP and NPR is calculated for each block.
f. Using the calculated NPR value, the model is to be coded as Ore/NAG/PAG by the Ore Control Technician and the resulting markup design is to be provided to the Surveyor.

3. The Ore Control Technician is responsible for the release of the final ore markup to the Surveyor. An example of a sample layout is included as Figure 2.

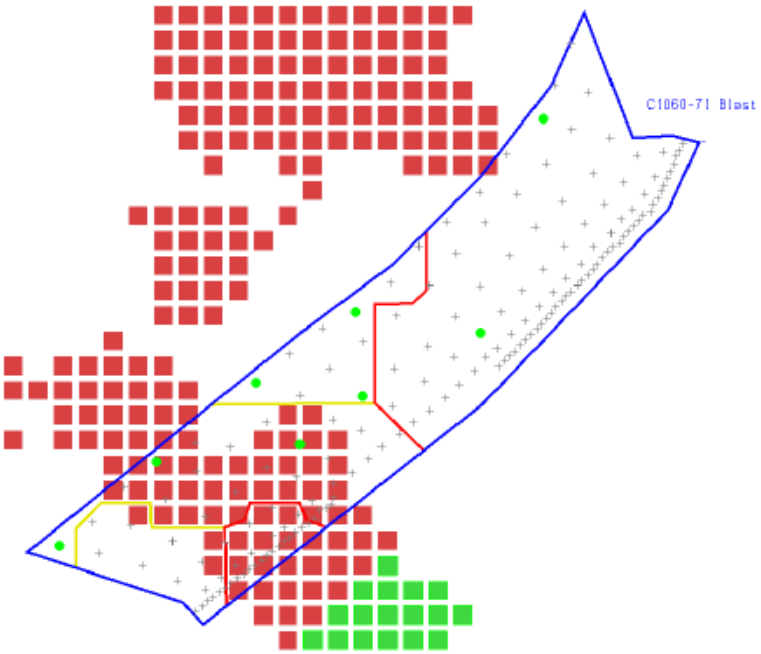

Figure 2. ABA results from samples shown in Figure 1 are used to update the blasthole PAG model item which identifies blocks which meet PAG criteria (red). The Ore Control Technician then marks up the PAG waste (yellow polygon) and the complete ore/waste markup is released to the Surveyor.

Surveyor:

1. The Surveyor will be responsible for the layout all Ore/NAG/PAG, as determined by the Ore Control Technician, in the field.

2. Using four (4) foot stakes spaced approximately 5 m apart, the Surveyor will mark out the contacts using marked placards.
   a. Red Placard = High Grade Ore
   b. White Placard = Super High Grade Ore
   c. Green Placard = Low Grade Ore
   d. Yellow Placard = PAG
   e. Blue Placard = NAG
   f. Pink Ribbon = High Grade Mill Feed Ore
3. Once complete, the Surveyor will print out maps of the area delineating material types for the shovel operator(s), and, if required, provide field verification of material types.

MATERIAL HANDLING

Shovel/Haul Truck Operators:

1. The Shovel Operator will mine the rock, following the contacts laid out by the Surveyor.
2. The Shovel Operator will ensure that all material contained within the contact stakes is routed as described by the markup and that any uncertainty in material classification is resolved by seeking the assistance of either the Pit Supervisor or the Engineering Department.
3. Upon loading a haul truck, the Shovel Operator shall direct the Haul Truck Driver as to the material type being hauled, and destination, using a horn sequence. The Haul Truck Driver will then take the material to the designated area.

IN-PIT MONITORING

Shovel Operator:

The Shovel Operator follows the staking of the Surveyor. Any material marked out as PAG is only to be hauled to approved locations. If a discrepancy is found, the Surveyor is to be called out to verify the material markup.

Pit Supervisor:

Throughout the shift, the Pit Supervisor will check in with the Shovel Operator and confirm the material type being loaded and that the destination is correct.

Haul Truck Driver:

If the Haul Truck Driver is uncertain of the material loaded, the Haul Truck Driver will confirm with the Shovel Operator or the Pit Supervisor.

Ore Control Technician:

The Ore Control Technician is to check Shovel Operator dig faces and confirm that the markup is appropriate and material is being routed appropriately.

Surveyor:

The Surveyor is to verify that material staking is visible and correct.

Environmental Department:

Once a month, the Environmental Department is to send a randomly selected drill hole pulp sample that MPMC analyzed for total sulfur and total carbon at the Assay Lab to a third-party laboratory (typically ALS Environmental in Burnaby, BC) for element analysis by ICP-MS following aqua regia digestion as an additional source of data to support site geochemical models.

Additionally, the Environmental Department takes water samples from all pit sumps to inform long-term geochemical predictions. Samples are collected as per MPMC-SOP-002: Surface Water Quality Monitoring. Monitoring locations and frequencies are regularly updated to reflect site developments and are summarized in the Comprehensive Environmental Management Plan.

TAILINGS MONITORING

Mill Metallurgy

1. The Mill Metallurgy Department is to take a monthly composite sample of the tailings generated through the month.
    - Slurry is to be sampled every two (2) hours and made into a composite for the shift.
    - The shift composite is then to be added to a monthly composite.
    - At the end of the month, the monthly composite is to be given to the Bucking Room and prepared for ABA total sulfur and carbon analysis.
2. The Environmental Department is to send the monthly tailings composite sample to a third-party laboratory (typically ALS Environmental in Burnaby, BC) for element analysis by ICP-MS following aqua regia digestion to provide data for site geochemical modelling.

WATER TREATMENT PLANT WASTE

Environmental Department:

1. Record the value on the waste line totalizer monthly when Water Treatment Plant (WTP) data are downloaded.
2. Collect samples of waste which has exited the WTP quarterly to characterize WTP wastes. Samples shall be taken of material that has exited the sludge line, to the West of the WTP and down-flow from where microsand is cycloned for re-use.
3. Sampling Method for liquid wastes (adapted from MPMC-WORK-002):
    - Record in-situ measures: pH, temperature, conductivity, and turbidity.
    - Take a water sample from the pipe outflow and send for lab analysis corresponding with other contact water samples as described in the Comprehensive Environmental Monitoring Plan, including but not limited to: physical parameters, pH, total and dissolved metals.
4. Sampling method for solid wastes (adapted from MPMC-WORK-016):
    - Take a composite sample of solids from the sludge pile adjacent to the WTP, with samples from at least 5 locations on the pile.
    - Send to an external laboratory for total sulfur, total inorganic carbon, elemental analysis by ICP-MS following aqua regia digestion and shake flask extraction testing to assess the ML/ARD potential of solids.
5. Review and archive lab data in a timely manner for use by personnel responsible for the Annual Reclamation Report.
6. The TSS concentration in wastewater will be used along with the waste line totalizer values to quantify the solids delivered to the TSF. The relationship between total and dissolved metals in the WTP waste line sample will be used to quantify the suspended (filterable) metals in this sample.

7. This information will be included in the MLARD materials inventory, and reported to EMLI in the Annual Reclamation Report as per Code Section 10.5.7 on water treatment wastes and by-products.

NAG Material Monitoring

Environment Department

1. As a confirmatory sampling measure, the Environmental Department is to take ABA grab samples from the NAG Dump and any area where NAG rock is used for construction on a weekly basis, while NAG dumping and/or NAG rock construction is occurring. Sampling will conform with MPMC-SOP-016: ABA and Soil Sampling.
2. To assure data quality, as recommended in the BC Field Sampling Manual, a minimum of one in ten samples will be a duplicate sample, as written in MPMC-SOP-016.
3. Seeps and contact water collected on site are sampled to provide data for site geochemical modelling. Samples are collected as per MPMC-SOP-002: Surface Water Quality Monitoring. The frequency and locations of these monitoring sites are updated regularly to reflect changes to the mine site are summarized in the Comprehensive Environmental Management Plan.

Response to Finding PAG in NAG Areas

Environmental Department

1. Upon reviewing data indicating PAG material has been found in a NAG area, without delay contact one or more Qualified Professionals listed in this document, and the Pit Supervisor or designate to pass along the relevant data and sampling location.
2. Return to the location where PAG material was discovered and stake the sampling location. Note that material may have been dozed, buried or pushed down the dump face, in which case personnel are to mark as close as possible.
3. At the discretion of Qualified Professionals, undertake additional ABA sampling to assess the prevalence of PAG material.

Pit Supervisor:

1. Discuss NAG/PAG separation with shovel and haul truck operators and investigate the possibility of a loading or dumping mix-up. This is not a punitive activity but meant to identify potential causes and estimate material volume.
2. At the discretion of Qualified Professionals, organize the removal of PAG material from the non-PAG area.

ML/ARD Qualified Professional

1. Work with site contacts to develop an appropriate plan of action to address the situation.
2. If it is not possible to demonstrate that PAG material meets conditions outlined in M-200 Section D.3.(c)(i)(d), it may be necessary to remove recoverable PAG material.

REVIEW OF RESULTS AND PROGRAM EFFICACY

Data collected and corresponding interpretation regarding the ML/ARD program are included in the Annual Environmental and Reclamation Report (AERR), due annually to the British Columbia Ministry of Environment and Ministry of Energy and Mines on March 31 of each year, reflective of the previous calendar year. Personnel responsible for the AERR may recommend updates to the ML/ARD program based on operational changes or findings of annual reporting. The AERR includes sections on: waste rock characterization and disposal; drainage water quality monitoring; and, updates to long-term predictions (kinetic testing).

Notes:

[1] MPMC estimates PAG rock above 1030 masl is 13%. Acidification will be progressive.

[2] Concentrations are "annual". Seasonal variation can be expected but these concentrations are intended to reflect seasonal worst for each case.

[3] Probabilities cannot be attached to the terms. Use the terms to assess proximity to trigger levels but not to assess probability of exceedance.

APPENDIX 2-3: Site Wide Water Balance Model Update and Calibration Technical Memorandum

TECHNICAL MEMORANDUM

DATE March 21, 2024 **Reference No.** CA0020527.4505-026-TM-Rev0-31141

TO Matt O'Leary
Mount Polley Mining Corporation

FROM Stella Cheng, Gonzalo Donoso, and Peter Morgan **EMAIL stella.cheng@wsp.com; gonzalo.donoso@wsp.com; peter.morgan@wsp.com**

2023 SITE WIDE WATER BALANCE MODEL UPDATE AND CALIBRATION – MOUNT POLLEY MINE

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) retained WSP Canada Inc. (WSP) to provide water balance modelling services to update and calibrate the Site Wide Water Balance Model (SWWBM) in support of MPMC's 2023 Annual Report. This exercise is a requirement of Section 4.2.1 (f) of MPMC's Discharge Permit 11678, issued under the *Environmental Management Act* and most recently amended through a Consent Order on December 31, 2020 (BC ENV 2020).

The SWWBM was developed using GoldSim™, a highly graphical software package for carrying out dynamic, probabilistic simulations to support decision-making (GoldSim 2018). GoldSim™ is frequently used to evaluate water management alternatives, perform sensitivity analyses, and conduct mass balance simulations.

The SWWBM was developed as part of the Mount Polley Mine Resumed Operations and Closure Water Management Plan Permit Amendment Application and Technical Assessment Report (Golder 2016a) to model water management across the site (e.g., runoff, water transfers, and storage). The details of the SWWBM were first presented in the Mount Polley Mine Water Balance report (Golder 2016b).

On May 26, 2019, Mount Polley Mine (the Mine) entered a care and maintenance phase. On June 1, 2022, the Mine resumed operations under the current EMA Permit 11678. Mining and tailings deposition occurred throughout 2023.

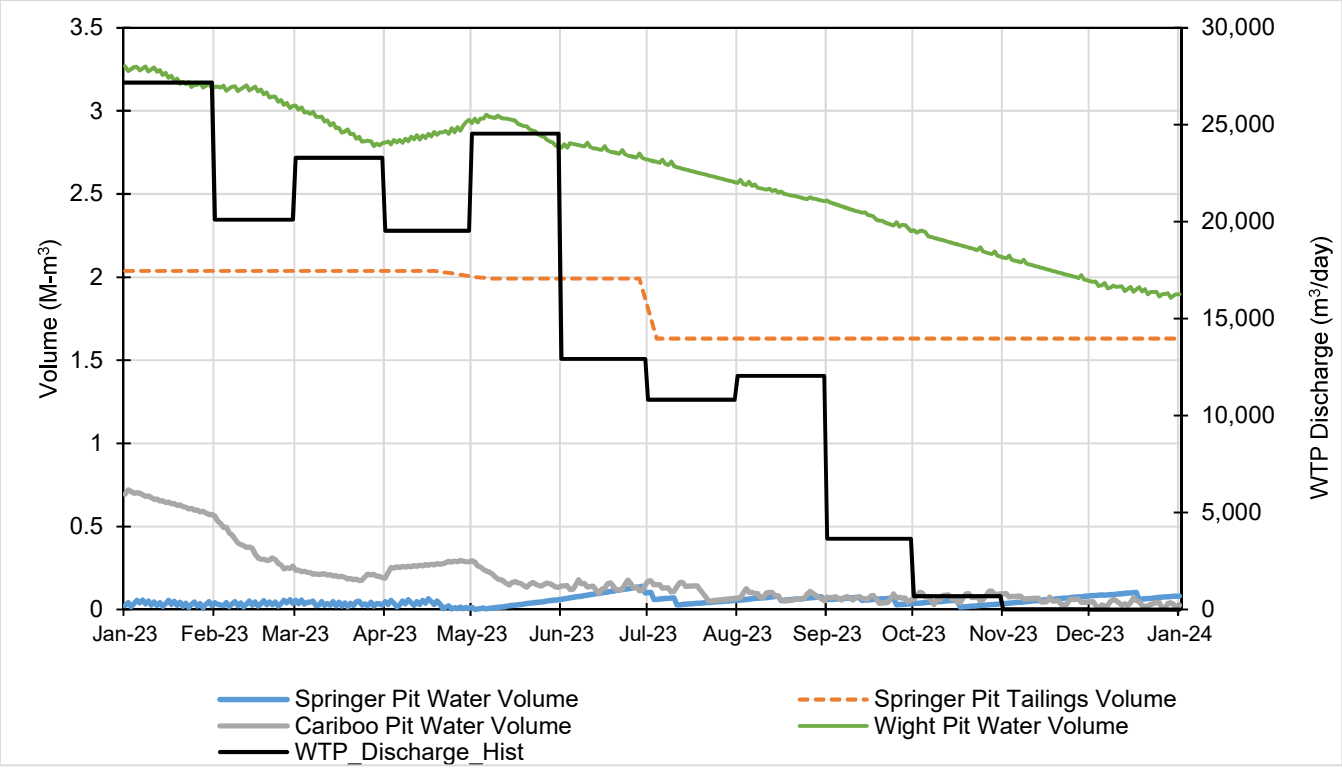
WSP updated the SWWBM in March 2023 to calibrate water volumes, water levels and discharges in the Tailings Storage Facility (TSF) for the period from January 1, 2022 to December 31, 2022 (WSP 2023a). An updated Water Balance Report was presented in 2023 (WSP 2023b) as part of the Water Management Plan for the Springer Expansion Life-of-Mine update (WSP 2023c).

This technical memorandum describes updates to the SWWBM to reflect site conditions in 2023, and calibration to measured water levels in the TSF for the period from January 1, 2023 to December 31, 2023. A summary of the model updates, the assumptions made in the calibration process, a discussion of the calibration results, and the end-of-year water balance for the Mine, is included in this document.

2.0 MODEL UPDATE

2.1 Data Received

MPMC provided WSP with measured data from site (MPMC 2024a). The following data were received from MPMC (2024a):



- "Snow Pack 2023.xlsx" Periodic snowpack measurements (snow water equivalent [SWE] in cm).
- "TSF Water Balance Jan 24, 2023 v3.xlsx" Periodic Springer Pit, Cariboo Pit and Wight Pit water level measurements in 2023 (m, mine grid).
- "2023 all weather station data.xlsx" Q1 to Q4 2023 climate data from site – including rainfall (mm), daily temperature (ºC) and evaporation (mm).
- "HMI WTP 2023 Total.xlsx" Monthly discharge of treated water (m^3) through the water treatment plant (WTP).
- "Weekly TSF Reports.pdf" TSF reclaim pond water level measurements (m, tailings grid) and Springer Pit remaining tailings (M-m^3) throughout 2023
- "2023 DSI Report Data Request.msg" Tailings deposited in the TSF throughout 2023 (tonnes).

2.2 Summary of Model Updates

Through discussions with MPMC, the SWWBM was updated to reflect site water management operations for the period of January 1, 2023 to December 31, 2023. The model updates were as follows:

- Tailings discharge from the ore processing plant to the TSF throughout 2023.
- Discharge to the environment through the WTP was updated. The volume of WTP discharge saw a significant decline beginning in September 2023. This decrease occurred because the WTP has been offline since September 13, 2023, as water has been redirected from Wight Pit to TSF (MPMC 2024a). Monthly discharge volumes through the WTP are shown on Figure 1.
- Water from Wight Pit was transferred to the WTP via Long Ditch for treatment and discharge in 2023. A time series plot of the modelled total water volume in Wight Pit is shown in Figure 1.
- Water from Springer Pit was transferred to the WTP via West Ditch for treatment and discharge throughout 2023. A time series plot of the modeled total water volume in Springer Pit is shown in Figure 1.
- Water from Cariboo Pit was transferred to the WTP via West Ditch for treatment and discharge throughout 2023. A time series plot of the modeled total water volume in Cariboo Pit is shown in Figure 1.

Additional details related to use of available surveys are provided in the following section.

Note: The primary y-axis unit (M-m3) denotes millions of cubic meters.

Stored water volume = surface water volume + voids water volume

Figure 1: Springer, Cariboo, Wight Pits Volumes and WTP Discharge Flow Rate

2.3 Site Surveys

2.3.1 TSF

Topographic surveys of the TSF were conducted by MPMC on October 30, 2023. A bathymetric survey within the TSF was conducted on August 25, 2023. The storage-elevation curve was developed using the combined bathymetry and topography, and it is used in the SWWBM to infer the TSF free water volume from measured water level data, recognizing that the surfaces described are a triangulation of a bathymetry survey (tailings surface under water) and a topographic survey (tailings surface above water). The triangulation of survey points near the transition between water and land, as well as the use of different dates for the Topographic and Bathymetric Surveys, introduce uncertainty into the resulting storage-elevation curves. However, the accuracy is considered acceptable for the required resolution of the model results.

Storage-elevation curves for the TSF up to a dam crest elevation of 974 m developed from the August 25, 2023 TSF survey were used in support of the free water volumes projection affected by tailings deposition after the survey date of October 30, 2023. Storage-elevation curves were used to model the facilities with linear interpolation throughout 2023.

2.3.2 Springer-Cariboo

A bathymetric and topographic survey of Springer-Cariboo Pit was conducted by MPMC on January 25, 2024, indicating that the Springer and Cariboo pits were divided up to the saddle level (approximate elevation of 964 m), and then combined from that level upward. Based on the recorded pit elevation data from MPMC (MPMC 2024a) and the fact that the Springer Pit was completely dewatered as of April 18, 2023 (MPMC 2024b), the Springer Pit and Cariboo Pit should be considered as separate reservoirs for modeling purposes in 2023. Storage-elevation curves for Springer Pit and Cariboo Pit were generated individually to infer the free water volumes within the pits from measured water level data in the SWWBM.

Springer Pit storage-elevation curves based on the bathymetric and topographic survey on November 7, 2019 were utilized in the model until April 18, 2023. These were then projected to the Springer Pit storage-elevation curve based on the January 25, 2024 survey. Projected storage-elevation curves were used to model the facilities with linear interpolation. Tailings were excavated during the calibration period, it is assumed that the excavation is reflected in the survey data. Figure 1 shows a time series plot of Springer Pit tailings volume.

Cariboo Pit storage-elevation curves (dated January 30, 2023, refer to MPMC 2023) were utilized until the end of 2022. These were then projected to the Cariboo Pit storage-elevation curve based on the January 25, 2024 survey. Projected storage-elevation curves were used to model the facilities with a daily linear interpolation between dates, throughout 2023.

2.3.3 Wight Pit

Wight Pit storage-elevation curves (dated March 1, 2022; MPMC 2022) were provided by MPMC. The curves include underground workings and pore space assumptions. Measured water level data from MPMC were used to infer the water volumes in the pit based on the storage-elevation curves provided.

3.0 MODEL CALIBRATION

3.1 Overview

The SWWBM was calibrated by adjusting outflows of the reservoirs and comparing modelled water levels to measured water levels recorded at the TSF. The TSF temporarily retains high runoff inflows experienced during freshet and storm events. The resulting modelled water levels in the TSF are the balance of site-wide inflows and outflows, including pumping to and from the pits and the booster station, which are temporary storage locations for surplus water on site.

An input climate dataset was generated (Section 3.2) and seasonal runoff coefficients were used during freshet (Section 3.3) to better represent measured site runoff conditions (i.e., reduction in measured snowpack depth) in 2023 and to facilitate the calibration.

3.2 Climate Data

A climate dataset at the Mine for 2023 was generated and used to represent site climatic conditions for the calibration.

The dataset consisted of the following:

- January through December rainfall data from MPMC.

- Freshet (March through April) snowmelt as determined from decreases in snowpack SWE depth recorded at the Mine.

3.3 Runoff Coefficients

Runoff coefficients in the SWWMB are adjustable loss parameters that translate measured climate trends and ground conditions into estimates of modelled runoff. Model performance from historical climate data for the year 2023 supported the delineation of runoff coefficients into two distinct seasonal climate periods:

- Freshet (March to June; inclusive) – Highest runoff coefficients to represent expected higher soil moisture content, and therefore greater runoff.
- General (January to February; inclusive and July to December; inclusive) – Mid range coefficients to represent soil moisture contents for intermittent runoff events. A 30% increase to the general coefficients is applied to the subsequent month if the previous month had a cumulative rainfall plus snowmelt depth greater than 50 mm.

The seasonal runoff coefficients defined for the catchment types remained unchanged from those used in the 2022 SWWBM calibration and are listed in Table 1.

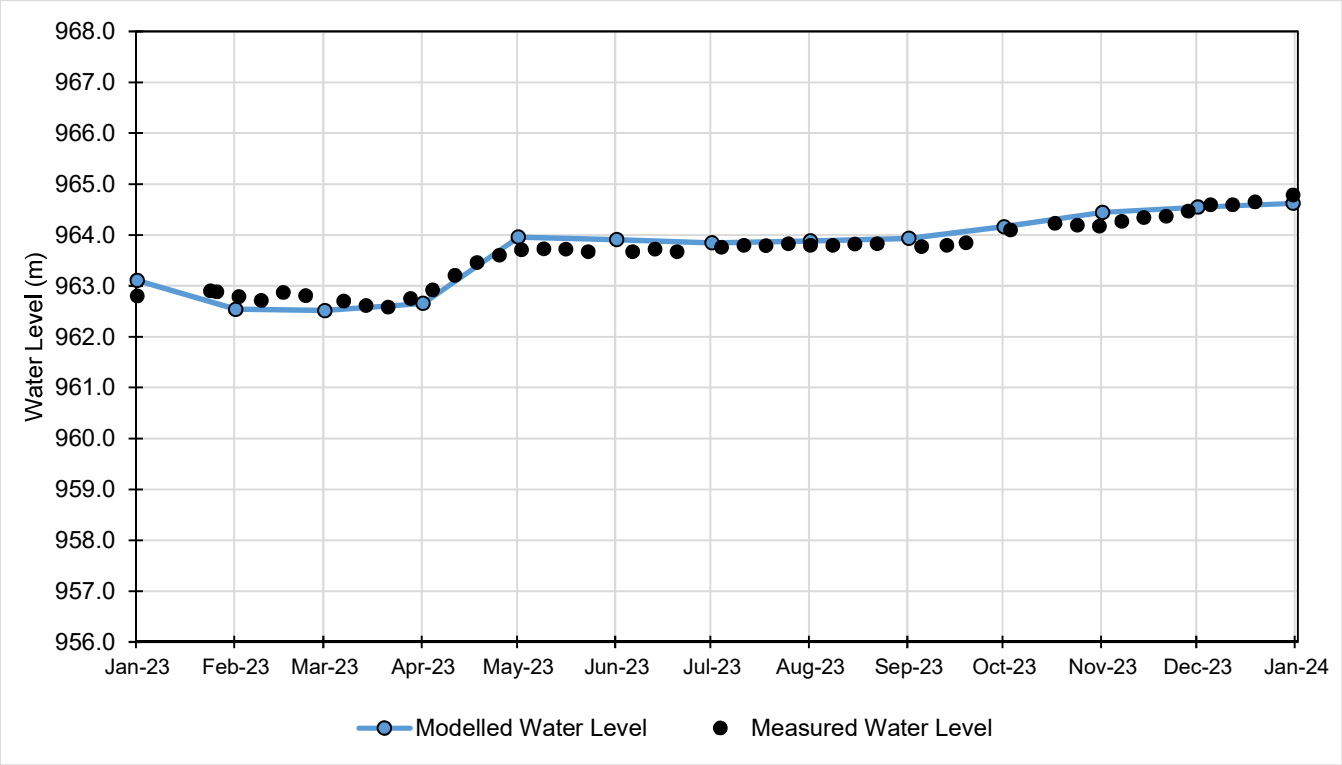


Table 1: Seasonal Runoff Coefficients

Catchment Type	General	Freshet
Exposed tailings	0.6	0.9
Disturbed areas	0.3	0.9
Rock disposal site areas	0.1	0.6
Open pits	0.75	0.9
Undisturbed catchments	0.4	0.42
Haul roads and access roads	0.15	0.9
Mill site area	0.1	0.1

Source: Golder 2020

4.0 CALIBRATION RESULTS

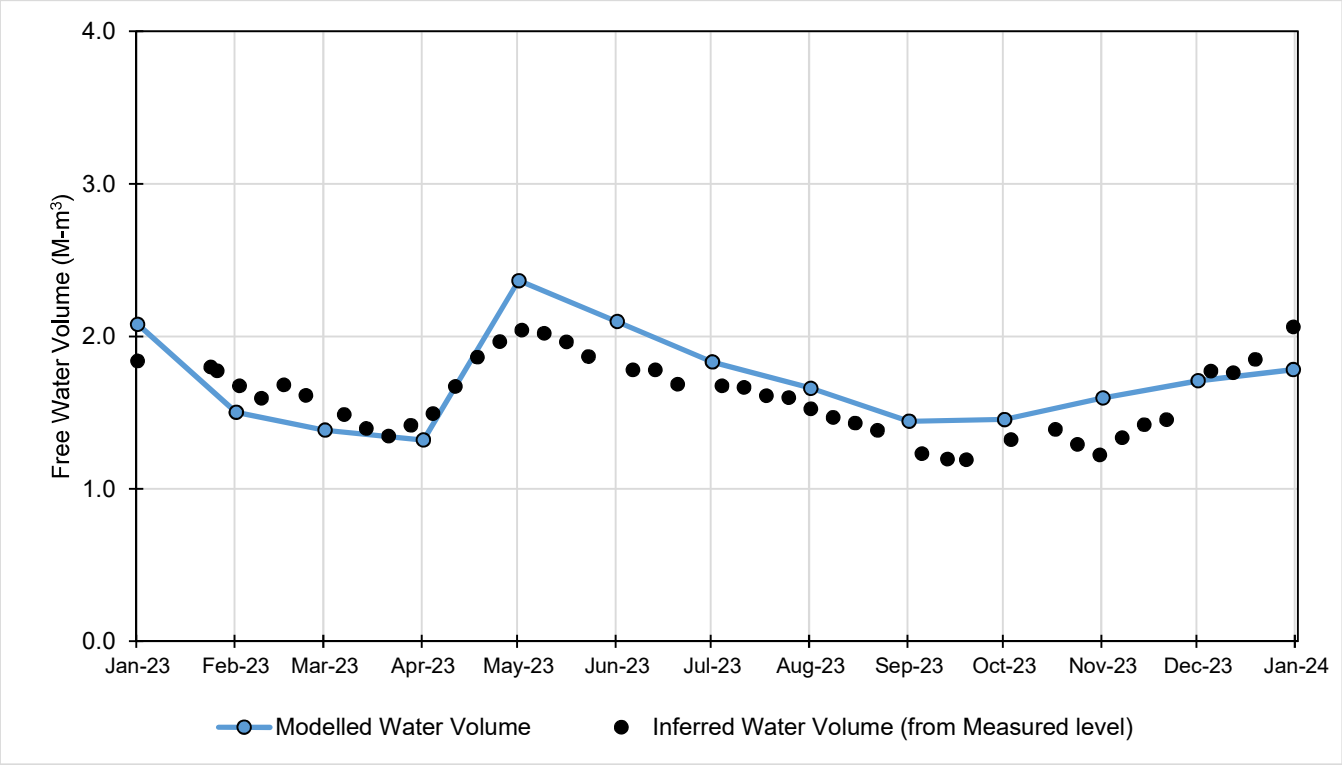

Figure 2 shows the modelled and measured water levels within the TSF for the 2023 calibration period. The modeled water levels were estimated from the modeled volume estimated using the storage-elevation storage curves. The average difference between modelled and measured water levels is approximately 0.14 m, which is considered acceptable for the purposes of the calibration exercise.

Note: Last measured water level occurred on 31 December 2023.

Figure 2: Water Levels in the TSF

Figure 3 shows the modelled free water volume in the TSF along with the inferred free water volume from measured water levels. The measured water levels were converted to an inferred water volume using the storage-elevation curves described in Section 2.3.

Note: Last measured water level occurred on December 31, 2023. The y-axis unit (M-m^3) denotes million cubic meters.

Figure 3: Free Water Volume in the TSF

Figure 2 and Figure 3 indicate that the model is reasonably calibrated and there is general alignment between measured free water levels and the inferred free water volume in the TSF. Differences between modelled and measured values may have several explanations:

- Variability in runoff coefficient throughout the year.
- Uncertainties in the climate data (e.g., snowpack surveys can miss intermittent snowmelt if conducted infrequently and the use of composite datasets may over or under-estimate actual conditions).
- Uncertainties in the TSF bathymetric survey (e.g., the transition between exposed tailings surface [i.e., beach] and free water can be complex).
- Uncertainties associated with the tie-in of the October 30, 2023 TSF storage curve with those utilized in the 2022 calibration, specifically referring to the projected storage curves from the 2020 TSF survey to the 987 m dam crest elevation.
- Uncertainties related to the projection of the Cariboo Pit storage curve from 2022 Calibration to the January 25, 2024 survey could lead to a situation where less storage capacity is modeled for the Cariboo Pit. Consequently, the volumes for the TSF and other pits may over estimated.
- Potential inaccuracies in water level measurements.

- Potential inaccuracies and/or missing WTP discharge data. The TSF weekly report noted that WTP ceased operations after September 13, 2023. However, there were still low volumes of WTP discharge recorded in October and November 2023. Additionally, the WTP discharge data are available for only 6 days in December 2023 (MPMC 2024a).
- Potential differences between modeled water transfer rates and actual transfers on site.
- There were minor discrepancies in the tailings deposition data between TSF Water Balance Spreadsheet and 2023 DSI Report data request (MPMC 2024a). WSP proceeded with tailings production umbers from the 2023 DSI Report data request to ensure consistency with the data used in the DSI.

The modelled results for the 2023 SWWBM calibration provide a reasonable approximation of site conditions and are considered suitable for water management planning.

5.0 END-OF-YEAR WATER BALANCE

Table 1 presents End of Year (EoY) modelled site water balance from 2017 through 2023. The modelled balance is the net storage of free water volume (total water) on site and net annual inflow. Storage locations include the TSF, pits, sumps, and ponds.

Table 2: EoY Modelled Site Water Balance Volume

Date	Total Water on Site[(a)(b)] (M-m^3)	Annual Water Net Inflow[(c)] (M-m^3)
December 31, 2017	6.0	4.6
December 31, 2018	3.9	5.3
December 31, 2019	3.8	6.4
December 31, 2020	8.2	9.5
December 31, 2021	7.5	6.1
December 31, 2022	6.0	6.4
December 31 ,2023	4.0	5.6

(a) End of year sum of water in TSF, pits, sumps, and ponds.
(b) Includes Wight Pit stored water volume.
(c) Net Inflows = Direct Precipitation + Runoff + Baseflows + Groundwater Inflow - Evaporation - Groundwater Outflow (for calendar year).

6.0 RECOMMENDATIONS

Based on the results of the 2023 SWWBM calibration, the following recommendations are provided to enable more robust water balance modelling:

- Increase the frequency of periodic snowpack measurements in the spring and fall seasons to generate more representative snowmelt data (e.g., in case mid-season snowmelt occurs outside of the freshet period).
- Record both snowfall and rainfall data measurements in the winter to produce more representative climate data (only rainfall and snowpack is recorded currently).

- Conduct both topographic and bathymetric surveys in spring and fall annually to achieve a more precise TSF storage curve progression.
- Review and validate available flow data on site to supplement the calibration of the SWWBM.
- Refine the runoff coefficients as part of future model updates.
- Refine the catchment areas to confirm various land types annually, thereby enhancing the precision of runoff estimations in the model through future updates.

7.0 CLOSURE

This technical memorandum summarizes the SWWBM calibration and end-of-year water balance for the model run period January 1, 2023 to December 31, 2023 (inclusive). The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

We trust that this technical memorandum satisfies your current requirements. Please contact the undersigned should you have any questions.

March 29, 2024

EXECUTIVE SUMMARY

The 2023 Annual Reclamation Report is submitted by Mount Polley Mining Corporation (MPMC) to the Ministry of Energy, Mines and Low Carbon Innovation (EMLI) in accordance with both operating permit M-200 and the *Mines Act*, Health, Safety and Reclamation Code for Mines in British Columbia (February 2021), Section 10.4.4(a). The contents of this report also include applicable information as specified in the document titled, "Mines Act Permit Annual Reclamation Report – General Information and Format Requirements" (Updated January 2021).

The Mount Polley Mine is a copper-gold open pit mine located approximately 56 km northeast of Williams Lake, BC that went into production in 1998. On August 4, 2014, a breach occurred in the Perimeter Embankment of the Tailings Storage Facility released tailings, water, and embankment construction materials to the downstream environments of Polley Lake, Hazeltine Creek and Quesnel Lake. Following the breach, the mine commenced restricted operations, with tailings being deposited in the Springer Pit in August 2015. In June 2016, the mine was approved to return to full operations permitting mining of Phase 4 Cariboo-Springer Pits. In January 2019, MPMC announced a decision to go on suspended operations (Care and Maintenance) on May 31, 2019 citing low metal prices. EMLI provided a Cessation of Operations Acknowledgement letter to MPMC on July 25, 2019.

Mining operations resumed in late 2021. Currently authorized operations allow for: open pit mining of the Phase 4 Cariboo-Springer Pit; milling of up to a maximum of 8,200,000 t of ore per year with deposition in the TSF; and construction and operation of the TSF up to an elevation of 970 metres above sea level (masl).

The current active project infrastructure consists of the mill site, mining in the Cariboo-Springer 4 Pit, two rock disposal sites (RDS) (the Southeast Rock Disposal Site (SERDS), and the Temporary Northwest (NW) Potentially-Acid Generating (PAG) Stockpile), the TSF, as well as access roads, power lines, a tailings pipeline, drainage collection systems, and sediment/seepage control pond. Back-filling of the Bell Pit and Pond Zone Pit with waste rock was completed in 2012, and the SEZ Pit was backfilled in 2013.

In 2023, mining of the Phase 4 Cariboo-Springer 4 Pit continued with development of the SP4 1000 through to the SP4 928 benches. Material classified as potentially-acid generating (PAG) was dispatched to the Temporary Northwest (NW) Potentially-Acid Generating (PAG) stockpile. Material classified as non-acid generating (NAG) was dispatched to the Southeast Rock Disposal Site (SERDS). Ore was dispatched to the crushing facility and or to the stockpiles.

Crushing of ore and milling operations continued throughout the year.

As permitted by the *Environmental Management Act* Permit 11678, the Water Treatment Plant operated almost continuously in 2023 and discharged a total of 4,439,062 m^3 of water. The annual average discharge

rate was 17,895 m^3/day and daily maximum discharge rates ranged from 0 m^3/day to 31,811 m^3/day. Reporting to Environment and Climate Change Canada under the Federal Metal and Diamond Mining Effluent Regulations continued accordingly.

Environmental management and monitoring in 2023 followed guidelines and procedures contained in the Comprehensive Environmental Monitoring Plan and was in accordance with regulations contained in *Environmental Management Act* Permit 11678 and *Mines Act* Permit M-200. Monitoring followed the updated 2019 Comprehensive Environmental Monitoring Plan which was approved on February 10, 2021, and immediately came into effect. Mining activities including production summaries and reclamation follow requirements contained in *Mines Act* Permit M- 200. Water chemistry results from monitoring sites were compared with appropriate permitted limits and British Columbia Water Quality Guidelines for aquatic life.

In 2023, there was one unauthorized release of mine-affected water and two spills reported to Emergency Management BC. There was one instance of results triggering the *Environmental Management Act* Permit 11678 limits. Proper notification was sent to the Director and other required parties, the Water Treatment Plant was promptly shut down, investigations were undertaken, and mitigation works were completed as required.

1 Introduction

1.1 Project History

The Mount Polley Mine, operated by MPMC (a wholly owned subsidiary of Imperial Metals (IM) Corporation), is an open pit copper/gold mine with an underground component located in south-central British Columbia. It is located eight kilometers (km) southwest of Likely and 56 km (100 km by road) northeast of Williams Lake, British Columbia (BC; Figure 1.1). The Mount Polley Mine has the capacity to process 20,000 to 22,000 tonnes per day (tpd) of ore when in normal operations. The mine property covers 24,096 hectares (ha), consisting of 7 mining leases totaling 2,007 ha, and 52 mineral claims encompassing 22,089 ha. Mount Polley Mine concentrates are trucked to facilities at the Port of Vancouver, then shipped to overseas smelters or transported by rail to smelters in North America.

Clearing of the site and construction of the entire facility began in 1995, with the mill commissioned in June 1997. In May 1997, the Mine received an ENV (previously the Ministry of Water, Land and Air) Effluent Permit, *EMA* Permit 11678, issued under the provisions of the provincial *EMA*. This permit authorized the discharge of concentrator tailings, mill site runoff, mine rock runoff, open pit water, and septic tank effluent to a tailings storage facility (TSF). Approval of the original Mount Polley Mine Reclamation and Closure Plan by the EMLI (previously EMPR) resulted in the issuance of *Mines Act* Permit M–200 in July 1997. The first full year of mining and milling at Mount Polley Mine took place in 1998. The Mine suspended operations in October 2001 due to low metal prices, then reopened in December 2004, with mill production commencing in March 2005.

Mount Polley mine phased out of care and maintenance and entered into full operations in November 2022, having been in care and maintenance since May 31, 2019. In June 2022, the mill restarted operations and tailings deposition into the TSF resumed. The operational period of the mine is planned to extend to 2034.

A summary of EMA Permit 11678 amendments is provided in Table 1.1.

Table 1.1 Summary of *EMA* Permit 11678 amendments

Date	Scope of Amendment
30-May-1997	Original permit
20-Oct-1997	Amended authorized tailings discharge rate (10,000 tpd increase)
12-Jun-1998	Amended reporting requirements
8-Sep-1999	Amended monitoring requirements
1-Feb-2000	Amended authorized tailings discharge rate (4,500 tpd increase)
7-Feb-2002	Approval to discharge effluent from the Perimeter Embankment Seepage Collection Pond (PESCP) and Main Embankment Seepage Collection Pond (MESCP); approval to store TSF supernatant and Mine site contact water in the Cariboo and Bell Pits
4-May-2005	Amended authorized tailings discharge rate (5,000 tpd increase); discharge of groundwater to Polley Lake; updates to reference analytical procedures and monitoring program
17-Apr-2009	Amended monitoring, water level and supernatant characteristic requirements for the Cariboo and Bell Pits
7-Nov-2012	Approval to discharge to Hazeltine Creek
7-Jun-2013	Sulphate guidelines
9-Jul-2015	Tailings discharge to the Springer Pit
29-Nov-2015	Approval to discharge to Hazeltine Creek
4-Apr-2016	Discharge of additional tailings to the Springer Pit
9-Sep-2016	Hazeltine Creek discharge total suspended solids limit change
7-Apr-2017	Direct pipeline from water treatment plant to Quesnel Lake
2-Oct-2018	Amendment to Sections 1.2.3, 1.2.6 and 2.7 of existing 11678 permit (Appendix A)
14-Mar-2019	Amendment to revisions for November 9, 2018 CEMP approval letter conditions including 3, 4, 8, 9, 11, 14 and 15
15-Jul-2019	Amendment to Section 6.14 of the approved August 15, 2018 CEMP
1-Feb-2020	Amendment to Sections 1.2, 1.2.5, 1.2.6, 2.7, 2.8, 2.8.1, 2.8.3, 2.9 2.10, 3.3, 3.5, 3.5.5 and 4.1.4 of existing 11678 permit (Appendix A)
18-Sep-2020	Consent Order amendments to Sections 2.8, 2.9, 2.10, and 4.2.1 of existing 11678 permit (Appendix A)
31-Dec-2020	Approved and amended Permit 11678 (Appendix A)
10-Feb-2021	Conditional approval received for the October 31, 2019 CEMP, replacing the 2018 CEMP and introducing a number of conditions which are in effect regulatory requirements.
1-Dec-2022	Amendment to Sections 2.3, 2.4, 2.5, 2.6, 2.10, 2.11, 2.12, 2.17, 3.7, 3.8, 4.1, 4.2, 4.3 and 4.4.

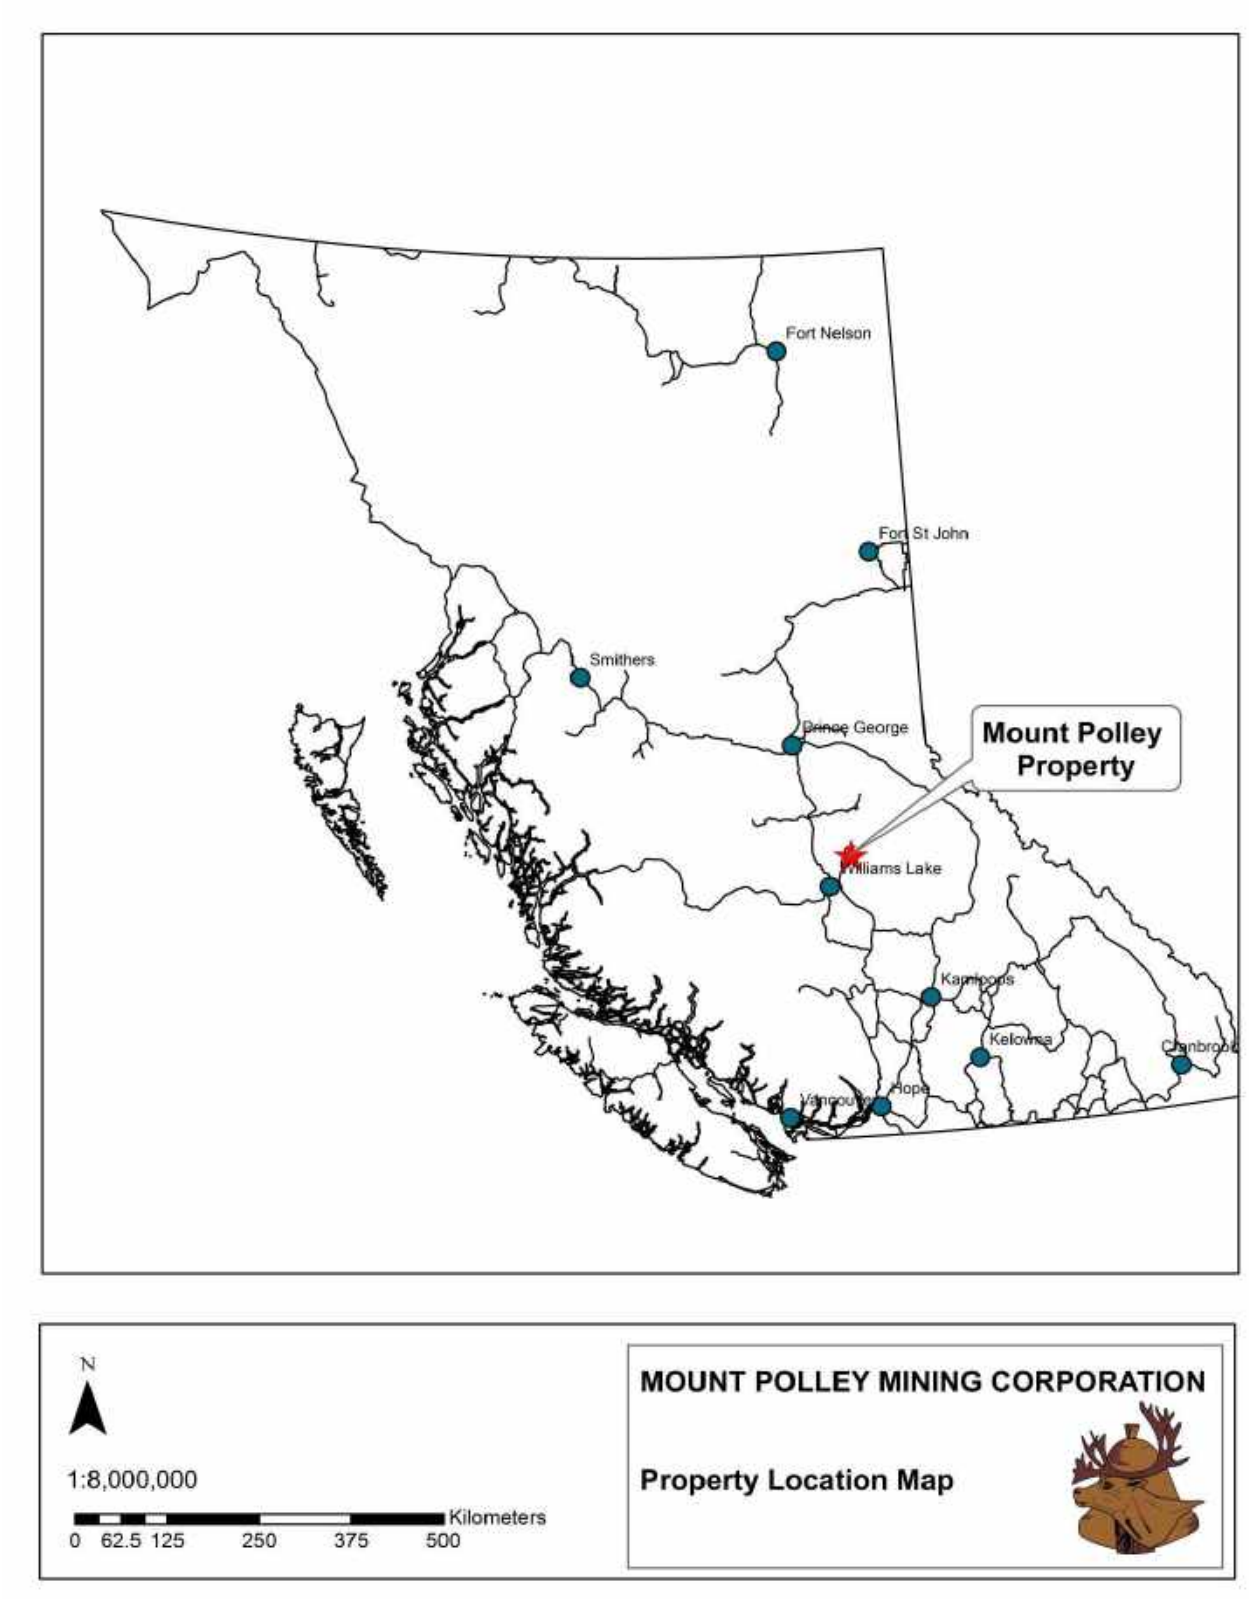

Figure 1.1 Mount Polley Mine property location

In 1995 and 1996, an environmental monitoring program, which expanded on previous studies from 1989 and 1990, was designed and implemented to support mine planning, operations, and reclamation activities at the Mount Polley Mine. The program included baseline studies documenting the pre-development land uses and the conditions of the aquatic and terrestrial ecosystems. This information provides the foundation upon which operational environmental monitoring programs were, and continue to be, based. The November 29, 2015, *EMA* Permit 11678 amendment included a revised condition, to develop a Comprehensive Environmental Management Plan (CEMP) to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek (HAC), Edney Creek (EDC), Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake (QUL), Quesnel River (QUR), and associated riparian and upland areas. The CEMP was submitted to the ENV on June 23, 2016, and an updated CEMP was submitted to the ENV on August 15, 2018 and was approved on November 9, 2018. The CEMP was updated in October 2019 in consultation with MPMC, Golder Associates, and BC-ENV. The 2019 CEMP was approved in February 2021, and was immediately implemented. The next revision of the CEMP was submitted on March 21, 2023, and is under review.

1.1.1 Tailings Storage Facility Embankment Breach

On August 4, 2014, a breach occurred in the Perimeter Embankment of the Tailings Storage Facility (TSF); this event is herein referred to as the "TSF embankment breach". The TSF embankment breach released tailings, water, and embankment construction materials to the downstream environments of Polley Lake, Hazeltine Creek and Quesnel Lake. The ENV issued MPMC *Pollution Abatement Order* (PAO) 107461, dated August 5, 2014, ordering MPMC to attend to the environmental impacts of the TSF embankment breach. The *PAO* was lifted on September 12, 2019.

1.1.2 Post TSF Embankment Breach Reporting

Following the TSF embankment breach, an environmental monitoring program was initiated in areas downstream of the TSF including Polley Lake and Hazeltine Creek, both of which were previously monitored under *EMA* Permit 11678 (***Appendix A***). Monitoring of these areas in 2014 and 2015 was carried out under the PAO; consequently, these monitoring results were presented in the *Post-Event Environmental Impact Assessment Report* (*PEEIAR*; MPMC, 2015a) and *PEEIAR* Version 2 (MPMC, 2016a). Results from monitoring conducted in 2016 were presented in the *Human Health Risk Assessment* (*HHRA*), (MPMC, 2017b) and *Ecological Risk Assessment (ERA*), (MPMC, 2017c) which have both been approved by ENV. Monitoring results from 2017 are presented in the 2017 *AERR*, (MPMC 2018a). A Conceptual Remediation Plan (*CRP)* was required by the PAO to address the remedial actions based on the findings, results, and conclusions on the risk assessments, and has been integrated in the updated CEMP. This plan was submitted on January 31, 2018, to ENV. Review comments were received from the ENV and the Government to Government Working Group on December 11, 2018, just prior to consultation meetings with local communities. All conditions of the PAO were met, and the PAO has since been rescinded. An updated CEMP was submitted to ENV in October 2019 and was approved February 2021. CEMP updates are a regular requirement in *EMA* Permit 11678. All current post breach reporting to ENV is done under *EMA* Permit 11678.

1.2 Post TSF Embankment Breach Project Status

1.2.1 Mine Operations

Following the TSF embankment breach, mine operations ceased. Restricted operations, with tailings being deposited in the Springer Pit, commenced on August 4, 2015. On November 6, 2015, MPMC applied for an amendment to *Mines Act* Permit M–200 to allow for the return to full operations at the Mount Polley Mine, with use of the TSF for tailings deposition. A corresponding *Mines Act* Permit M–200 amendment was received from the EMLI (previously the EMPR) on June 23, 2016. Authorization to resume deposition of tailings in the TSF under *EMA* Permit 11678 was received from the ENV on June 23, 2016. MPMC resumed deposition of tailings in the TSF on June 27, 2016.

On January 7, 2019, MPMC announced a decision to go on suspended operations (Care and Maintenance) on May 31, 2019, citing low metal prices. EMLI, formerly EMPR, provided a Cessation of Operations Acknowledgement letter to MPMC on July 25, 2019. During Care and Maintenance, MPMC committed to continue environmental monitoring and sampling as well as rehabilitation of Hazeltine Creek and any other commitments as required in the permits and CEMP.

Mining operations resumed in late 2021. Currently authorized operations allow for: open pit mining of the Phase 4 Cariboo-Springer Pit; milling of up to a maximum of 8,200,000 t of ore per year with deposition in the TSF; and construction and operation of the TSF up to an elevation of 970 metres above sea level (masl).

The current active project infrastructure consists of the mill site, mining in the Cariboo-Springer 4 Pit, two rock disposal sites (RDS) (the Southeast Rock Disposal Site (SERDS), and the Temporary Northwest (NW) Potentially-Acid Generating (PAG) Stockpile), the TSF, as well as access roads, power lines, a tailings pipeline, drainage collection systems, and sediment/seepage control pond. Back-filling of the Bell Pit and Pond Zone Pit with waste rock was completed in 2012, and the SEZ Pit was backfilled in 2013. A detailed Mount Polley Mine site map is included in ***Appendix B***.

In 2023, mining of the Phase 4 Cariboo-Springer 4 Pit continued with development of the SP4 1000 through to the SP4 924 benches. Material classified as potentially-acid generating (PAG) was dispatched to the Temporary Northwest (NW) Potentially-Acid Generating (PAG) stockpile. Material classified as non-acid generating (NAG) was dispatched to the Southeast Rock Disposal Site (SERDS). Ore was dispatched to the crushing facility and or to the stockpiles.

In 2023, 22,115,054 tonnes of material were removed from the pit of which 6,814,144 tonnes was ore. This material was directly fed into the crusher and or stockpiled.

Approximately, 12,032,329 tonnes of waste were removed from the pit, of which 3,784,284 tonnes were classified as PAG and dispatched to the PAG stockpile. Approximately, 8,248,045 tonnes were classified as NAG, of which 1,093,900 tonnes were dispatched to the PAG stockpile and 7,154,145 tonnes were

dispatched to SERDS. Additionally, approximately 3,268,581 tonnes of In-Pit Tailings were removed from the pit and dispatched to the SERDS.

Identified ore reserves indicate a viable mine life of 10 years expected to continue to 2034. Given the uncertainty around future operations and mine life, reclamation and closure planning described in this document are subject to review and updates.

Crushing/milling of ore continued in 2023.

1.3 Site Description

1.3.1 Topography and Climate

The Mount Polley Mine property is located on the eastern edge of the Fraser Plateau physiographic sub-division, characterized by rolling topography and moderate relief. Elevations range from 920 masl at Polley Lake to 1266 masl at the summit of Mount Polley. Volcanic rocks generally underlay this part of the plateau with inclusions of intrusive rocks. Most of the area is covered by a deposit of unconsolidated till which contains fluvial, lacustrine, and colluvial deposits. Some patches of organic soils are present in poorly drained areas (i.e., wetlands). The property is in an alkali porphyry copper-gold deposit hosted in the Central Quesnel Belt along the Intermontaine Belt of BC.

The site is located within the Interior Cedar Hemlock bio geoclimatic zone. Local forests consist of western red cedar, Douglas-fir, hybrid spruce, and subalpine fir, with a lesser presence of trembling aspen, black cottonwood, and paper birch. Much of the area was historically harvested in commercial logging operations and is also used for cattle grazing.

The average annual precipitation in the area is ~625 millimetres (mm). Precipitation typically occurs as snowfall from November through March, with an average maximum of snowpack of 187 mm snow water equivalent occurring at the end of March. Average monthly temperatures at the Mount Polley Mine range from -5.6 degrees Celsius (°C) in December to 16.1 °C in July (Section 4.6). Prevailing winds are from the northwest (and to a lesser extent in the northeast) near the TSF, and from the southwest (and to a lesser extent from the northwest) near the mill.

1.3.2 Hydrogeology

The groundwater flow at the site occurs primarily in the bedrock units in response to recharge from precipitation in the area between Polley Lake and Bootjack Lake. Flow in the overburden is less significant due to its limited thickness and discontinuous nature. Prior to mining, the water table at the site generally followed the surface topography, but the water table was deeper below the topographic heights and shallower in the low areas. At that time, the direction of groundwater flow was inferred to be from the top of the ridge between Polley Lake and Bootjack Lake towards the low-lying areas associated with these lakes' northeast and southwest from the ridge. The regional topography, water bodies, and pre-mining

watersheds are shown in Figure 1.2.

Mine dewatering has altered the groundwater flow pattern at the site, with the open pits and underground workings acting as sinks for groundwater flow. Mine dewatering lowered the water table elevation and created radial patterns of groundwater flow towards these facilities. In 2018, Springer Pit water levels continued to be drawn down by dredging. Near the end of 2018, when dredging operations ceased, water levels became static and remained static the rest of 2018 and 2019. The currently available information suggests that some seepage from the pit lake towards Bootjack Lake could occur once the Springer Pit lake level reaches 1020 to 1030 masl elevation (Golder 2015a). From June 2020 to June 2021, the Springer Pit was used for temporary storage of surplus water by following the Quantitative Performance Objectives (QPO) outlined by the EoR. The water level in the pit reached a maximum elevation of 1004 masl during this period. From June 2021 to December 2021, the Springer Pit water level had been steadily lowered to the elevation of 983 masl to dewater the pit lake and resume mining operations in the area. Dewatering activities continued in 2022 and 2023 to facilitate mining activities. While tailings remain in the pit awaiting removal the interstitial water is being pumped out via three dewatering wells that were installed in 2022.

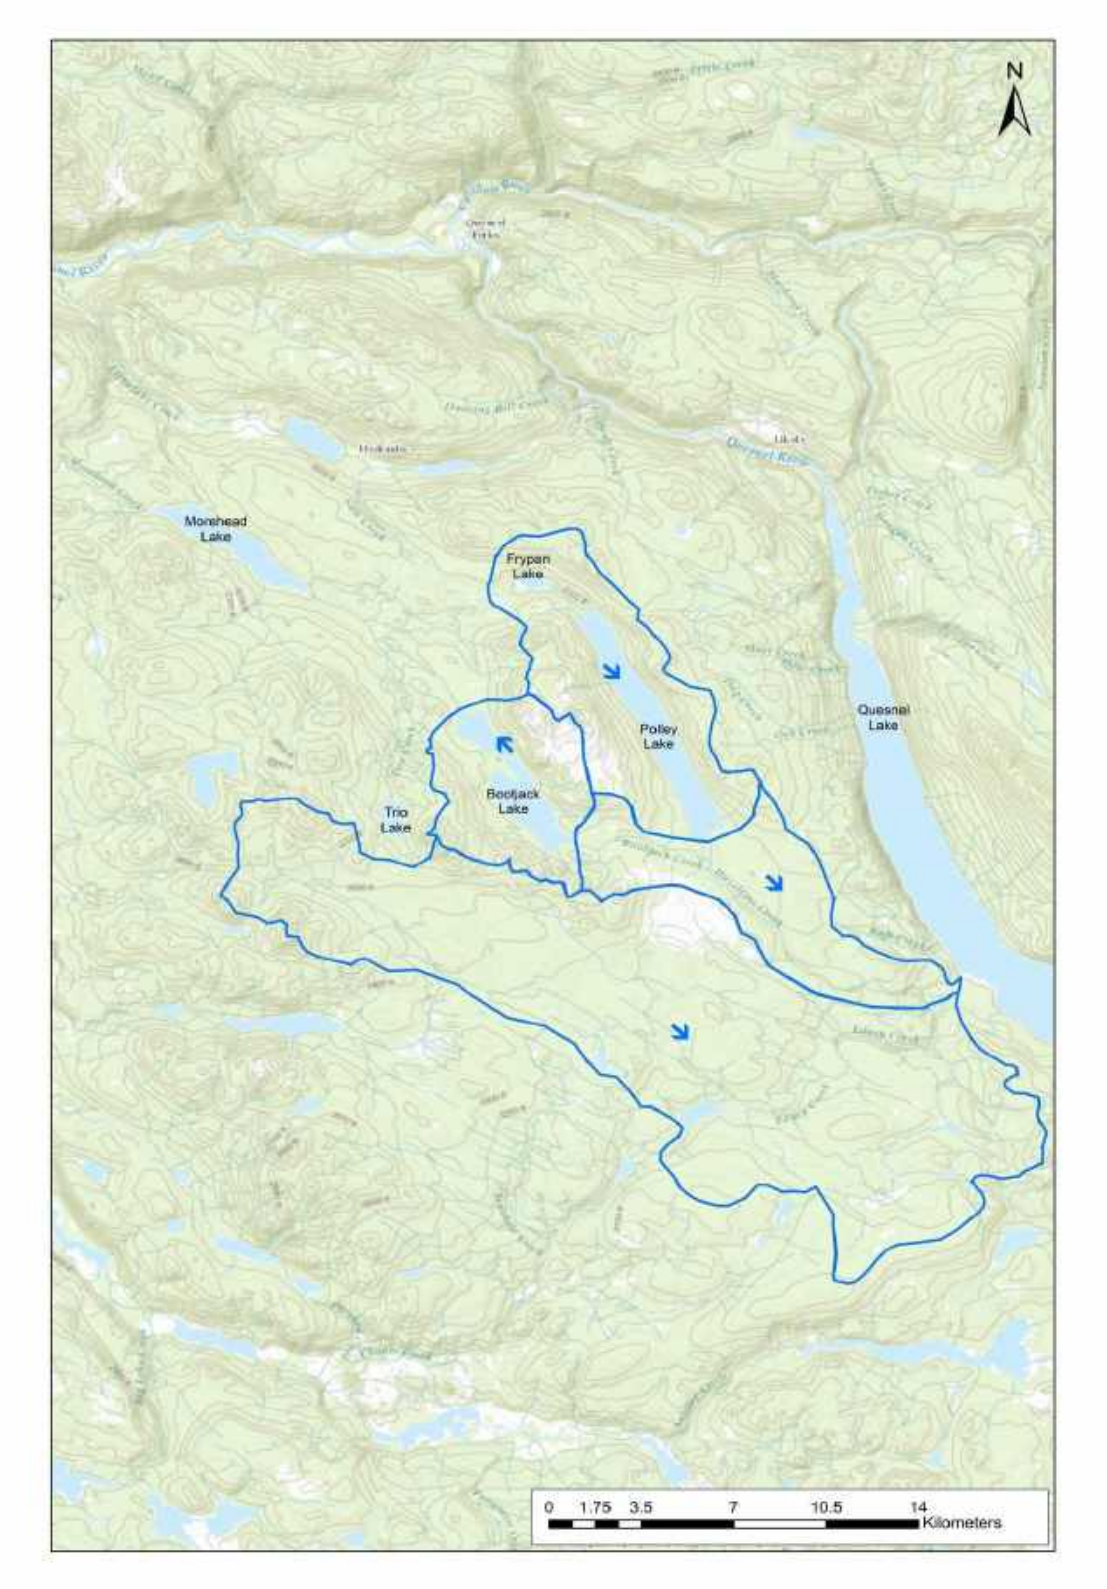

Figure 1.2 Mount Polley Mine Site and Surrounding Area Water Bodies and Topography

1.3.3 Deposit Geology

The Mount Polley Intrusive Complex (MPIC) hosts the Mount Polley copper-gold porphyry deposit (Figure 1.3). It is a Late Triassic magmatic center approximately 6 km by 4 km, elongate in a NNW direction. It consists of alkalic, marginally silica-undersaturated intrusions, and magmatic-hydrothermal breccias. The age of the deposit is approximately 205 million years, based on uranium-lead isotopic dating; there is close agreement between age determinations from MPIC intrusions and minerals associated with sulfide mineralization. Mineralization occurs in almost all constituent rock types of the MPIC, and thus occurred late in its formation. Nearly all economic mineralization is in breccias, or in mineralized stockwork veins in adjacent wall rock intrusion. Country rocks of the Nicola Group closest to the MPIC are mafic to intermediate volcanic and subvolcanic coherent rocks, and related breccias, and may form components of mineralized hydrothermal breccias in the periphery of the MPIC (MPMC 2016c).

As is typical of alkalic porphyry copper systems, mineralization at Mount Polley formed in a number of several distinct zones rather than as a simple zoned deposit. The most important (remaining) ore zones can be divided into two main groups: the Springer-Cariboo area and the Northeast-Boundary area. The original discovery at Mount Polley was in the Springer zone in the center of the MPIC, which was followed by the adjacent Cariboo Zone to the east across the Polley fault (MPMC 2016c).

The Springer-Cariboo area represents the largest volume of mineralization in the MPIC, has contributed most of the historic production at Mount Polley This area has the most intense alteration, and likely formed on the main feeder or conduit from the parent magma source at depth. The smaller but copper and gold-enriched Northeast-Boundary area of brecciation was caused by a different, probably more focused magma-fluid feeder, 1 to 2 km away to the north. This deposit area differs from the Springer-Cariboo group by coarser sulfide mineralization and a much higher bornite content (MPMC 2016c).

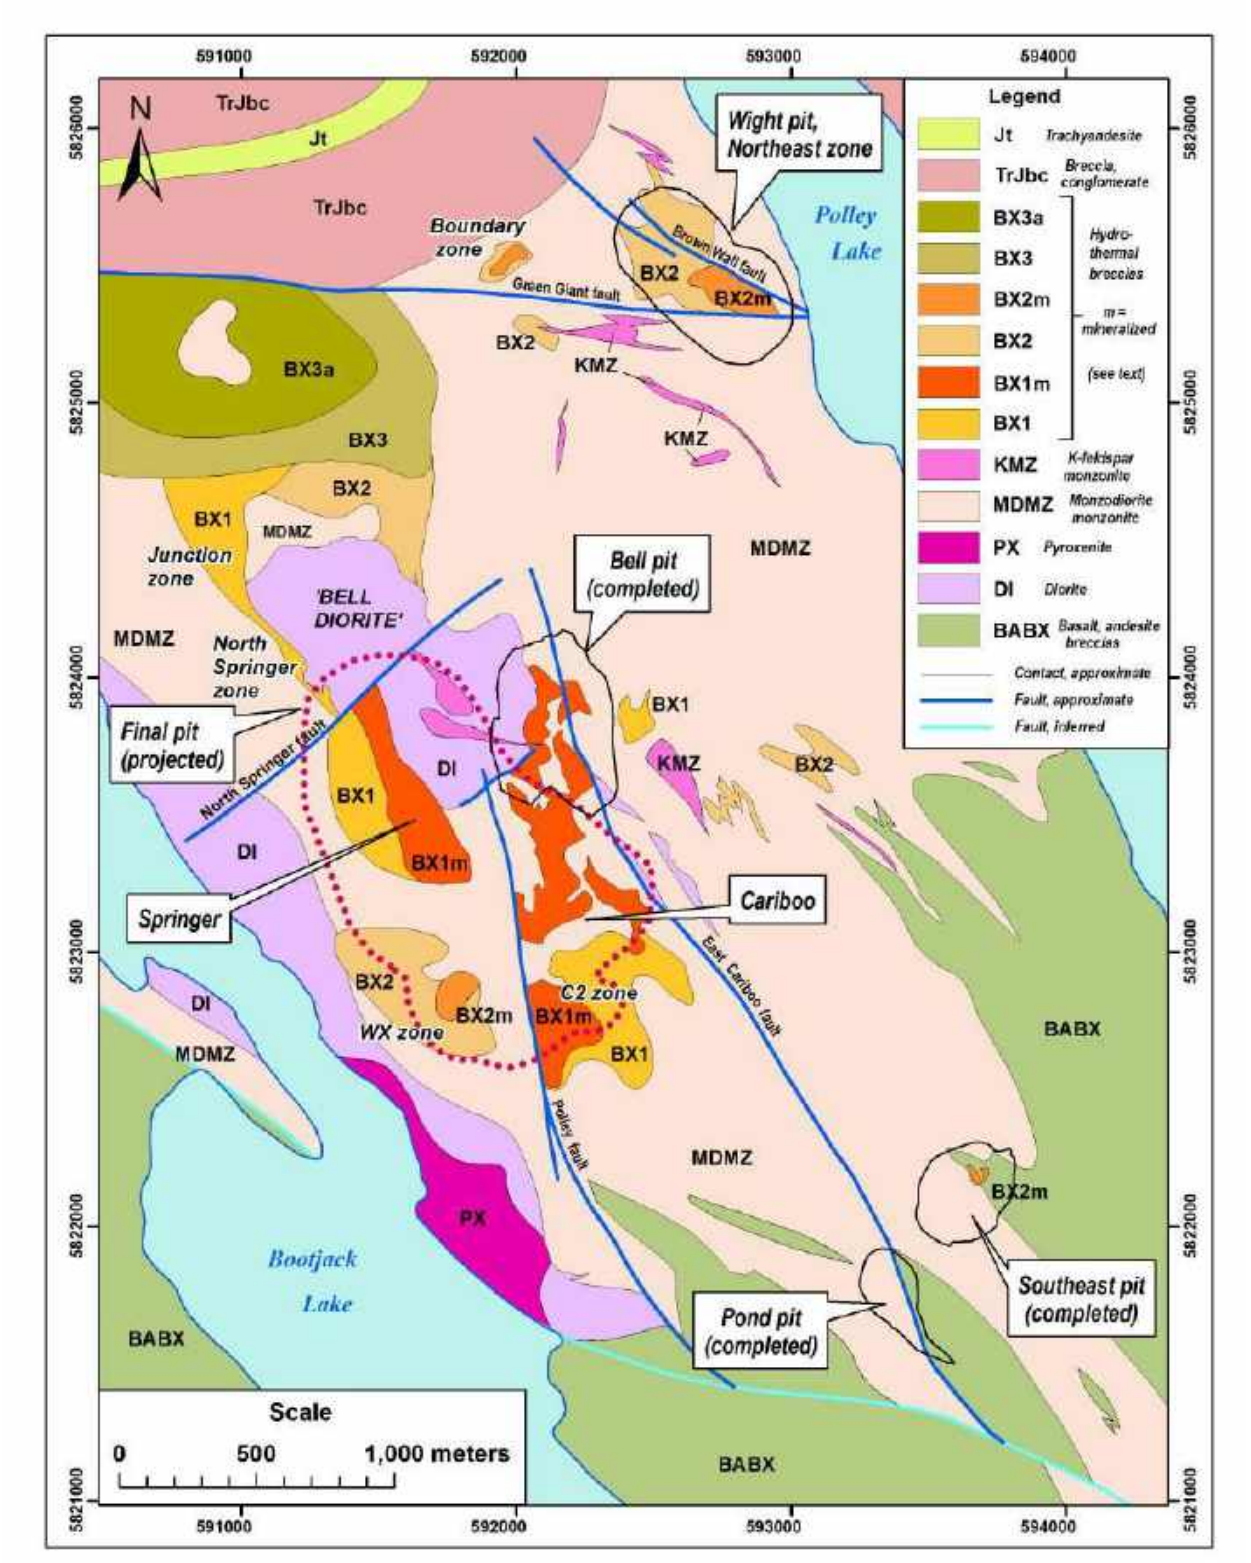

Figure 1.3 Simplified Geology of the Mount Polley Intrusive complex

1.3.4 Reclamation Objectives

The main objective of the reclamation program is to return all areas that have been disturbed by mining operations (except pit walls) to equivalent or greater land capability than existed prior to mining, on an average property basis. To help achieve this overarching goal, an End Land Use Plan has been developed, which focusses on ecosystem rehabilitation as the main goal with a target towards ecosystems that occurred prior to disturbance.

The End Land Use Plan also estimates shifts in the end land use objectives over time as the ecological trajectories of the ecosystem evolve. This allows for end land use planning to be considered over the long-term and considers that a variety of end land uses can occur on the landscape over different temporal scales. To achieve successful closure of the Mine Site, the following objectives must be achieved:

- Long-term stability of engineered structures, including the RDSs, TSF and open pits, as well as all exposed erodible materials
- Removal and proper disposal of access roads, structures, and equipment not required after the Mine Site closes
- Sufficient cover soil (e.g., reclamation material) to achieve the desired target ecosystems on the post-closure landscape
- Geochemical stability of WRDs, open pits, the TSF, and all other major components of the Mine Site in the post-closure landscape
- Long-term preservation of water quality within and downstream of decommissioned operations
- A water balance that meets the requirements for a functional landscape that aligns with the targeted end land use
- Natural integration of disturbed lands into surrounding landscape, and restoration of the natural appearance of the area after mining ends, to the extent practicable
- Self-sustaining vegetation covers established, consistent with the end land uses and desired ecosystems
- Use of reclaimed ecosystems by their desired stakeholders (e.g., recreational users, wildlife, and traditional use practitioners)

Once these aspects are in place, flexibility exists to modify ecosystem composition, patch size, and vegetation mosaic and to provide additional structural components, as desired. By reclaiming disturbed land to stable, functioning, and locally appropriate ecosystems that can reasonably be expected to thrive on a specific landform or location, a variety of end land use objectives can also be met.

To track progress towards closure objectives and overall adherence with the End Land Use Plan, Success criteria, which are more specific than closure objectives, were developed. These success criteria are used as milestones that indicate progress to achieving specific land use objectives. The success criteria include parameters such as:

- landform stability
- erosion control
- visual and functional integration into the surrounding environment
- establishment of self-sustaining native vegetation consistent with target site series
- vegetation quality

End land use objectives envelop a multitude of values that may exist beyond biocentric ecological conditions and are driven by what regulators, MPMC, First Nations, and local communities prefer for the landscape once the Mine is closed. End land use decisions are influenced by several factors, including:

- Permit obligations;
- Regulatory requirements;
- Landform design;
- Surface and subsurface materials at closure;
- Surface water hydrology;
- Slope;
- Aspect,
- Elevation;
- Input from First Nations, local communities and stakeholders; and
- Traditional and cultural land use.

End land use objectives may be adapted over time as interests evolve; however, once a landform is constructed, the end land uses are limited to the conditions and ecological trajectories associated with the particular abiotic rehabilitation.

2 Mining Program

2.1 2022 Exploration

In early 2023, two phases of diamond drilling were completed at Mount Polley Mine. The objective of the diamond drill programs was to explore in an area surrounding and below the Springer and Cariboo mineralized zones. The first phase consisted of five drill holes totaling 2720 meters. Phase one was successful at delineating new zones of copper and gold mineralization adjacent to the current mine plan. The second phase consisted of 10 drill holes totaling 2885 meters and were oriented as step-out and infill-drill holes from the phase one drilling. The program was successful and adding copper and gold mineralization surrounding and below the Springer and Cariboo open pits. Exploration diamond drilling is planned for early 2024 to continue following the new zones delineated from 2023 diamond drilling.

2.2 Surface Development to Date

At the end of 2023, the total disturbed area at the Mount Polley Mine site was 1195.19 ha. Discussion of disturbed areas in this report does not include areas disturbed due to the TSF embankment breach as this area is beyond the scope of *Mines Act* Permit M-200. Table 2.1 provides a breakdown of disturbed areas by Mine component and serves to fulfill the annual reclamation reporting requirement for Standard Table 1 in the guidelines. These areas are also shown on the site facilities map in the *RCP* (MPMC, 2017a). Concurrently with surface development, progressive reclamation is ongoing. In 2023 a review of the required shapefile submission was complete and identified several duplicate polygons. The duplicate polygons were removed, and this resulted in a small net reduction of total disturbed and reclaimed areas when compared to 2022 reported areas.

Table 2.1 Mount Polley Mine Site SUMMARY OF AREAS DISTURBED AND RECLAIMED TO DECEMBER 31, 2023, represents EMLI Standard Table

2.2.1 Underground Mining Program

No mining occurred in the Wight Pit in 2021. It has been in Care and Maintenance since May 2017.

2.3 Current Life of Mine Plan

The mine came out of Care and Maintenance in November 2021 with limited production out of the Phase 4 mine plan. Mining continued throughout 2023 with the development of SP4 benches 1000 though to SP4 924. The permitted Phase 4 mine plan includes three years of production in the Springer followed by one year of PAG waste re-handled back into the Springer Pit. MPMC has been in discussions with EMLI, ENV and the Major Mines Office (MMO) since August 2021 for an application to extend the LoM by following the Joint Applications Information Requirements (JAIR) for *Mines Act* and E*nvironmental Management Act* Permits. The JAIR pre-application was submitted to the MMO in Q4 2023 and proposes to extend the LoM to approximately 2034 for the following factors:

-delayed by an interval approximately equal to the duration of the temporary Care and Maintenance period

-increase in reserves due to increase in commodity prices

2.4 Surface Development in the Past Year

In 2023 mining of the Phase 4 Cariboo-Springer 4 Pit continued with development of the SP4 1000 through to the SP4 924 benches. Material classified as potentially-acid generating (PAG) was dispatched to the Temporary Northwest (NW) Potentially-Acid Generating (PAG) stockpile. Material classified as non-acid generating (NAG) was dispatched to the Southeast Rock Disposal Site (SERDS). Ore was dispatched to the crushing facility and or to the stockpiles.

Milling of the ore continued in 2023.

In 2023, 22,115,054 tonnes of material were removed from the pit of which 6,814,144 tonnes was ore. This material was directly fed into the crusher and or stockpiled.

Approximately, 12,032,329 tonnes of waste were removed from the pit, of which 3,784,284 tonnes were classified as PAG and dispatched to the PAG stockpile. Approximately, 8,248,045 tonnes were classified as NAG, of which 1,093,900 tonnes were dispatched to the PAG stockpile and 7,154,145 tonnes were dispatched to the SERDS.

2.5 Surface Development Projected Over the Next 5 Years

MPMC submitted a JAIR on December 8, 2023 to extend the LoM to 2034.

Identified ore reserves indicate a viable mine life for 8 to 10 years expected to continue to 2031. Given the uncertainty around future operations and mine life, reclamation and closure planning described in this document are subject to review and updates.

- Mining will consist of Springer Phase 4 and Springer Expansion. When the mine is unable to provide all the mill feed directly, mill feed will be supplemented by feed from the low-grade stockpile. Underground mining is not included in the update LoM (Springer Expansion).
- PAG waste will be hauled into the mined-out Springer Pit during the last 3 years of the mine plan totaling 68 million tonnes.

The projected closure disturbance area for the proposed LoM plan is 1,302.01 ha. This increase in disturbance is the result of the development of components under the authorized Mine plan, including pits (continued mining), SERDS and Temporary NW PAG Stockpile development (material placement), and road infrastructure (i.e., the Tailings Dam Access Road; TDAR).

The projected changes in disturbed areas with the closure footprint are outlined in Table 2.5. Further information on projected surface development can be found in *RCP* (MPMC, 2017a) and later in *Mine Plan and Reclamation Program Update 2022* (MPMC, 2022).

Table 2.5 Changes in disturbed areas with closure footprints

Area	Existing Area (ha)	Closure Area (if changed) (ha)	Delta	Description
Dumps				
North Bell Dump	62.47	*62.07*	-0.40	Cariboo-Springer Pit Expansion
SERDS	109.97	*110.27*	0.30	Final re-sloped footprint
Temporary NW PAG Stockpile	80.48	*77.93*	-2.55	Final re-sloped footprint
Pits				
Boundary Pit	12.26	*19.41*	7.15	Boundary Pit Development
Cariboo-Springer Pit	145.77	*163.57*	17.80	Cariboo-Springer Pit Development
Stockpiles				
#1 Stockpile	10.76	*10.06*	-0.70	Cariboo-Springer Pit Expansion
SERDS Soil Stockpile	12.76	*12.09*	-0.67	SERDS Expansion
Roads				
West Haul Road	59.21	*103.72*	44.51	Assumes completion of TDAR; if not, no additional disturbance.
Miscellaneous				
Old Orica Sites	1.73	*0.76*	-0.97	TDAR Construction (West Haul Road)
South SERDS Ditch	2.61	*0.40*	-2.21	TDAR Construction (West Haul Road)
CWTS	1.05	*1.05*		CWTS Construction 9k Sump

2.6 Salvaging and Stockpiling of Surficial Materials

2.6.1 Volumes and Storage Locations

As per the *MPMC Soil Management Plan*, MPMC tracks volumes and locations of soil stockpiles and has a sampling program in place to characterize soil suitability for reclamation. 2023 soil stockpiling and transfers are shown in Table 2.6 below. Mining activities in November and December occurred in areas from which soil had already been stockpiled.

Table 2.6 2023 soil stockpiling and transfers

Soil Volume (M^3)	Transfers and Stockpiling
68776	Upper Cariboo Stockpile to Upper Cariboo Stockpile
3969	TSF to TDAR Sand/Soil Stockpile
563,000	SEZ-3 surveyed and volume updated to replace previous estimation
38634	Till borrow to TDAR Sand Soil Stockpile

Table 2.7 summarizes the quantities of soil at the Mine site and meets the requirements for EMLI reporting for Table 5 in the guidelines document.

Table 2.7 MPMC Soil Inventories as of December 31, 2023

Stockpile Name	Location	Soil Volumes (m^3)
TSF Corner 1 - Windrow	TSF Corner 1	5,100
Upper Plug Acces Road (PAR) - Windrow	Along upper PAR	1,700
Plug - tockpiles	Polley Lake Plug	127,017
Perimeter Pond - Stockpile	Bottom of Corner One (near old Perimeter Pond)	4,700
Till Borrow - Windrow	North of (Perimeter) Till Borrow	42,800
Perimeter Embankment - Windrow	Edge of Perimeter Embankment	3,800
Main Embankment - Stockpile	SE of Main Embankment	94,900
South Till Borrow - Stockpile 1	NW stockpile in South Till Borrow	11,600
South Till Borrow - Stockpile 2	S stockpile in South Till Borrow	65,300
South Till Borrow - Stockpile 3	NE stockpile in South Till Borrow	9,600
Gavin Lake Road - Windrow	Gavin Lake Road (along South/Main Embankment)	24,200
TSF Access Road (TAR) - Windrow	Adjacent to TAR	43,500
Tailings Reclaim Road - Windrow	Tailings Reclaim Road	44,300
Cariboo Stockpile - Stockpile	Below Cariboo Stockpile	33,967
Upper Cariboo Stockpile	Upslope from Cariboo Stockpile	3,300
Mill Site - Stockpile	East of Mill/Admin Building (includes berms)	10,700
Access Road km 11.5 - Stockpile	Across from NBD Reclamation Parcels 1 - 10	8,200
Access Road km 12 - Stockpile	S-SW of Mount Polley Peak (by km 12 on Acces Rd)	83,700
East RDS - Stockpile	Top of East RDS	58,500
Leach Pad - Stockpile	Top of East RDS	4,800
Highway to Heaven - Windrow	Highway to Heaven Access Road	21,500
NEZ Dump Top - Stockpile	Top of NEZ Dump	6,500
		14,365
		25,000
NEZ Dump Lower - Stockpile	Off Wight Pit Haul Road	71,300
Wight Pit Till - Stockpile	Bottom of Wight Pit Haul Rd	135,100
Wrap Around Road - Windrow	Wight Pit - TSF Connector Road (below NEZ Dump)	101,600
North Bell Dump Till - Stockpile	North Bell Dump	164,000
North Bell Dump Top - Stockpile	Top of North Bell Dump	8,500
Springer North	Between North Bell Dump and Springer Pit	20,000
Northwest Sump Road - Windrow	Northwest Sump Road	7,500
PAG Dump - Windrow	Below PAG Dump	39,300
SEZ 1 - Stockpile	Top of Old Pond Zone Pit	108,687
SEZ 2 - Stockpile	Top of SERDS (near SEZ - 1)	14,000

SEZ-3	Below Co-mingling Project	563,000
SERDS - Stockpile	Below SERDS Dump	58,000
SERDS - 3	Edge of SERD near old Pond Zone	14,800
Old TSF Haul Road	Along old TSF Haul Road (SERDS)	27,200
Lower SERDS - Stockpile 1	Below SERDS Dump	27,870
Lower SERDS - Stockpile 2	Below SERDS Dump	27,539
Lower SERDS - Stockpile 3	Below SERDS Dump	140,100
TDAR Sand/Soil Stockpile	Tailings Dam Access Road	89,028
	Total Volume of Stockpiled Soils	**2,366,573**

Further details regarding soil balance and usage during progressive and final reclamation can be found in *Mine Plan and Reclamation Program Update 2022* (MPMC, 2022).

2.6.2 Soil Stockpile Inspections

All non-active soil stockpiles on site are periodically inspected for erosion and vegetative cover and any non-active stockpiles requiring additional vegetative cover and/or showing signs of erosion are added to the bi-annual (spring and fall) seeding list. Most soil stockpiles are well vegetated and do not demonstrate issues with erosion, sedimentation or invasive species which would trigger remedial actions.

2.6.3 Soil Stockpile Quality

MPMC did not undertake stockpile sampling and characterization in 2023. A stockpile sample program was undertaken in 2013 and 2014. Information regarding stockpile quality can be found in MPMC 2013 and 2014 *AERR*s (MPMC, 2014, 2015b).

MPMC has collaborated with researchers from the Department of Forest and Conservation Sciences at the University of British Columbia to assess changes in the biological communities of stockpiled soil. Soil organisms play a critical role in nutrient cycling, contribute to development of soil structure and form symbiotic mutualistic relationships with plants. Yet during storage, soil can undergo degradation (e.g., die-off of vegetative propagules and decreases in available nutrients) reducing its quality for use in reclamation. This project aimed to quantify changes in soil biological communities and understand the time periods over which they occur.

3 Environmental Protection Program

3.1 Environmental Management Systems

An Environmental Management System (EMS) is a framework that helps an organization achieve their environmental targets through regular review, evaluation, and improvement of its environmental performance (ISO 2015). This framework relies on a cycle of planning, implementation, monitoring, and improvement, and is broadly similar to the adaptive management paradigm (Westgate et al., 2013). Regular review and evaluation of environmental practices reduces the risk of non-compliance and allows opportunities for improvement to be identified and implemented. The objective of these procedures is scientifically informed management of local natural systems, and a minimization of environmental impact. MPMC's EMS consists of procedures and processes for training of staff, monitoring environmental systems, and documenting performance. Environmental targets and reporting requirements are based on those outlined in *EMA* Permit 11678 and *Mines Act* Permit M-200.

The following Environmental Management Plans (EMP) are part of MPMC's EMS:

- Annual Discharge Plan
- Comprehensive Environmental Management Plan
- Water Management Plan (Mine Operations)
- Dust Management Plan
- Environmental Emergency Response Plan
- Hazeltine Creek Fish Exclusion Plan
- Invasive Plant Management Plan
- Erosion and Sediment Control Plan
- Soil Management Plan
- Biosolids Management Plan
- Wildlife Management Plan
- Nitrogen Management Plan
- Flocculant Management Plan

MPMC also maintains a QAQC Manual that consists of Standard Operating Procedures and Work Methods including but not limited to: water chemistry and toxicity monitoring and sampling (groundwater, surface water, lake water and seep water), periphyton sampling, phytoplankton sampling, vegetation sampling, soil sampling, hydrological sampling, meteorological sampling, snowpack measurements and the associated sample preservation and shipping and field sample record keeping as well as safety protocols including safe boating and check-in and check-out procedures.

Periodic inspections of infrastructure on the Mount Polley Mine site are also conducted and documented as part of MPMC's EMS. The following inspections and their corresponding frequencies were conducted in 2023:

- Waste Inspections – Weekly/Monthly
- Sump/Ditch Inspections – Monthly by MPMC staff, bi-annually by a QP
- Quesnel Lake Pipeline Inspections – Monthly by MPMC staff, annually by a QP
- Tailings Storage Facility Inspections – Weekly

3.2 Environmental System Audits

EMPs are scheduled for updating and submitting according to the requirements set out by the *EMA* Permit 11678 and *Mines Act* Permit M–200. The following EMPs were reviewed and/or updated in 2023:

- Erosion and Sediment Control Plan
- Soil Management Plan
- Environmental Emergency Response Plan
- Annual Discharge Plan
- Dust Management Plan
- Invasive Plant Management Plan
- Biosolids Management Plan

MPMC also maintains a QAQC Manual that consists of the aforementioned Standard Operating Procedures and Work Methods that is updated annually. The most recent update is ongoing at the time of writing, occurring from January-March 2024.

Geotechnical (2), Geoscience (1) and Safety (15) inspections were conducted by EMLI in 2023. There are a total of 2 outstanding orders from EMLI inspections and details are located in Table 3.1 below.

Table 3.1 Outstanding orders from EMLI inspections

Date	Permit	Type	Requirement/ Description	Compliance	Findings/Details	Response/ Action	Status
05-Oct-22	M-200	Ergonomics Inspection #197466	Order 197466-S1-O1	Out	The site does not have a written Musculoskeletal Disorder (MSD) Prevention Program.	Mount Polley currently has training materials to address MSD prevention and awareness. A review of the current program will be conducted and a plan of action for the 2023 program will be provided on or before 2023-01-06.	In progress

22-Nov-23	M-200	Occupational Health Inspection #218024	Order 218024-S1-O1	Out	During discussions on site, it was reported that the site Workplace Monitoring Program is not up to date and that work is being done to create and prioritize Similar Exposure Groups.	A draft 2023 Workplace Monitoring Program was submitted on Jan 5, 2024. Updates and a final copy of the WMP as well as testing results will be submitted by the April 1st deadline for this order.	In progress

A summary of non-compliance and not determined findings as well as MPMC's responses/actions is provided in ***Appendix S***.

The MPMC ML/ARD Management Procedure Manual was reviewed by SRK, as part of a permit amendment application in 2023. SRK recommended and implemented updates to the ML/ARD Management Procedure Manual. The updated ML/ARD Management Procedure Manual is included in ***Appendix V***.

In 2023 a Flocculant Management Plan (FMP) was developed and implemented for WTP operations. The objective of the plan is as follows: "The objective of the FMP is to describe the methods for settling of solids at the Plant using settling aids including coagulant (polyaluminum chloride), flocculant (polymer), and ballast (microsand), while preventing potential detrimental effects such as toxicity in the receiving environment. The FMP also describes the procedures and equipment used for storage and dosing of settling aids, including monitoring of influent and effluent water quality." (WSP, 2023).

3.3 Water Management

A map of all drainages and watersheds around the Mount Polley Mine site is shown in Figure 1.2 in Section 1.3.2. Further information regarding pre-mining drainage and watershed can be found in the *Mine Plan and Reclamation Program Update 2022* (MPMC, 2022a). The water management system is designed to accommodate flows all flows up to a 1 in 10-year 24-hour storm event and withstand all flows up to a 1 in 200 year 24-hour storm event, without significant damage.

3.3.1 Evaluation of Effectiveness of Water Management

MPMC continually evaluates water management infrastructure through routine inspections to ensure that it performs as expected. On March 27, 2023, a 30" pipeline in the Mount Polley Mine site contact water collection system became obstructed and contact water spilled to the environment. More details of this water release are in Section 3.7.2. A rental Veolia water treatment plant was commissioned in April 2022 to increase treatment throughput. The rental unit was decommissioned and removed from site May 18, 2023. Ditches and pipelines are inspected by Environmental personnel monthly and a QP twice annually.

3.3.2 Water Management System Update

A map of the water management system as of the December 31, 2023, is presented in ***Appendix B***. There

are two updates to the Water Management System in 2023.

1. Removal of the Veolia Water Treatment Plant May 2023
2. Notice of Departure to remove the Mill Site Sump

Mount Polley Mining Corporation (MPMC) has retained a mobile water treatment plant from Veolia Water Solutions (Veolia) on a temporary basis until the site water balance has been significantly reduced. The mobile plant is a portable Veolia ACTIFLO® water treatment plant with a maximum design capacity of 250 m^3/hour (Figure 3.1). The treatment process is the same as the MPMC permitted Veolia Water treatment plant (WTP) which has been authorized and in operation at the mine site since 2015.

Figure 3.1- Veolia ACTIFLO mobile rental water treatment plant

The mobile unit will be installed inside the existing WTP facility. The layout of the mobile plant inside of the WTP facility is shown in Figure 3.2.

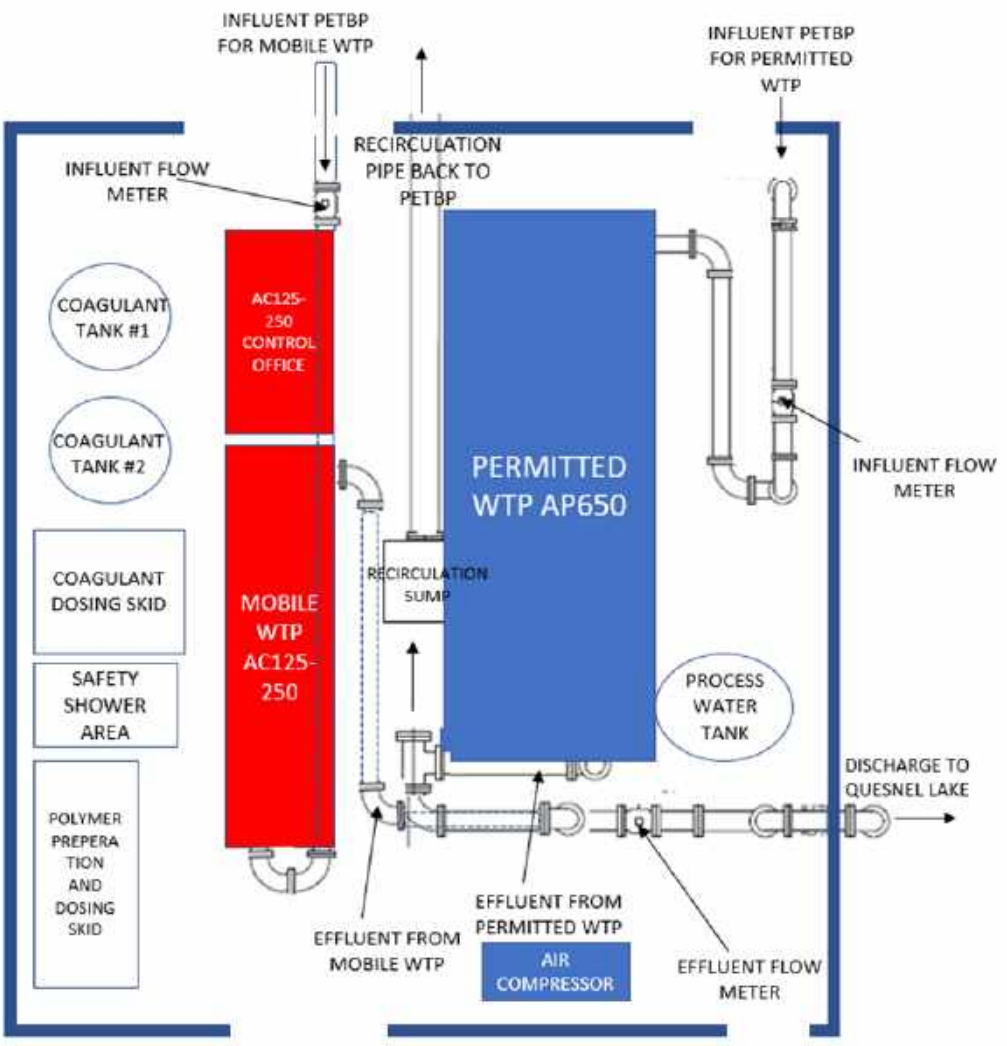

Figure 3.2 – Water treatment plant facility layout

Electrical utilities are drawn from the same source as the permitted WTP, with a transformer to meet the specific voltage requirements of the portable system being installed. No concrete foundation or permanent infrastructure was needed for the mobile rental plant. Influent is pumped using existing infrastructure and flow is monitored using a flow meter. The effluent discharge is directed into the permitted WTP discharge pipe and a new sampling port End-of-Pipe (HAD-3) was installed outside of the building. Both plants have the ability to go into recirculation mode independently from one another by way of inline sensors set to trigger limits or by operator intervention.

To simplify operation, the mobile plant utilizes the larger capacity polymer mixing tank and coagulant tank which is currently used for the permitted WTP. Mount Polley pipe fitters and Veolia technicians completed the assembly of all components prior to commissioning the plant. Commissioning of the plant was completed on March 31, 2022. The mobile Veolia water treatment plant was decommissioned and removed from site in May 2023 once the site water balance was reduced to management amounts.

The Mill Site sump is an existing water management facility and grouped into Mill Site Dewatering infrastructure. Water in this facility is pumped into the Tailings line to be conveyed to the Tailings Storage Facility. This sump is classified as a Dam and was outlined in EMLI by Mark Smith (Inspection 200443). During commissioning of the mill in 2022, refurbishment and upgrades to the mill basement sumps has been completed and the majority of water that flowed into the Mill Site sump is now directed into the mill basement. The mill basement sumps are pumped to the tailings box and water is conveyed to the TSF. The surface water remaining will be diverted to an existing sump located near the Magnetite facility. This sump will be pumped into the Tailings line to convey water to the TSF.

Due to these upgrades in the mill and potential to divert surface water to another existing sump, the Mill Site sump is no longer required for water management and can be removed. The Notice of Departure was approved on June 12, 2023.

3.3.3 Water Discharge Background

The Mount Polley Mine site has historically had a positive water balance, meaning more yearly precipitation occurs at the site than evaporation. This means that water discharge is needed regardless of whether the Mount Polley Mine operates or manages the site on Care and Maintenance, or in operations.

The water surplus was forecast before the Mine started operation and was discussed with neighboring communities during the original consultations that were carried out, along with the Environmental Assessment process, during the 1990s. At that time, the authorized plan was to settle the surplus water in sedimentation ponds and discharge to the local lakes and creeks near the Mine.

During the development and operation phases of the Mine, MPMC continued to assess and plan for water management at the Mine, obtaining and utilizing effluent discharge permits during the Mine's construction and operating period between 1997 and 2000, Care and Maintenance period between 2001 and 2005, and during operations between 2005 and 2014. Effluent was permitted to discharge into Edney Creek during Care and Maintenance until 2005. In years following 2005 the Mine site operated at an annual water balance surplus in excess of water recycling, dust suppression and evaporation. The excess water inventory was stored in mined-out pits and the TSF.

The effluent discharge permit of 2012 authorized 1.4 million cubic meters (Mm^3) per annum into Hazeltine Creek of which 12% could be discharged due to constraining discharge volumes. In 2013, MPMC sought authorization for an additional interim measure to alleviate the critical need to discharge surplus water accumulating on the Mine site.

A reverse osmosis (RO) system was pursued as a short-term solution in 2014; however, MPMC did so knowing that RO would not be a suitable technology for the long-term management of site contact water. In fact, the RO system was proposed as an "interim" discharge strategy, to be employed to address the site water surplus inventory existing at the time, while allowing a sustainable long-term water management plan to be developed. The preferred long-term water management strategy continued to envision passive

treatment and distributed discharge. Notably, at the time, MPMC had already been researching, trialing and operating passive treatment systems in partnership with the University of British Columbia and Genome BC since 2009 and had recently started a partnership with Thompson Rivers University for research into wetland treatment systems.

Following the failure of the TSF foundation in 2014, all water management planning was essentially 'reset', as the existing effluent authorizations were no longer practicable, and the site conditions for what was then the "interim" (RO) water management planning work was significantly advanced in 2014 were no longer applicable. MPMC had no permitted discharge, and all contact water was being stored in the Springer Pit. However, the Mine site continued to have a positive water balance (Golder 2015a), with open pits having finite capacity. Golder estimated that once the Springer Pit water elevation reaches approximately 1,030 masl, the water will exfiltrate to the groundwater and discharge towards Bootjack Lake (Golder, 2015a). At 1,050 masl the Springer Pit will overflow.

With this new paradigm for water management planning, MPMC worked in collaboration with ENV, EMLI, First Nations, local communities, and stakeholders to develop a "roadmap" towards future water management. This "roadmap" recognized that a phased approach to water management planning (and corresponding *EMA* Permit 11678 amendments) would be required for the Mine and contemplated an initial phase (the authorized Short-term Water Management Plan [STWMP]), an operating phase (the current authorized Water Management Plan (Mine Operations), and transitioning toward the Long-term Water Management Plan (LTWMP), which includes plans and details for closure and post-closure conditions.

The effluent discharge strategy commonly referred to as the STWMP, was authorized on November 29, 2015, and reflects the effluent discharge authorized by *EMA* Permit 11678 to November 30, 2017. The STWMP includes discharge of treated effluent to Quesnel Lake via the Hazeltine Channel, and the key objective in its development and authorization was to manage contact water that had accumulated at the Mine site following the TSF foundation failure, while allowing time to develop the LTWMP.

MPMC have continued to follow the approach of this "roadmap" in accordance with the process established in collaboration with the aforementioned parties to ultimately return water flows to their original watersheds in what is known as distributed discharge, to the extent that is possible. Table 3.2 provides a summary of water discharge authorizations from the Mount Polley Mine. An interim permit amendment was authorized on December 1, 2022 to allow effluent discharge from to Quesnel Lake until June 30, 2025. This amendment allows time for the processing of a major permit amendment to be handled jointly by ENV and EMLI under both the *Environmental Management Act* and *Mines Act*, to seek a solution for water surplus to the planned end of mine life in 2034. The current authorized discharge is discussed in further detail in Section 4.12.

Table 3.2 Summary of *EMA* Permit 11678 authorizations for water discharge from the Mount Polley Mine

Date	Discharge Source Permitted	Discharge Location	Comments
7-Feb-2002	MESCP	Edney Creek	Discharge discontinued in 2005; no longer permitted.
7-Nov-2012	Dam filtered	Hazeltine Creek	Discharge discontinued in 2014; no longer permitted.
29-Nov-2015	Springer Pit, and site runoff and seepage collection water management systems	Quesnel Lake via Hazeltine Creek	Discharge discontinued in 2017; see Section 4.12.
30-Nov-2017	TSF, and site runoff and seepage collection water management systems	Quesnel Lake via direct pipeline	Active since 2017
1-Dec-2022	TSF, and site runoff and seepage collection water management systems	Quesnel Lake via direct pipeline	Active in 2022 (Interim solution sought to allow time for ENV/EMLI joint major permit amendment); See Section 4.12
Upcoming 2023-2025	Unknown	Unknown	ENV/EMLI joint EMA/MA major permit amendment for mine plan to 2034.

3.3.4 Long-Term Water Management Plan Development

MPMC retained qualified environmental professionals to review and modernize the previous water management plans and make sure that MPMC were applying best practices to manage surplus site water. This work has resulted in a detailed LTWMP Technical Assessment Report (TAR) submitted on October 17, 2016, in support of the currently authorized *EMA* Permit 11678. The TAR incorporated feedback from and comments by ENV, EMLI, and First Nations (and their respective consultants).

Subsequently, the Water Management Plan (Mine Operations), dated November 27, 2020, was developed for the planned period of mine operations to 2034, which includes management past the newly authorized date when discharge into Quesnel Lake ceases to be authorized under Permit 11678, June 30, 2025.

The *EMA* Permit 11678 allows MPMC to manage site contact water in accordance with the expectations laid out in the *EMA* and Ministry policy pertaining to effluents. The Veolia Actiflo® water treatment system, was commissioned in 2015 by MPMC has met the site water management and will remain as the primary treatment facility for the during of operations.

The *EMA* Permit 11678 authorized annual discharge is 10.5 Mm^3 when discharging to Quesnel Lake, sufficient to manage the 1:200-year wet annual rainfall while the Mine is in operation (LTWMP TAR).

The 2023 Annual Discharge Plan (ADP) is meant to outline, among other items, the expected volume, timing,

and quality of effluent released to Quesnel Lake, and plan the discharge in such a manner that avoids "pollution", as defined in the *EMA* and as determined by the evaluation of parameter concentrations at the edge of the Initial Dilution Zone (IDZ) in Quesnel Lake. Parameter concentrations at the edge of the IDZ will be monitored using a new, model-based approach as part of a Trigger Response Plan (TRP) (Section 4.12.2.6; Appendix I). The ADP was reviewed but not substantially revised in 2023.

A condition of *EMA* Permit 11678 is the development of a revised Water Management Plan (WMP) (Golder, 2020a) to address water management and treatment beyond the end of 2022 for the period from January 2023 to December 2031. The WMP revision does not address water management during closure or post-closure. During operations, the water management infrastructure (i.e., collection ditches, pipes, sumps, pumps, etc.) will remain in its current configuration. During the remainder of operations, plans will be put in place to develop the final design for water management and treatment into closure and post-closure.

A key component of developing the final design during operations is developing alternative treatment technologies that could be considered for closure of the site. The WMP provides an update on progress on a number of possible treatment technologies, included in the water treatment technology inventory. Good engineering practice typically requires a project to follow the requisite engineering design process for the selection and progressive refinement of options. The project progresses from a pre-concept phase for the identification of multiple treatment options, through concept, pre-feasibility, and feasibility phases to project execution. Generally, the engineering studies performed for each of the aforementioned project phases are supported by test work that progresses from proof-of-concept and detailed bench-scale testing to pilot-scale and demonstration-scale test work. It is MPMC's intent to follow this project framework to develop suitable and applicable treatment technologies for the site.

A proposed implementation schedule for developing these technologies has been included in the WMP. Additionally, operational events or changes that are expected to trigger future updates to the WMP are provided, as more site information becomes available. The need for changes to water treatment technologies will be evaluated for each operational trigger event. If it is determined that an operational trigger requires a change to the water treatment approach, the requisite engineering design process will be followed for the selection and progressive refinement of options.

Requirements under *EMA* Permit 11678 relating to water treatment technologies include the development and reporting of annual plans for BAT assessment, and twice-annual progress reports on the development of water treatment technologies. The 2024 BAT Assessment Plan was submitted in January 2023 (MPMC 2024). Water Treatment and Discharge Progress Reports #12 and #13 were submitted in June and December, 2023 (MPMC 2023a; MPMC 2023b) and are included in ***Appendix W***.

As part of closure planning and long-term water management, MPMC's objectives are to provide systems with long-term resilience and effectiveness so that water leaving the Mine site is the best alternative for the receiving environment. Moreover, MPMC are also seeking to distribute treated waters into the pre-mining

catchments, to the extent that is practical.

3.3.5 Water Balance

MPMC retains Golder to maintain a predictive water balance model for the Mount Polley Mine site using GoldSim™ software. This model generates probabilistic flow and water balance forecasts for site water management system components, and has been adapted to model conditions during operations, closure, and post-closure following reclamation work.

The GoldSim™ water balance model is used for planning purposes such as water discharge planning, with calibration and revised projections made based on actual observed site conditions (i.e., water levels and storage volumes). The model also undergoes routine validation through comparison of predicted and observed accumulations, based on actual climate conditions and water management data recorded from site. Model validation was most recently carried out in March 2024 for data covering the period January 2023 to December 2023. Golder provided Site Wide Water Balance Model and Water Quality Calibration Technical Memorandums and they are included in ***Appendix P***.

In addition to the GoldSim™ model developed by Golder, MPMC has an operational spreadsheet that is used to record, and track components of the onsite water balance for operational purposes. Water storage conditions on site from 2018-2023 are summarized in Table 3.3. Under conditions of *Mines Act* Permit M–200 authorizing the return to full operations and use of the TSF, Quantitative Performance Objectives (QPOs) were established. Some of the QPOs are specific to free water storage in the TSF. Under current authorizations, the TSF is operated with a normal operation free water surplus between 1,500,000 m^3 and 1,700,000 m^3 and is authorized for temporary detention of water for contingency (e.g., freshet) storage provided that a minimum freeboard of 1.1 m is maintained.

Under the *EMA* Permit 11678, elevations of the Springer Pit must be recorded monthly for water balance purposes. The Springer pit was dewatered for phase 4 mining operations to continue. The Springer Pit is not expected to be used as water storage for the remaining of the approved and projected mine life. Monthly elevations for the Springer Pit, Cariboo Pit and Wight Pit are provided in Table 3.4.

Table 3.3 Water storage conditions at end of each year, 2018-2023.

Item	2018 Year End	2019 Year End	2020 Year End	2021 Year End	2022 Year end	2023 Year end	Change from previous year
Springer Pit Elevation (masl)	986.96	982.87	1,003.66	982.88	975.31	0	-975.31
Springer Pit Water Volume (m^3)	426,226	2,447,925	2,817,333	508,511	42,061	0	-975
Springer Pit Tailings Volume (m^3)	2,537,251	2,109,030	2,109,030	2,109,030	2,109,030	691,000	-1,418,030.00
Cariboo Pit Water Elevation (masl)	920[(a)]	980	999.11	1,020.31	976.13	956.1	-20.03
Cariboo Pit Water Volume (m^3)	0[(a)]	1,174,691	2,451,580	4,603,358	766,835	235,953	-975
Wight Pit Water Elevation (masl)					916.24	900.46	-15.78
Wight Pit Water Volume (m^3)					3,010,477	1,658,553	-1,351,924.00
TSF Elevation (masl)	961.69	962.01	962.77	962.09	962.947	964.47	1.52
TSF Volume (m^3) - Total	13,45,222	17,683,495	17,760,450	16,336,288	16,705,491	17,387,876	-975
TSF Volume (m^3) – Tailings + Interstitial Water	12,551,668	15,726,999	15,906,067	14,476,633	14,476,633	15,863,836	1,387,203.00
Total Free Water Volume (Springer + Cariboo + TSF)	1,171,147	3,542,008	7,833,992	6,971,524	6,502,415.00	3,418,645.00	-975
Total Water Discharged (m^3)	5,265,722	3,480,268	5,024,328	6,733,553	7,216,768	4,478,726	-2,738,041.80

(a) Active mining was occurring in the Cariboo Pit at the end of 2018. 920 MASL represents bottom of pit elevation.

(a) Due to safety and loss of GPS communication from power outages, last elevation for 2019 was November 6, 2019.

(b) The Springer Pit was dewatered and Phase 4 mining operations commenced

3.3.6 Water Management System Upgrades

Bi-annual sump and ditch inspections (required under *EMA* Permit 11678*)* were completed in 2023, as well as daily water management infrastructure inspections, environmental monitoring, and other observational activities as per MPMC's *Operation, Maintenance and Surveillance (OMS) Manual* (as well as part of MPMC's Sediment and Erosion Control Plan; Section 3.5). No upgrades to the water management system were conducted in 2023.

3.4 ML/ARD Characterization and Mine Waste Management

3.4.1 Waste Rock Characterization and Disposal

Active monitoring of ARD/ML potential in the Mount Polley waste rock continued in 2023 as part of the established protocol which encompasses two stand-alone acid-base accounting (ABA) procedures: ARD analysis of diamond drill core pulps to model a preliminary Potentially Acid Generating (PAG) body; and ongoing ABA determination of individual blast hole samples during mining operations to enhance the segregation of PAG from non-acid generating (NAG) waste (MPMC 2017a). The program characterizes all material types that will be handled during the Mine life. Analysis is completed on site by Mount Polley's LECO™ analytical machine which allows the Mine to characterize waste and direct it to suitable storage sites or designate it for construction usage when required and if deemed suitable. No acid-base accounting procedures occurred between May 2019 and November 2021 due to the mine being in Care and Maintenance. These procedures were reinstated as MPMC resumed mining operations.

On each bench, a sample of cuttings is collected from each blast hole and analyzed for total copper, total carbon, total sulfur, non- sulphide copper, iron, and gold. Areas of ore and waste are identified by indicator kriging and assigning assay values, mill head value, etc. using an inverse distance calculation. The ore control staff member then establishes ore/waste boundaries based on the calculated mill head values. Mill feed ore areas are excluded from ABA analysis, as this material is processed through the mill. Only waste rock is submitted for ABA analysis. Waste rock material was not sampled between May 2019 and November 2021

as no active mining was conducted at the mine site.

Samples with both a Neutralizing Potential Ratio (NPR) greater than 2 and a Sulphur content less than 0.1% are considered NAG, and samples with both an NPR less than 2 and a Sulphur content greater than 0.1% are considered PAG. PAG is currently stored in the Temporary NW PAG Stockpile to the northwest of the Springer Pit and will be relocated to the bottom of the Springer Pit and submerged upon Mine closure. This material rehandling is planned to take place near the end of mine life

A summary of quantities of waste rock, tailings, and other Mine waste added to site storage areas in 2023 and the total quantities on site as of December 31, 2023, are provided in Table 3.5.

Table 3.5 Quantities of waste rock, tailings, low grade ore, and other mine waste for 2023

Name of Waste Pile or Pond	Acid Generating Waste		Potentially Acid Generating Waste		Non-Acid Generating Waste	
Waste Dumps						
	2023	**Total**	**2023**	**Total**	**2023**	**Total**
1. Southeast Rock Dump	0	0	0	0	7,083,080	69,815,254
2. NAG/PAG Dump	0	0	3,789,784	34,768,129	1,093,900	9,557,116

Springer Pit

MPMC provided a Mine Restart Notice on August 25th 2021 to EMLI indicating a departure from Care and Maintenance to Operational status per the Health, Safety and Reclamation Code for mines in B.C., part 6.2.1. Surface Mining in Cariboo-Springer Pit Phase 4 resumed in 2021 and continued throughout 2022. The remaining material in the permitted Phase 4 mine plan comprises of the saddle rock between the Cariboo and Springer pits as well as several benches below the Springer Pit.

In 2023 mining of the Phase 4 Cariboo-Springer 4 Pit continued with development of the SP4 1000 through to the SP4 924 benches. Material classified as potentially-acid generating (PAG) was dispatched to the Temporary Northwest (NW) Potentially-Acid Generating (PAG) stockpile. Material classified as non-acid generating (NAG) was dispatched to the Southeast Rock Disposal Site (SERDS). Ore was dispatched to the crushing facility and or to the stockpiles.

Milling operations continued in 2023.

In 2023, 22,115,054 tonnes of material were removed from the pit of which 6,814,144 tonnes was ore. This material was directly fed into the crusher and or stockpiled.

Approximately, 12,032,329 tonnes of waste were removed from the pit, of which 3,784,284 tonnes were classified as PAG and dispatched to the PAG stockpile. Approximately, 8,248,045 tonnes were classified as NAG, of which 1,093,900 tonnes were dispatched to the PAG stockpile and 7,154,145 tonnes were dispatched to the SERDS.

Identified ore reserves indicate a viable mine life for 8 to 10 years expected to continue to 2031. Given the uncertainty around future operations and mine life, reclamation and closure planning described in this document are subject to review and updates.

Cariboo Pit

The remaining mining in Phase 4 does not include mining in the Cariboo Pit. No productive mining occurred in the Cariboo Pit in 2023.

Wight Pit/Underground

No mining occurred in the Wight Pit in 2023. This facility has been in Care and Maintenance since May 2017 and used for surplus contact water storage since 2021.

ABA Data

There were 950 ABA samples analyzed in 2023. Of these, 608 were divided between NAG and PAG waste. The remaining ABA samples were taken in various types of ore. ABA samples were to be taken at a minimum rate of 1 sample per 20,000 tonnes. At 950 samples there was sufficient sampling density for a total tonnage of 19 mT. There was a total of 18.6 mT of ore and waste mined in 2023 therefore sampling density exceeded the minimum by 1.4 mT or 70 ABA samples.

These samples were collected to characterize the ML/ARD potential of possible materials milled. ABA samples are collected from blastholes in the pit and from waste stockpiles. No ABA samples were taken from ore stockpiles as the blasthole ABA samples will have already provided a profile of the material. The results of these analyses are summarized here in Table 3.6 and the raw data are tabulated in ***Appendix Q***.

Note that the differences in tonnages between tables reflect error margins on haul truck counts.

Table 3.6 Summary of ABA data from the operating pits in 2023

Pit	Samples	Tonnes	NPR	NP	C (%)	AP	S (%)
Springer - NAG	496	8,028,025	55.4	24.36	0.29	3.85	0.12
Springer - PAG	112	3,786,044	1.33	21.45	0.25	28.61	0.91
Total	608	11,814,069	28.43	22.91	0.27	16.23	0.51

Field Grab Samples

In 2023, 56 ABA grab samples were collected from active NAG waste rock dumps and construction areas for QA/QC purposes during periods when PAG was mined. This includes duplicate samples and confirmatory samples. Full details of the ABA field grab sample program can be found in *Metal Leaching/Acid Rock Drainage Characterization and Monitoring Program – Annual Report 2023* prepared by SRK in ***Appendix Q***.

Tailings

Representative composite tailings samples were collected and analyzed for ABA every month when processing of ore occurred to represent the tonnage of tailings. From January 1, 2023 to December 31, 2023, approximately 5,861,715 tonnes of tailings were deposited in the TSF with an average daily discharge rate of 16,059 m^3 per day. Table 3.7 shows the ABA data for all the tailings composite samples taken in 2023. The composite tailings samples had an average NPR value of 9.603 and range NPR values from 4.32 to 14.78.

Table 3.7 ABA results from 2023 monthly tailings composite samples

Month	Tailings Composite NPR
January 2023	4.80
February 2023	4.08
March 2023	12.6
April 2023	4.32
May 2023	5.60
June 2023	11.03
July 2023	10.01
August 2023	14.78
September 2023	13.16
October 2023	10.36
November 2023	12.04
December 2023	12.46
Average	9.603

Monthly Milling Rates

The total amount of ore sent to the crusher in 2023 was 6,345,066 tonnes. A monthly summary of the various ore feeds is provided in Table 3.8 and monthly custom milling production in Table 3.9.

Table 3.8 Summary of monthly milling rates 2023

Truck Count - Crusher Feed Summary				
Month	Source			
	Springer Pit Crusher Feed (t)	Stockpiles to Crusher Feed (t)	Total Crusher Feed (t)	Springer Ore to Stockpiles (t)
23-Jan	447,435	66,735	514,170	80,270
23-Feb	294,240	79,765	374,005	68,495
23-Mar	515,735	45,440	561,175	94,895
23-Apr	384,992	87,841	472,833	33,460
23-May	416,754	70,975	487,729	60,311
23-Jun	427,509	28,000	455,509	131,050
23-Jul	447,035	86,710	533,745	49,975
23-Aug	548,414	56,795	605,209	201,640
23-Sep	476,986	76,385	553,371	144,127
23-Oct	348,170	113,305	461,475	160,825
23-Nov	571,825	97,970	669,795	64,575
23-Dec	583,395	72,655	656,050	92,460
Total	**5,462,490**	**882,576**	**6,345,066**	**1,182,083**

The total ore milled in 2023 was 5,948,239 t. A summary is provided in Table 3.9. When in operation, the mill receives crushed ore from the crusher by conveyor belts, which measure the actual tonnage of material feeding the mill.

Table 3.9 2023 mill production summary

Mill Production Summary								
Month	Mill Feed Tonnage (t)	Tail Tonnage (t)	Feed Grades			Metal Produced		
			Copper (%)	Gold (g/t)	Oxide Ratio	Cu (lbs)	Au (oz)	Ag (oz)
23-Jan	510,935	507,183	0.257	0.294	6.76	2,334,532	3,326	5,171
23-Feb	350,719	348,117	0.248	0.309	7.58	1,512,720	2,499	3,521

Rock Borrow Pit

No rock was extracted from the Rock Borrow Pit in 2023.

3.5 Sediment and Erosion Control

MPMC maintains a Sediment and Erosion Control Management Plan that was revised in 2023 following a review by WSP. The plan was reviewed by WSP and a review report prepared in 2023 as required by the permit.

3.6 Waste Management

Mount Polley practices responsible waste management, and training on this topic is a component of mandatory site orientation. Multiple waste streams exist to ensure that recyclable materials are recycled, and that wildlife attractant waste is disposed of off-site. MPMC holds an *EMA* permit, number 14590, to operate an on-site landfill, which receives most non-recyclable, non-food waste. Reporting to ENV under the landfill permit is performed under a separate cover. Waste management is discussed in greater detail in Section 5.9.

3.6.1 Storage

In its mining operations, Mount Polley utilizes a variety of chemicals, reagents, and other products. At any one time, the approximate volumes of materials in Table 3.10 could be on site.

Table 3.10 Approximate volumes of treatment and processing chemicals stored at the Mount Polley Mine site

Materials	On Hand (kg) on Jan 1, 2023	On Hand (kg on Jan 1, 2024
PAX (Mill Reagent)	17000	3400
Lime	38843	74723
Polyclear 3180M	3000	1814.38
Polyfroth W22C	5138	18833
NaHS	138000	117700

Blasting activities at Mount Polley Mine were carried out by Orica Ltd. Allowable limits on blasting product storage are listed in Table 3.11 below.

Table 3.11 Approximate volumes of blasting chemicals and reagents stored at the Mount Polley Mine site

Blasting Products	Maximum Allowable Limits Stored
Ammonium Nitrate Emulsion	50 t
Ammonium Nitrate Prill	100 t
Sodium Nitrite	3000 kg
Ethylene Glycol	4000 kg

3.6.2 Chemical, Reagent, and Contaminated Waste Disposal

Mount Polley Mine operations utilizes potentially hazardous chemicals, reagents, and other products that are subject to waste disposal procedures. In 2023, GFL Environmental Inc. routinely removed and disposed of waste products compliant with relevant regulations. In 2022, GFL Environmental Inc. Ltd. resumed the disposal of waste products at the mine, as waste production picked up in conjunction with the ramp-up to operations. Materials that are routinely segregated and removed include aerosol cans; contaminated gasoline and diesel; waste oil (in drums); waste oil filters; waste grease fuel or oil-soaked rags, debris, and floor dry; and leachable liquid toxic waste, such as glycol/anti-freeze mix. The site bulk waste oil tanks are emptied, and the oil removed from site. MPMC is registered with ENV under the *Hazardous Waste Regulation* (Ministry of Attorney General, 2017) for generation and temporary storage of these materials.

3.6.3 Recycling

MPMC recognizes the value of responsible waste management and recycling plays a big role in site waste management practices. Mount Polley continues to recycle used materials including waste oil, scrap steel,

batteries, plastic pails, electronic waste, light bulbs and associated fixtures, paper, cardboard, and beverage containers. In 2020, very little recyclable materials were generated at the mine and were stored temporarily. Removal of recycled materials resumed in late-2021 and continued in 2023. Mount Polley donates funds generated by its beverage container recycling program to the Big Brothers and Big Sisters of Williams Lake. Recycling and waste management educational presentations are a part of the mandatory site orientation given to Mount Polley employees, contractors and visitors.

3.7 Incidents

3.7.1 Spills of Hydrocarbon or Dangerous Goods

All spills of hydrocarbons, coolant, and chemicals are reported to the MPMC Environmental Department. In 2023, there were 2 reportable hydrocarbon and dangerous goods spills at the mine. On January 21, 2023, approximately 200L of antifreeze was spilled (DGIR #230286) and on September 5, 2023, approximately 40-60L of antifreeze was spilled (DGIR #233425). In addition to the reportable spills, 10 non-reportable spills were reported internally.

3.7.2 Water Releases

On March 27, 2023, a 30" pipeline in the Mount Polley Mine site contact water collection system became obstructed and contact water spilled to the environment. A contingency pipeline at that location was engaged but was also partially obstructed by a pneumatic knife gate valve that had slowly closed from approximately 2013 to present due to depressurization of the cylinder. The contingency pipeline accommodated the flow eventually but not the initial surge of water once the pipeline was fully obstructed. The contingency pipeline was working as intended within ~6.75 hours. Increased flows were occurring in the ditch due to pumping water from the Wight Pit to supplement the onsite water treatment plant. Details of the event can be found in DGIR #231129 Incident Report (MPMC, 2023c) in ***Appendix R***.

3.8 Archaeological Resources

First Nations with recognized claimed traditional territory for the Mount Polley Mine are the T'exelc (WLFN) and the Xatśūll (XFN). Pre-mining studies noted that the area had low heritage resource potential due to the extensive disturbance in the area from logging and earlier mining projects (Points West Heritage Consulting, 1989).

There were no archaeological or historic sites identified at Mount Polley Mine in 2023 however a preliminary field reconnaissance was conducted to support permitting activities and it identified an area of high archaeological potential that will be further investigated in 2024. The field reconnaissance report can be found in ***Appendix P***.

4 Environmental Monitoring

4.1 Data Quality Assurance/ Quality Control

The purpose of the data quality assurance/quality control (QA/QC) program is to verify the reliability of monitoring data through the implementation of procedures for controlling and monitoring the measurement and analysis process. The QA/QC program provides information for evaluation of the analytical and monitoring procedures, and identification of issues pertaining to possible contamination, both in the field and in the analytical laboratory. The QA/QC program includes:

- Quality assurance (QA): management and technical practices designed to confirm that data were consistent with the objectives of the water quality program.
- Quality control (QC): specific data quality objectives (DQOs), statistical assessment of data quality, and corrective measures taken whenever the DQOs were not met.

The QA/QC program is conducted at all stages of the sampling program: sample collection, transport, and analysis for all sites including contact water quality sites, surface water quality sites, lakes, and groundwater wells.

MPMC maintains a Quality Assurance/Quality Control Manual. The most recent version was updated for 2020 and submitted to ENV in January 2021, herein referred to as the "MPMC QA/QC Manual" (MPMC 2021a). This document is reviewed and audited annually, and most recently in January-March 2023. This manual oversees all the standard operating procedures and work methods pertaining to monitoring and sampling activities on the Mount Polley Mine site.

4.2 Scheduling

To coordinate sampling and schedule all planned monitoring, as per the CEMP and to be compliant with all applicable regulations MPMC prepares internal monthly sampling schedules. Effluent toxicity sampling and receiving environment sampling in Quesnel Lake is scheduled at least 30 days in advance, as required in MDMER Section 14 (2). An example of the monthly sampling schedules as used by MPMC can be found as Appendix C of the 2019 CEMP

4.3 Field Methods

4.3.1 Sample Collection

Sample collection was consistent with the procedures described in the current British Columbia Field Sampling Manual: 2013 – For Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples (ENV, 2013) and MPMC QA/QC Manual (MPMC 2021a). Monitoring procedures for the discharge locations (see Section 4.12) were consistent with the Metal Mining

and Diamond Effluent Regulations (MDMER) (Environment Canada, 2019), as appropriate.

4.3.2 Sample Suites

Each full sampling suite for water chemistry analysis consists of a variety of bottles. As outlined in Table 4.1, the type and volume of bottle will depend on the analysis and is determined by the BC Field Sampling Manual (ENV 2013) and laboratory criteria (Section 4.4). In 2023, the full sampling suite for surface and lake water chemistry consisted of six bottles: Nutrients-1, TSS, total nitrogen and ammonia, dissolved organic carbon, total metals and dissolved metals bottles. The full sampling suite for groundwater chemistry consisted of three bottles: Nutrients-2, total nitrogen and ammonia and dissolved metals (Table 4.1).

Table 4.1 MPMC full sampling suite

Type and volume of bottle	Name of analysis	Type of analysis
250 mL plastic bottle	Nutrients-1 (surface and lake water)	pH, conductivity, turbidity, total dissolved, solids, nitrate, nitrite, hardness, alkalinity, chloride, fluoride, sulphate, and ortho-phosphorus
	Nutrients-2 (groundwater only)	pH, conductivity, hardness, alkalinity, chloride, fluoride, sulphate, nitrate, nitrite
145 mL plastic bottle	TSS	Whole bottle TSS
120 mL amber bottle	Total nitrogen and ammonia	Total nitrogen, ammonia, phosphorus total and dissolved
	Dissolved organic carbon	Dissolved organic carbon
60 mL plastic bottle	Total metals Dissolved metals	Inductively coupled plasma mass spectrometry, some physical tests

4.3.3 Field Meters and Monitoring Equipment

Field meters were used to measure dissolved oxygen, conductivity, pH, temperature, turbidity, oxidation reduction potential (ORP) and water flow. Meters and other field equipment were operated and calibrated following the manufacturers' instructions and the MPMC QA/QC Manual, which includes specific work methods for the equipment discussed below.

For measuring field parameters for surface water and lakes, YSI EXO multimeters were used. The YSI EXO multimeter was operated based on the equipment manual and guidance from the supplier (Hoskin Scientific), with specific MPMC calibration practices being followed.

In-situ turbidity was most often measured with the YSI EXO, but also with LaMotte 2020e and 2020we turbidity meters, when needed. Conductivity and pH meters were used for field analysis of seep samples

and groundwater. The WTW pH/Conductivity 340i and 3430 handheld multimeters, and Oakton 50 series pocket tester multimeter were used for this purpose. Calibration records were recorded in the calibration logbook, as outlined in the MPMC QA/QC Manual (MPMC, 2021a).

Flow measurements were taken using a Sontek FlowTracker2 Acoustic Doppler Velocimeter. The user measures flow rates across a creek or ditch cross section using the FlowTracker handheld device and the device then calculates the discharge rate based on these measurements and input parameters. The meter has QA/QC standards programed into it and provides error notifications if these standards are not met. An International Organization for Standardization and statistical U.S. Geology Survey percent error are calculated for each discharge reading based on depth, velocity, width, method, number of stations, and calibration accuracy to evaluate accuracy of the discharge measurement. The dry salt slug injection tracer method was used by WaterSmith during benchmarking surveys and station assessments in July 2023 and was subject to WaterSmith's QA/QC procedures.

The staff gauge benchmarking (calibrating) and hydrology station calibrating program occurs annually as required by Section 3.4 of *EMA* Permit 11678 and as per protocol in the MPMC QA/QC Manual (MPMC, 2021a). Station specific details are provided in Sections 4.8 and ***Appendix L***.

Field Secchi disk monitoring was undertaken during lake sampling (Section 4.15.2; ***Appendix M***). Chlorophyll a, phytoplankton and zooplankton samples were collected as per the protocol in the MPMC QA/QC Manual (MPMC, 2021a). Chlorophyll a and zooplankton tissue metals analysis was sent to ALS (see Section 4.4). Enumeration and species identification of phytoplankton community and zooplankton taxonomy samples were sent to specialized labs (Section 4.4) as described in the CEMP (***Appendix A***).

4.4 Quality Control and Data Quality Objectives

Analytical processing of samples collected by MPMC is ordinarily conducted by ALS Environmental (ALS) in Burnaby, BC. ALS is a Canadian Association for Laboratory Accreditation (CALA) accredited laboratory for the analyses requested. The Laboratory DQOs provided to MPMC by ALS are included in ***Appendix D***.

Bioassay (toxicity) testing is carried out by Nautilus Environmental (Nautilus) in Burnaby, BC. Nautilus is CALA accredited for these analyses. Acute and chronic bioassays methods are conducted as outlined in the MDMER Environmental Effects Monitoring (EEM) studies and *EMA* Permit 11678 requirements. The toxicity tests are scheduled 30 days prior to sampling as required by MDMER (see Section 4.12.3). The laboratory QA/QC measures provided to MPMC by Nautilus are included in ***Appendix D***.

Phytoplankton and zooplankton community samples from Quesnel, Polley and Bootjack lakes were sent to Biologica Environmental Services Ltd. in Victoria, BC. The laboratory QA/QC measures provided to MPMC by Biologica Environmental Services Ltd. are included in ***Appendix D***.

Samples submitted to labs were tracked to verify that sampling and analysis protocols were followed, including hold times, sample containers, preservatives, detection limits, and approved methodology. Instances in which these protocols were not followed were recorded in the sample tracking spreadsheet. This spreadsheet tracked individual samples and recorded the locations of samples, along with the date, duplicate and blank sample information, sample shipping information, laboratory correspondence, analytical results, and potential data integrity issues.

4.4.1 Duplicates and Blanks

For water chemistry, QC samples were collected as a component of the monitoring program as per the MPMC QA/QC Manual. The recommended minimum number of duplicates and blanks is 10% of the overall samples as set out by the current BC Field Sampling Manual (ENV, 2013). In 2023, MPMC achieved 20% of total QC samples. A combined QC schedule across the various MPMC monitoring programs as described in the CEMP is summarized in Table 4.2.

Table 4.2 Water chemistry QC sample frequencies for MPMC monitoring programs

QC Samples	Minimum Frequency
Duplicate samples	2 per month/10% of samples
Equipment blanks	Monthly/Quarterly per piece of equipment (when used)
Trip blanks	2 per month
Field blanks	2 per month
Filter blanks	Quarterly
Deionized (DI) water blanks	Annually
Inter-laboratory replicate	Annually

Field Duplicates

The semi-blind duplicates are intended to evaluate the QA/QC surrounding the sampling methods. Duplicates are prepared by collecting two full sample suites from one location at the same time, one after the other, labelling one with the sampling location name (e.g., E4, HAC-13) and labelling the second sample suite with a duplicate name in which a numeral is replaced with a letter (e.g., ED, HAC-M). When the results are reported back from the analytical laboratory, all parameters from the duplicate and the actual sample are screened to confirm likeness, or potential of sampling error or contamination. The screening process also considers accuracy of the analytical procedures and small-scale natural variations in water quality which may occur over the timescale of collection (approximately 10 minutes). In particular, there is considerable potential for variations in water quality over short-time scales during periods of high sediment loads.

Semi-blind field duplicates were compared to evaluate the precision of the methods used (i.e., combined precision of field methods, laboratory methods and the environmental variability between the side-by-side samples). A relative percent difference (RPD) is calculated to identify significant differences between the duplicate and sample, where the RPD (as %) can be defined as:

$$\text{RPD } (\%) = \frac{|X_x - X_y|}{\bar{X}} \times 100$$

Where X_x = the concentration of the original sample
X_y = the concentration of the blind field duplicate sample
$\bar{X}$ = the average of the original and duplicate samples

The acceptance criteria for RPDs for water chemistry are defined as 1.5x the laboratory RPD criteria, which is summarized in Table 4.3. For results less than five times the detection limit, significant differences are identified if the difference of the two results is greater than twice the detection limit. When either sample is less than detection limit, differences are not calculated.

Table 4.3 Duplicate Sample RPD acceptance criteria

Analyte Group	RPD Acceptance Criterion
Metals	30%
Inorganics	30%
Organics	45%
Other parameters	1.5 x Laboratory RPD

4.4.1.1 Field QA Results and Discussion

There were 112 field duplicate samples collected in 2023, as shown in Table 4.4. The raw data are available in ***Appendix D***. Note the prefixes refer to location areas (i.e., 'W' refers to non-contact water site, 'EDC-01', refers to Edney Creek); additional information on naming conventions are found in the CEMP (***Appendix A***). Groundwater duplicates (e.g., GW15-2a) do not include total metal analysis, as groundwater monitoring for metals involves only dissolved metals analysis. In addition, the BAC samples (e.g., BAC-01) are only analyzed for E-coli and total bacteria coliform, not for CEMP parameters. All results above the respected RPDs were requested to be rechecked by the analyzing laboratory, usually ALS.

Total and Dissolved Metals

- For total metal analyses, the applicable duplicate criterion was exceeded in the following cases:
- Ten occasions for aluminum (seven RPDs of 60%, 42%, 32%, 154%, 113%, 70% and 54%; and three significant differences of 0.0105, 0.0102 and 0.0244 mg/L).
- One occasion for cadmium (RPD of 57%)
- Six occasions for copper (RPDs of 33%, 136%, 46% and 30%; and two significant differences of 0.0071 mg/L and 0.0022 mg/L).

- Four occasions for iron (RPDs of 40% and 66%; and two significant differences of 0.0650 mg/L and 0.1280 mg/L).
- Four occasions for manganese (RPDs of 65%, 108%, 74% and 39%).

Total metal comparisons are available in ***Appendix D***. There are 25 exceedances of the applicate duplicate criterion for total metals in 2023. This is greater than the 23 in 2022, 10 in 2021, 9 in 2020, 12 in 2019 and the 22 in 2018. In 2023 there were 11% of results that did not meet the duplicate criteria (several exceeded criteria for multiple parameters). Comparatively, 2017 retained 10%, 2018 retained 22%, 2019 retained 12%, 2020 retained 9%, 2021 retained 6% and 2022 retained 14%. Note that there is some degree of variability that can be expected in duplicate samples for parameters such as total metals, which are influenced by total suspended solids (TSS).

For dissolved metals analyses, the applicable duplicate criterion was exceeded on the following occasions:

- Eight occasions for aluminum (one RPD of 56%; seven significant differences of 0.0134, 0.0092, 0.0080, 0.0082, 0.0227, 0.0241 and 0.0430).
- One occasion for copper (significant difference of 0.00512 mg/L).
- One occasion for potassium (significant difference of 0.0869 mg/L).
- Two occasions for magnesium (one RPD of 48%; significant difference of 22 mg/L).
- One occasion for manganese (significant difference of 1.81 mg/L).
- One occasion for selenium (significant difference of 0.000114 mg/L).

All dissolved metal comparisons are available in ***Appendix D***. In 2023 there were 11% of results that did not meet the duplicate criteria. Comparatively, 2022 had 8% of results that did not meet the duplicate criteria, 2021 had 9% of results that did not meet the duplicate criteria, 2019 had 20% of results that did not meet the duplicate criteria, 2017 and 2018 have the same 9% while 2016 had 16% of its duplicates that did not meet the duplicate criteria. Failure to meet duplicate criteria is usually associated with high turbidity or suspended sediment in samples.

General Parameters

For general parameters (ammonia, total nitrogen, total phosphorus, TSS, TDS and turbidity), the applicable duplicate criterion was exceeded on the following occasions (***Appendix D***):

- Two occasions for ammonia (significant differences of 0.0308 and 0.0255 mg/L).
- Four occasions for total nitrogen (significant differences of 0.010, 0.006, 0.026 and 0.017 mg/L).
- Six occasions for total phosphorus (significant differences of 0.007, 0.0066, 0.0069, 0.0159, 0.0064 and 0.059 mg/L).
- One occasion for TSS (significant difference of 4.61 mg/L).

For E-coli and total coliform analysis, no differences were identified between samples. All duplicate results were below detection limit (***Appendix D***).

There was one inter-laboratory duplicate collected in 2023. This replicate is intended to evaluate the QA/QC surrounding the analytical laboratory. This replicate was prepared as described above; the sample with the sampling location name was sent to ALS in Burnaby, BC and the sample with the anonymous name was sent to CARO in Kelowna, BC. Results from CARO had not been received at the time of this report's writing. Results will be reviewed and RPDs calculated upon receipt.

Blanks

Trip/travel blanks and field blanks, prepared by the analytical laboratory, do not contain environmental media sampled from the field. The blanks are exposed to the same conditions and treatments as the water samples collected and are intended to monitor contamination that may occur during sampling or shipping. Field blanks are opened and preserved at a sample location to expose them to the natural environment and trip blanks remain closed at all times. Trip blanks are not opened and are pre-preserved, if required by the lab, and are submitted to the laboratory with sample sets for total suspended solids, total metals, and nutrient and anion analysis, as well as dissolved organic carbon analysis for field blanks.

Trip Blanks

In 2023, 50 trip blanks were submitted to ALS, as listed in Table 4.5.

Table 4.5 Trip blanks sent for analysis in 2023

Total phosphorus, total copper, total lead and total molybdenum were above detection limits in one or more of the trip blanks (***Appendix D***). None of these parameters were greater than five times the detection limit, indicating a high degree of reliability of the data. All above-detection limit samples from 2023 are listed in Table 4.6

Table 4.6. Full results are found in Table 6, ***Appendix D***.

Table 4.6 Summary of trip blank results that are above the lab detection limit

Date Sampled	Parameter	Detection Limit	Result
7-Feb-23	Total phosphorus	<0.0020 mg/L	0.0024 mg/L
7-Feb-23	Total molybdenum	<0.00005 mg/L	0.000136 mg/L
12-Dec-23	Total lead	<0.00005 mg/L	0.000148 mg/L
19-Dec-23	Total copper	<0.0005 mg/L	0.00058 mg/L
19-Dec-23	Total lead	<0.00005 mg/L	0.000187 mg/L

Field Blanks

Thirty-eight field blanks, listed in Table 4.8 were submitted to ALS in 2023. Total aluminum, total barium and total manganese were above detection limits in one or more of the field blanks. None of these results were above five times the detection limit, indicating a high degree of reliability of the data. All above-detection limit samples from 2023 are listed in Table 4.7. Full results are found in Table 7, ***Appendix D***.

Table 4.7 Summary of field blank results that are above the lab detection limit

Date Sampled	Parameter	Detection Limit	Result
26-Apr-23	Total aluminum	<0.0030 mg/L	0.0077 mg/L
1-May-23	Total aluminum	<0.0030 mg/L	0.0036 mg/L
1-May-23	Total barium	<0.00010 mg/L	0.00018 mg/L
23-May-23	Total aluminum	<0.0030 mg/L	0.0094 mg/L
23-May-23	Total barium	<0.00010 mg/L	0.00021 mg/L
23-May-23	Total manganese	<0.00010 mg/L	0.00016 mg/L
6-Jun-23	Total aluminum	<0.0030 mg/L	0.0061 mg/L
6-Jun-23	Total manganese	<0.00010 mg/L	0.00013 mg/L

The field blank parameters that are above detection limit are rechecked by ALS laboratory. A code is associated with the parameters in the ALS results spreadsheet to indicate that the result was rechecked and verified. Investigations for the parameters above detection limit are on-going.

Filter Blanks

Filter blanks are prepared by filtering deionized water and submitting it for dissolved metals analysis. This tests for potential sample contamination during in-field filtering of dissolved metals samples. Four filter blanks were submitted in 2023. All parameters analyzed in the filter blanks were below reported detection limits with the exception of dissolved potassium in the February 6, 2023 sample (Detection limit of <0.050 mg/L; result of 0.080 mg/L) (***Appendix D***).

De-ionized Water Blanks

Deionized water blanks are prepared by submitting a full sample suite (minus dissolved metals since filter blanks are prepared) of deionized water. One deionized water blank was submitted in 2023. All parameters in this blank were below reported detection limits (***Appendix D***).

Equipment Blanks

Equipment blanks are collected to test for potential sample contamination being introduced from sampling equipment. When conducting lake water quality sampling, an equipment blank sample is taken with the Kemmerer (KEM 1 or KEM 2) sampler monthly during each sampling program. When groundwater samples are collected within the quarter according to the CEMP, an equipment blank is collected. MPMC has two groundwater pumps: Grundfos (GW-Grundfos) and Low-flow (GW Low-Flow). Equipment blanks (KEM 1 or KEM 2) are submitted to the laboratory for full sample suites for lake quality sampling (minus dissolved metals since filter blanks using syringes are also prepared); while groundwater equipment blanks (GW-Grundfos and/or GW Low-Flow) are submitted for physical tests, anions and nutrients and dissolved metals.

Eleven Kemmerer equipment blanks were taken in 2023 and are shown in Table 4.9.

Table 4.9 Equipment blanks taken in 2023

19-Sep-23	GW-Grundfos	Dissolved strontium	<0.00020 mg/L	0.00104 mg/L
19-Oct-23	GW-Grundfos	Dissolved manganese	<0.00010 mg/L	0.00352 mg/L
22-Nov-23	GW-Grundfos	Dissolved manganese	<0.00010 mg/L	0.00053 mg/L
14-Dec-23	GW-LowFlow	Dissolved cadmium	<0.0000050 mg/L	0.0000558 mg/L
14-Dec-23	GW-Grundfos	Dissolved manganese	<0.00010 mg/L	0.00205 mg/L

The equipment blank parameters that are above detection limit are rechecked by ALS laboratory. A code is associated with the parameters in the results spreadsheet to indicate that the result was rechecked and verified.

4.5 Data Quality Review and Data Management

A data quality review was conducted for results, including screening of laboratory QA/QC data, sample

integrity issues, detection limits achieved, and metadata accuracy, as well as potential outliers/extreme values. This information was catalogued in the MPMC sample tracking spreadsheet described in Section 4.4.

MPMC uses the MonitorPro database by EHS Data Limited for data management: soil, sediment, and tissue chemistry data were uploaded to separate MonitorPro databases prior to the 2017 cyberattack and the data are now currently managed via spreadsheets and filed on the MPMC network. After the cyberattack, the database responsible for water chemistry samples and in situ parameters was rebooted and water chemistry data using files generated by the analytical laboratory, as well as weather station downloads were uploaded into the database. Accompanying field data were manually entered and uploaded into the database. Original laboratory-produced results files are filed on the MPMC network according to location, and date, and are linked to the data stored in the database. Sample names, dates, and times are cross-referenced with the MPMC sample tracking sheet before final upload to the database and field data undergo a QC screening prior to upload. Parameter restrictions are in place in the MonitorPro database to reduce the likelihood of a typographical or laboratory reporting error being uploaded. Any errors identified by the database underwent further audit before final acceptance.

Non-chemistry data, including toxicity testing results, benthic invertebrate and plankton taxonomy data, and hydrology data (logger downloads and FlowTracker exports) are filed according to year and sample location on the MPMC network.

4.5.1 Rating Curve Development

A new hydrometric station was established on Lower Edney Creek (H3a) on July 17, 2023, mid-way through the monitoring season. The pre-existing station (located ~60 m downstream) was decommissioned on July 17 because of concerns with the configuration and function of the station (e.g., unstable channel cross-section from sediment mobility). Manual discharge measurements and stream temperature data are available from 2023 for both stations; however, a stage-discharge rating curve could not be developed for either station, resulting in no continuous (i.e., automated) stream discharge data for H3a in 2023.

A new hydrometric station was established on Lower Hazeltine Creek (H2) for the 2022 monitoring season. A new stage-discharge rating curve was developed for H2 in 2023; however, there is an absence of manual flow measurements on the lower end of the curve (below 0.1 m^3/s). A new stage-discharge rating curve was developed for the Polley Lake weir outlet (H4) in 2023 because of recent erosion of gravels and large cobbles from the rock weir that controls the water level for the hydrometric station. The staff gauge on Upper Morehead Creek (W1b) was relocated slightly (moved ~1.5-2 m downstream and toward the left bank) because of recent mobility in the channel substrates that resulted in a standing wave at the location of the old staff gauge. A stage-discharge rating curve was developed for this station using 2023 data.

The rating curve is well defined across a large range of flows for W1b and, thus, is not considered provisional. The rating curves are considered provisional for H2 and H4, and incomplete for the new H3a station. Once the rating curves are fully developed for H2, H4, and H3a, they will be applied retroactively to continuous

(i.e., automated) water level data being acquired at these stations. For all other stations, an updated stage-discharge rating curve was developed using multiple years of record, and the rating curves are not considered provisional.

All stage-discharge rating curves were developed by relating manual staff gauge and stream discharge measurements acquired by MPMC (velocity-based measurements using a SonTek FlowTracker2, and bucket flow method) and WaterSmith (dry salt slug injection tracer method [Hudson and Fraser, 2005]). The rating curves were fit statistically [R Development Core Team, 2010] using a least-squares regression model based on one of the following generic forms:

$$Q = a + b\,H \quad (1)$$

$$Q = 10^{(a + b \log10(H - c))} \quad (2)$$

where,

Q is discharge measured manually (m^3/s),

H is water level measured manually (i.e., stage) (m),

a, b, and c are regression coefficients.

Vented pressure transducers (model INW PT2x) were installed at multiple stations (Upper Hazeltine [H1], Lower Hazeltine [H2], Lower Edney [H3a], Polley Lake Weir [H4]) to continuously monitor water pressure (i.e., relating to water level) at 10-minute intervals during non-freezing months. According to the manual, PT2x sensors maintain a sensor accuracy of ±0.25% (Seametrics 2016). For stations with sufficient continuous pressure data from 2023 (H1, H2, and H4), a linear stage-pressure relation was developed between the continuous pressure recordings and the manual stage (i.e., staff gauge) readings. Continuous stage values were generated from the continuous pressure recordings using these stage-pressure relations. The continuous stage values were then substituted into the stage-discharge rating curve equations to estimate continuous discharge at 10-minute intervals throughout the 2023 monitoring season. Continuous discharge data were removed for periods with sustained freezing weather conditions and when the recorded water temperature was below 0.5ºC, due to an elevated potential for ice build-up on the weir crest.

With applying stage-discharge rating curves to continuous pressure data, any estimation above or below the highest or lowest manually measured discharge, respectively, is considered an extrapolation of the rating curve, which can result in substantially biased estimates of discharge. The level of extrapolation allowed when generating the continuous discharge data varied according to the richness of the data used for developing the rating curve, and according to the overall quality of the statistical fit (i.e., certainty) of the rating curve. The maximum allowable extrapolations were as follows:

- H1: maximum extrapolation to 150% greater than the highest manually measured discharge (unconstrained extrapolation for low flow).

- H2: maximum extrapolation to 150% greater than the highest manually measured discharge, and to 50% of the lowest manually measured discharge.
- H4: maximum extrapolation to 150% greater than the highest manually measured discharge, and to 50% of the lowest manually measured discharge.

Results from statistical analysis of the manual staff gauge readings are reported in Section 4.8 and in ***Appendix L***. Routine monitoring incorporated equipment inspections, including stilling wells and pressure transducers (e.g., to identify sedimentation inside the stilling well, or debris build-up in the transducer ports). QA/QC of all collected data was completed to identify spurious errors and/or drifts in the manual or continuous data, or potential station changes. This process included comparisons with previously collected data. As required by Section 3.4 of the *EMA* Permit 11678, verification measurements (dry salt slug injection tracer method) and benchmark surveys of hydrological stations were conducted by a qualified professional (Russell Smith, WaterSmith) on May 3-5, 2023 (discharge only) and July 18-19, 2023 (discharge and benchmarking). Details of the site visits are reported in Section 4.8 and ***Appendix L***.

4.6 Climate

EMA Permit 11678 Section 3.6 (***Appendix A***) requires the collection of detailed meteorology data. The objective of this data collection program is to provide site-specific precipitation, temperature, and evaporation data for use in water balance calculations and hydrological predictions. Mount Polley Mine maintains two automated HOBO weather stations. These stations monitor temperature, rainfall, solar radiation, relative humidity, wind direction, wind speed, and wind gust speed. Weather Station #1 is located approximately one km southeast of Polley Mountain and was installed in September 2012. Weather Station #2 is located northeast of the TSF (between the Rock Quarry and Biosolids Storage Facility) and was installed in November 2012. A summary of the monthly site precipitation, evaporation, and temperature data collected in 2023 is provided in Table 4.13. Further climactic data including daily summary of weather parameters from 2023, can be found in ***Appendix E***.

Evaporation is calculated by using the Penman-Monteith equation using the WaSIM software developed by Cranfield University. Snowfall measurements are based on monthly snowpack testing done at four locations across the mine site. These measurements are taken at the end of every month, as well as between melting and snowfall events, if forecasted. Snowpack sample data including field results are found in ***Appendix E***. The snow course method aligned with the Snow Survey Sampling Guide (ENV, 1981).

Table 4.13 Mount Polley 2023 monthly precipitation, evaporation, and temperature data

Month	Monthly Precipitation as Rain (mm)	Monthly Snowpack (mm Snow Water Equivalent)	Evaporation (mm)	Average Temperature (°C)	Maximum Temperature (°C)	Minimum Temperature (°C)
January	21.0	111	12.9	-3.02	5.49	-21.52
February	10.7	263	15.85	-6.23	3.16	-26.11
March	5.5	243	33.2	-3.30	9.81	-16.88
April	15.7	109	58.7	3.21	22.13	-6.23
May	37.70	0	54.60	13.70	26.81	4.22

December	34.4	18.3	10.9	-0.47	7.92	-6.9

4.6.1 Wind Monitoring

Wind data is monitored continuously by two on-site weather stations. Data from 2023 show that high speed winds are typically observed from the northwest and southeast directions.

4.6.1.1 Weather Station 1 – Leach Pad

In 2023, the strongest and most common winds at Weather Station 1 were observed at around 140°-160°, corresponding with the SE-SSE direction. Other predominant wind directions are at 260-280° (W), and 320°-340° (NNW). Winds were rarely measured from the East, in the 60°–90° range.

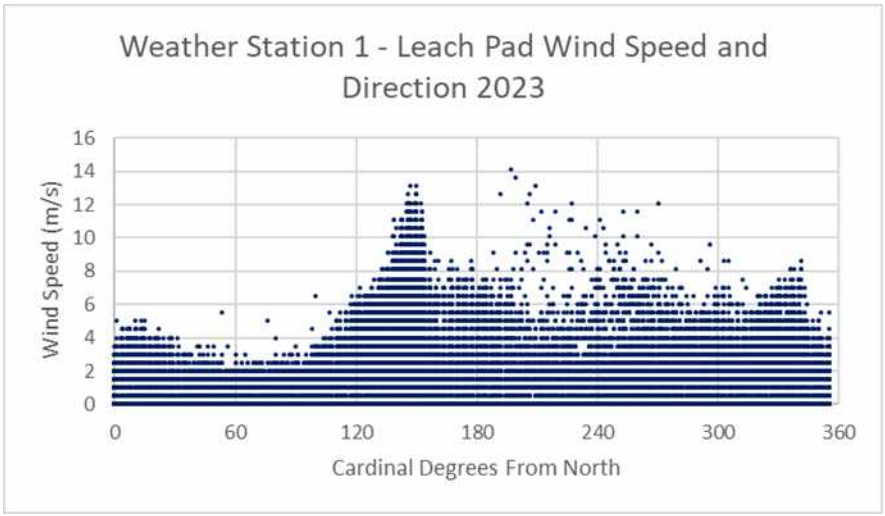

Figure 4.1 Wind data at Weather Station #1 in 2023

4.6.1.1 Weather Station 2 – Orica

Weather Station 2 corresponds with Station 1 but with some notable differences. Here, winds are relatively more common in the range from 280-320, from the NW direction. This is likely to be reflective of variations in topography between the stations, which are within a kilometer of each other. Strong winds in the 60–140-degree range, from the East, are more common. Winds from the South, at approximately 150-220 are relatively less common.

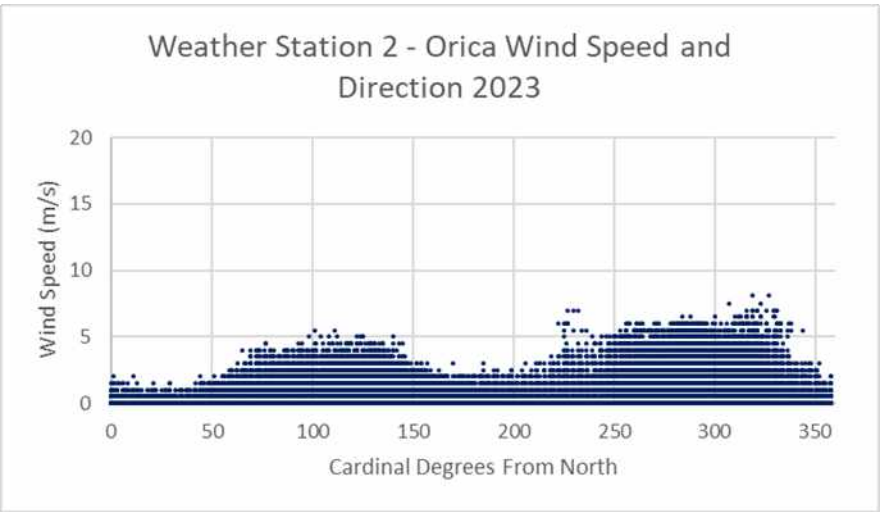

Figure 4.2 Wind data at Weather Station #2 in 2023

4.6.2 Temperature

In 2023, the lowest monthly mean temperature was -6.23°C recorded in February. The highest monthly mean temperature was 29.11°C recorded in August. Temperatures were colder than average in February, March and April but were warmer than average for the rest of the year when compared to site data collected since 1995. Figure 4.3 presents a comparison of 2023 maximum, mean, and minimum monthly temperatures with average monthly temperature data (based on data collected at Mount Polley since 1995). This data is shown in tabular form in Table 4.13.

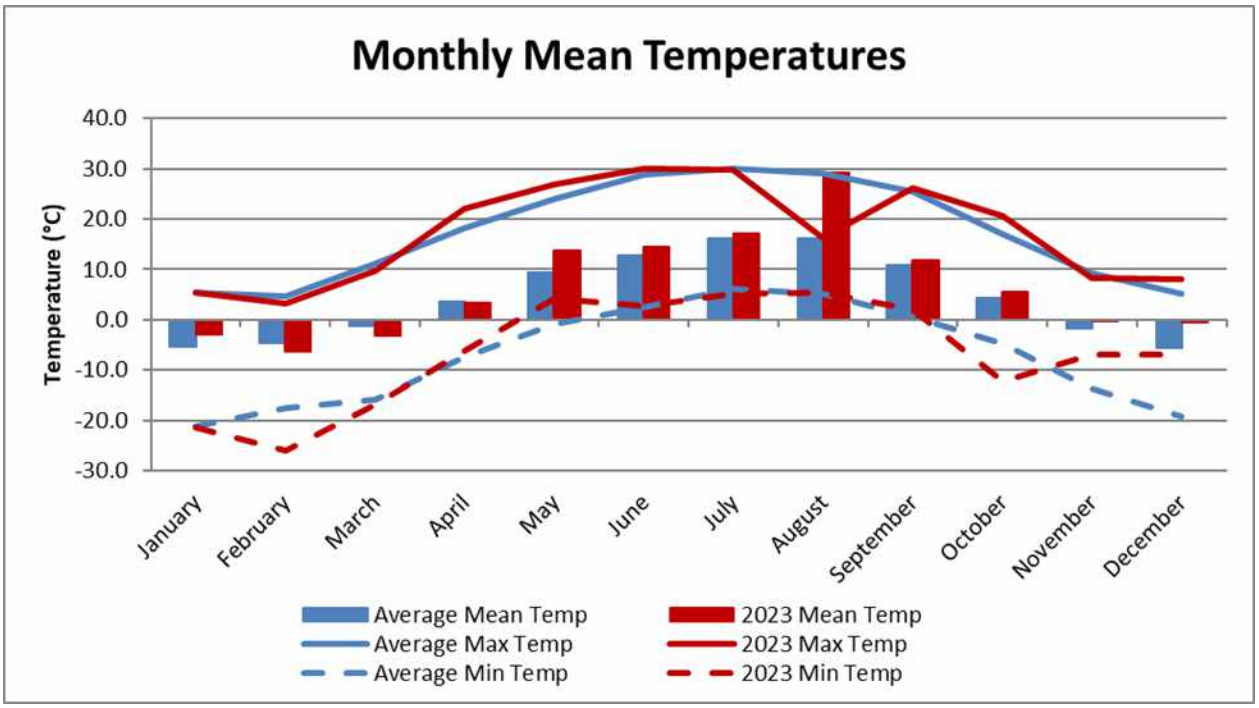

Figure 4.3 Maximum, mean and minimum monthly temperature data for Mount Polley (2023 versus average)

4.6.3 Precipitation

In 2023, 581 millimetres (mm) of precipitation was recorded: 337 mm as rain and 224 mm as snow water equivalent (SWE). This is below the average annual precipitation of 622 mm, with rainfall below its respective annual average but with snowfall above its respective annual average. The 2023 snowpack peaked in February at 263 mm SWE, above the annual average of 224 mm SWE. Total rainfall was lower compared to monthly averages for all months, except in August (52.4 mm), November (31.6 mm) and December (34.4 mm). The driest non-freezing month was April, with 15.7 mm of rain recorded. Precipitation data by month are presented in Table 4.13, Figure 4.4 and Figure 4.5. All precipitation averages are calculated based on data collected at the Mount Polley Mine since 1995.

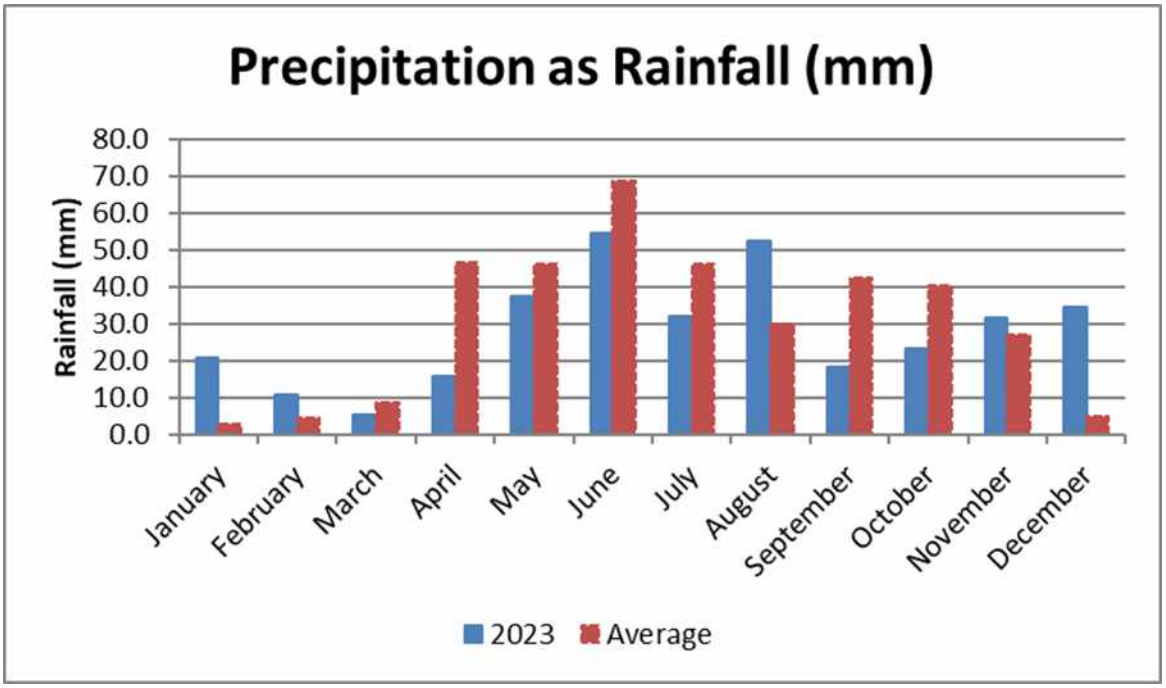

Figure 4.4 Monthly rainfall at Mount Polley (2023 versus average)

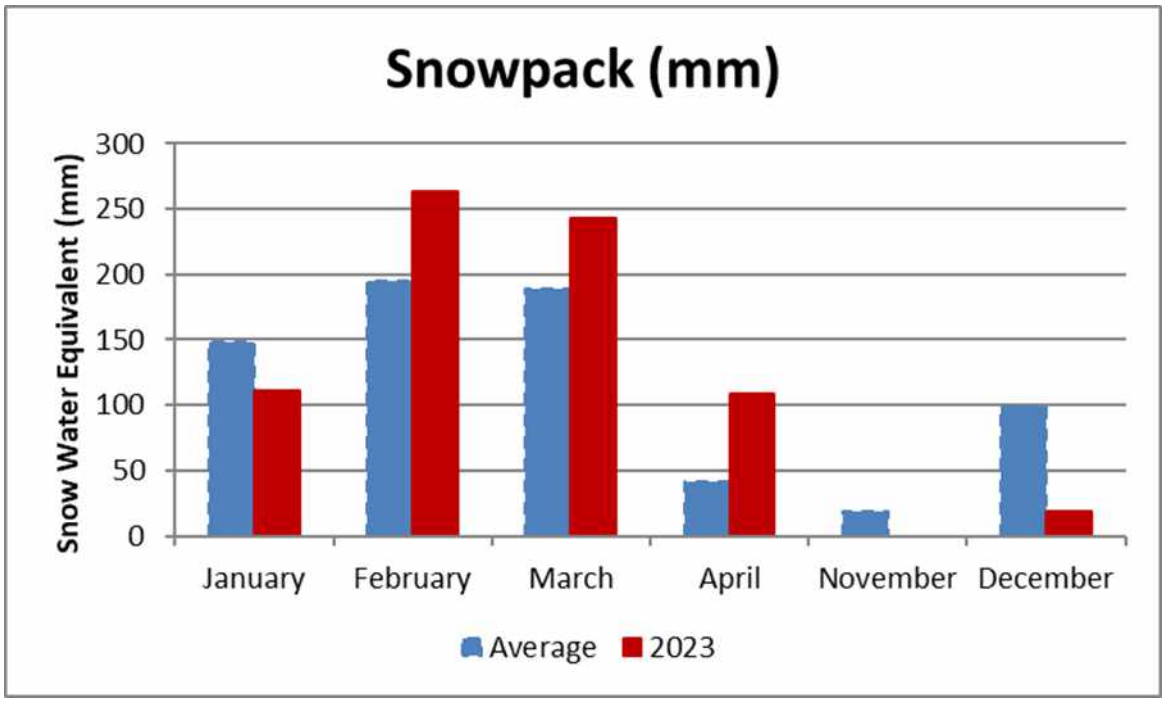

Figure 4.5 Monthly snowpack at Mount Polley (2023 versus average)

4.6.4 Evaporation

Total open water evaporation in 2023 was calculated to be 427 mm. June experienced the greatest amount

of evaporation at 61.7 mm. Monthly evaporation data are presented in Table 4.13. Figure 4.6 presents monthly comparisons of precipitation and evaporation for 2023.

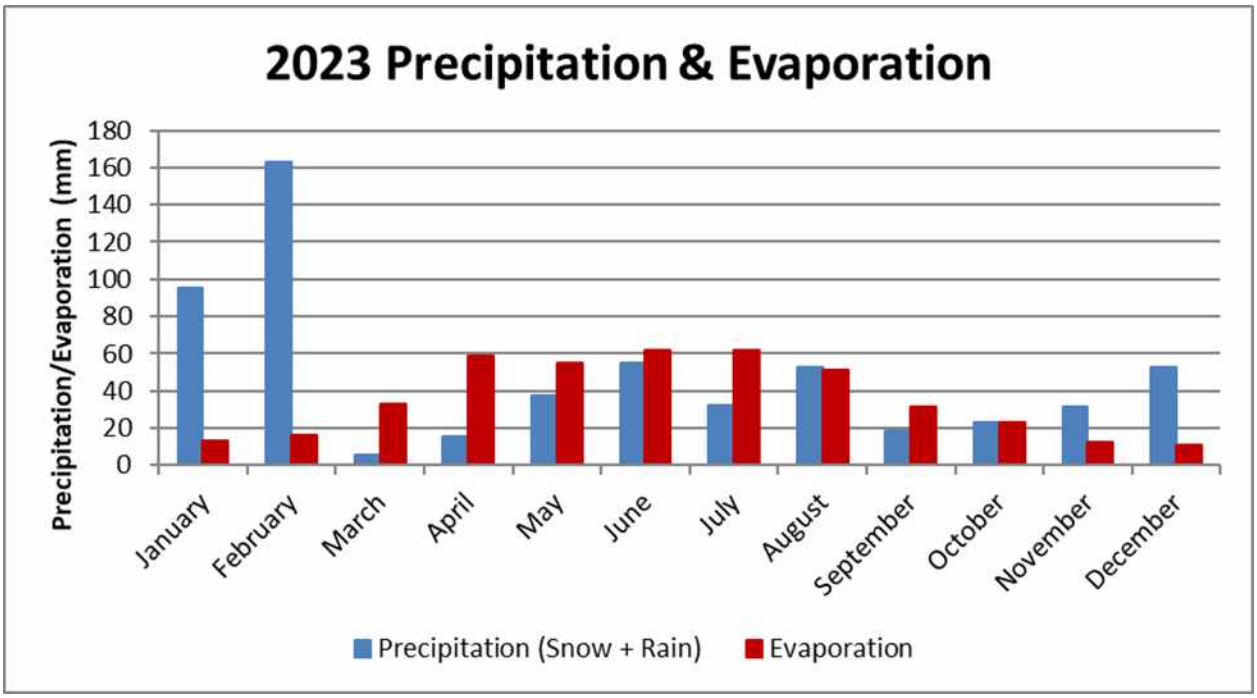

Figure 4.6 Mount Polley 2023 monthly precipitation and evaporation

4.7 Surface Water Monitoring

4.7.1 Hazeltine Creek

Water quality was monitored weekly and monthly at various sites throughout Hazeltine Creek in accordance with the 2019 CEMP (see Table 4.14). Flows in the creek are regulated by the Polley Lake weir structure.

Discharge from the WTP into Hazeltine Creek ceased in 2017. Full Hazeltine Creek water quality is provided in ***Appendix F***.

Table 4.14 2023 sampling events in Hazeltine Creek

Site Name	Site Identifier (EMS No.)	Full Sample Suite Frequency 2016 *CEMP*	Full Sample Suite Frequency 2018 *CEMP*	Full Sample Suite Frequency 2019 *CEMP*	Samples taken
HAC-05a	E304510	Monthly	Monthly	Monthly	12
HAC-08	E303013	Monthly	Monthly	Monthly	12
HAC-10	E303010	Monthly	Monthly	Monthly	12
HAC-13	E304810	Weekly	Monthly	Monthly	12
HAC-14	E331391	N/A	Monthly[(b)]	Monthly[(b)]	8

[(a)] HAC-01 was removed from the monitoring program per the 2019 CEMP approval letter dated February 10, 2021.
[(b)] Monthly only from May to November - not accessible during winter months.

Table 4.15 Summary of 2023 acute BC WQG for aquatic life exceedances in Hazeltine Creek

Site	Parameter	Date	Level (mg/L)	Acute BC WQG (mg/L)
HAC-05a	Dissolved aluminum	01-May-23	0.103	0.1
HAC-08	Dissolved aluminum	01-May-23	0.165	0.1
HAC-13	Dissolved aluminum	01-May-23	0.104	0.1
HAC-14	Dissolved aluminum	01-May-23	0.231	0.1

4.7.1.1 BC WQG at HAC-10

HAC-10 is located immediately downstream of the Polley Lake weir. The weir was open throughout the year, with the sluice gate at varying levels between 4 and 30 “turns”, corresponding with staff gauge elevations between approximately 920.0 and 920.5 MASL. Samples were collected monthly; therefore, chronic BC WQG for aquatic life are not applicable. No exceedances in acute BC WQG for aquatic life occurred at HAC-10 in 2023.

4.7.1.2 BC WQG at HAC-13

HAC-13 is located midway in Reach 1 in Upper Hazeltine Creek. Samples were collected monthly at this site, therefore the chronic BC WQG for aquatic life are not applicable. One exceedance in the acute BC WQG for aquatic life for dissolved aluminum occurred at HAC-13 in 2023 (Table 4.15). The exceedance occurred in May, corresponding with freshet. These results are associated with higher-than-normal turbidity and TSS measures, indicating chemical mobilization during periods of high flow.

4.7.1.3 BC WQG at HAC-05a

HAC-05a is located upstream of the Gavin Lake Road bridge. Samples were collected monthly; therefore, chronic BC WQG for aquatic life are not applicable. One exceedance in the acute BC WQG for aquatic life for dissolved aluminum occurred at HAC-05a in 2023 (Table 4.15). The exceedance occurred in May,

corresponding with freshet. These results are associated with higher-than-normal turbidity and TSS measures, indicating chemical mobilization during periods of high flow.

4.7.1.4 BC WQG at HAC-08

HAC-08 is located upstream of the Ditch Road bridge (on the Likely-Horsefly Forest service road) at Lower Hazeltine Creek. Samples were collected monthly; therefore, chronic BC WQG for aquatic life are not applicable. One exceedance in the acute BC WQG for aquatic life for dissolved aluminum occurred at HAC-08 in 2023 (Table 4.15). The exceedance occurred in May, corresponding with freshet. These results are associated with higher-than-normal turbidity and TSS measures, indicating chemical mobilization during periods of high flow.

4.7.1.5 BC WQG at HAC-01c

HAC-01c replaced HAC-12 in late 2017 and is located approximately 150 m downstream of HAC-12, representing the outlet of Hazeltine Creek into Quesnel Lake. Due to remedial construction, HAC-01c was requested to be removed from the CEMP in November 2020 and replaced by EDC-01a. This change was approved by ENV in their 2019 CEMP Approval letter, dated 10 February 2021, at which time sampling of this site ceased. For additional water quality data representing the flow from Hazeltine Creek to Quesnel Lake, see EDC-01a in Section 4.7.2.7.

4.7.1.6 Supplemental Sites: POF-1 and POF-5

Additional monitoring was continued in the Polley Flats to identify any potential influential sources seeping into Hazeltine Creek. Site POF-1 was established in 2016, and POF-5 was established in summer 2017. Both sites were sampled monthly (except when dry) in 2023. Influence from these sites is represented by monitoring sites in Hazeltine Creek upstream and downstream from the Polley Flats confluence. Sampling details are provided in Section 4.3 and the water quality is provided in ***Appendix F***.

4.7.2 Aquatic Receiving Environment

Surface water monitoring and analysis was conducted as outlined in the 2019 CEMP (***Appendix A***). Refer to Section 4.3 for a discussion of field sampling equipment and methodology. Sampling stations and frequency are summarized in Table 4.16 and locations are shown in ***Appendix B***.

Table 4.16 2023 Sampling events at surface water quality sites.

Site	Site Identifier (EMS No.)	Frequency			
		2016 *CEMP*	**2018 *CEMP***	**2019 *CEMP***	**Samples taken**
W1	E225084	Monthly	Quarterly	Quarterly	4
W4a	E298551	Monthly Weekly [(a)]	Monthly	Monthly	16
W5	E208039	Monthly Weekly [(a)]	Monthly	Monthly	18
W8	E216743	Quarterly Weekly [(a)]	Quarterly	Quarterly	8
W8z	E223292	Quarterly	Quarterly	Quarterly	2

EDC-01a	E303014	-	-	Monthly[(b)]	12
W12	E216744	Quarterly	Quarterly	Quarterly	6
W20	E297070	Quarterly	Semi-annual	Semi-annual	2

[(a)] Weekly TSS and turbidity sampling for five weeks during spring freshet.

[(b)] EDC-01a to replace EDC-01 per 2019 CEMP Approval Letter, dated February 10, 2021.

Samples at aquatic receiving environment sites were submitted to ALS for analysis of:

- Physical parameters (pH, turbidity, TSS, total dissolved solids, and hardness);
- Anions and nutrients (alkalinity, chloride, fluoride, sulphate, total nitrogen, nitrate, nitrite, ammonia, phosphorus total and dissolved, and ortho-phosphorus);
- Organics (dissolved organic carbon); and
- Total and dissolved metals (metals suite as listed in CEMP; ***Appendix A***).

Water chemistry results from the surface sites were compared with the BC WQG for aquatic life for both short-term (maximum or acute) and long-term (chronic) exposures. In 2023, there were 7 exceedances, and two possible exceedances of the acute BC WQG for aquatic life at the permitted surface water monitoring sites (Table 4.17). Note that the list of analytes with concentrations greater than BC WQG is similar to baseline.

At sites W4a, W5, and W8 weekly intensive sampling of TSS and turbidity occurred during spring (freshet); and a 30-day average could be calculated; these were therefore appropriately compared to chronic TSS and turbidity BC WQG. Additional details for each site are provided in the following sections and ***Appendix F*** (which includes tables of results for the past five years and graphs of select parameters). Note that only parameters with trends and/or exceedances are discussed in the sections below. Note that results below method detection limit (MDL) are represented as half (0.5x) the MDL in statistical calculations and graphs.

Table 4.17 Summary of 2023 acute BC WQG exceedances for aquatic life at surface water monitoring sites

Site	Parameter	Date	Results	Acute BC WQG (mg/L)
W4a	Dissolved copper	2-May-23	0.0165 mg/L	0.008[a]
	Turbidity	24-Apr-23	14.3 NTU[b]	8 NTU change from background in 24 hours in all waters during clear flows or in clear waters
W5	Dissolved aluminum	12-Apr-23	0.252 mg/L	0.1
		2-May-23	0.266 mg/L	
	Turbidity	12-Jan-23	10.8 NTU[b]	8 NTU change from background in 24 hours in all waters during clear flows or in clear waters
W8	Dissolved aluminum	2-May-23	0.148 mg/L	0.1
W8z	Dissolved aluminum	28-Mar-23	0.186 mg/L	0.1
		25-May-23	0.284 mg/L	
W12	Dissolved iron	12-Oct-23	0.777 mg/L	0.35
	Total iron	12-Oct-23	1.05 mg/L	1
EDC-01a	Dissolved aluminum	1-May-23	0.160 mg/L	0.1

[a] Copper guideline calculated with BLM software.

[b] Turbidity events are considered possible exceedances, not actual exceedances, because it is unknown whether the change from background occurred for a duration of 24 hours.

4.7.2.1 Site W1 – Morehead Creek (E225084)

This site has been monitored since 1990. It was sampled 4 times in 2023. There is no notable increasing or decreasing trend in water quality at this location. Graphs for a subset of parameters are provided in *Appendix F*.

Dissolved aluminum: No exceedances of acute BC WQGs for dissolved aluminum occurred in 2023. In 2018, monitoring results in November showed one exceedance of the BC WQG for dissolved aluminum. This result appears to be an outlier (potentially a sampler or lab error) as it is the only observed exceedance for dissolved aluminum at this location, and there were no other elevated parameters observed in this sample. The mean value for dissolved aluminum at W1 between 2019 and 2023 was 0.0462 mg/L.

Copper: Though no monitoring results showed exceedances of acute BC WQG for copper in 2023, these types of exceedances have been observed since monitoring began in 1990 (before mining). From 2019 to 2023 the minimum recorded value for copper was 0.00272 mg/L, the maximum was 0.0125 mg/L, and the mean was 0.00662 mg/L. The mean value for copper in 2023 was 0.00786 mg/L.

Sulphate: A slight increase in sulphate levels has been recorded at W1 since 2005, though the levels remain well below appliable guidelines. From 2019 to 2023 the minimum recorded sulphate value was 2.41 mg/L, and the maximum was 11.7 mg/L with a mean of 6.01 mg/L. Note the applicable guideline for this environment is either 218 or 309 mg/L (hardness dependant).

Chloride: From 2019 to 2023 the minimum recorded chloride value was 0.25 mg/L, the maximum was 5.36 mg/L, and the mean was 1.30 mg/L.

4.7.2.2 Site W4a – North Dump Creek below Wight Pit Road (E298551)

This site has been monitored since 2014. W4a was sampled 12 times in 2023 for the full analytical suite, and 4 times for turbidity and TSS only. Graphs are provided in ***Appendix F***. There were acute exceedances in dissolved copper and turbidity at this location in 2023. Most exceedances at this location have occurred during freshet in spring, however, during periods of heavy rains in summer and fall, it is not uncommon to see spikes. There is no notable increasing or decreasing trend in water quality at this location.

Copper: In August 2019, the BC WQGs were amended to include a guideline for dissolved copper and removed the total copper guideline. The BC BLM software was used to calculate applicable WQGs. Copper concentrations in 2023 remained similar to historical values. One acute dissolved copper WQG exceedance occurred in 2023 (Table 4.17). This sampling event is associated with high flows and sediment loads. Between 2019 and 2023, the minimum concentration of total copper recorded at W4a is 0.00232 mg/L and the maximum concentration is 0.963 mg/L (likely sediment-influenced). The mean concentration between 2019 and 2023 is 0.0218 mg/L.

Dissolved aluminum: There were no acute exceedances in dissolved aluminum in 2023. From 2019 to 2023 the minimum recorded dissolved aluminum is 0.0015 mg/L, the maximum is 0.111 mg/L, and the mean is 0.0173 mg/L.

TSS: In 2023 there were no TSS exceedances. From 2019 to 2023, the minimum value is 0.50 mg/L, the maximum is 24.6 mg/L, and the mean is 2.280 mg/L. The mean value during the 30-day sampling event in the spring was similar to background.

Turbidity: In 2023, there was one possible acute BC WQG exceedance (Table 4.17). A recording on April 24 was 14.3 NTU, which is more than 2 NTU above the background value of 2.4 NTU. This event cannot be considered a WQG exceedance because it is unknown whether this turbidity value persisted for 24 hours. Between 2019 and 2023 the minimum value is 0.05 NTU, the maximum is 15.5 NTU and the mean is 2.41 NTU. In 2023 the mean value is 2.09 NTU.

Total iron: In 2023, there were no acute exceedances for total iron. The most recent WQG exceedance for this parameter took place in 2017. Between 2019 and 2023 the minimum value is 0.015 mg/L, the maximum

is 0.999 mg/L (occurring April 21, 2020; just on the edge of the WQG), and the mean is 0.135 mg/L. In 2023 the mean value is 0.108 mg/L.

Total selenium: While not considered a WQG exceedance, total selenium values were above the 0.001 mg/L chronic "Alert" level for selenium in 66 of 78 samples from 2019 to 2023. During this time the minimum recorded total selenium is 0.0006 mg/L, the maximum is 0.0471 mg/L (April 07, 2021; likely to be influenced by suspended sediment), and the average is 0.00377 mg/L. The average for 2023 was 0.0017 mg/L.

4.7.2.3 Site W5 – Bootjack Creek (E208039)

This site has been monitored since 1990. It was sampled 14 times in 2023 for the full parameter suite and 4 times for TSS and turbidity only. There is no notable increasing or decreasing trend in water quality at this location. Graphs for a subset of parameters are provided in ***Appendix F***.

Due to the TSF breach in August 2014, Bootjack Creek no longer flows directly to Hazeltine Creek resulting in a disconnection in fish habitat. In October 2014, fish were salvaged and are excluded from Bootjack Creek.

Sulphate: From 2019 to 2023, the minimum recorded sulphate was 0.82 mg/L, and the maximum was 147 mg/L with a mean of 19.43 mg/L. The mean for 2023 was 44.58 mg/L.

Dissolved aluminum: In 2023 there were 2 exceedances of the acute BC WQG for dissolved aluminum at this location (Table 4.17). Dissolved aluminum has been elevated at this monitoring location since before the mine was established and there is no observed increasing trend. Between 2019 and 2023 the minimum value recorded is 0.0076 mg/L, the maximum is 0.266 mg/L, and the mean is 0.10 mg/L. The mean for 2023 is 0.050 mg/L.

Copper: Prior to the August 2019 changes to the copper BC WQG-AL, exceedances at this site were common, with 22 acute total copper exceedances between 2016 and 2019. However, water chemistry here is favorable, and under the new dissolved copper guideline utilizing the Biotic Ligand Model, no acute copper exceedances have been recorded since 2019. As with dissolved aluminum, this site had elevated copper since before the mine was established and there is no observed increasing trend. Between 2019 and 2023 the minimum total copper value recorded is 0.00243 mg/L, the maximum is 0.0702 mg/L, and the mean is 0.00939 mg/L. The mean for 2023 is 0.0068 mg/L.

TSS: No TSS BC WQG exceedances were recorded in 2023. The minimum value recorded between 2019-2023 is 0.5 mg/L, the maximum is 102 mg/L, and the mean is 3.798 mg/L. The mean for 2023 is 6.22 mg/L.

Turbidity: In 2023 there was one possible exceedance of the acute BC WQG, occurring on January 12, at a value of 10.8 NTU (Table 4.17). This is not considered an exceedance because it is unknown whether this value was consistent over 24 hours. Between 2019 and 2023 the minimum value is 0.007 NTU, the maximum is 14.2 NTU and the mean is 1.87 NTU. In 2023 the mean value is 2.50 NTU.

4.7.2.4 Site W8 – Northeast Edney Creek Tributary (E216743)

This site has been monitored since 1995. It was sampled 4 times in 2023 for full metals suite and 4 times for TSS and turbidity only.

Dissolved aluminum: There was one acute exceedance at this location in 2023 (Table 4.17). This occurred in May and is associated with high spring freshet flows. Between 2019 and 2023 the minimum value recorded is 0.0047 mg/L, the maximum is 0.180 mg/L, and the mean is 0.0669 mg/L. The mean for 2023 is 0.0470 mg/L.

Copper: No acute dissolved copper exceedances were measured in 2023. BC BLM-calculated WQGs tended to be an order of magnitude higher than recorded values. From 2019 to 2023, total copper varied from a minimum value of 0.00052 mg/L to the maximum of 0.00656 mg/L and a mean of 0.00250 mg/L. The mean for 2023 is 0.00269 mg/L.

TSS: No TSS exceedances were observed in 2023. From 2019 to 2023, the minimum value recorded is 0.5 mg/L, the maximum is 16.2 mg/L, and the mean is 1.82 mg/L. The mean for 2023 is 2.73 mg/L.

Turbidity: In 2023 there were no exceedances for turbidity. Between 2019 and 2023, the minimum value recorded is 0.10 NTU, the maximum is 10.92 NTU and the mean is 1.40 NTU. The mean for 2023 is 2.52 NTU.

4.7.2.5 Site W8z – Southwest Edney Creek Tributary (E223292)

This site has been monitored since 1997. It was sampled twice in 2023.

Dissolved aluminum: There were two acute BC WQG exceedances at this location in 2023 (Table 4.17). All samples at this location since 1997 except for two have exceeded this threshold. Between 2019 and 2023 the minimum value recorded is 0.138 mg/L, the maximum is 0.340 mg/L, and the mean is 0.218 mg/L. The mean for 2023 is 0.235 mg/L.

Copper: Prior to 2020, exceedances of the acute guideline for total copper were common at this location (in August 2019 the BC WQG were amended and the total copper guideline was removed). However, between 2019-2023, there are no observed exceedances of the updated 2019 BLM-calculated WQGs. This site has had elevated copper since before the mine was established and there is no observed increasing trend. Between 2019 and 2023 the minimum total copper value recorded is 0.00222 mg/L, the maximum is 0.00713 mg/L, and the mean is 0.00413 mg/L. The mean for 2023 is 0.00681 mg/L.

Dissolved iron: There were no acute BC WQG exceedances at this site in 2023. As with dissolved aluminum, this site had elevated dissolved iron since before the mine was established and there is no observed increasing trend. Between 2019 and 2023 the minimum value recorded is 0.140 mg/L, the maximum is 0.425 mg/L, and the mean is 0.270 mg/L. The mean for 2023 is 0.3385 mg/L.

TSS: Between 2019 and 2023 there were no major fluctuations in TSS. The minimum value recorded during this time period is 0.50 mg/L, the maximum is 1.90 mg/L, and the mean is 0.593 mg/L. The mean for 2023 is <1.0 mg/L.

Turbidity: Between 2019 and 2023 turbidity remained stable. The minimum value recorded is 0.29 NTU, the maximum is 2.22 NTU and the mean is 1.07 NTU. The mean for 2023 is 0.57 NTU.

4.7.2.6 Site W10 – Edney Creek (E291209)

Prior to this becoming a permitted site there were only a few samples collected here since 1995. This site is a reference site, selected for comparisons to the sites downstream from the mine disturbance, including a site in the re-engineered channel of Edney Creek. Graphs are provided in ***Appendix F***. This site was sampled twice in 2023.

Dissolved aluminum: There were no acute BC WQG exceedances at this site in 2023. There were five exceedances of the BCWQG between 2019 and 2023. This site has had elevated dissolved aluminum since before the mine was established and there is no observed increasing trend. Between 2019 and 2023 the minimum value recorded is 0.0036 mg/L, the maximum is 0.161 mg/L, and the mean is 0.0563 mg/L. The mean for 2023 is 0.009 mg/L.

Copper: There were no acute BC WQG copper exceedances at this site in 2023. Between 2019 and 2023 the minimum total copper value recorded is 0.00093 mg/L, the maximum is 0.00383 mg/L, and the mean is 0.00233 mg/L. The mean for 2023 is 0.00091 mg/L.

TSS: No TSS exceedances were observed in 2023. From 2019 to 2023, the minimum value recorded is 0.5 mg/L, the maximum is 17.3 mg/L, and the mean is 4.14 mg/L. The mean for 2023 is < 1.0 mg/L.

Turbidity: No turbidity exceedances were observed in 2023. From 2019 to 2023, the minimum value recorded is 0.10 NTU, the maximum is 7.28 NTU, and the mean is 2.15 NTU. The mean for 2023 is 0.31 NTU.

4.7.2.7 Site EDC-01a – Edney Creek below confluence with Hazeltine Creek (E303014)

Sampling at EDC-01a began in 2021. This site was established to replace EDC-01, which was disrupted by remedial construction in Lower Hazeltine Creek. These sites are considered analogous, both representing water quality downstream from the confluence of Hazeltine and Edney Creeks, prior to their drainage into Quesnel Lake. EDC-01 was not sampled after 2020, and EDC-01a was not sampled prior to 2021. Water quality at these sites can be compared to W10, which is upstream in Hazeltine Creek and is relatively unimpacted by mining activities, remedial activities, and the 2014 tailings breach.

Dissolved aluminum: There was one acute BC WQG exceedance at this site in 2023 (Table 4.17). Between 2021 and 2023, the minimum value recorded is 0.0015 mg/L, the maximum is 0.160 mg/L, and the mean is 0.028 mg/L. Comparing these results to W10, the levels at EDC-01a were similar.

Copper: There were no acute BC WQG exceedances for copper at this site in 2023. The minimum total copper value recorded between 2021 and 2023 was 0.00492 mg/L, the maximum is 0.0123 mg/L, and the mean is 0.0070 mg/L. Comparing these results to W10, the levels at EDC-01a were similar.

Total iron: There were no acute BC WQG exceedances at this site in 2023. Between 2021 and 2023 the minimum value recorded is 0.015 mg/L, the maximum is 1.37 mg/L, and the mean is 0.176 mg/L. Comparing these results to W10, the levels at EDC-01a were similar.

Sulphate: In 2023, no sulphate WQG exceedances are recorded. The minimum value recorded is 3.10 mg/L, the maximum is 54.0 mg/L, and the mean is 35.75 mg/L. Comparing these results to W10, the levels at EDC-01a were similar.

TSS: In 2023, no TSS exceedances are noted. The minimum value recorded is 0.50 mg/L, the maximum is 25.7 mg/L, and the mean is 3.06 mg/L. Comparing these results to W10, the levels at EDC-01a were similar.

Turbidity: In 2023, no exceedances or possible exceedances are recorded. Between 2021 and 2023 the minimum value recorded is 0.22 NTU, the maximum is 9.77 NTU and the mean is 1.76 NTU. Comparing these results to W10, the levels at EDC-01a were similar.

4.7.2.8 Site W12 – 6K Creek at Road (E216744)

This site has been monitored since 1990. It was sampled six times in 2023. There is no notable increasing or decreasing trend in water quality at this location. Graphs for a subset of parameters are provided in *Appendix F*.

Dissolved aluminum: In 2023, no dissolved aluminum exceedances are noted. Between 2019 and 2023 the minimum value recorded is 0.0048 mg/L, the maximum is 0.0618 mg/L, and the mean is 0.0200 mg/L. The mean for 2023 is 0.0163 mg/L.

Copper: Between 2019 and 2023 there are no recorded exceedances of BCWQGs for copper. The minimum total copper value recorded is 0.00112 mg/L, the maximum is 0.00118 mg/L, and the mean is 0.00459 mg/L. The mean for 2023 is 0.00299 mg/L.

Sulphate: A slight increase in sulphate levels has been recorded at W12 since 2005, though the levels remain well below any applicable guidelines. Between 2019 and 2023 the minimum recorded sulphate was 0.15 mg/L, and the maximum was 23.0 mg/L with a mean of 8.50 mg/L. The mean for 2023 was 4.28 mg/L.

TSS: No TSS exceedances have been observed in 2023. Between 2019 and 2023 the minimum value recorded is 0.5 mg/L, the maximum is 6.7 mg/L, and the mean is 1.815 mg/L. The mean for 2023 is 2.77 mg/L.

Turbidity: Between 2019 and 2023 turbidity values are stable at W12, with no exceedances. The minimum value recorded is 0.0 NTU, the maximum is 3.26 NTU and the mean is 1.485 NTU. The mean for 2023 is 0.59 NTU.

4.7.2.9 Site W20 – W20 Creek (E297070)

This site has been monitored since 2013 when the West Ditch was constructed. In 2023, two samples were collected. There have been no trends or notable changes in water quality at this location. Graphs for a subset of parameters are provided in ***Appendix F***.

Dissolved aluminum: There were no acute BC WQG exceedances for dissolved aluminum in 2023. Historically, most samples at this location have high dissolved aluminum values. Between 2019 and 2023 the minimum value recorded is 0.0087 mg/L, the maximum is 0.299 mg/L, and the mean is 0.107 mg/L. The mean for 2023 is 0.030 mg/L.

Copper: In 2023, no acute copper WQG exceedances were recorded. The minimum total copper value recorded during this period is 0.00244 mg/L, the maximum is 0.00661 mg/L, and the mean is 0.00448 mg/L. The mean for 2023 is 0.00408 mg/L.

4.7.3 Lake Sampling

In 2023, lake sampling was completed as outlined in the 2019 CEMP in Section 6.6. Refer to Section 4.3 for a discussion of field sampling equipment and methodology and ***Appendix B*** for a site map. ***Appendix M*** includes tables of all results for the past five years and graphs of the parameters measured.

Table 4.18 2023 Lake water quality sampling locations

Site	Site Identifier (EMS No.)	Profile Frequency		Sample Frequency	
		CEMP	**Samples 2023**	**Permit Requirement**	**Samples 2023**
P1	E207974	Monthly[a], and as described in the Permit Requirement column.	7[c]	Spring overturn, twice in summer, fall overturn, once under ice	7[c]
P2	E207975	Monthly[a], and as described in the Permit Requirement column.	8	Spring overturn, twice in summer, fall overturn, once under ice	8
B1	E207972	Monthly[a]	6	Semi-annually	6
B2	E215897	Monthly[a]	6	Semi annually	6
B4	E216744	For closure only	0	For closure only	0
QUL-ZOO-1	E306455	Semi-annually	3	Semi-annually	3
QUL-ZOO-7	E306456	Semi-annually	3	Semi-annually	3
QUL-ZOO-8	E306457	Semi-annually	0[b]	Semi-annually	0[b]
QUL-2a	E303020	Four times annually	5[d]	Four times annually	5[d]
QUL-18	E303019	Four times annually	4	Four times annually	4
QUL-120a	E303022	Semi-annually	4	Semi-annually	4

[a] Between spring and fall overturn

[b] Site was removed from the sampling program in June 2019

[c] P1 could not be sampled on March 1, 2023; therefore, P1 and P2 were sampled under ice on March 15, 2023

[d] Sampling was conducted at QUL-2a on June 19, 2023 as a result of a total phosphorus exceedance at QUL-58 on June 6, 2023

Some WQG exceedances were noted in lake samples in 2023, as shown in Table 4.19.

Table 4.19 2023 Lake BC WQG acute exceedance events

Site	Depth	Parameter	Date	Level (mg/L)	Acute BC WQG (mg/L)
P1	Surface	Dissolved copper	9-May-23	0.00404	0.0040[a]
B1	Surface	Dissolved copper	12-Jul-23	0.00298	0.0017[a]
			10-Oct-23	0.00204	0.0013[a
	Bottom	Total manganese	23-Aug-23	1.0	≤1.06

[(a)] Site-specific WQG calculated using BLM or hardness

4.7.3.1 Bootjack Lake

In Bootjack Lake, station B1 is located at the northwest end of the lake and station B2 is located at the southeast end. It was discovered that in late 2016, the previous stations were not at the deepest locations for the 2016 monitoring season and these sites were relocated to the deepest areas for monitoring in 2017 and continued from 2018 to present. Sampling occurred during spring turnover in May, in late summer in August and September and during fall turnover in October in 2023. Limnological profiles were taken monthly between spring and fall turnover at B1 and B2. Profile and chemistry data are presented in ***Appendix M***.

In 2016, four locations (B3, B4, B5, and B6) were created near areas of potential exfiltration from the Springer Pit supernatant. Based on the 2016 results it was determined in 2017 that one location, B4, would be profiled bi-monthly, as the Springer Pit supernatant is well below the recommended 1,030 masl (Golder, 2016a). This monitoring was discontinued in 2019 until post-closure. In 2023, monitoring took place at B1 and B2, representing the north and south ends of Bootjack Lake.

In Situ Data

In 2023, MPMC recorded profile data at B1 and B2 six times. Limnological profiles of pH, conductivity, dissolved oxygen, turbidity, and temperature as well as Secchi depth were measured at B1 and B2 on a monthly basis from approximately May to October, including during lake turnover events in spring and fall. In 2023, field parameters including conductivity and turbidity were consistent with previous years.

Lake Water Chemistry

Water samples for analytical chemistry were collected at surface, bottom, and mid depths when the lake is isothermal, and at surface, bottom, above and below the thermocline when the lake is not isothermal. These sampling depths are consistent between sites B1 and B2. ***Appendix M*** contains water chemistry data tables with results from the last five years. Bootjack Lake has been routinely sampled for water quality twice a year during spring turnover and in late August. In 2017, total iron, total manganese, and total phosphorus levels exceeded (outdated) aquatic BC WQGs for samples collected near the bottom of B1 and B2 during sampling events in September, though to be related to conditions at the bottom becoming anoxic with the fall turnover. More recently in the period from 2019-2023, a few WQG exceedances have been recorded for total and dissolved iron, dissolved copper, and total manganese; mostly associated with bottom samples taken in fall of 2019, 2022 and 2023.

Total and dissolved iron: There were 15 acute BC WQG for aquatic life exceedances in Bootjack Lake between 2019 and 2023 (seven total iron and eight dissolved iron). These occurred in August and September 2019, September 2021, September and October 2022, and August, September and October 2023. All exceedances were observed in bottom samples, and are likely to be related fall overturn, possibly attributable to fine sediment resuspension. Total iron levels in Bootjack Lake between 2019 and 2023 ranged from 0.030 to 1.64 mg/L, with an average of 0.155 mg/L. In 2023, the average total iron level was 0.247 mg/L.

Total manganese: Six total manganese acute BC WQG exceedances occurred in Bootjack Lake between 2019 and 2023, three of which happened on August 29, 2019 at B1-bottom, B2-surface and B2-bottom. Additional manganese exceedances occurred at B2-bottom in September 2021, B1-bottom in September 2022, and B1- and B2-bottom in August 2023. The cause of these manganese spikes is unknown; however, all of these events occurred at or around fall overturn, which is likely related. The August 29, 2019, sampling date resulted in many exceedances in Bootjack Lake for elements which are naturally present in sediment and would be expected to mobilize during overturn. Between 2019 and 2023, Bootjack Lake total manganese concentrations varied widely; between 0.0062 and 1.29 mg/L and with an average concentration of 0.121 mg/L.

Dissolved copper: Three acute dissolved copper BCWQG exceedances occurred between 2019 and 2023, at the B2-bottom site on June 10, 2021, and B1-surface on July 12, 2023 and October 10, 2023. The dissolved copper measures at these locations and times were lower-than-average for Bootjack Lake; however chemical conditions for biotic uptake were not favorable and the concurrent BLM-calculated WQGs for dissolved copper were exceeded. Dissolved copper concentrations in Bootjack Lake from 2019 and 2023 varied between 0.00103 and 0.00378 mg/L, with an average concentration of 0.00186 mg/L.

4.7.3.2 Polley Lake

In Polley Lake, station P1 is located at the deepest point at the north end of Polley Lake and station P2 is located at the deepest point at the south end of Polley Lake and are shown in ***Appendix B***. Sampling occurred monthly between spring and fall overturn; limnological profiles were conducted monthly along with the Secchi depth during the same period as per the CEMP (***Appendix A***). Sampling in Polley Lake took place in March (under ice) and then monthly during the ice-free season in 2023. A total of 8 sampling events took place in 2023. Profile and chemistry data are presented in ***Appendix M***.

Polley Lake was impacted by the TSF embankment breach that occurred in 2014 (MPMC, 2015a) and sample results for water quality show that some water chemistry results are elevated from historic and baseline levels. All results are included in ***Appendix M***.

In Situ Data

In 2023, MPMC recorded profile data at P1 seven times and P2 eight times. Profiles of pH, specific

conductivity, dissolved oxygen, turbidity and temperature were measured monthly at these locations during the ice-free season, and under-ice in February or March of each winter.

In Polley Lake, conductivity historically ranged from 121 to 215 µS/cm, with an average of 186 µS/cm. Following the breach, the conductivity increased to a maximum of 410 µS/cm at P1 and 396.9 µS/cm at P2 in September 2015, with an average of 284.2 µS/cm. Conductivity throughout Polley Lake appears to be decreasing slightly since the breach; however, it remains above historic levels. In 2023, the average conductivity recorded at P1 was 261 µS/cm and at P2 was 265 µS/cm. These values are lower than those recorded in 2015 and are similar to the period from 2016 onward.

In Polley Lake, pH historically ranged between 6.90 and 9.55, with an average of 8.27 at P1. At P2, pH has ranged from 7.12 to 9.55 with an average of 8.34. In the period from 2019-2023, pH remains similar, with a range of 6.89 to 8.46 at P1 with an average of 7.80 and from 6.93 to 8.79 with an average of 7.82 at P2. In 2023, the averages were 7.71 at P1 and 7.76 at P2.

Lake Water Chemistry

In 2023, water samples for analytical chemistry were collected at surface, bottom, and mid depths when the lake is isothermal, and at surface, bottom, above and below the thermocline when the lake is not isothermal. These data are presented in ***Appendix M***.

Total copper: Copper concentrations have been higher since 2014, with a post-breach average of 0.0044 mg/L compared with the average of 0.0024 mg/L pre-breach. In the period from 2019 to 2023, the mean total copper value was 0.00428 mg/L, and the lowest value was 0.00317 mg/L. The maximum total copper concentration recorded was 0.0112 mg/L.

Total selenium: Selenium concentrations on Polley Lake waters have decreased to below pre-breach levels. The pre-breach average was 0.0009 mg/L compared to the post-breach average of 0.0007 mg/L. The maximum recorded value between 2019 and 2023 was 0.000834 mg/L. While an initial increase was noted following the breach with a maximum of 0.0012 mg/L, the downward trend is apparent. The maximum concentrations in 2015, 2016 and 2017 are 0.00011 mg/L, 0.0008 mg/L, and 0.0007 mg/L, respectively, with maximal measures remaining near the 0.0006 mg/L level since 2018.

Minnow installed DGTs in Polley Lake from 2015 to 2021 and provided memos that have been appended to previous years' annual reports (MPMC 2016b, 2017d, 2018a, 2019, 2020). According to Minnow, total and dissolved metals over-represent the metal fraction that is potentially available for uptake by aquatic organisms in natural surface waters. Minnow's technical memos describe the methods and results for the DGT deployments. Key findings for Polley Lake include that mean DGT-labile copper concentrations are very low, however they are higher than in Bootjack Lake (reference), and DGT labile concentrations in Polley Lake of arsenic, molybdenum, selenium and vanadium were enriched compared to Bootjack Lake. However, total concentrations of these metals were below applicable BC WQGs.

4.7.3.3 Quesnel Lake

Quesnel Lake is the receiving environment for Quesnel Lake discharge and is extensively monitored as described in the CEMP (***Appendix A***). Note that this section contains information on Quesnel Lake sites away from the IDZ. Monitoring locations at the edge of the IDZ (QUL-57, -58, -59) are discussed in the context of the discharge system, in Section 4.12.2.6.

Quesnel Lake Zooplankton Sites

In Quesnel Lake, site QUL-ZOO-1 is in the center of the West Basin and QUL-ZOO-7 is located in front of Horsefly Bay (***Appendix B***). Sampling and limnological profiles occurred three times in the ice-free season, as per the CEMP (***Appendix A***). In 2023, samples were collected in June, July and August. There were no acute BC WQG exceedances at these sites between 2019 and 2023. MPMC continues to collect profile and surface water quality data from these sites to be used in the analysis of plankton results (see Section 4.15).

Quesnel Lake Receiving Environment and Reference Sites

According to the 2019 CEMP, the far-field receiving environment in Quesnel Lake is monitored at QUL-18 (the deepest area of the West Basin, downstream far-field exposure station) and QUL-2a (West Basin upstream of the mouth of Hazeltine Creek; to monitor for potential eastward flow of effluent due to seiche events). Sampling and limnological profiles at depths occurred five times at QUL-2a and four times at QUL-18 in 2023.

An upstream reference station, QUL-120a, is located east of Cariboo Island, and sampling in this location is stipulated in the 2019 CEMP approval letter, dated February 10, 2021. Sampling and limnological profiles at depths outlined in the CEMP (***Appendix A***) occurred four times in 2023.

Lake Water Chemistry

Quesnel Lake is an oligotrophic lake, therefore, it is common to see total phosphorus concentrations lower than the BC WQG for lakes containing salmonids (Total P between 0.005 and 0.015 mg/L), as was observed at all sites in Quesnel Lake (***Appendix M***), except for certain locations discussed below. One acute BC WQG exceedance (dissolved copper) was found at the receiving environment sites (QUL-120a) in 2023. Since only four times annual or semi-annual sampling is conducted at QUL-18, QUL-2a, and QUL-120a, the required five samples taken in 30 days to calculate the chronic average was not met. Therefore, these comparisons are for screening purposes only and are discussed below. Additional information related to the discharge water quality is in Section 4.12.2 and discharge plume modeling in Quesnel Lake are in ***Appendix J***.

At QUL-18, there were no observed changes or trends in the water quality between 2019 and 2023, compared to historic data. An increase in total phosphorus at the surface, 20m, and 50m depths in September of 2018 was noted. This may have been due to remnants of spawning and debris from the

wildfires; the total phosphorus limit is only applicable during spring overturn at the epilimnetic water if residence time exceeds 6 months (according to the BC WQG for total phosphorus – nutrients and algae), therefore, total phosphorus remained in compliance with the BC WQG. Total phosphorus concentrations at the surface, 20m and 50m depths decreased in August 2019 and remained at similar levels in 2020. In 2021, 7 of 16 samples were below detection limit (<0.002 mg/L) for total phosphorus. In 2022, 5 of 16 samples were below detection limit for total phosphorus. In 2023, 3 of 16 samples were below detection limit for total phosphorus. The average of total phosphorus from 2019-2023 at QUL-18 was 0.00364 mg/L and the maximum concentration was 0.0093 mg/L throughout the water column (Figure 4.7).

Historically, concentrations of total copper have exceeded chronic limits (since amended) at a 100m depth once in August 2019, once in August 2018, once in April 2017 and three times in 2016 (May, June, and November); and once at 20 m depth in November 2016 (Figure 4.8). With the 2019 revision of copper guidelines to rely on dissolved copper and the BLM-calculated limit, only one acute exceedance has been detected at the Quesnel Lake reference sites. Dissolved copper at QUL-120a-0m was 0.00073 mg/L on May 10, 2023 and exceeded the BLM-calculated guideline of 0.0006mg/L. This exceedance occurred at the surface and could be attributed to a number of environmental factors. The total copper at QUL-18 between 2019 and 2023 varied between 0.0005 and 0.0015 mg/L, with an average concentration of 0.0007 mg/L. The 2023 average concentration was 0.00068 mg/L.

At QUL-2a, there were no observed changes or trends in the water quality between 2019 and 2023, when compared to historic data. Elevated phosphorus concentrations (0.0488 mg/L) were observed in 2018 but have decreased since that time. Between 2019 and 2023, total phosphorus ranged from 0.002 to 0.0114 mg/L, with an average concentration of 0.0039 mg/L. In 2023, the average total phosphorus concentration was 0.0028 mg/L. There were two instances of total copper exceeding the (now outdated) chronic BC WQG at surface and at 40 m depth in July 2018. The only other time a result exceeded the chronic limit occurred at 60 m depth in May 2016. Since the introduction of the BLM-based dissolved copper guideline in 2019, no exceedances have been observed. Total copper concentrations between 2019 and 2023 at QUL-2a were between 0.00051 and 0.00175 mg/L throughout the water column, with an average concentration of 0.0007 mg/L. The average concentration in 2023 was 0.000642 mg/L.

At QUL-120a, there were no observed changes or trends in the water quality. Similar to other Quesnel Lake sites, an increase in total phosphorus was recorded in late 2018 (up to 0.077 mg/L). This may be due to remnants of spawning and debris from the wildfires; the total phosphorus limit is only applicable during spring overturn at the epilimnetic water if residence time exceeds 6 months (according to the BC WQG for total phosphorus – nutrients and algae), therefore, total phosphorus remains in compliance with the BC WQG (Figure 4.7). Total and dissolved copper concentrations remain similar to previous years at QUL-120a (Figure 4.9). There was one acute dissolved copper exceedance found at QUL-120a in May 2023. This exceedance occurred at the surface and could be attributed to a number of environmental factors.

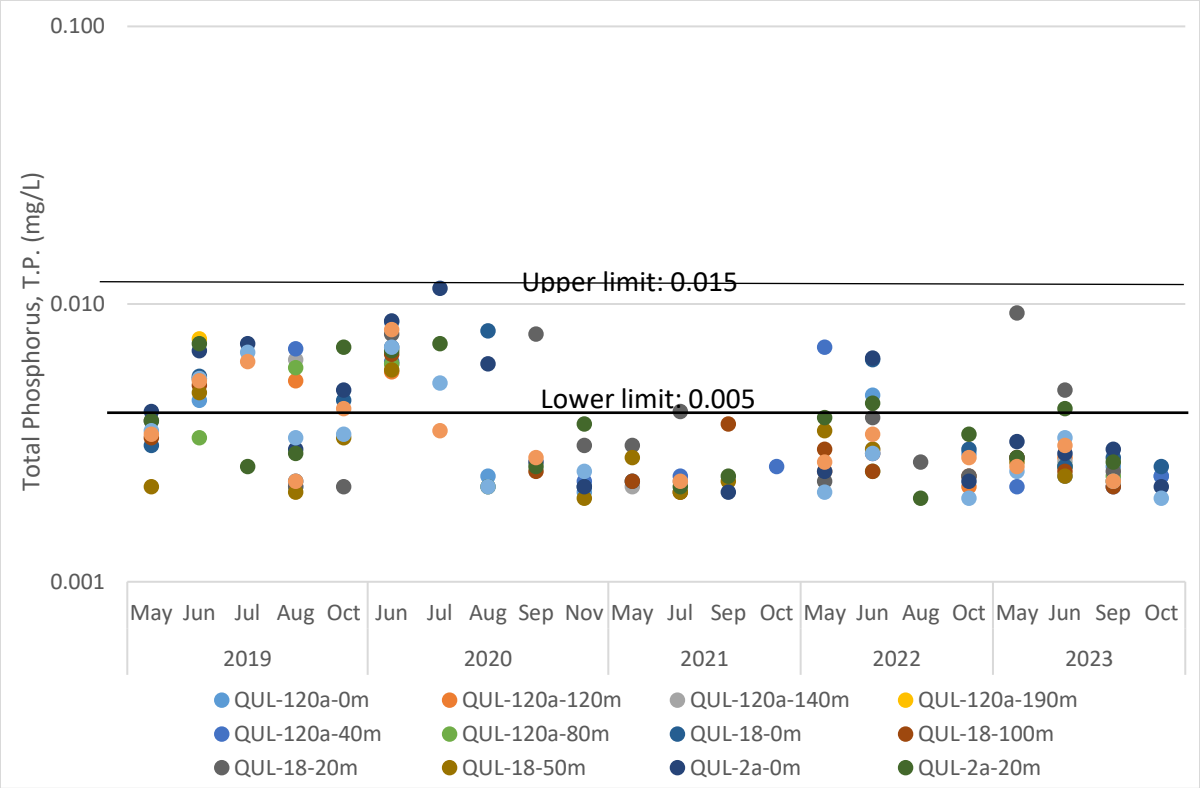

Figure 4.7 Total phosphorus concentrations at QUL-120a, QUL-2a, and QUL-18 from 2019 to 2023

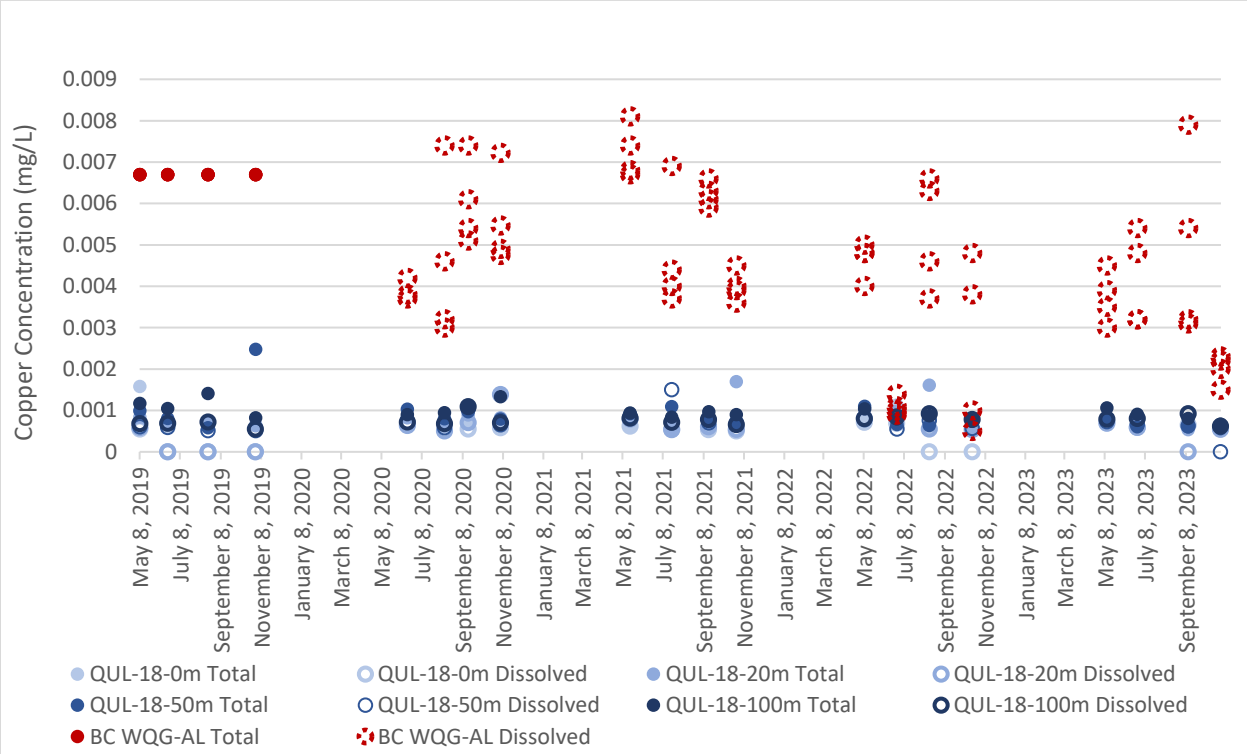

Figure 4.8 Total and dissolved copper results at QUL-18 from 2019 to 2023

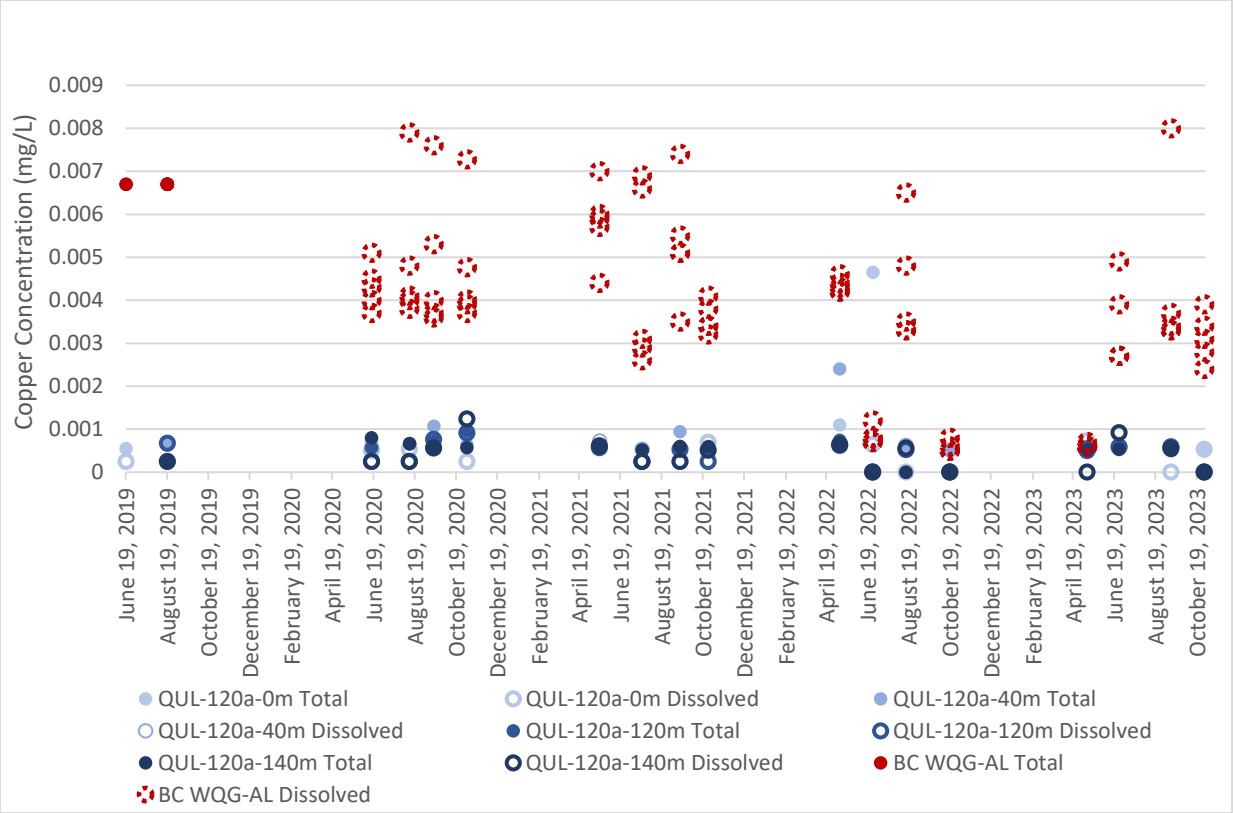

Figure 4.9 Total and dissolved copper results at QUL-120a from 2019 to 2023

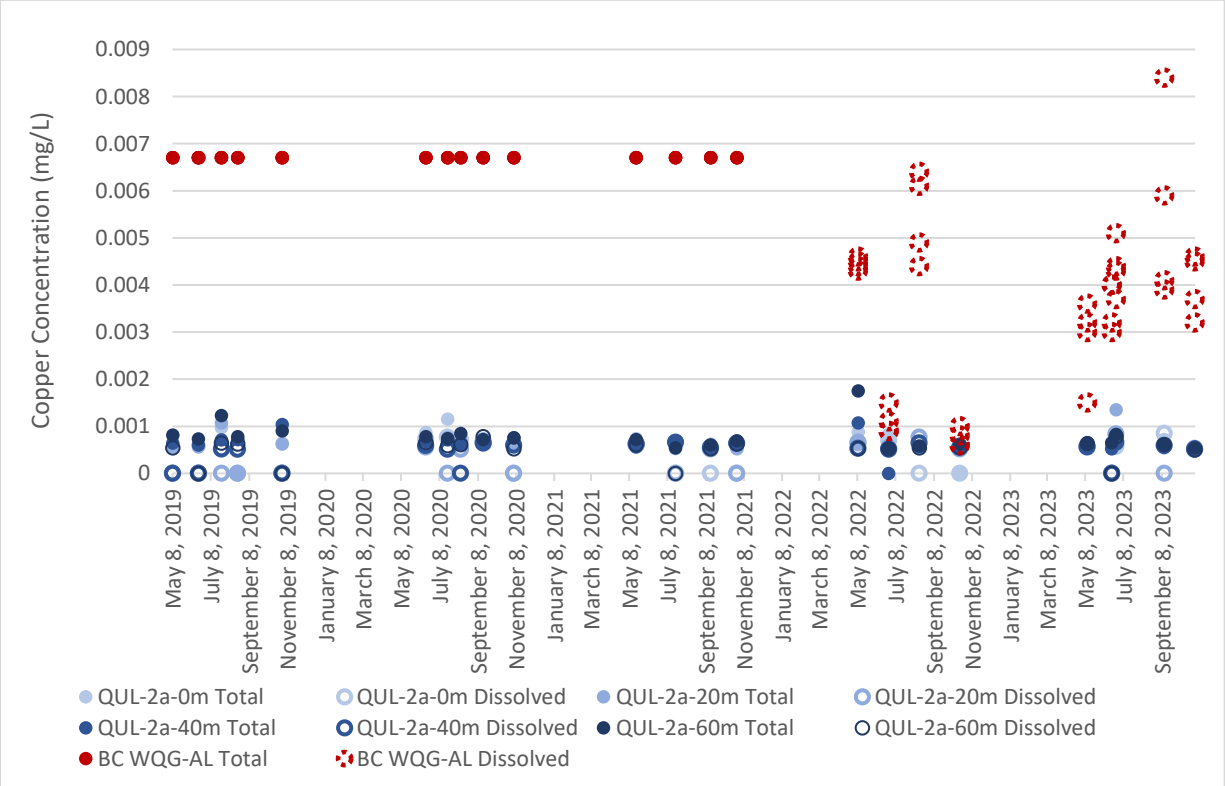

Figure 4.10 Total and dissolved copper concentrations at QUL-2a from 2019 to 2023

4.8 Hydrology

In 2023, hydrological monitoring in Hazeltine Creek was completed at Upper Hazeltine Creek (H1), Lower Hazeltine Creek (H2), and the Polley Lake weir outlet (H4), as required by Section 3.4 of *EMA* Permit 11678 and Section 6.7 in the CEMP. Streamflow was measured manually at these stations during the months of May through October. Flow was controlled by the Polley Lake weir continuously and, thus, was not indicative of the natural flow regime.

The 2023 hydrometric data are provided in ***Appendix L*** including hydrographs, stage-discharge rating curves, stage-pressure relations, goodness of fit statistics, and photographs.

4.8.1 Site H1 - Upper Hazeltine Creek

Ten staff gauge readings and manual flow measurements from the 2022-2023 period were utilized for developing an updated stage-discharge rating curve. The highest manually measured discharge used for developing the rating curve was 0.72 m^3/s on May 4, 2023. An assessment of the goodness of fit of the manual discharge measurements to the rating curve yielded a mean absolute difference of 8% and a standard error of 12%.

In 2023, pressure transducer data were recorded using a PT2x from April 19 to November 21. The transducer was removed in the mid-fall due to freezing temperatures. Continuous discharge data were removed from the dataset for April 20 and 22 (<6 hour gaps), and for all dates after October 21, due to freezing temperatures and, thus, an elevated potential for ice build-up on the weir crest. A benchmark survey conducted by WaterSmith on July 18 indicated the stilling well and staff gauge had been stable.

The 2023 peak flow period occurred primarily in late April and early May. Discharge receded through May, then remained low through the June-October period. The highest recorded continuous discharge in 2023 was 0.78 m^3/s on May 4.

4.8.2 Site H2 - Lower Hazeltine Creek

Seven staff gauge readings and manual flow measurements from the 2022-2023 period were utilized for developing an updated stage-discharge rating curve. The highest manually measured discharge used for developing the rating curve was 0.93 m^3/s on June 22, 2022. An assessment of the goodness of fit of the manual discharge measurements to the rating curve yielded a mean absolute difference of 4% and a standard error of 5%.

In 2023, pressure transducer data were recorded using a PT2x from April 19 to November 21. The transducer was removed in the mid-fall due to freezing temperatures. Continuous discharge data were removed from the dataset for all dates after October 21 due to freezing temperatures and, thus, an elevated potential for ice build-up on the weir crest. A benchmark survey conducted by WaterSmith on July 18 indicated the

stilling well and staff gauge had been stable.

The 2023 peak flow period occurred primarily in late April and early May. Discharge receded through May, then remained low through the June-October period. The highest recorded continuous discharge in 2023 was 0.95 m^3/s on May 4.

4.8.3 Site H4 - Polley Lake Weir

Seven staff gauge readings and manual flow measurements from the 2022-2023 period were utilized for developing an updated stage-discharge rating curve. The highest manually measured discharge used for developing the rating curve was 0.70 m^3/s on May 4, 2023. An assessment of the goodness of fit of the manual discharge measurements to the rating curve yielded a mean absolute difference of 4% and a standard error of 8%.

In 2023, pressure transducer data were recorded using a PT2x from April 19 to November 21. The transducer was removed in the mid-fall due to freezing temperatures. Continuous discharge data were removed from the dataset for all dates after October 21 due to freezing temperatures and, thus, an elevated potential for ice build-up on the weir crest. A benchmark survey conducted by WaterSmith on July 18 indicated the stilling well and staff gauge had been stable.

The 2023 peak flow period occurred primarily in late April and early May. Discharge receded through May, then remained moderate or low through the June-October period. The highest recorded continuous discharge in 2023 was 0.73 m^3/s on May 4.

4.8.4 Hydrology – Mine Site

In 2023, additional hydrological monitoring was completed at sites W1b (Morehead Creek), W4a (North Dump Creek), W5 (Bootjack Creek), W12 (6km Creek), and H3a (Lower Edney Creek), as required by Section 3.4 of *EMA* Permit 11678 and the Section 6.7 in the CEMP. Supplemental monitoring was carried out at the SERDS, the NW Ditch, Junction Zone Ditch, Joe's Creek Pipe, and the East Main and South Toe Drains at the TSF. Refer to ***Appendix B*** for a map of monitoring locations.

The 2023 hydrometric data are provided in ***Appendix L***, including hydrographs, stage-discharge rating curves, stage-pressure relations, and goodness of fit statistics.

4.8.5 Site W1b – Upper Morehead Creek

Five staff gauge readings and manual flow measurements from 2023 were utilized for developing an updated stage-discharge rating curve. The highest manually measured discharge used for developing the rating curve was 0.48 m^3/s on May 5, 2023. An assessment of the goodness of fit of the manual discharge measurements to the rating curve yielded a mean absolute difference of 5% and a standard error of 5%. No

pressure transducer was installed at the site in 2023. A benchmark survey conducted by WaterSmith on July 19 indicated the staff gauge had been stable.

4.8.6 Site W4a – North Dump Creek

Nineteen staff gauge readings and manual flow measurements from the 2021-2023 period were utilized for developing an updated stage-discharge rating curve. The highest manually measured discharge used for developing the rating curve was 0.10 m^3/s on May 4, 2023. An assessment of the goodness of fit of the manual discharge measurements to the rating curve yielded a mean absolute difference of 39% and a standard error of 71%. The high uncertainty in the rating curve is associated with imprecision in the bucket flow method for measuring discharge, and with large relative differences in discharge (i.e., measured vs. calculated discharge) under low flow conditions in this very small stream. Velocity based discharge measurements are not feasible at this station. No pressure transducer was installed at the site in 2023. A benchmark survey conducted by WaterSmith on July 18 indicated the staff gauge had been stable.

4.8.7 Site W5 – Bootjack Creek above Hazeltine Creek

Twenty-five staff gauge readings and manual flow measurements from the 2016-2023 period were utilized for developing an updated stage-discharge rating curve. The highest manually measured discharge used for developing the rating curve was 0.22 m^3/s on May 4, 2023. An assessment of the goodness of fit of the manual discharge measurements to the rating curve yielded a mean absolute difference of 46% and a standard error of 114%. The high uncertainty in the rating curve is associated with imprecision in the velocity method for measuring discharge under low flow conditions in this very small stream. No pressure transducer was installed at the site in 2023. A benchmark survey conducted by WaterSmith on July 18 indicated the staff gauge had been stable.

4.8.8 Site W12 – 6 km Creek at Bootjack Road

Eleven staff gauge readings and manual flow measurements from the 2021-2023 period were utilized for developing an updated stage-discharge rating curve. The highest manually measured discharge used for developing the rating curve was 0.57 m^3/s on May 4, 2023. An assessment of the goodness of fit of the manual discharge measurements to the rating curve yielded a mean absolute difference of 18% and a standard error of 29%. The high uncertainty in the rating curve is associated with imprecision in the velocity method for measuring discharge under low flow conditions in this very small stream. No pressure transducer was installed at the site in 2023. A benchmark survey conducted by WaterSmith on July 19 indicated the staff gauge had been stable.

4.8.9 Site H3a – Lower Edney Creek

Three staff gauge readings and manual flow measurements were obtained in 2023 at the new station that was established on July 17, 2023. All three measurements were acquired under low flow conditions, and were not sufficient for developing a stage-discharge rating curve. The highest manually measured discharge

in 2023 was 7.6 m^3/s on May 4 (combining manual data from the old station and the new station).

In 2023, pressure transducer data were recorded at the old station from April 19 to July 17 using a PT2x. The continuous water level data were removed from this dataset due to instability in the channel cross-section at the old station (discussed above). The continuous temperature data were removed for the May 30 to July 17 period because the old station became dewatered.

Pressure transducer data were recorded at the new station from July 17 to November 1 using a PT2x. The transducer was removed in the mid-fall due to freezing temperatures. Continuous water level data were removed from the dataset for all dates after October 21 due to freezing temperatures and, thus, an elevated potential for ice build-up on the weir crest. Once a rating curve is fully developed for the new station, it will be applied retroactively to the continuous water level data that were acquired. Benchmarks were established by WaterSmith on July 18 for the new station.

4.8.10 Supplemental Sites

Flow monitoring and/or staff gauge measurements were also collected at supplemental sites, including the SERDS, Long Ditch (LD), the NW Ditch, Junction Zone Ditch, Joe's Creek Pipe, South Toe Drain (STD), the East Main (East MTD) and West Toe Drain (West MTD) at the TSF. Results are presented in ***Appendix L***. These flow measurements from site water management system components are primarily used for verifying the site water balance.

4.9 Groundwater Monitoring

4.9.1 Mine Site

Based on the results of this monitoring program, the following conclusions are provided:

- Based on the review of the groundwater elevation on the west side of the mine site, it can be inferred that a groundwater divide between the Springer Pit and Bootjack Lake remains in the area of GW12-2(a,b), GW15-1(a,b) and GW15-2(a,b), as groundwater elevations at these wells remained higher than the surface water elevation in the Springer Pit. This groundwater divide results in groundwater flow both towards the east and west from the groundwater divide.
- Slightly increasing and/or decreasing POI concentration trends at some locations were noted.
- Based on requirements of monitoring/sampling frequency set out in the CEMP (varies dependent on well), no deficiencies were identified. Although select wells were not monitored/sampled, this was a result of the monitoring wells being dry, or containing an insufficient volume of water, which is not considered a permit deficiency. Wells not monitored/sampled included:
    - GW05-01 required quarterly groundwater sampling; however, only two samples were collected in 2023 (January and November). MPMC noted that groundwater beyond the capabilities of the pump were present during the May and September sampling events.
    - GW15-1a and GW15-1b required quarterly groundwater sampling; however, no samples were collected in 2023 due to groundwater being beyond pumping capabilities in GW15-

1a. GW15-1b was dry during each monitoring event.

- Concentrations of dissolved arsenic, dissolved copper, dissolved iron, dissolved zinc, pH, sulphate, ammonia (as N), and fluoride exceed either the applicable BC CSR standards and/or the BC WQGs.

Based on the results of the 2023 annual groundwater monitoring report (***Appendix O***), the following recommendations are provided:

- Continue the groundwater level and quality monitoring program at the mine site. This includes measuring the depth to groundwater at the various on-site monitoring wells as per the requirement of the 2019 CEMP (preferably on the same days during the various required sampling events in 2024).
- Static water levels at GW12-2a, GW12-2b. GW15-1a and GW16-1 should be obtained prior to removing and after replacement of transducers.
- Surface water elevations at Polley Lake, Bootjack Lake, and the TSF should be conducted within a similar time period as the groundwater elevations are collected to inform the groundwater contour figure.
- Springer Pit surface water elevations should be conducted throughout the full extent of the year to better inform seasonal and annual trends.
- Several samples gathered at the mine site surpassed the hardness, dissolved organic carbon (DOC), and pH-dependent copper standards concerning the chronic BC WQGs for aquatic life. However, a significant portion of these samples fell below the laboratory's detection limit. WSP advises MPMC engage with the laboratory and consider reducing the detection limit in 2024 to accurately evaluate the copper concentrations detected.

4.9.2 Hazeltine Creek

Following the TSF embankment breach an investigation of the groundwater quality in the Hazeltine Creek riparian area was conducted in 2015 to confirm the results of the geochemistry assessment conducted by SRK Consulting Inc. (SRK, 2015a). A second groundwater assessment was completed in 2016 in support of the risk assessments, and in 2017, a third assessment was completed by Golder. The 2017 assessment recommended one more year of sampling which was completed in 2018. The Golder groundwater review included a review of the 2016 to 2018 groundwater results but did not make recommendations and no trends were found. In 2022 additional groundwater monitoring was conducted to collect samples that were representative of freshet conditions from monitoring wells that are representative of background conditions as well as those within tailings impacted areas along Hazeltine Creek (WSP, 2024). No monitoring or sampling of groundwater wells in the vicinity of Hazeltine Creek was conducted in 2023 (***Appendix G***).

4.10 Contact Water Chemistry

Contact water sampling and analysis was conducted as outlined in Section 3.2 of *EMA* Permit 11678 (***Appendix A***). Contact water sampling is also outlined as per the 2019 CEMP (***Appendix A***). As described in the *CEMP*,

monitoring and changes of many contact water sites fall under *Mines Act* Permit M-200. Refer to Section 4.3 of this report for a discussion of field sampling equipment and methodology.

This section contains data for the permitted effluent site prefixed with the letter "E". Sample site and frequency are summarized in Table 4.20. Sample locations are shown in ***Appendix B***. As per the CEMP (***Appendix A***), legacy sites such as East and West Main Toe Drains, Main Embankment Seepage Collection Pond (MESCP) (E4) and Central Collection Sump (CCS) (E18) that no longer discharge into Hazeltine or Edney Creek have been removed. E11a (Springer Pit Supernatant) was a source of contact and discharge water under the 2016 *CEMP* and was sampled accordingly until the LTWMP discharge permit was approved in 2017 and dredging of the Springer Pit in January 2018, which made that location inaccessible. From 2018 to 2021, the Springer Pit was used for in-situ treatment and storage of water prior to transfer to the WTP and discharge. In 2022, dewatering of the Springer Pit commenced and mining resumed. Three dewatering wells were installed in the pit to facilitate pumping of interstitial water to a booster station, where it was sampled (E11c). The dewatering wells were used for a period in 2023. Once they were no longer required, the Springer Pit sump was once again developed and sampled (E11). Note that E19- Perimeter Embankment Till Borrow Pit (PETBP) was previously included as a surface contact water site, but in this report is discussed under Discharge System and Monitoring (Section 4.12).

E1a, previously E1, is the water chemistry sampling location for the TSF supernatant. The site, E1, was established in 1997 to monitor changes as it was the primary source of discharge water before the TSF embankment breach. No water was stored, or samples collected at the site after August 4, 2014. The TSF was operational once again in November 2016 and sampling resumed. Upon receipt of the 2017 *EMA* Permit 11678 amendment, the site name was changed to E1a to reflect the water chemistry post-TSF embankment failure.

Table 4.20 2023 Sampling events at contact water quality sites

Site	Site Identifier (EMS No.)	Frequency	
		Permit Requirement	Actual
E1a[(a)]	E225309	Monthly/Quarterly[(b)]	46

[(a)] Deposition of tailings into TSF is ongoing; TSF supernatant being used as reclaim water as of November 8, 2016. E1 has been replaced by E1a.
[(b)] Required monthly by the 2016 *CEMP* and quarterly by the 2018 and 2019 *CEMPs*.

Samples were submitted to ALS for analysis of:

- Physical parameters (pH, turbidity, TSS, total dissolved solids, and hardness);
- Anions and nutrients (alkalinity, sulphate, total nitrogen, nitrate, nitrite, ammonia, chloride, fluoride, total phosphorus, dissolved phosphorus, and ortho-phosphate);
- Organics (dissolved organic carbon); and
- Total and dissolved metals (metals suite as listed in the *CEMP*, ***Appendix A***).

Thirteen parameters of interest (POIs) were identified in the Chemical Characterization of the Proposed

Effluent for Discharge to Hazeltine Creek (Knight Piésold Ltd. 2009) based on site geochemistry and historical characteristics, as well as existing and projected waste and water management practices. To monitor changes in the effluent surface water quality, in the subsequent sections, these POIs were reviewed for each water quality site over time:

- **Physical Parameters**: Hardness, TSS;
- **Anions**: Chloride, sulphate;
- **Nutrients**: Nitrate, total phosphorus; and
- **Metals**: Dissolved aluminum, total cadmium, total and dissolved copper, total molybdenum, total and dissolved iron, total selenium.

Results for POI concentrations for the effluent sites are noted and included in tabular format in ***Appendix F***. Note that results below method detection limit (MDL) are represented as half (0.5x) the MDL in statistical calculations and graphs.

Water quality data, including summary statistics (number, minimum, maximum, mean, standard deviations, and method detection limit) are provided in ***Appendix F***.

4.10.1 Site E1a – Tailings Supernatant (E225309)

Water quality at this location was sampled 46 times in 2023. Graphs and results for a subset of parameters only for the post-breach years, are provided in ***Appendix F***. Notable observations in POI results are compared with data over the last five years (pre-breach: 2012-2014, and post-breach: 2019-2023):

Hardness: A general increase in concentration occurred after tailings deposition started post-breach in 2016. However, hardness (Expressed as CaCO3) concentrations are continuing to trend downward, stabilizing at around 400 mg/L, which is similar to levels seen prior to the breach during active mining. The 2014 mean hardness was 450.7 mg/L, and the mean hardness between 2019 and 2023 was 408.6 mg/L. The mean in 2023 was 412.9 mg/L, and the overall post-breach mean is 420.7 mg/L. The maximal hardness value measured from 2019 to 2023 was 717 mg/L, measured in October 2023.

TSS: Concentrations have remained stable post and pre-breach. The 2019 to 2023 mean was 6.18 mg/L, the 2023 mean is 7.53 mg/L and the overall post-breach mean is 7.45 mg/L. The maximum TSS post-breach is similar to pre-breach with concentrations of 46.9 mg/L and 54.9 mg/L, respectively.

Chloride: Concentrations remained similar pre- and post-breach during the period between 2008 and 2019, at around 20-35 mg/L. These concentrations fell markedly in early 2020, with concentrations between 3 and 17 mg/L. In 2023, chloride concentrations have increased but are still within the pre- and post breach range of 20-35 mg/L. The 2019 to 2023 mean value was 13.2 mg/L. The maximum measured value in between 2019 and 2023 was 30.7, recorded in February 2019.

Sulphate: Concentrations have remained stable post and pre-breach. The 2019 to 2023 mean was 477.9 mg/L. The overall post-breach mean of 493 mg/L is similar to, but lower than, the pre-breach mean of 542 mg/L. Since the resumption of TSF usage in 2016 until late 2023, sulphate concentrations have ranged from 400 to around 600 mg/L. In October, November and December 2023, sulphate concentrations increased to the 700-800 mg/L range. The maximum sulphate post-breach is 868 mg/L measured in December 2023.

Nitrate: Concentrations initially increased post-breach but have decreased markedly between 2017 and present, possibly due to the mine being in Care and Maintenance for much of that time. The maximum nitrate post-breach was 10.4 mg/L in February 2018 and steadily decreased through the end of 2021 to its lowest concentration of 0.0556 mg/L (pre-breach minimum was 4.93 mg/L). The 2019 to 2023 mean was 1.93 mg/L.

Total phosphorus: Concentrations have remained stable post and pre-breach. The 2019 to 2023 mean was 0.020 mg/L, while that in 2023 alone was similar, at 0.0158 mg/L. Two anomalously high recordings were sampled in November and December of 2021, at 0.087 and 0.118 mg/L, possibly a result of operational ramp-up and the resumption of blasting occurring at this time.

Dissolved aluminum: Concentrations have remained stable post and pre-breach (note that there are no data from February 2013 to 2014). The 2019 to 2023 mean was 0.0319 mg/L and the 2023 mean was 0.0302 mg/L. This is very similar to the overall post-breach mean 0.0302 mg/L (with the removal of outliers from March 2018 and April 2023). The pre-breach mean was 0.0215 mg/L. Concentrations of this compound are stable and do not display any particular trend.

Total cadmium: Concentrations have remained stable post and pre-breach as the vast majority of results were below detection limit. Between 2019 and 2023, only 21 of 142 samples were above detection limit; one in 2019, one in 2020, 11 in 2021, seven in 2022 and one in 2023. The increase in non-BDL samples in 2021 and 2022 could be perceived as a temporally increasing trend but is likely an artefact of a switch to weekly sampling; as opposed to monthly sampling as was performed in prior to March 2021.

Total copper: Concentrations have increased post-breach and were stabilizing in 2017 and 2018. The 2017 and 2018 annual means were stable at 0.019 mg/L. However, copper concentrations have varied widely between 2019 and 2023. In 2019 the annual mean was 0.028 mg/L, in 2020 the annual mean was 0.357 mg/L, in 2021 the annual mean was 0.193 mg/L, in 2022 the annual mean was 0.123 mg/L and in 2023 the annual mean was 0.122 mg/L. The overall post-breach mean of 0.109 mg/L is considerably higher than the pre-breach mean of 0.010 mg/L. In the period from 2019 to 2023, copper values were stable at approximately 0.02 mg/L from January to June 2019, then rose steadily to a peak value of 0.316 in May of 2020, before falling back to values around 0.08 in August to October 2020. Values subsequently spiked again, to 0.577 mg/L in November 2020, before falling steadily to approximately 0.1 mg/L in the summer of 2021. Copper values increased to 0.2 mg/L from November 2021 to February 2022 when they decreased to 0.1 mg/L. From March to December 2022, copper values decreased to 0.001 mg/L. Copper values remained

at similar concentrations throughout 2023 with a few slight increases experienced throughout the year. At the end of the five-year period, copper values in the TSF are again trending downward. These swings in copper concentration are likely to due to heap leachate being disposed of in the TSF on a periodic basis from 2019 to 2023. The recent decreasing trend in copper is likely the result of the resumption of milling and mining activities at the site in the fall of 2021.

Total molybdenum: Concentrations initially increased post-breach and have subsequently fallen and stabilized in 2020-2022. The 2023 annual mean was 0.206 mg/L compared to the 2022, 2021, 2020, 2019 and 2018 annual means of 0.160 mg/L, 0.140 mg/L, 0.158 mg/L 0.242 mg/L and 0.226 mg/L, respectively. The overall post-breach mean was 0.178 mg/L. The pre-breach mean was 0.184 mg/L. The maximum total molybdenum in 2023 was 0.246 mg/L and the maximum between 2019 and 2023 was 0.290 mg/L

Total iron: Concentrations have remained stable post and pre-breach. The 2019 to 2023 mean concentration of iron was 0.186 mg/L, and the mean in 2023 was 0.204 mg/L. These values can be compared to the 2022 annual mean of 0.190 mg/L, 2021 annual mean of 0.171 mg/L, 2020 annual mean of 0.188 mg/L, 2019 annual mean of 0.101 mg/L and 2018 annual mean of 0.184 mg/L. The overall post-breach mean is 0.189 mg/L and the pre-breach mean is 0.272 mg/L. The maximum total iron in between 2019 and 2023 is 1.19 mg/L.

Dissolved iron: Concentrations have remained below detection limits in pre- and post-breach results, except for three instances. One in December 2021, with a result of 0.047 mg/L, one in April 2023, with a result of 0.163 mg/L and another in May 2023 with a result of 0.036 mg/L.

Total selenium: Concentrations have remained approximately stable post and pre-breach. The 2019 to 2023 mean value was 0.026 mg/L, and the 2023 annual mean was 0.0274 mg/L. There appears to be a steady downward trend in selenium concentrations between January 2019 and 2021. Selenium concentrations measured in late-2021 were among the lowest since the breach, with values consistently below 0.02 mg/L from September to December 2021. Total selenium concentrations remained around 0.02 mg/L in 2022 and 2023.

Only three parameters have shown a relatively continuous increasing trend in concentration after post-breach deposition of tailings commenced. Total molybdenum and chloride have shown a general increasing trend, with total copper almost doubling in concentrations in post-breach and increasing significantly in 2020. Total copper has shown a decreasing trend in 2021-2023. Monthly monitoring was scheduled for E1a under the 2016 CEMP. Under the 2019 CEMP, the frequency has moved to quarterly, and tailings water is discharged through the WTP via the PETBP.

4.10.2 Long-Term Predictions

Kinetic rate information is an important component of drainage chemistry prediction that provides a

measure of the dynamic performance or "reactivity" of the material being tested. Stephen Day, MSc, PGeo, of SRK has been retained to interpret results of the ongoing kinetic-testing program and recommend additional testing, if required. SRK provided a report titled *Metal Leaching/ Acid Rock Drainage Characterization and Monitoring Program- 2023 Annual Report* is included in ***Appendix Q***. Additionally, SRK completed a report describing the derivation and use of the source terms (SRK, 2016) for the *TAR* submitted to ENV for the long-term water management application (Golder, 2016b).

The most recent data from kinetic testing from 2023 (***Appendix Q***) indicates that Pond Zone test water is increasing towards neutral pH. It is recommended this test be ceased based on positive results. Waste rock column tests appeared very stable and indicated low levels of weathering. Termination of this test is also recommended. It was recommended that humidity cell tests containing grey tailings released during the dam breach, and magnetite sand column tests continue. In addition, as NEZ Seep 1 is not representative of seepage from the NEZ Dump, it was recommended that an additional seep (NEZ Seep 3 was selected by MPMC Environmental personnel) be monitored quarterly. These recommendations can be found in full in ***Appendix Q***.

4.10.3 Heap Leach Research

In 2006, Mount Polley applied for an amendment to the *Mines Act* M-200 Permit allowing for the construction of a Heap Leach Pad and Copper Recovery facility. The amendment was granted on March 29, 2007. The *Mines Act* M-200 Permit requires that all monitoring data from the facility be included in this report.

In 2014, Mount Polley participated in a research project with Kemetco Research who has been developing a sulphur oxidation bioreactor system for potential use in generating sulphuric acid for copper oxide heap leaching. The heap leach at Mount Polley has been decommissioned until the research is complete. Three batch tests were started at Kemetco Research, but the project has been postponed since the TSF embankment breach. No samples were collected in 2023.

During Care and Maintenance, leachate is pumped from the facility into the mill for lime treatment. Lime is added to raise the pH to 8.2 to allow the dissolved copper to precipitate out of the solution. Lime treatment is a common practice during the operations phase as well. The leachate is then sent to the TSF once treated. Leachate is currently pumped to the concentrator building to supplement process water and ultimately reports to the TSF with tailings slurry.

Table 4.21 Heap leach sump level in 2023

Month	Heap Leach Sump Level (ft)
January 2023	13.275
February 2023	15.519
March 2023	16.785
April 2023	18.100
May 2023	19.267

June 2023	13.606
July 2023	16.606
August 2023	18.019
September 2023	13.450
October 2023	15.166
November 2023	7.607
December 2023	10.974

4.10.4 Sulphur Pile

Approximately 23,000 t of sulphur were acquired by MPMC from 2006-2008 to facilitate the production of sulphuric acid at the Heap Leach Pad. In 2014, elevated copper concentrations were discovered in the LD and, through an extensive investigation, traced back to NEZ Seep 1 and 2. Further investigations identified the sulphur pile as being a source of sulphuric acid which has leached into the underlying wast e rock (Litke, 2019). The rock has neutralized the acid, but it has resulted in elevated metal concentrations in the seepage. Research is ongoing into the geochemical characteristics of the affected rock. To prevent ongoing leaching, the sulphur pile was moved to the LCRS in October 2018. A sump was constructed at the base of the NEZ waste rock pile to collect the affected NEZ seeps. To isolate the seepage, dedicated sumps and pipelines were constructed to prevent the affected waters from reporting to the LD. Seepage water from NEZ Seeps 1 and 2 now report to the mill to supplement the process water supply. Once used in the concentrate processing the water reports to the TSF. Monitoring of the affected NEZ seeps will continue as part of the Source Control optimizations in *EMA* Permit 11678 Section 2.8.3.

4.11 Seepage Water Chemistry

An important component in determining and monitoring long-term chemical stability of drainage from the pits and waste rock dumps is water quality monitoring. Locations monitored by MPMC (in addition to sampling required under the *Mines Act* Permit M-200 and *EMA* Permit 11678 [refer to the CEMP in ***Appendix A***]), sampling periods, and sampling frequencies are provided in Table 4.22.

These water collection facilities and drainage monitoring locations are shown in ***Appendix B***. MPMC continued the bi-annual seep survey program of all rock waste dumps on site in 2023, with representative seeps being monitored monthly or quarterly, however numerous seeps stop flowing during dry periods. Seep monitoring locations are shown in ***Appendix B***. Note that when field parameters of adjacent seeps are consistent, typically only the seep with larger flow is sampled. Results are reported in ***Appendix F***. Collection of this data are used in long-term water quality predictions.

Table 4.22 Site drainage water quality monitoring locations, and sampling periods and frequencies

Sample Location	Drainage Area	Sampling Period	2016 *CEMP* Sampling Frequency	2018 *CEMP* Sampling Frequency	2019 *CEMP* Sampling Frequency
Cariboo Pit Sump (E8)	-	1997 – current	Bi-annually[1]	Bi-annually[1]	Bi-annually[1]

Perimeter Toe Drain (PTD)	TSF Perimeter Embankment toe drain	2009 – 2014	N/A	N/A	N/A
South Toe Drain (STD)	TSF South Embankment toe drain	2011 – current	Quarterly	Quarterly	Quarterly

[1] When pit is not storing water from other sources on site

[2] When barge in TSF is supplying reclaim water to mill; started sampling November 2016

No obvious trends in the water quality at the drainage location sampling sites have been observed. This is consistent with SRK ore characterization and geochemical source term reports (SRK 2015b; 2016; 2022; 2023).

4.12 Discharge System and Monitoring

The WTP is a Veolia ACTIFLO® system, which was commissioned in October 2015. Discharge began on December 1, 2015, and continues to present. MPMC commissioned an interim rental Veolia ACTIFLO® mobile WTP to increase discharge throughput and assist with management of onsite water inventory. Commissioning of the mobile WTP began on March 16, 2022, by Veolia automation and process technicians and was completed on April 1, 2022. The mobile WTP began discharging to Quesnel Lake on April 9, 2022 and ceased on May 10, 2023. The HAD-3 sample results from April 12, 2022 to May 10, 2023 represent the combined effluent from both plants. To properly represent end-of-pipe conditions, the sample port was located downstream from the wye where effluent from both plants was mixed. The total water discharged in 2023 was 4,439,062 m^3. The ADP (***Appendix I***) was prepared and submitted to ENV on July 30, 2018, and was approved on September 6, 2018. The ADP has been reviewed annually since that time, most recently in January 2023. It is likely that the ADP will be updated in 2024 to reflect the outcome of the currently ongoing permitting process, and the Numeric Performance Metric condition included in the most recent amendment to Permit 11678 (December 1, 2022).

4.12.1 Discharge System

Based on site water management objectives, site contact water can be conveyed to multiple locations around site to either discharge treated water via the WTP into the pipeline or store water as needed. Discharging treated water is often a priority for water management, as MPMC has a year-over-year positive water balance. Site contact water reports to the gravity-driven sections of the West Ditch or Long Ditch, which both ultimately flow to the CCS. Water in the CCS flows to the PETBP which is the source of the WTP influent. Pumping infrastructure also exists at the CCS and the PETBP such that it can be directed to the TSF. Water from the TSF is primarily pumped to the mill via the Booster Station to meet process requirements such as fire suppression, diverted to the Wight Pit for temporary water storage or be diverted to the CCS to increase the influent flow in the WTP. Storage of water in the TSF or pits can be used for:

- Process Plant milling requirements;
- Maintaining pond volume in the TSF to meet Quantified Performance Objectives
- In-situ treatment and particle clarification/ settling;
- Pit storage as contingency for large water events (freshet) or failures in the water management systems (power or equipment failure).

4.12.1.1 Treatment Works and Source Control Optimization

MPMC is required to assess and optimise the existing treatment process and works on a regular basis under Section 2.11 of *EMA* Permit 11678. MPMC undertakes ongoing maintenance, monitoring and improvements of water management systems and source control measures across the Mount Polley Mine site. This is a well-established part of operations at the Mine.

Numeric Performance Metric

As outlined in Section 2.11.2 (c) of Permit 11678, the NPM annual average of total copper is based on a 52-week rolling average, calculated using the average of 52 grab samples collected at HAD-3 when the WTP is discharging.

In 2023, the WTP samples achieved the NPM target 98% of the time, in 51 of 52 samples. This represents an improvement over 2022 when the NPM was achieved 71% of the time, 2021 when the NPM was achieved 43% of the time, which was an improvement over 2020, when the NPM was achieved 23% of the time. The NPM annual average of total copper was 0.00937 mg/L on December 21, 2023 and was trending down.

This year-over-year improvement in reaching the NPM target is a result of improved WTP optimization with the addition of the second ACTIFLO® WTP, and the establishment of pre-treatment processes developed as part of the water treatment train preceding the WTP; in-situ pit lake treatment and improved source control. Further discussion can be found in Progress Reports #12 and #13, included in ***Appendix W***.

NEZ Seeps Pipeline

The NEZ seeps have been identified as a source of high copper during flush events such as freshet and heavy rains and have contributed to permit exceedances in the effluent discharge in regard to copper levels on multiple occasions. A contributing factor used to be electrical power loss to the pump at the NEZ seeps. Previously, the NEZ seep water was pumped to the Wight Pit and upon power failure the pump stopped operating and NEZ seep water migrated to the Long Ditch and subsequently to the WTP influent pond (Perimeter Embankment Till Borrow Pond). Upgrades were made to this system in early-2021, and NEZ seep water now reports to Wight Pit on gravity drainage. The NEZ seep water has been reporting to the Wight Pit rockfill since April 2021.

4.12.1.2 WTP Operations

During treatment, the feed water of the WTP undergoes suspended solids removal using Veolia ACTIFLO® water treatment technology prior to discharge. The WTP doses the raw water with coagulant to a tank where a polymer is injected to create floc particles. Microsand is added to ballast the flocculants, which move on to another tank that allows them to swell and mature. The water flows to the next stage, which uses lamella to clarify the water and promote fast settling of the microsand ballasted sludge. The clarified water is discharged, and the sludge is separated from the microsand, which is reused. An on-line turbidity meter measures the turbidity every ten seconds and calculates the TSS using a calibrated factor based on a site-specific correlation between turbidity and TSS. If an on-line TSS measurement is above 11 mg/L for 10 minutes, or over 12 mg/L instantaneously, an alarm sounds to alert the operator and the WTP automatically goes into recirculation mode and ceases discharge.

In 2021, due to supply chain issues, a change was made to the polymer used in the WTP. Prior to July 2021,

the product "A-2501 polyclear" was used for treatment. From this point onward, the analogue product "Magnafloc 338" was used instead. Toxicity testing on this new polymer product was performed by Golder and Nautilus Environmental prior to its adoption at the WTP, finding that the product is not acutely toxic at the tested concentrations, which exceed those used in water treatment (Golder 2021).

In 2023, there were periodic times when the WTP was shut down or put into recirculation mode due to various issues described in Table 4.23. More shutdowns occurred in 2023 relative to past years because of limited water onsite for discharge. The annual average discharge rate was 0.207 m^3/sec, or 17,895 m^3/day and daily maximum discharge rates ranged from 0 m^3/day to 31,811 m^3/day. According to the *EMA* Permit 11678, the authorized annual average discharge rate is 29,000 m^3/day and a daily maximum discharge rate of 52,000 m^3/day. Daily maximum rates are provided in ***Appendix H***.

Table 4.23 Instances and reasons for discharge stoppages in 2023

Date	WTP	Discharge Action	Reason
07-Jan-23	Permanent	Ceased	Malfunction of the HMI
08-Jan-23	Permanent	Resumed normal operation	Repair of the HMI
15-Jan-23	Mobile	Ceased	Low water levels in the PETBP
17-Jan-23	Permanent	Ceased	Maintenance
18-Jan-23	Permanent	Resumed normal operation	Maintenance complete
19-Jan-23	Mobile	Resumed normal operation	Suitable water levels in the PETBP
09-Feb-23	Mobile	Ceased	Reduced throughout as a result of high turbidity in the influent
11-Feb-23	Mobile	Resumed normal operation	Reduced turbidity
14-Feb-23	Mobile	Ceased	Low water levels in the PETBP
18-Feb-23	Mobile	Resumed normal operation	Suitable water levels in the PETBP
22-Feb-23	Mobile	Ceased	No night shift personnel to operate the plant followed by a mechanical failure of the polymer mixing system
24-Feb-23	Mobile	Resumed normal operation	Repair of the polymer mixing system
21-Mar-23	Mobile	Ceased	High turbidity in the influent
24-Mar-23	Mobile	Resumed normal operation	Reduced turbidity

Date	WTP	Discharge Action	Reason
02-Apr-23	Mobile	Ceased	Low water levels in the PETBP
08-Apr-23	Mobile	Resumed normal operation	Suitable water levels in the PETBP
11-Apr-23	Permanent	Ceased	Site wide power outage
11-Apr-23	Mobile	Ceased	Site wide power outage followed by a lack of polymer reagent
14-Apr-23	Mobile	Resumed normal operation	Polymer reagent replenished
22-Apr-23	Permanent	Ceased	Maintenance and TSS sensor replacement
23-Apr-23	Mobile	Ceased	Maintenance and TSS sensor replacement
24-Apr-23	Permanent/ Mobile	Resumed normal operation	Maintenance complete
05-May-23	Permanent	Ceased	Unknown
05-May-23	Mobile	Ceased	Sludge line pump fault alarm

4.12.1.3 Water Treatment plant Costs

As required by M-200 Permit Section C.6(b)(ii); the total annual costs associated with the Veolia WTP is $1,383,564.94. The breakdown is located in Table 4.24 below.

Table 4.24 – 2023 WTP costs

	2023 Costs		Comments
Power (Electric)	$	154,916.62	
Labor	$	488,608.43	4 operators
Polymer	$	73,664.64	
Flocculant	$	66,482.69	
Clarifier Sand	$	86,534.83	
Rental	$	495,348.72	Temporary rental unit from Veolia and removed from site May 2023
Trucking / Freight	$	18,009.01	
Total per annum	$	1,383,564.94	

4.12.1.4 Outfall and Pipeline Commissioning and Inspection

As required by Section 3.5 of *EMA* Permit 11678 (***Appendix A***), routine visual inspection of the outfall into Quesnel Lake, along with the pipeline, must be conducted. MPMC conducts routine monthly inspections and maintains records of these routine inspections.

A comprehensive inspection and testing program of the outfall must be conducted, and an underwater inspection of the diffuser every 5 years. A comprehensive inspection of the diffusers was conducted on September 5, 2018 and November 2, 2023, and next needs to occur by the end of 2028. The inspection at the Quesnel Lake diffusers has been conducted annually from 2015 to 2023 by a QP. The 2023 detailed inspection occurred on September 18.

The annual pipeline inspection report found the pipeline to be in generally good condition, but with some recommendations for improved performance or preventative maintenance.

4.12.2 Discharge Monitoring

This section provides an assessment of the compliance with the amended *EMA* Permit 11678 limits with respect to the data collected at the WTP discharge end-of-pipe site (HAD-3) and at the edge of the initial dilution zone (IDZ) site (QUL-58) in Quesnel Lake. These data were collected in accordance with the approved CEMP (***Appendix A***) and the ADP (***Appendix I***). This compliance is primarily based on the permit conditions stipulated in the *EMA* Permit 11678 dated April 7, 2017, October 2, 2018, February 1, 2020, December 31, 2020 and December 1, 2022. This section addresses the *EMA* Permit 11678 Section 4.2 requirements:

- *(h) a summary of any non-compliance with the permit and other incidents that may have led to*

impacts to the receiving environment;

- *(m) a comparison of monitoring data with water quality guidelines, predictions, and targets.*

This discharge requires monitoring and reporting under MDMER to Environment and Climate Change Canada. These activities occurred in 2023 as outlined in the MDMER. Table 4.25 outlines the number of sampling events at each site in 2023 (a map of these locations is provided in ***Appendix B***).

Table 4.25 Sampling events in 2023 at discharge monitoring sites

Site Name	Site Identifier (EMS No.)	Full Sample Suite Frequency 2016 *CEMP*	Full Sample Suite Frequency 2018 *CEMP*	Full Sample Suite Frequency 2019 *CEMP*	2023 Sampling Events
E19	E305050	Weekly [(a)]	Weekly [(a)]	Weekly [(a)]	52
HAD-3	E304230	Weekly [(a)]	Weekly [(a)]	Weekly [(a)]	52
QUL-57	E304874	Weekly/Monthly [(b)]	4 times per year	4 times per year	5
QUL-58	E304876	Weekly/Monthly [(c)]	4 times per year	4 times per year	9
QUL-59	E304875	Weekly/Monthly [(b)]	4 times per year	4 times per year	5
QUL-2a	E303020	Monthly	4 times per year	4 times per year	5[(f)]
QUL-18	E303019	Monthly	4 times per year	4 times per year	4
QUL-120a	E303022	Seasonally	Bi-annually	4 times per year[(e)]	4
QUR-11	E306454	Monthly	Removed [(d)]	Removed	1[(g)]

[(a)] When discharging.

[(b)] Limnological profiles occur weekly for 5 weeks during spring and fall turnover; monthly all other times of the year.

[(c)] Samples and limnological profiles occur weekly for 5 weeks during spring and fall turnover; monthly all other times of the year.

[(d)] Effective as of on November 9, 2018 with the acceptance of the 2018 *CEMP*.

[(e)] Stipulated in CEMP Approval letter issued in February 2021.

[(f)] Additional sampling was conducted at QUL-2a on June 19, 2023 because of a total phosphorus exceedance at QUL-58 on June 6, 2023.

[(g)] Supplemental sampling conducted.

4.12.2.1 Permit Compliance

The *EMA* Permit 11678 requires the following regulatory compliance be met:

1. Effluent chemistry data from end-of-pipe at HAD-3 (WTP outflow) must be equivalent to or less than specified values in Section 1.2.5 of the Permit (***Appendix A***). In addition, the trigger and response plan required under Section 2.8 (c) must show how the concentrations of the parameters meet the objectives for the "Edge of Quesnel Lake Initial Dilution Zone (IDZ)" in Quesnel Lake specified in Section 1.2.5 of the Permit.
2. Effluent must meet the acute toxicity requirement of less than 50% mortality in 100% effluent in

96-hour rainbow trout (*Oncorhynchus mykiss*) and *48-hour Daphnia magna* toxicity tests (*EMA* Permit 11678 Section 3.3 and Section 4.5). These results are presented in Section 4.12.3.

4.12.2.2 Influent Chemistry – E19

In accordance with the CEMP, E19 (WTP feed) water samples were collected weekly and concurrently with HAD-3 samples during effluent discharge. E19 represents the water entering (influent) into the WTP; the influent is pumped from the PETBP which collects the contact water from the Mount Polley Mine site. The influent results are compared with the effluent results to gauge treatment efficiency. The WTP monitors the influent flow rate, turbidity, and temperature.

4.12.2.3 Effluent Chemistry – HAD-03

To meet the requirements of the *EMA* Permit 11678 and MDMER requirements, water chemistry samples were collected weekly at the end-of-pipe site at the WTP outlet (site HAD-3) when discharging. This requirement was met by the collection of 52 samples at HAD-3 in 2023. Note that the mobile WTP was commissioned in April 2022, and samples collected after April 12 included treated water from both the permanent and mobile plants. The mobile WTP was decommissioned on May 10, 2023, and the samples collected thereafter included treated water from the permanent plant only. There were periodic times when there was no discharge; see Table 4.23 for details. All parameters were met or were below the concentration limits in Section 1.2.5 of the Permit except for a few instances (Section 4.12.2.4).

The permit limit for total copper according to Section 1.2.5 of the *EMA* Permit 11678 is 0.033 mg/L. There were no sampling events in 2023 where total copper exceeded the permit limit (Section 4.12.2.4). The maximum result for total copper at HAD-3 in 2023 was 0.0193 mg/L on April 25, 2023; the annual average was 0.00959 mg/L. Results for the influent and effluent are shown below in Figure 4.11.

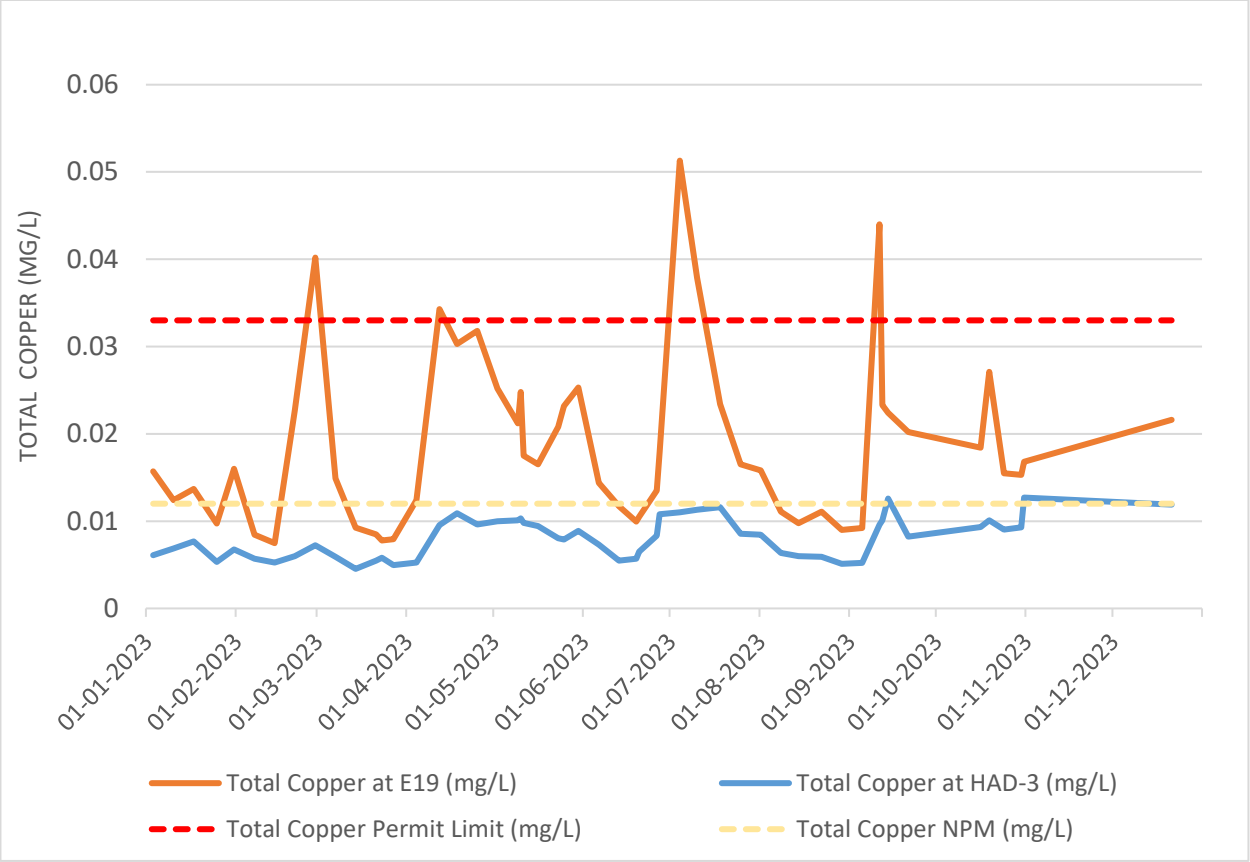

Figure 4.11 Total copper concentrations in influent (E19) and effluent (HAD-03) in 2023

There were no exceedances of TSS in 2023. The maximum total TSS limit must be equivalent to or less than 30 mg/L with a monthly average equivalent to or less than 15 mg/L. Results for influent and effluent are shown in Figure 4.12.

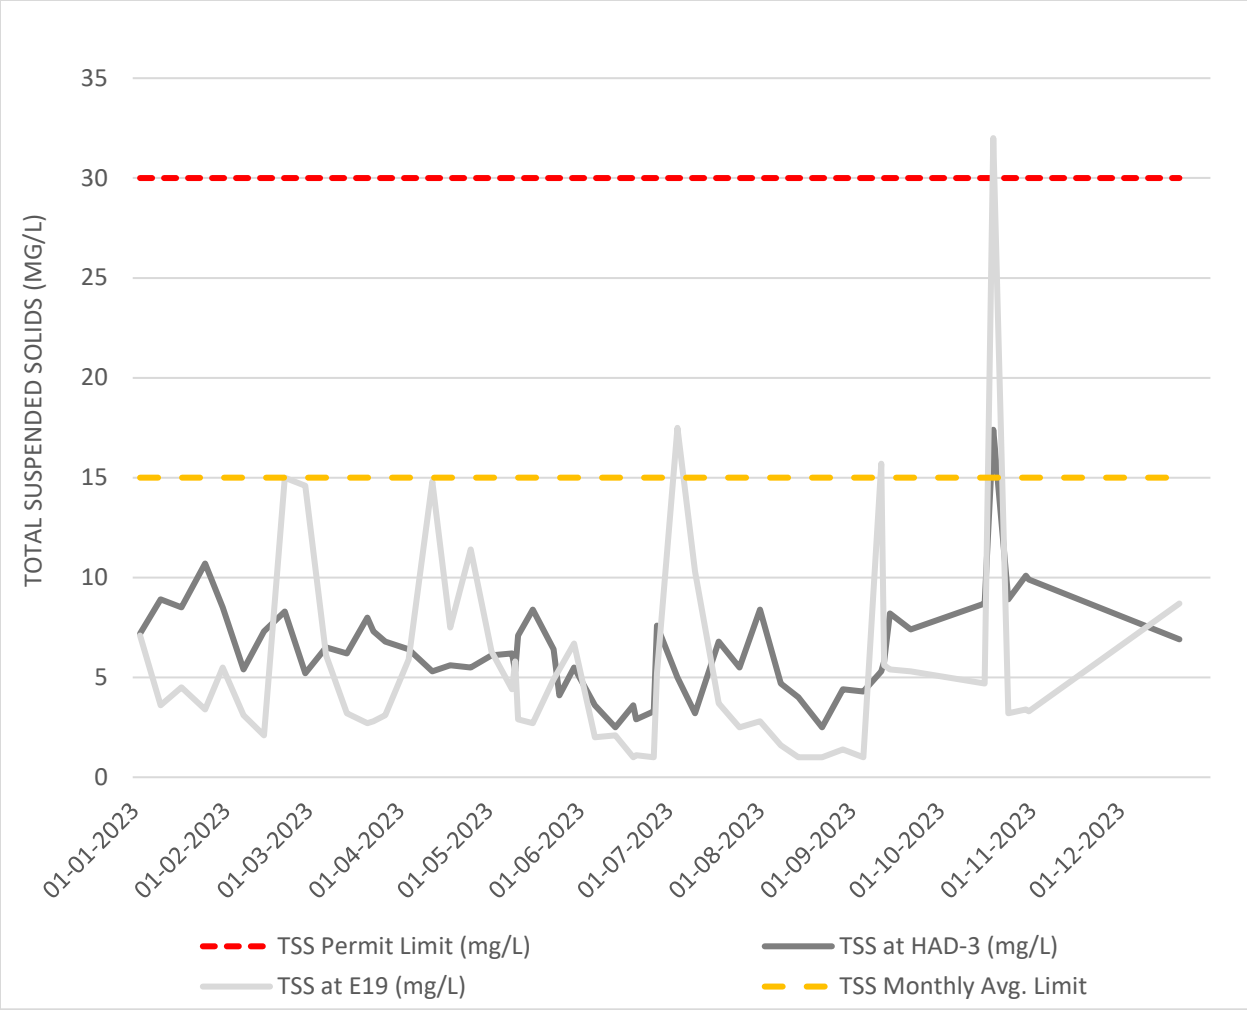

Figure 4.12 Total suspended solids concentrations in influent (E19) and effluent (HAD-03) in 2023

4.12.2.4 HAD-03 Permit Limit Exceedance Events

In 2023, there were no instances where results from HAD-3 samples were above the permit limits. However, there were two instances where the sulphate results from HAD-3 were within 80% of the permit limit prompting a Level 1 Trigger per MPMC's ADP.

Sulphate

Permit 11678 ADP Level 1 Triggers

- Sulphate was within 80% of the Permit 11678 limit in the August 1 and 8, 2023 HAD-3 samples. Upon receipt of the August 1, 2023 HAD-3 sample results on August 9, 2023, priority analysis of the August 8, 2023 HAD-3 sample was requested from the laboratory. The August 8, 2023 HAD-3 sample results were received and reviewed on August 10, 2023, and yielded a sulphate concentration which is within 80% of the Permit 11678 limit. At this time, a Level 1 Trigger Response

per MPMC's Annual Discharge Plan was initiated. The WTP throughput was reduced by 20% and the Ministry of Environment and Climate Change Strategy and Public Liaison Committee were notified of the Level 1 Trigger. An additional sample was collected at HAD-3 on August 14, 2023 and priority analysis requested from the laboratory. Results were received on August 16, 2023 and the sulphate concentration was below 80% of the Permit 11678 limit. In spite of the reduction in sulphate observed on August 16, 2023, management at Mount Polley Mine maintained the WTP throughput at 80% for the remainder of August.

- Sulphate concentrations were within 80% of the permit limit in the October 16 and October 19, 2023 HAD-3 samples; however, the WTP was in recirculation mode and not discharging. All parameters in the October 24, 2023 sample were below the permit limits and 80% thresholds and as such the WTP resumed normal discharge on October 30, 2023.

4.12.2.5 Plume Dispersion Model

Tetra Tech Inc. (Tetra Tech) was retained by MPMC to assess the long-term and far-field fate of effluent discharged from the diffusers in Quesnel Lake. Tetra Tech applied the existing hydrodynamic model of Quesnel Lake to simulate effluent concentrations throughout the lake as a result of the discharge. After the simulations were completed, MPMC requested advice with respect to the likely position of the effluent plume by month, to support monitoring in the field (Tetra Tech, 2016).

In 2017, Tetra Tech was retained to determine the relationship between the volumetric dilution by a dilution test and dilution calculated from observed specific conductivity from limnological profiles in Quesnel Lake. The results improved the confidence of the estimated dilution factor applied to the profiles. Tetra Tech ran the near-field model to discuss the plume width and dilution and concluded that there was only a 3% chance of detecting the plume at the IDZ. In addition, the field models suggest the plume concentrations are generally less than 1% at the edge of the IDZ (MPMC, 2018a). In 2018 and 2019, Tetra Tech was requested to conduct analyses of the limnological profiles and data from Quesnel Lake and provide conclusions and recommendations in order to better understand the lake circulation, and the interaction of the lake with the effluent discharge. Tetra Tech's 2018 and 2019 reviews identified some of the specific conductivity spikes observed at shallower depths stemmed from surrounding creek sources. Other observations noted that the effluent's density during certain periods of the year may be greater than originally modeled. This may be contributing to a gradual increase of dilute effluent under the thermocline and is expected to flush out during the spring and fall overturns (Tetra Tech, 2018; Tetra Tech, 2019).

To support an Environmental Effects Monitoring study, as required by MDMER, MPMC retained DWB to perform additional effluent plume dilution modelling in 2020-2021. Using the CORMIX software, this model utilized effluent volume and water quality data from 2015-2021, as well as lake profiles in Quesnel Lake, to model both discharge and receiving environment conditions as accurately as possible (***Appendix N***). This model was validated successfully using conductivity data from Quesnel Lake sites near the discharge point. Three different seasonal scenarios are modelled, to represent different limnological profiles in the lake with differing depth and strength of stratification. The finding was that under the modelled scenarios, effluent

concentrations rarely exceed 1% volumetric concentration beyond 100m from the discharge point. The modelled concentrations in excess of this threshold were between 1.01% and 1.09%. The highest concentrations beyond 100 m distance are found when the thermocline in Quesnel Lake is deep in the profile, trapping effluent in a narrow layer near the bottom of the lake.

4.12.2.6 Receiving Environment Chemistry – Quesnel Lake

The receiving environment for the water discharge plan is Quesnel Lake and further downstream Quesnel River. In accordance with the CEMP, (see Table 4.25), monitoring at the edge of the IDZ, site QUL-58, in Quesnel Lake occurred at least 4 times per year, with intensive sampling during overturn periods, when treated effluent was discharging.

In situ limnological profiles, Secchi measurement (see Section 4.15.2) and grab samples were collected for water chemistry at the inferred centerline of the effluent plume (when discharging) at the compliance site QUL-58 (when weather conditions were safe). A reasonable amount of effort was spent looking for the discharge plume by observing any increases in specific conductivity. If the plume was detected, grab samples were taken at surface (QUL-58-S), 5 m above the plume (QUL-58-AP), middle of plume (QUL-58-MP), 5m below the plume (QUL-58-BP), and at bottom (QUL-58-B), with additional profiling at supplemental stations, QUL-57 and QUL-59, located at the edge of the IDZ, 25 m on either side of QUL-58 (plume centerline). If the plume could not be detected, then sampling occurred at the default QUL-58 site at the surface (QUL-58-S), bottom (QUL-58-B), mid-depth (QUL-58-MID) (if no thermocline) or 1 m above (QUL-58-AT) and below (QUL-58-BT) the thermocline (if present).

In 2023, there were 9 sampling events at edge of the IDZ (QUL-58). The plume may have been detected during the field investigations along the IDZ on May 17, May 25, May 30, June 6, June 27, September 14 and October 31, 2023 when the WTP was discharging treated effluent.

Table 4.26 Effluent discharge condition during IDZ sampling at QUL-58

Date sampled	Treated effluent condition
10-May-23	Discharging
17-May-23	Discharging
25-May-23	Discharging
30-May-23	Discharging
06-Jun-23	Discharging
19-Jun-23	Not discharging
27-Jun-23	Discharging
14-Sep-23	Discharging
31-Oct-23	Discharging

Permit Limits at the edge of Quesnel Lake IDZ

The amended *EMA* Permit 11678 includes compliance limits at the edge of the Quesnel Lake IDZ. There was one instance where total phosphorus exceeded the concentration limit in Section 1.2.5 of the Permit (***Appendix H***).

Permit 11678 ADP Level 3 Trigger

On June 6, 2023, MPMC Environmental Department staff collected routine water samples at the discharge point of the WTP into Quesnel Lake, identified as QUL-58, and referenced as E304876. This data was reviewed by MPMC staff on June 19, 2023 at approximately 9:00am. At this time, it was confirmed that the sample results for total phosphorus at QUL-58-AP (above plume) and QUL-58-MP (mid plume) were 0.0378 mg/L and 0.0126 mg/L, respectively, both of which exceeded the EMA Permit 11678 edge of Quesnel Lake Initial Dilution Zone (IDZ) limit of 0.010 mg/L. MPMC staff notified the Director and site management, and put the WTP into recirculation mode immediately. These elevated total phosphorus concentrations initiated a Level 3 Trigger: Exceedance of Receiving Environment Trigger Levels- Monitoring and Response as per the MPMC 2022 Annual Discharge Plan (ADP), Section 5.1.2.1.

Samples were collected at QUL-58 and the background site QUL-2a (E303020) on June 19, 2023 and priority service was requested from the lab. A sample was also collected from the WTP before it was put into recirculation on June 19, 2023. The results from the samples collected on June 19, 2023 were received by email on June 21, 2023 and reviewed by MPMC. The sample results indicated total phosphorus concentrations of 0.0036 mg/L at QUL-58-AP and 0.0029 mg/L at QUL-58-MP, which are below the permit limit of 0.010 mg/L. The samples collected at QUL-2a, also yielded total phosphorus concentrations less than the permit limit. Modelled QUL-58 data was compared to the receiving environment trigger levels with no exceedances identified. The Director was notified via email on June 21, 2023 and the WTP resumed normal operation in accordance with the ADP on June 22, 2023.

In the *Permit 11678- Total Phosphorus Exceedance at QUL-58, February 26, 2019- Follow Up Report* previously submitted to ENV, it was noted that investigations from 2016 and 2017 revealed that the elevated phosphorus in Quesnel Lake was the result of an equipment cleaning agent containing phosphate. The cleaning agent was replaced with a non-phosphate cleaner. It was also noted in the February 26, 2019 follow up report that the elevated total phosphorus concentrations in Quesnel Lake in 2018 were suspected to have been from Hazeltine and Edney Creeks.

Total phosphorus data from 2019 to 2023 supports the belief that the higher concentrations of phosphorus in Quesnel Lake are coming from Hazeltine and Edney Creeks. Four of the 6 total phosphorus concentrations recorded at EDC-01 (Edney Creek outlet) in 2019 and 2020 were above the permit limit with an average of 0.0177 mg/L. The outlet of Edney Creek changed from EDC-01 to EDC-01a in 2021. Seventeen of the 29 total phosphorus concentrations recorded at EDC-01a in 2021-2023 were above the permit limit with an average of 0.0136 mg/L. The outlet of Hazeltine Creek to Quesnel Lake changed from HAC-12 to HAC-01c

in 2018 and the WTP was no longer discharging into Hazeltine Creek. The maximum concentration of total phosphorus at HAC-01c in 2019 and 2020 was 0.041 mg/L in May 2020 and the average was 0.018 mg/L. The outlet of Hazeltine Creek to Quesnel Lake changed from HAC-01c to HAC-08 in 2021. Eighteen of the 28 total phosphorus concentrations recorded at HAC-08 in 2021-2023 were above the permit limit with an average of 0.0146 mg/L. The maximum concentration of total phosphorus at HAC-08 was 0.0435 mg/L in August 2022.

Historical total phosphorus data from Horsefly River from 2016 to 2021 also indicates that higher concentrations of phosphorus in Quesnel Lake are the result of tributary inputs to the lake. Ten of the 12 total phosphorus concentrations recorded at HOR-2 (Horsefly River outlet) were above the permit limit with an average of 0.025 mg/L.

HAD-3 total phosphorus concentrations fluctuated above and below 0.010 mg/L from 2018 to 2023 with an overall maximum of 0.0305 mg/L in May 2023, and averages of 0.0093 mg/L in 2019, 0.0104 mg/L in 2020, 0.0069 mg/L in 2021, 0.010 mg/L in 2022 and 0.015 mg/L in 2023.

HAD-3 results were above 0.010 mg/L when total phosphorus at the IDZ was above the permit limit, except at the time that the July 9 and 25, 2019, June 9, 2020 and June 6, 2023 Quesnel Lake samples were collected.

MPMC will continue to monitor total phosphorus concentrations of the effluent at the discharge point and at the Quesnel Lake IDZ.

ADP – Trigger Response Plan

The ADP was submitted to ENV on July 30, 2018 as required per Section 2.7 of *EMA* Permit 11678 and accepted on September 6, 2018 (***Appendix I***). The permit was amended on October 2, 2018 to reflect the changes brought forth with the updated ADP (***Appendix A***). The major requirement of the ADP was to include a TRP, which outlines the steps in the event that the water quality results are within 80% of the limits at HAD-3 and/or exceed permit limits at HAD-3 and/or QUL-58. The ADP was reviewed in 2019, 2020, 2021, 2022 and 2023; however, updates were not made and therefore, the plans were not resubmitted to ENV.

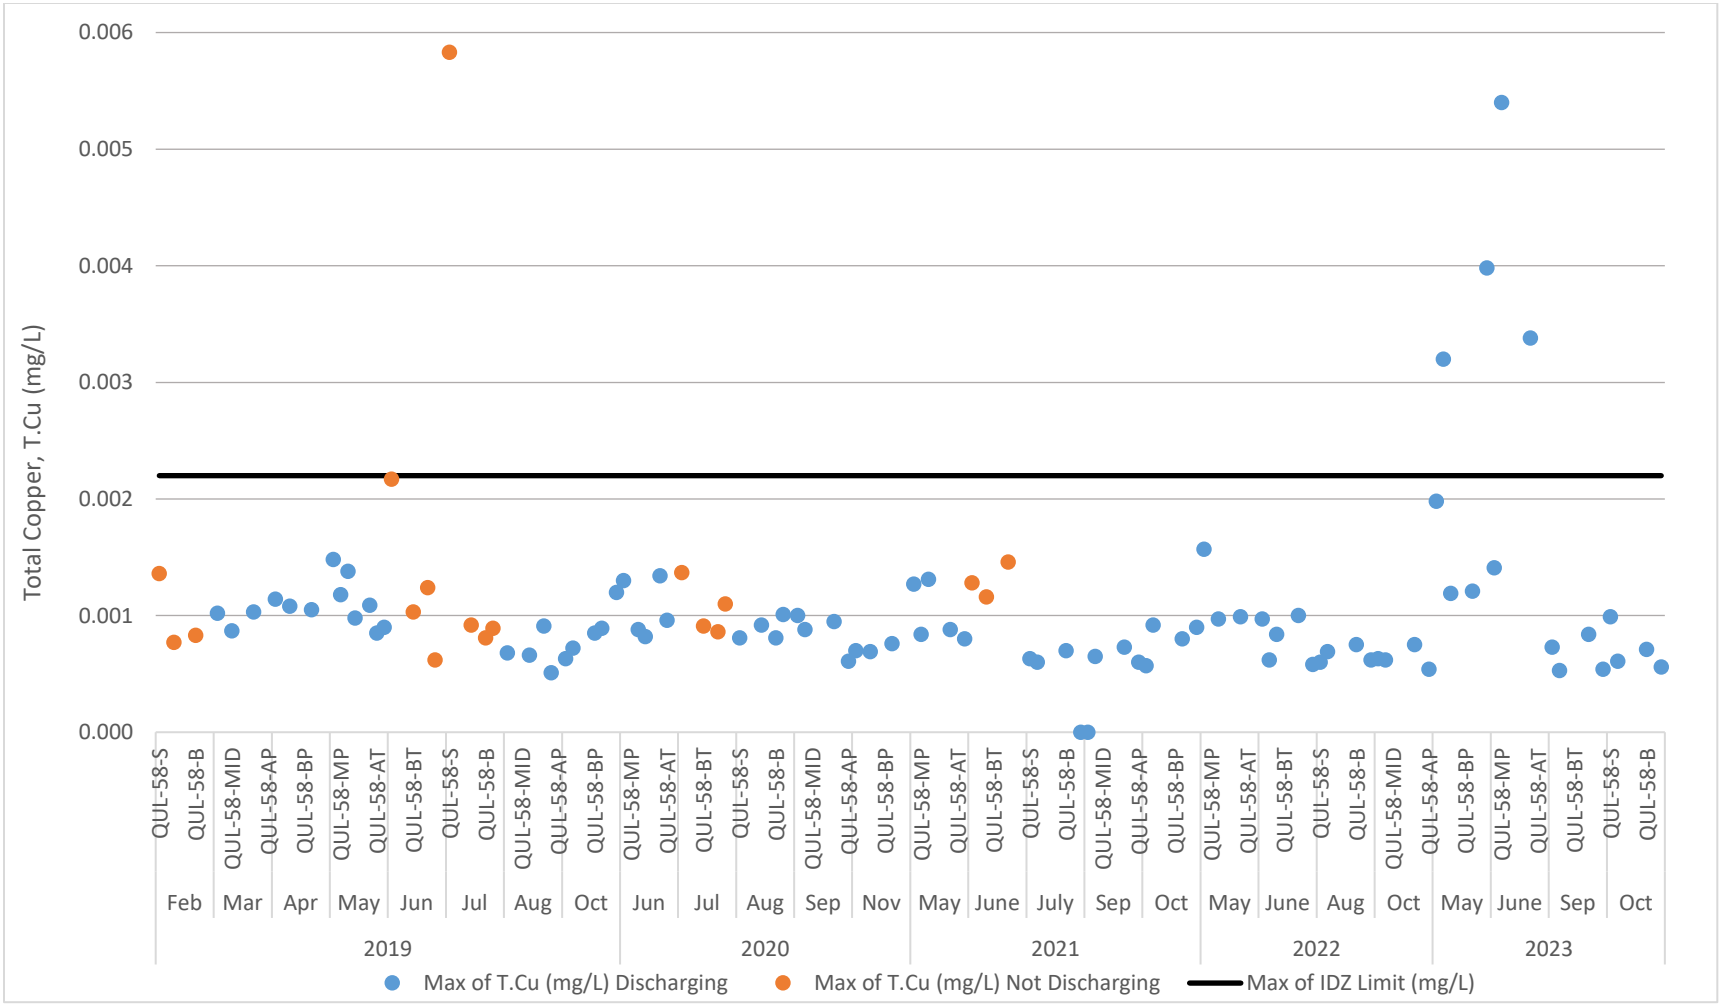

Figure 4.13 Total copper results at the IDZ (QUL-58) from 2019-2023

In addition, the ADP contains an analysis of the remaining capacity of Quesnel Lake using the dispersion model and background concentrations (Figure 4.14). MPMC maintains this tool to check if permit limits and water quality guidelines are being met at the IDZ without monitoring on the lake during unsafe conditions (***Appendix I***).

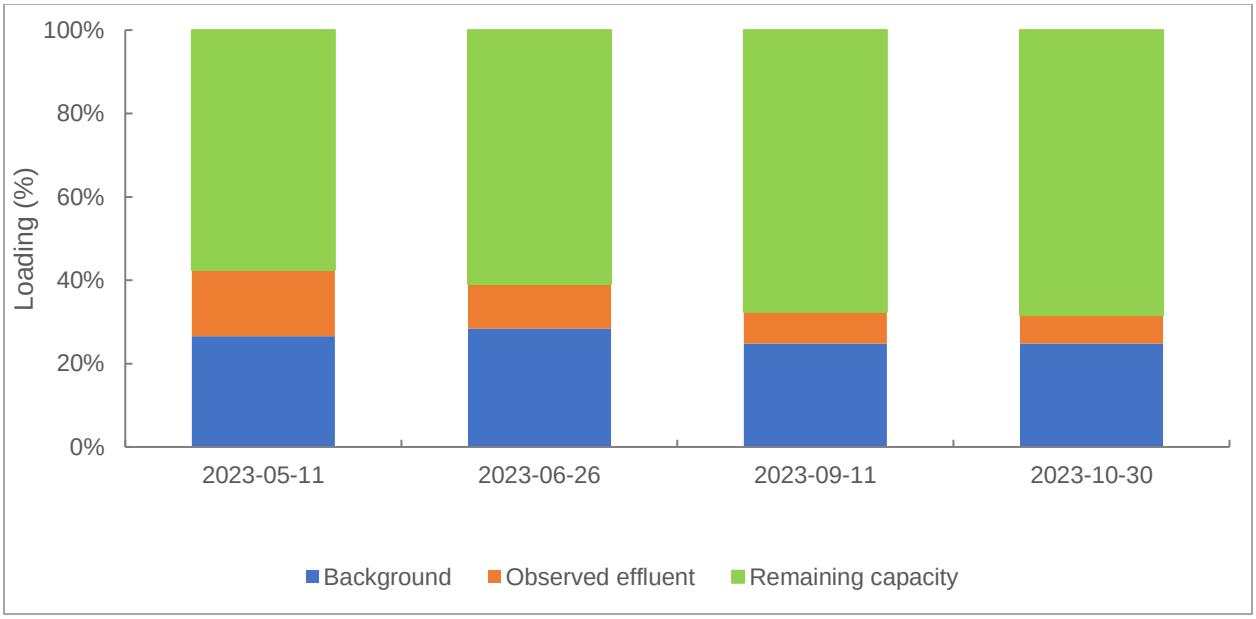

Figure 4.14 Calculated assimilative capacity of total copper on a daily basis for 2023

Further to the ADP, Golder completed two memos: 2023 Verification of Near-Field Modelling in Quesnel Lake and a Comparison of Water Quality Model Predictions and 2023 Measured Concentrations-Mount Polley Mine (***Appendix J***). These documents provided updates to the previous near field dispersion modelling validation and water quality models at the discharge with 2023 data. The first memo involved calculating the dilution factors in Quesnel Lake during periods of discharge and no discharge from the WTP. The calculated dilution factors ranged from 40 to above 100 when the discharge was active. These results confirm the conservative model predictions (***Appendix O***). The second memo compares the 2023 data with predictions described in the Water Management Plan Report (Golder, 2020a). The comparison indicates the measured concentrations are below model predictions and *EMA* Permit 11678 limits with some exceptions (***Appendix O***).

BC WQG at the edge of Quesnel Lake IDZ

Short-term maximum and long-term average BC WQG for aquatic life concentrations were compared with the water chemistry data from QUL-58. These limits are not considered compliance limits as MPMC is regulated with *EMA* Permit 11678 requirements at the IDZ. In 2023, dissolved copper (Figure 4.15) and other parameters for the acute BC WQGs for aquatic life were met, including total phosphorus (Figure 4.17).

Note that samples were taken four times per year at QUL-58, with annual intensive sampling during spring turnover (dependent on weather conditions and safety). As summarized in Table 4.25, spring intensive sampling occurred during May-June 2023. This 5-samples-in-30-days event can be compared to chronic WQGs (Figure 4.15). The data in Figure 4.15 are depth-integrated average concentrations, which is necessary because sample depths are not consistent, varying depending on thermocline presence, whether the plume is encountered, and how deep the plume is. Note that all concentrations from QUL-58 were below the short-term maximum BC WQG for total copper in 2023 except for QUL-58-S, QUL-58-MID and QUL-58-B on May 11, 2023. All concentrations from QUL-58 were above the long-term average BC WQG for total copper except for samples collected on September 14 and October 31, 2023, and the sample collected from above the plume on June 27, 2023. Figure 4.16 shows acute guidelines and measured concentrations data for 2023.

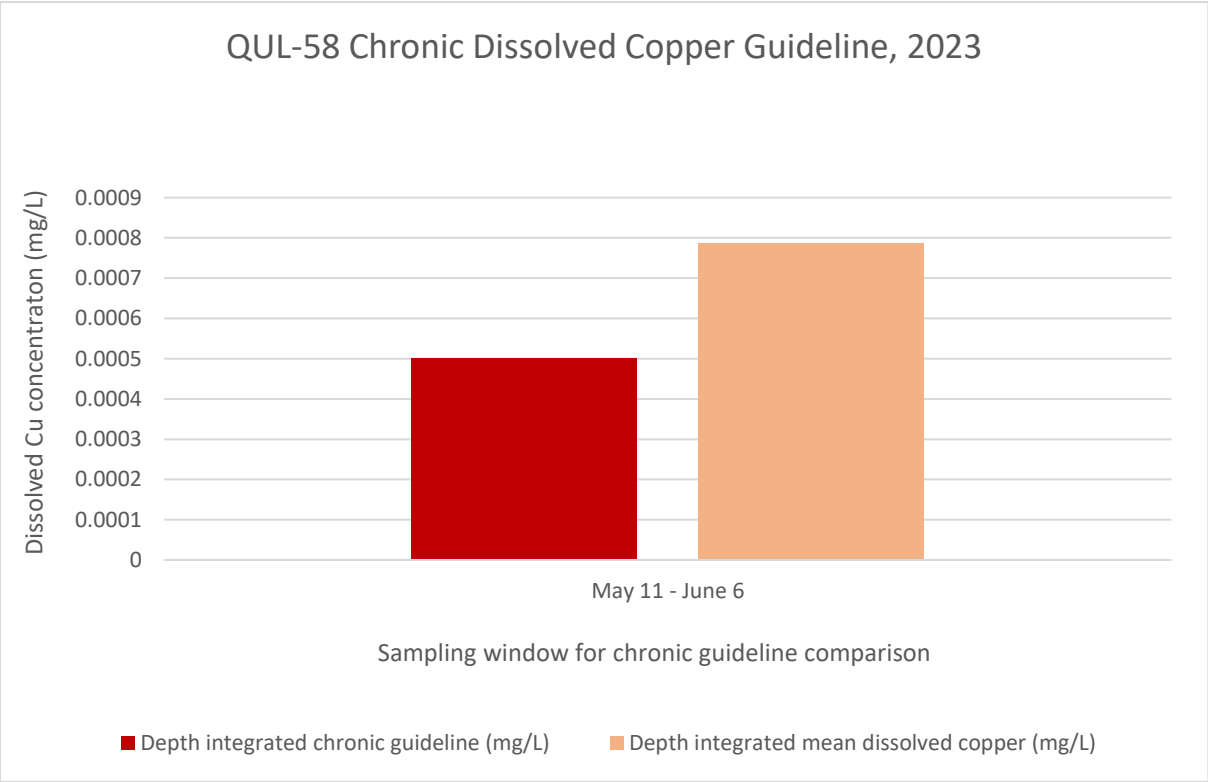

Figure 4.15 Chronic average BC WQG for aquatic life dissolved copper concentrations at QUL-58 in 2023

When comparing QUL-58 copper values to the acute guidelines, as shown in Figure 4.16, dissolved copper levels from 2023 are always below the applicable WQG values with the exception of the surface sample collected on June 27, 2023. Depth integration is not performed for comparison with acute WQGs because spatial and temporal averaging is not required, and individual point values can be compared to the WQG.

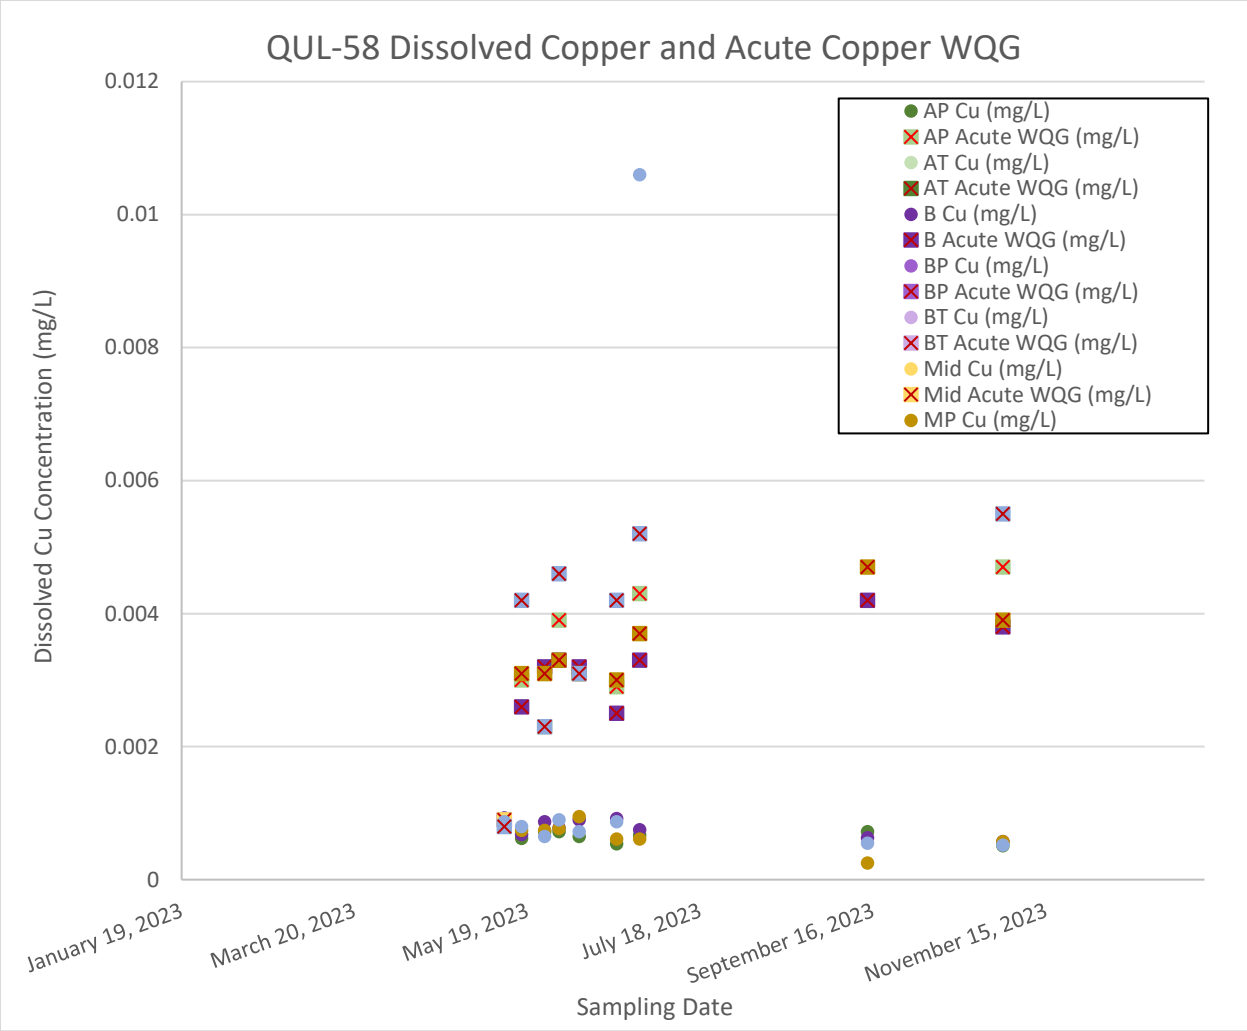

Figure 4.16 Acute BC WQG for aquatic life dissolved copper concentrations at QUL-58 in 2023

Historically, total phosphorus in Quesnel Lake and at QUL-58 has often failed to meet the BC WQG for aquatic life in lakes (where salmonids are the predominant fish species). The BC WQG limit is a range from 0.0050 mg/L to 0.0150 mg/L (ENV, 2021) and in 2023, the monthly mean results range from 0.00282 mg/L to 0.00709 mg/L at QUL-58 (including data from the surface, above plume or above thermocline sites [representing the WQG qualifiers]). While it has met the BC WQG during all 2023 sampling events, except for the above plume sample on June 6, 2023, the total phosphorus limit is only applicable during spring overturn at the epilimnetic water if residence time exceeds 6 months (according to the BC WQG for total phosphorus – nutrients and algae [ENV, 2022]).

Total phosphorus measurements at QUL-58 in 2023 are shown in Figure 4.17, in comparison to the WQG. Note that all depths are shown (and not distinguished), and many samples in this chart do not technically apply temporally to the WQG, but the full data set is shown for explanatory purposes. As mentioned above, while total phosphorus met the WQG during all sampling events at QUL-58 in 2023 with the exception of the above plume sample on June 6, 2023, the total phosphorus limit is only applicable during spring

overturn at the epilimnetic water if residence time exceeds 6 months (according to the BC WQG for total phosphorus – nutrients and algae [ENV, 2022]).

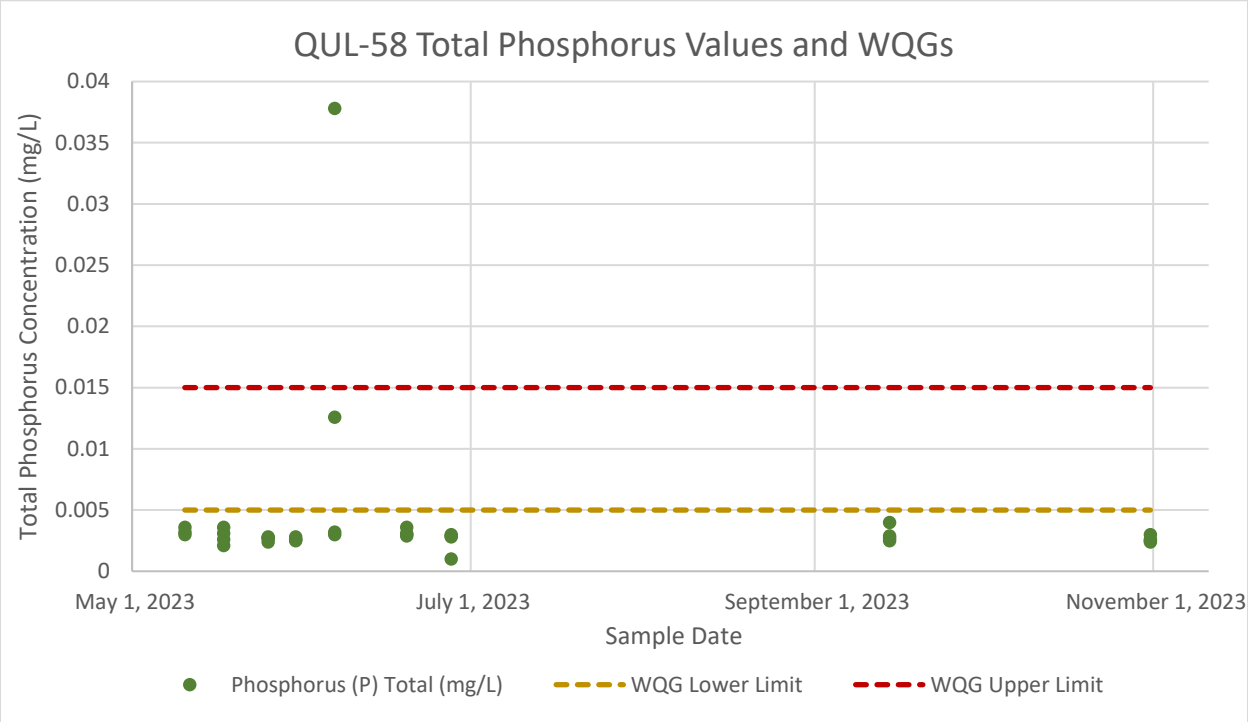

Figure 4.17 Total phosphorus WQG compared with QUL-58 values

4.12.2.7 Receiving Environment Chemistry – Quesnel River

Quesnel River, site QUR-11, was sampled monthly by MPMC as a downstream site in the receiving environment according to the 2016 CEMP. Grab samples and in situ parameters were collected off the Likely Bridge using the Kemmerer sampler. MPMC previously provided payment for a joint federal and provincial water quality monitoring site that is monitored at this same location; however, this program has been discontinued. QUR-11 was removed as a monitoring site in the 2018 CEMP; however, one sample was collected in 2023 for supplemental data.

4.12.3 Discharge Toxicity Testing Results

As per Section 3.3 of the *EMA* Permit 11678 issued on April 7, 2017 (amended last on December 1, 2022), monthly acute toxicity testing is required at the discharge, location HAD-3. Further toxicity test sampling occurred as required by the 2019 CEMP and MDMER; testing was completed at Nautilus.

Table 4.27 Toxicity sampling events in 2023

Site Name	Site Identifier (EMS No.)	Test Type	Frequency	Actual Sampling Events
HAD-3	E304230	96-h rainbow trout LC50	Monthly	11[(a)]
		48-h *D. magna* LC50	Monthly	11[(a)]
		7-d *C. dubia* survival and reproduction	Semi-annually	2
		7-d rainbow trout embryo-alevin	Semi annually	2
		72-h *P. subcapitata* growth inhibition	Semi-annually	2
		7-d *L. minor* growth inhibition	Quarterly	4

[(a)] Monthly toxicity samples were not collected in November as the WTP was not discharging

4.12.3.1 Acute toxicity testing

Monthly acute toxicity testing occurred at HAD-3 throughout 2023, when the WTP was discharging (see Table 4.27). These tests were conducted on 100% (i.e. full strength) treated effluent in accordance with the following standard methods as required by *EMA* Permit 11678 and MDMER:

- 96-hour acute lethality to juvenile rainbow trout (procedures described by Environment Canada (2000a))
- 48-hour acute lethality to the water flea *D. magna* (procedures described by Environment Canada (2000b))

Acute toxicity tests of rainbow trout and *D. magna* both met the *EMA* Permit 11678 requirement of no acute toxicity by determining that the mortality was less than 50% in 100% effluent (results are provided in ***Appendix H***). Note that the lab control had 20% mortality which invalidated the test conducted on the October 31, 2023 sample.

4.12.3.2 Chronic toxicity testing

Chronic toxicity tests at HAD-3 (see Table 4.27) were conducted on 100% treated effluent according to the following standard methods as required by *EMA* and MDMER requirements:

- 7-day survival and reproduction of the water flea *C. dubia*
- 7-day early life stage with salmonid (rainbow trout embryo-alevin)
- 7-day growth inhibition in the aquatic plant *Lemna minor*
- 72-hour growth inhibition in the alga *Pseudokirchneriella subcapitata*

C.dubia and rainbow trout early life stage met the permit requirement of no chronic toxicity by determining that the inhibition of both tests was less than 25% (results are provided in ***Appendix H***).

Effects were noted for *L. minor* during the chronic toxicity testing in 2023. Inhibitory effects on frond growth and/or dry weight of *L. minor* were observed with an IC25 and IC50 (%v/v) for frond growth and dry weight, however these are not considered toxicity failures.

4.13 Sediment Quality

Sediment quality and toxicity samples were collected in Quesnel Lake, Hazeltine Creek and Edney Creek at various periods in 2023 by Minnow Environmental to support 14-day *Hyalella azteca* toxicity testing and benthic invertebrate community monitoring. These results are presented in the Minnow (Minnow Environmental Inc.) report provided in ***Appendix K***.

4.14 Benthic Invertebrates

Benthic invertebrate community samples were collected in Quesnel Lake in 2023 by Minnow. These results are presented in the CEMP 2023 – Sediment and Aquatic Life Minnow report provided in ***Appendix K***.

Benthic invertebrate sampling was conducted by Minnow in Hazeltine and Frypan creeks to meet the CEMP requirements (***Appendix A***). Benthic invertebrate total biomass, tissue quality, and community samples as well as composite taxa and single taxon (caddisfly) tissue samples were collected. These results are presented in the Minnow report provided in ***Appendix K***.

4.15 Plankton, Chlorophyll *a*, and Secchi Disk

4.15.1 Plankton and Chlorophyll *a*

Minnow recommended modifications to the Mount Polley Mine plankton monitoring plan in a letter provided to ENV (Zooplankton and Phytoplankton Program Recommendations provided to ENV by Minnow, dated May 28, 2019). These modifications included the initiation of a depth-integrated sampling methodology for the collection of phytoplankton productivity and community samples. Depth-integrated sampling methods involve the collection of phytoplankton from depths throughout the photic zone (the layer of the water column receiving sunlight). Since phytoplankton inhabit the entire photic zone, Minnow recommended depth-integrated sampling methodology as a more effective means of characterizing phytoplankton community and productivity conditions than surface grabs (which were previously implemented for monitoring). The recommendations provided by Minnow were incorporated into a CEMP approval amendment letter issued by ENV on July 15, 2019 (Re: Amendment of the November 9, 2018 and March 14, 2019 Approval of the August 15, 2018 Comprehensive Environmental Monitoring Plan [CEMP] – Mount Polley Mine Permit #11678) and into the updated CEMP (which was submitted on October 31, 2019 and approved with conditions on February 10, 2021). The collection of both surface and depth-integrated phytoplankton samples was outlined as a requirement for 2019 monitoring in the CEMP approval condition letter dated July 15, 2019 to serve as a bridge between the two methodologies. This requirement was fulfilled in 2019, with results of this comparison between the surface and depth-integrated methodologies

presented by Minnow (***Appendix K***). Phytoplankton monitoring in 2023 was completed using depth-integrated methods in accordance with conditions outlined by ENV in the CEMP Amendment letter dated July 15, 2019 since the requirement for sampling using both surface and depth-integrated methods was satisfied in 2019.

Historically, chlorophyll *a* samples in Polley and Quesnel Lakes were generally collected two times (i.e. June and August) per growing season (Table 4.28). In 2016, chlorophyll *a* was collected three times at QUL-58, P1, and P2 for additional data. In 2017, an additional sample was collected at QUL-58; no samples were collected at QUL-ZOO-8 due to unsafe conditions from wildfires. In 2018, some chlorophyll *a* samples were collected in July and September as samples were missed at QUL-58 and QUL-2a in June, and QUL-ZOO-1, -7, and-8 and QUL-2a in August due to the proximity of forest fires limiting visibility and deteriorating air quality. An additional sample was collected at QUL-18 in May 2018. In 2019, only one sample was collected from QUL-ZOO-8 as it was removed from the sampling program later in the year. Chlorophyll *a* results from Polley Lake since 2019 are included in Figure 4.19. Chlorophyll *a* results from Quesnel Lake since 2019 are included in Figure 4.20. Comparison of the surface and depth-integrated methodologies is included in Minnow's report in ***Appendix K***.

Results from 2023 are in ***Appendix M***, and discussion for 2023 results are in Minnow's report in ***Appendix K***

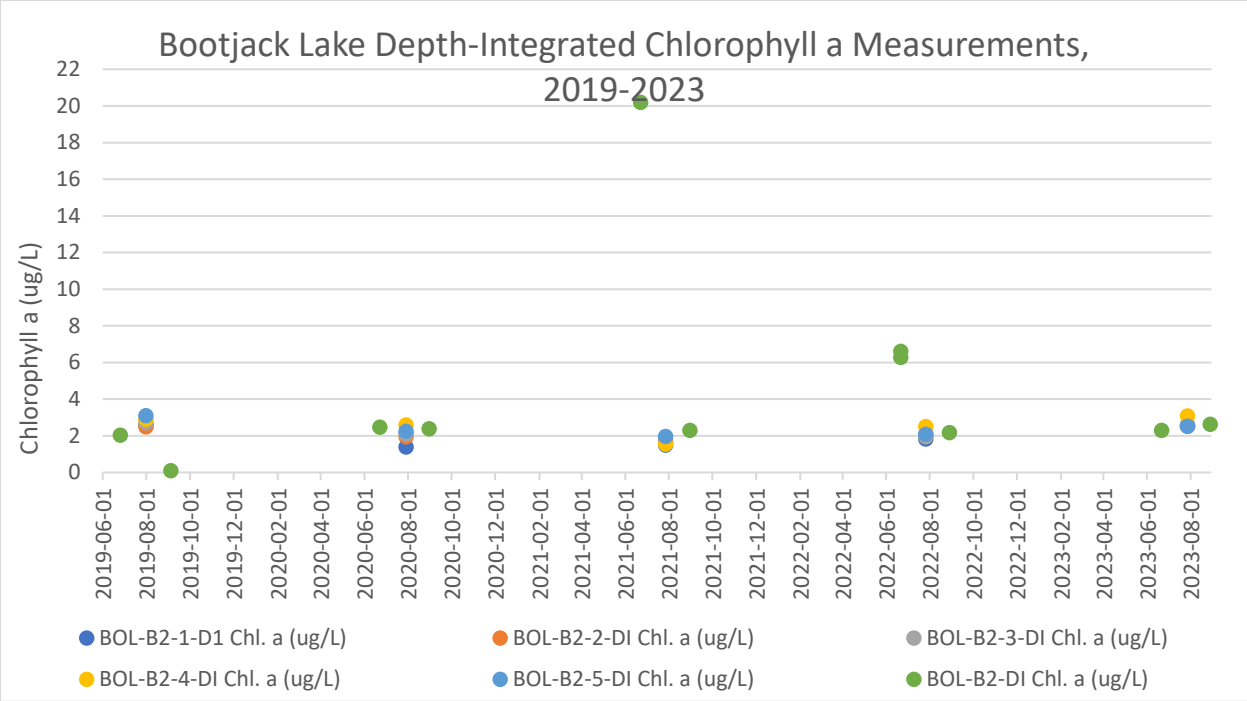

Figure 4.18 Depth-integrated chlorophyll *a* results from Bootjack Lake from 2019 to 2023

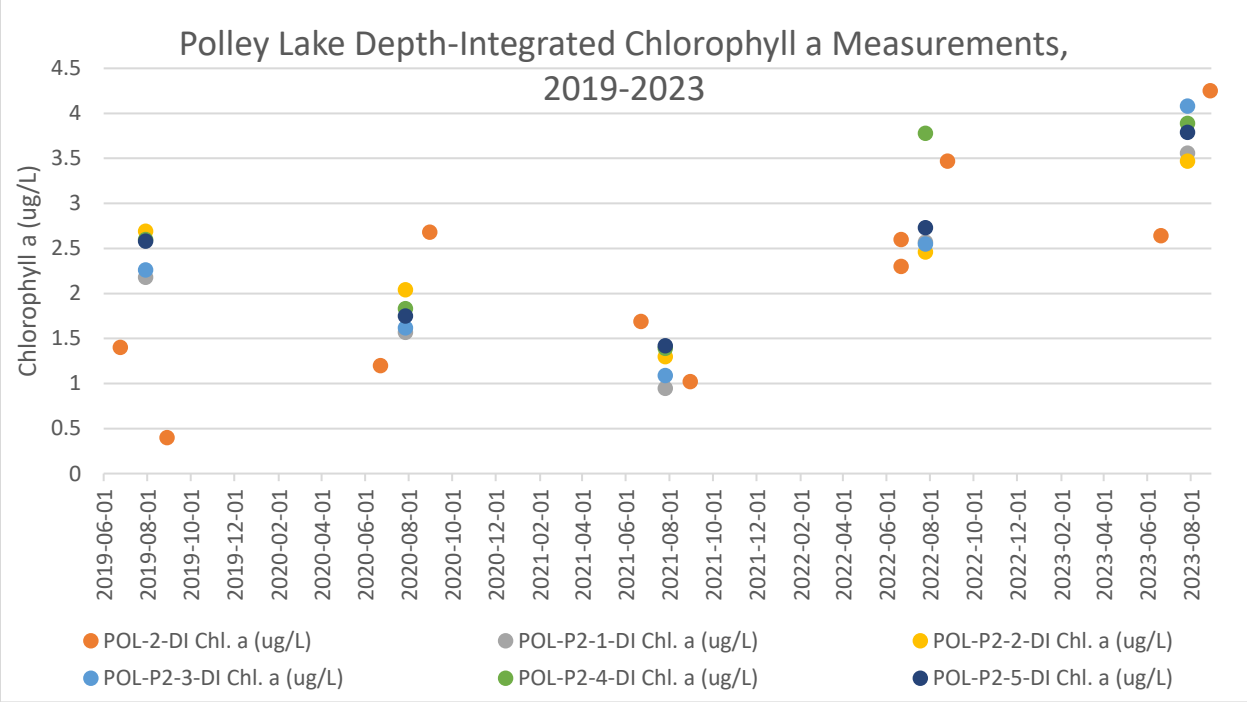

Figure 4.19 Depth-integrated chlorophyll *a* results from Polley Lake from 2019 to 2023

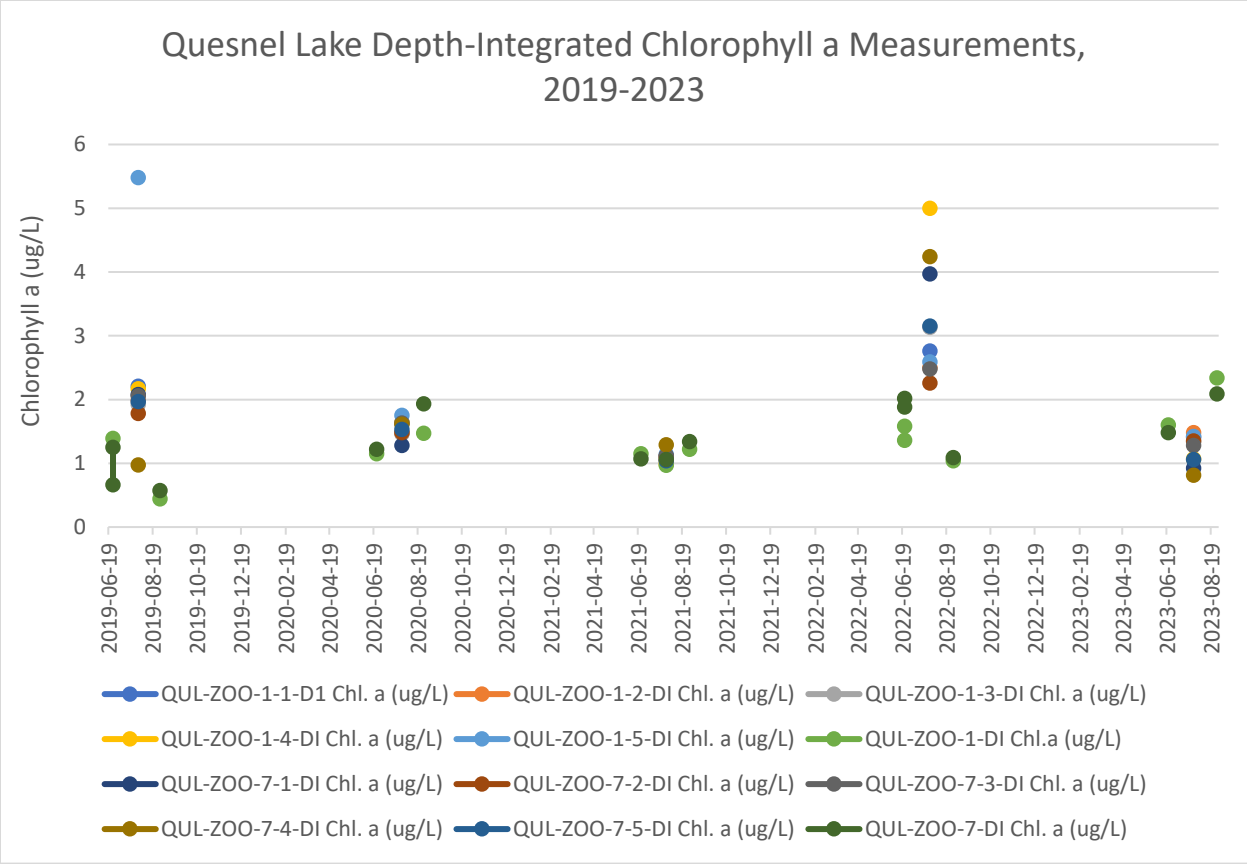

Figure 4.20 Chlorophyll *a* results from Quesnel Lake from 2019 to 2023

As explained above, zooplankton and phytoplankton samples were also historically collected at surface depth rather than depth-integrated, twice per growing season (June and August) at the same water quality monitoring stations in Polley Lake (P1 and P2). Quesnel Lake monitoring was conducted at three stations historically sampled by Department of Fisheries and Oceans (DFO) Station 1. (QUL-ZOO-1) is located in the center of the West Basin and station 7 (QUL-ZOO-7) is located in front of Horsefly Bay. In 2023, zooplankton and phytoplankton samples were collected in Polley Lake (P2), Bootjack Lake (B2) and Quesnel Lake (QUL-ZOO-1 and QUL-ZOO-7). Station 8 (QUL-ZOO-8) was removed from the program in 2019 and was not sampled in 2023. In 2023, zooplankton and phytoplankton samples were collected by Minnow in June, July and/or August. Results are in ***Appendix M***.

Phytoplankton productivity results are not directly comparable between the surface and depth-integrated monitoring methodologies. Comparison of the two sampling methods in 2019 (surface and depth-integrated) indicated that chlorophyll-a concentrations in depth-integrated samples were significantly higher than surface samples from Polley and Bootjack Lake, while the opposite was true at QUL-ZOO-7 in Quesnel Lake. Despite these differences in results between the two methodologies, phytoplankton sampling efforts in 2023 focused solely on the depth-integrated method in accordance with the CEMP Amendment letter dated July 15, 2019, and to ensure that the complete phytoplankton community was being evaluated. Depth-integrated sampling methods will continue to be used going forward, as it is the expert opinion of

Minnow and MPMC personnel that this methodology represents an improvement over discreet-depth sampling.

Depth-integrated chlorophyll a sampling results from 2023 indicate that productivity in Polley Lake, Quesnel Lake and Bootjack Lake has remained relatively stable over the period from 2019 to 2023. Chlorophyll a measurements may demonstrate an upward trend in all three water bodies, with most 2023 results having higher concentrations than in 2022, 2021 and/or 2020, however, 2019 data was more variable, there is one outlying result of in Bootjack Lake of 20.2 ug/L, and the trend is not striking, most likely a result of seasonal variation. Additional review of phytoplankton, and zooplankton are presented in Minnow's report in ***Appendix K***. The raw Quesnel Lake Plankton taxonomy are included in ***Appendix M***.

4.15.2 Secchi Disk

During each sampling and profiling event, a Secchi depth measurement (Table 4.29) was collected (except if conditions were too windy/wavy) as per the 2019 CEMP (***Appendix A***). Secchi depth data are included in ***Appendix M***.

Table 4.29 Secchi depth measurement events in 2023

Site	Site Identifier (EMS No.)	Secchi Measurement Events
P1	E207974	6
P2	E207975	7
B1	E207972	6
B2	E215897	6
B4	E216744	0
QUL-ZOO-1	E306455	3
QUL-ZOO-7	E306456	3
QUL-ZOO-8	E306457	0
QUL-120a	E303022	4
QUL-18	E303019	4
QUL-58	E304876	9
QUL-57	E304874	5
QUL-59	E304875	5
QUL-2a	E303020	5

All Secchi depths measured in 2023 were within the range of measurements from previous years.

4.16 Periphyton

Periphyton sampling was conducted by Minnow in Hazeltine, Frypan and Edney Creeks to meet the CEMP requirements (***Appendix A***). Periphyton biomass (ash-free-dry-mass), productivity (chlorophyll *a*), community samples, and tissue chemistry were collected for analysis in 2023. These results are presented in the Minnow report provided in ***Appendix K***.

4.17 Fish

Several fish studies were conducted by Minnow in 2023. Spring sampling was completed in Polley and Bootjack lakes. Fish tissue quality monitoring was conducted in Quesnel Lake (north, east and west arms) and the Quesnel River. Discussion of these results will be presented in the Minnow report provided in ***Appendix K***.

4.17.1 Fish and Habitat Surveys

Fish surveys were conducted twice in 2023: spring sampling was completed in May in Polley Lake, with Bootjack Lake serving as a reference and fall sampling was completed in October in Polley Lake. The 2023 monitoring was conducted to provide data for the evaluation of fish population structure and abundance in Polley Lake and to provide data for the evaluation of fish tissue quality in Polley Lake compared to the reference (Bootjack Lake). Discussion of these results is presented in much greater detail in the Minnow report provided in ***Appendix K***.

Minnow continued to document rainbow trout spawning and Young of the Year (YOY) abundance in Hazeltine Creek as well as habitat suitability in 2023. The CEMP 2023 – Sediment and Aquatic Life Minnow report will be provided under a separate cover.

4.18 Terrestrial Monitoring

2023 was a period of extensive terrestrial monitoring and planning for future monitoring programs. Terrestrial monitoring under the supervision of QP's from DWB occurred in the Hazeltine Creek corridor. In 2021, DWB completed an updated Study Design for Wildlife Monitoring in the Hazeltine Creek Corridor (DWB 2021a), which received revisions from MPMC regulators and advisory groups, and was implemented to build on the work previously completed by Golder. This wildlife monitoring plan is a 10-year program currently in year 4, with intensive analysis and reporting planned for years 5 and 10.

In 2021, DWB completed a Wildlife Management Plan (DWB 2021b) for the mine site, which is a requirement of the most recent M-200 permit amalgamation for wildlife management and not a study component.

4.18.1 Wildlife Monitoring

The Mount Polley site and surrounding area is home to a wide variety of wildlife including ungulates, carnivores, raptors, waterfowl, songbirds, mustelids, amphibians and a host of terrestrial and aquatic organisms. With extensive wildlife activity on the mine site, MPMC provides training to all employees regarding management of food waste and bear awareness. This training and information are intended to help keep MPMC employees and the wildlife safe.

To meet requests by the ENV, first nations, and various stakeholders, to provide valuable data for evaluating the effects of the mine on wildlife, and to monitor wildlife habitat creation through reclamation, the MPMC Environmental Department records wildlife observations and incidents on the mine site. In addition, MPMC maintains seven motion triggered wildlife cameras which are staged in various locations, primarily in the Hazeltine Corridor. This information is considered valuable for future reclamation and land use planning, and is incorporated into wildlife monitoring programs, elaborated in Appendix N.

Following the TSF embankment breach, MPMC submitted the Post Event Environmental Impact Assessment Report (PEEIAR) (MPMC, 2015a) that included an investigation of the impacts to wildlife. The findings indicated that there was no evidence of direct impacts to local populations of larger mammals such as deer, moose or bear, but impacts due to bioavailability of metals was yet unknown. The ERA (MPMC, 2017c) evaluated the possible risks of metal bioaccumulation in various animals. The findings showed that metals were likely to have low bioavailability and a low risk of bioaccumulation. The ERA also compared the frequency of wildlife observations in 2015 to 2016, and noted that the observation of deer, small mammals and birds increased, possibly due to increased forage ability. Ongoing remediation of the impacted areas are providing habitat and food for a variety of mammals and birds, which is an important step to rebuilding the ecosystems.

In 2023 there were 198 recorded wildlife observations excluding photo captures from wildlife cameras. The total number of individuals is higher than the number of observations because many wildlife observations encountered a group size greater than one. Since normal operations have resumed, more wildlife observations are expected when there are more employees and workers on site. The observations include actual sightings, and observations of scat and tracks (

Table 4.30). Observations comprise a wide range of different birds, carnivores, moose, and deer. It is assumed that the number of reported observations is only a fraction of the actual observations but suggests regular use of the site by wildlife.

Table 4.30 indicates some generic observations such as "Deer", these entries refer to sightings with no positive species identification.

One wildlife incident occurred at Mount Polley Mine in 2023. A BC Conservation Officer was called to dispatch 3 nuisance bears that were regularly interacting with MPMC staff, parked vehicles, and garbage bins.

Table 4.30 2023 wildlife observations at Mount Polley Mine.

4.19 Soil

No soil works were completed in 2023.

4.20 Soil Invertebrates

No soil invertebrate works were completed in 2023. Soil invertebrate sampling is planned in the future as part of the 2021 Wildlife Monitoring Program (Appendix N) which is a 10-year study currently in year 4.

4.21 Vegetation

An ecological risk assessment was performed by Golder in 2019, which determined that the risk of terrestrial uptake and trophic transfer of trace metals is low, especially when compared to the ecological risk posed by the physical impact of the spill, and disrupted Hazeltine Creek ecological communities. Golder also wrote a Terrestrial Monitoring Plan (2019c) which included the establishment and monitoring of vegetation plots in Hazeltine Creek, which were carried out starting in 2020 by DWB. The terrestrial monitoring plan was subsequently modified by DWB (2021) to align with the timeline and goals of the bird and mammal monitoring program, and to respond to comments made by the Government-to-Government Technical Working Group.

DWB conducted vegetation surveys along the Hazeltine Creek corridor in July of 2023. These activities represent Year 4 of the planned study. The results indicate that approximately 113 species of plants were detected within the Hazeltine Creek corridor, including 9 species of trees, 20 species of shrubs, approximately 84 species of herbs and an unrecorded number of moss and lichens. The results of the surveys from Year 1 to 4 will be incorporated into the final trend analysis in 2025. Year 5 of the 5-year study will be conducted during the recommended period for vegetation surveys, which has been identified as early-July, 2024.

A summary of the current status of the endpoints for vegetation monitoring following Year 4 of the study is below:

Objective 1: Vegetation cover is "self sustaining"

- Most seedling mortality at the site does not appear to be occurring as the result of anthropogenic factors and is expected to be a result of extreme weather conditions observed over recent years.

- Vegetation cover does not appear to be reducing over time; depending on soil conditions, some areas vegetation cover is increasing and some areas, vegetation cover remains consistent.
- Vegetation overall throughout the reclaimed areas appears resilient to dry periods due to species diversity.
- Recruitment is occurring and will likely continue to occur for most reclaimed areas. Further recruitment in areas where soil surface conditions are limiting will likely continue to see low or no recruitment until surface conditions change.
- In most reclaimed areas, vegetation cover is very diverse and similar to early successional forest ecosystems.

Objective 2: Vegetation cover is following the natural successional trajectory that aims to satisfy the end land use objective

- A diversity of native tree and shrub species are well established throughout most reclaimed areas.
- Although some invasive plants and noxious weeds have been identified, they currently do not pose a risk to limiting natural succession. Areas dominated by agronomic grass cover have become successionally stagnant and are limiting for native plant species.
- Limiting factors will likely remain long term unless remedial actions are taken in those areas where they are present.

The full 2023 vegetation report is included in ***Appendix N***. More information on reclamation is found in the following section.

5 Reclamation Program

The objectives of the reclamation program are outlined in Section 1.3. To achieve these objectives, as outlined in the most recent *Mine Plan and Reclamation Program Update 2022* (MPMC, 2022a), and Reclamation Research Program (MPMC 2021e). MPMC has established projects at the site to research reclamation and closure methods, including soil amendments and application methods, re-vegetation, vegetation metal uptake, and passive/semi-passive water treatment. The Reclamation Research Program is included in ***Appendix T***. The *Mine Plan and Reclamation Program Update 2022* was submitted under a separate cover. Based on the results of these research projects, larger scale progressive reclamation has been ongoing at Mount Polley since 2010, with two primary benefits:

1. Conducting reclamation during the operating life of the Mine reduces the size of disturbed area requiring reclamation at closure and minimizes liabilities.
2. Sites undergoing progressive reclamation can be continually monitored, and reclamation prescriptions modified based on findings. Using this approach, it is anticipated that a refined prescription for meeting reclamation objectives will be developed and can be applied site-wide at Mine closure.

No reclamation work was conducted in 2023 but is anticipated to begin again in 2024.

5.1 End Land Use

End land use is discussed in Section 1.3.4 under the heading "Reclamation Objectives".

5.2 Land Capability

MPMC plans to re-establish a sustainable, diverse, functional landscape that, on a property average basis, is greater than or equal to the capability that existed prior to mining. By restoring functional, locally common ecosystems to the reclaimed landscape, similar land uses will be available as were present prior to Mine Site disturbance. This will involve mimicking natural systems wherever possible by:

- Creating natural looking, irregular landforms;
- Restoring effective drainage patterns;
- Replacing soil to the depth that mimics natural conditions based on elevation, slope, and aspect (i.e., biogeoclimatic zone site series); and
- Revegetating each area of the site with locally common, native vegetation appropriate to the target site series, that can be expected to thrive on each polygon, including culturally important species.

This, in turn, will result in equivalent land capability.

By planning for multiple end land use objectives occurring in the same areas, the result is a more holistic approach to reclamation planning and prescription development. The entire process can also be quantitatively assessed by measuring reclaimed areas and comparing them to pre-existing ecosystem conditions or relative local benchmarks, if pre-existing ecosystem community data is not available.

Success criteria may include parameters such as:

- Landform stability;
- Erosion control;
- Visual and functional integration into the surrounding environment;
- Establishment of self-sustaining native vegetation consistent with target site series;
- Vegetation quality; and
- Presence of culturally important and rare or listed species.

5.3 Stability of Works

5.3.1 Rock Disposal Sites (RDS)

Consideration of physical long-term stability of RDSs begins prior to dumping of waste rock, continues through the construction phase, and is completed when reclamation techniques are implemented. A chronology of events to ensure this stability is as follows:

- A QP conducts a footprint stability assessment to determine if any special construction techniques are required to ensure the long-term stability of the RDS;
- The soft organic soils within the footprint of the RDS are removed and stockpiled, so that they can be used for future reclamation. By removing the soft organic materials prior to dumping, the stability of the waste dump will be improved, as it will be constructed on more solid materials such as naturally occurring tills and bedrock;
- When the RDS is under construction, a QP conducts annual (at a minimum) visits to determine if the construction technique being utilized is consistent with long-term stability objective;
- When the RDS is complete, it is re-sloped from an angle of 37° to 26.5° (from the angle-of-repose to a slope ratio of 2H:1V); and
- While the currently approved final configuration for the RDS includes a uniform slope angle of 2H:1V, geomorphic approaches to RDS closure will be investigated and, if implemented, may result in local variations in slope angle. Part of the application of geomorphic design would include reassessment of stability as needed from any proposed modifications to final dump configuration.

Greater long-term physical stability can be achieved at locations where excavated pits are backfilled with waste as compared to RDSs being constructed exclusively on flat to gently sloping terrain.

This is the case with the North Bell Dump over top of the Bell Pit, and the SERDS over top of Pond Zone and SEZ Pits.

Examinations of RDSs are made in accordance with Section 6.10.1 of the *Health, Safety and Reclamation Code for Mines in British Columbia (HSRC),* (EMPR, 2017). Monitoring of RDSs occurs according to the terms and conditions of a variance granted by the EMLI on February 9, 2001. A report on the 2023 RDS inspection, prepared by a QP will be submitted to the EMLI by March 31, 2024.

5.3.2 Pit Walls Stability

During the excavation of the pits, stability of the surrounding surfaces and pit walls is a priority, as this is necessary for the safety of the Mine workers. As such, ensuring the needed degree of long-term stability is relatively straightforward. A chronology of events to ensure this stability is as follows:

- The pits are excavated with wall angles that have been discussed and agreed to with a qualified geotechnical consultant. The angle of the walls is to be chosen to ensure the stability of the pits throughout the excavation phase, as well as for long-term stability;
- Routine inspection of pit walls and benches is completed, and maintenance is completed as required (i.e., wall scaling and bench cleaning). A formal annual (at minimum) inspection of all pit walls is conducted by a qualified professional;
- Prior to the excavation of benches below the top surfaces, all soils and tills are removed and pulled away from the area immediately surrounding the maximum boundary of the pits. This is completed to prevent the sloughing of loose materials down the pit walls; and
- The closure approach for the Cariboo-Springer Pit includes backfilling of the pit with PAG rock from the Temporary NW PAG stockpile. While this backfilling is planned to promote chemical stability of the PAG waste with subaqueous disposal once the pit re-floods, the placement of material in the pits will also effectively buttress the pit walls, further promoting the long-term post-closure stability of the pit. Partial backfilling of the Wight Pit is also planned and will also enhance pit wall stability.

Pit walls are monitored for stability using surface inspections. Pit wall stability is reviewed annually by a third party QP from an engineering services firm. A report on the 2023 pit slope inspection, prepared by a QP, will be submitted to the EMLI by March 31, 2024.

5.3.3 Road Stability

The large access and haul roads are constructed with NAG waste rock and are essentially waste rock dumps. There long-term stability will be ensured using techniques similar to those employed for the RDSs, with specific differences as described below. A chronology of events to meet long-term stability objectives is as follows:

- The roads have been constructed for stability. The soft organic soils from within the footprint of the roads were stripped to ensure adequate foundation conditions under the roads for stability. The soil that was stripped was stockpiled for future use in reclamation;
- Culverts that were used in the construction of the road and have potential to affect fish-bearing streams will be removed and water bars will be dug across the roads to continue to facilitate the movement of water past the structure to the downstream slopes.

When roads are no longer needed, if possible (without encroaching on watercourses or sensitive undisturbed areas), road edges will be re-sloped from an angle of 37° to 26.5° (from the angle-of-repose to a slope ratio of 2:1). There will be limitations on the re-sloping possible in specific areas of the Mine Site.

5.3.4 Tailings Storage Facility and Associated Works

MPMC received authorization to proceed with construction activities at the TSF to a maximum elevation of 970 m under the *Mines Act* Permit M-200 June 23, 2016 amendment. Construction of the Main Embankment and Perimeter Embankment Buttresses for the 970 m approved design were deemed completed by the Engineer of Record (EoR) in 2016 and the embankment elevation reached 970m in Fall 2023. Full details of the design are available in Golder (2017d).

The embankment slopes to satisfy the 970m design are at approximately 1.3H:1V ("repose"). This angle satisfies the stability requirements for the embankments at their designed height. Proceeding above 970m will require flattening the downstream embankment slopes to 2H:1V and extending some of the buttresses to maintain the desired Factor of Safety. The 2H:1V reslope and buttress design was finalized by the Engineer of Record on December 6, 2023 and permit application amendment being compiled for submission to EMLI in early 2024.

The base case (2015 Golder design to 970m) TSF reclamation configuration considers the re-sloping of the TSF embankment downstream slope to a 2H:1V slope by flattening the repose slope embankment. This will not be required once the resloping to go above 970m is completed, as it will be constructed at the closure angle.

A spillway, sized with capacity for the probable maximum flood, will also be installed so that the long-term water table will be maintained at a safe elevation.

Ongoing monitoring through operations and closure is planned to help assure compliance with all needs for maintaining physical stability of the TSF. Monitoring instruments, including vibrating wire piezometers, slope inclinometers, and ShapeAccelArray, will continue to be monitored as per the *Operations, Maintenance and Surveillance (OMS) Manual*. The *OMS Manual* is a "live" document administered by MPMC, created in collaboration with the Engineer of Record (EoR) for the facility., and updated copies are submitted to EMLI. The TSF will continue to be monitored by the EoR to ensure the facility is operated and performs according to its design, that stability is maintained and to provide changes to the monitoring program, if required.

Relevant aspects of the current monitoring program are as follows:

- The EoR administers, reviews and approves quality assurance/quality control (QA/QC) in accordance with the construction monitoring manual, the EMLI M-200 Permit, and all BC-ENV permits. Results are reported annually to BC-ENV in an as-built report (documenting construction activities) and annual review;
- An annual TSF inspection is performed by the EoR and submitted as the Annual Dam Safety Inspection (DSI) Report, which conforms to the Health, Safety and Reclamation Code (HSRC) and Canadian Dam Association requirements.
- A Summary of the construction activities performed in a given year are provided to BC-ENV in an annual as-built report (documenting construction activities).
- MPMC has an Independent Engineering Review Panel (IERP), to whom technical and operational developments are presented, such that they can provide review and recommendations, as necessary. The MPMC IERP is specifically used to review water management, engineering-related aspects of reclamation, and TSF performance and design;
- Re-sloping of the embankment, or any other modifications of the embankment to meet final closure and reclamation configuration needs, will be performed according to the requirements of the EoR..

Construction to raise the embankments to elevation 970 m resumed in July 2022 and continued through 2023, with a break during the winter months. The final working height of 970m was attained for all Embankment elements in November 2024 (Upstream Sand, Till Core, Filter, Transition, and Downstream Rockfill). Official certification by the EoR of heights attained will be documented within the DSI for 2023 and submitted to EMLI and BC-ENV by March 31, 2024.

Tailings have been deposited as a low-density slurry since the restart of operations of the TSF in 2016. The tailings slurry has been conveyed from the mill to the TSF via gravity driven tailings discharge pipelines. Tailings were not deposited in the TSF in 2020 and 2021 while the mine was in care and maintenance.

In 2022, tailings slurry deposition resumed in the TSF and continued through 2023. Deposition was managed to maintain beach widths and freeboard and occurred at various locations along the embankments, with the only exception being the mid-way point along the Main Embankment.

The following inspections occurred at the TSF in 2023:

- 2023 Spring Site Visit – MPMC Tailings Storage Facility, conducted by the EoR between May 8 and 10, 2023
- Annual Dam Safety Inspection (DSI), conducted by the EoR on October 3 and 4, 2023 as required by Section 4.2 of the *HSRC* (EMPR, 2017).

In addition to the physical activities, MPMC also submitted the following reports:

- The 2023 DSI report, as required under the *HSRC* (EMPR, 2017) to be submitted to EMLI by March 31, 2024.

5.3.5 Underground Stability

For the closure of underground mine works, one of the key issues related to stability is the potential for subsidence, which at some sites may be caused by the collapse of underground mine voids, leading to movement of the ground surface. As documented in the MPMC analysis in Appendix R in the *RCP*, the risk of subsidence at the Mine Site is minimal due to the depth and size of the voids below ground surface, the quality of the rock, and the mining methodology. The only additional closure work planned for reclamation of the underground mine will be backfilling of the Alimak Raise, which will be done primarily for access control.

The location of the underground works is presented in Section 2.3.1 in the *RCP*. The stability of the underground during operations is a priority for the safety of mine workers and for personnel entering the mine. During operations, the long-term stability of the underground mine is promoted by the mining method used, which is conventional long hole open stoping with backfilling. After mining of each stope, the opening is backfilled with cemented rock fill before mining the next stope. The purpose of the cemented rock fill is to fill the empty stopes and provide lateral support and stability to the stoping block. In terms of closure, this operational measure ensures a decrease in the deformation of the surrounding host rock that may tend to fill in the void, and also assures the long-term stability of the ground. The combination of the rock support used during operation and the backfilling of the mined-out stopes maximizes long-term stability of the openings and will minimize long-term monitoring needs.

5.4 Revegetation

MPMC recognizes re-vegetation as a critical aspect of site maintenance and reclamation. Disturbed areas are grass seeded on an ongoing basis to prevent erosion and invasive species establishment. Soil stockpiles and areas that are unlikely to be disturbed are typically prescribed a native seed mix Table 5.1). Sites that may be re-disturbed (or where preventing establishment of native species is the primary goal) are typically prescribed an aggressive seed mix (Table 5.1). This mixture is intended to grow rapidly in the short term but dies off allowing the ingress of native species from surrounding areas.

All non-active soil stockpiles on site are routinely inspected for erosion and vegetative cover and any non-active stockpiles requiring additional vegetative cover and/or showing signs of erosion are added to the bi-annual (spring and fall) seeding list. This seeding list serves to track areas that require seeding, their size, description and type of seed.

Ground cover seeding was limited in 2023 and was completed on new soil stockpiles.

In addition to seeding ground cover (herbaceous) vegetation, the primary re-vegetation objectives at the Mine include the establishment of woody shrubs and trees (coniferous and deciduous). MPMC recognizes

the importance of appropriate seed source and selection for long-term success and endeavors to use local seed sources. All the conifer management at the Mine is consistent with provincial forest management practices as governed by the *Forest and Range Practices Act* (FLNRO 2021). This includes participation in regional silviculture strategies, stocking standards, tree species selection, and seed planning and registration. Additional erosion control is provided through re-vegetation associated with site progressive reclamation

Table 5.1 Aggressive and native seed mixes for reclamation

Species	% by Weight
Aggressive Seed Mix	
Dahurian Wildrye	25
Slender Wheatgrass	30
Perennial Ryegrass	15
Timothy	5
Native Seed Mix	
Mountain Brome	25
Native Red Fescue	10
Rocky Mountain Fescue	14.31
Bluebunch Wheatgrass	25
Blue Wildrye	25
Fireweed	0.014
Big Leaf Lupine	0.68

5.4.1 Invasive Plant Management

Invasive plant species are managed under MPMC *Invasive Plant Management Plan*. This plan was reviewed in 2023 (as required by *Mines Act* Permit M-200). In 2023 MPMC retained DWB to survey and monitor invasive plant presence within stockpiled soil. The monitoring report can be found in ***Appendix X***.

The invasive species currently known to be present at Mount Polley Mine that are listed in the *2018 Regional Strategic Plan for Invasive Plant Management* (the most recent regional plan) by the Cariboo Chilcotin Coast Invasive Plant Committee (CCCIPC, 2018) are oxeye daisy, Canada thistle, orange hawkweed, yellow hawkweeds (non-native), and scentless chamomile. All these plants have the priority ranking "3 – Established", and are common and widespread, with widespread control not currently possible. As such, MPMC's approach is to manage invasive species at this site such that they do not inhibit reclamation activities, with recognition that all outside sources (for example, cattle, wildlife, wind, and water) pose challenges to eradicating invasive plants at the Mine site that are widespread in the surrounding areas.

5.5 Growth Medium

Salvaging and stockpiling of surficial materials is recognized as an essential component of reclamation planning. Mount Polley implements the *MPMC Soil Management Plan* which can be found in the *Mine Plan*

and Reclamation Program Update 2022 (MPMC, 2022a). Volumes and locations of soil stockpiles are tracked and inspected.

5.6 Landforms

Creating natural looking and stable landforms are reclamation objectives as described in Section 5.2 on Land Capability. Additionally, restoration of the pre-disturbance watersheds and natural hydrology, with distributed discharge, are objectives described in detail in the Mine Plan and Reclamation Program Update 2022 (MPMC, 2022). Reclamation research is ongoing to achieve these objectives, including soil cover test plot design and geomorphic slope guidance, as discussed in Section 5.10 on Reclamation Research.

5.7 Structures and Equipment

No structures or equipment was reclaimed in 2023.

5.8 Waste Dump Reclamation

Progressive reclamation is being practiced by MPMC as described in the following sections. Table 5.2 details the progressive reclamation completed to date.

Table 5.2 Progressive reclamation completed at Mount Polley Mine as of December 31, 2023

Area	Parcel	Re-contoured (ha)		Soil/Till Applied (ha)		Seeded (ha)		Fertilizer/Biosolids (ha)		Tree-Planted (ha)

5.8.1 Waste Dumps: North Bell Dump

No new reclamation work was completed on the North Bell Dump in 2023. Monitoring of past reclamation work is ongoing.

5.8.2 Waste Dumps: NEZ Dump

No new reclamation work was completed on the North East Zone Dump in 2023. Monitoring of past reclamation is ongoing.

5.8.3 Waste Dumps: Boundary Dump

No new reclamation work was completed on the Boundary Dump in 2023. Monitoring of past reclamation is ongoing.

5.8.4 Waste Dumps: East RDS

No new reclamation work was completed on the East Rock Disposal Site in 2023. Monitoring of past reclamation is ongoing.

5.8.5 Watercourse Reclamation

No watercourse reclamation was conducted in 2023.

5.8.6 Pit Reclamation

No pit reclamation was conducted in 2023. The Bell Pit, Pond Zone Pit, and Southeast Zone (SEZ) Pit have been backfilled by waste dumps and will not require reclamation. The Wight pit remained flooded in 2023.

5.8.7 TSF Reclamation

No reclamation was conducted at the TSF in 2023.

5.8.8 Road Reclamation

No road reclamation was conducted in 2023.

5.8.9 Securing of Mine Openings

There was no sealing or securing of any Mine entrances in 2023. The only underground portal is located in the flooded Wight Pit and is currently submerged.

5.9 Disposal of Hazardous Materials, Chemicals and Reagents

Mount Polley Mine operations utilizes potentially hazardous chemicals, reagents, and other products that are subject to waste disposal procedures. In 2023, hazardous and non-hazardous waste was generated and GFL Environmental Ltd. routinely removed and disposed of waste products compliant with relevant regulations. Materials that are routinely segregated and removed include aerosol cans; contaminated gasoline and diesel; waste oil (in drums); waste oil filters; waste grease fuel or oil-soaked rags, debris, and floor dry; and leachable liquid toxic waste, such as glycol/anti-freeze mix. The site bulk waste oil tanks are emptied, and the oil removed from site by GFL Environmental Ltd. GFL Environmental Ltd. acts as an advisor for waste management activities that are not routine. MPMC is registered with ENV under the *Hazardous Waste Regulation* (Ministry of Attorney General, 2017) for generation and temporary storage of these materials.

5.9.1 Recycling

MPMC recognizes the value of responsible waste management and recycling plays a big role in site waste management practices. Mount Polley continues to recycle used materials including waste oil, scrap steel, batteries, plastic pails, electronic waste, light bulbs and associated fixtures, paper, cardboard, and beverage containers. In 2020, very little recyclable materials were generated at the mine and were stored temporarily. Removal of recycled materials from site continued in 2023. Mount Polley donates funds generated by its

beverage container recycling program to the Big Brothers and Big Sisters of Williams Lake. Recycling and waste management educational presentations are a part of the mandatory site orientation given to Mount Polley employees, contractors and visitors.

5.10 Reclamation Research

In 2021, a Reclamation Research Program (MPMC 2021e) was submitted to EMLI under Permit M-200. It outlines future planned and ongoing reclamation research. A large number of topics are covered in this document, including water management, revegetation, culturally important species, post-closure ecosystems, disturbance mitigation, ecological succession, soil amendment, landform modelling, erosion control, and many others. Figure 5.1 illustrates how these activities are inter-related, and link to reclamation objectives outlined in 2017 Reclamation and Closure Plan (MPMC, 2017a) and further built upon in the *Mine Plan and Reclamation Program Update 2022* (MPMC, 2022).

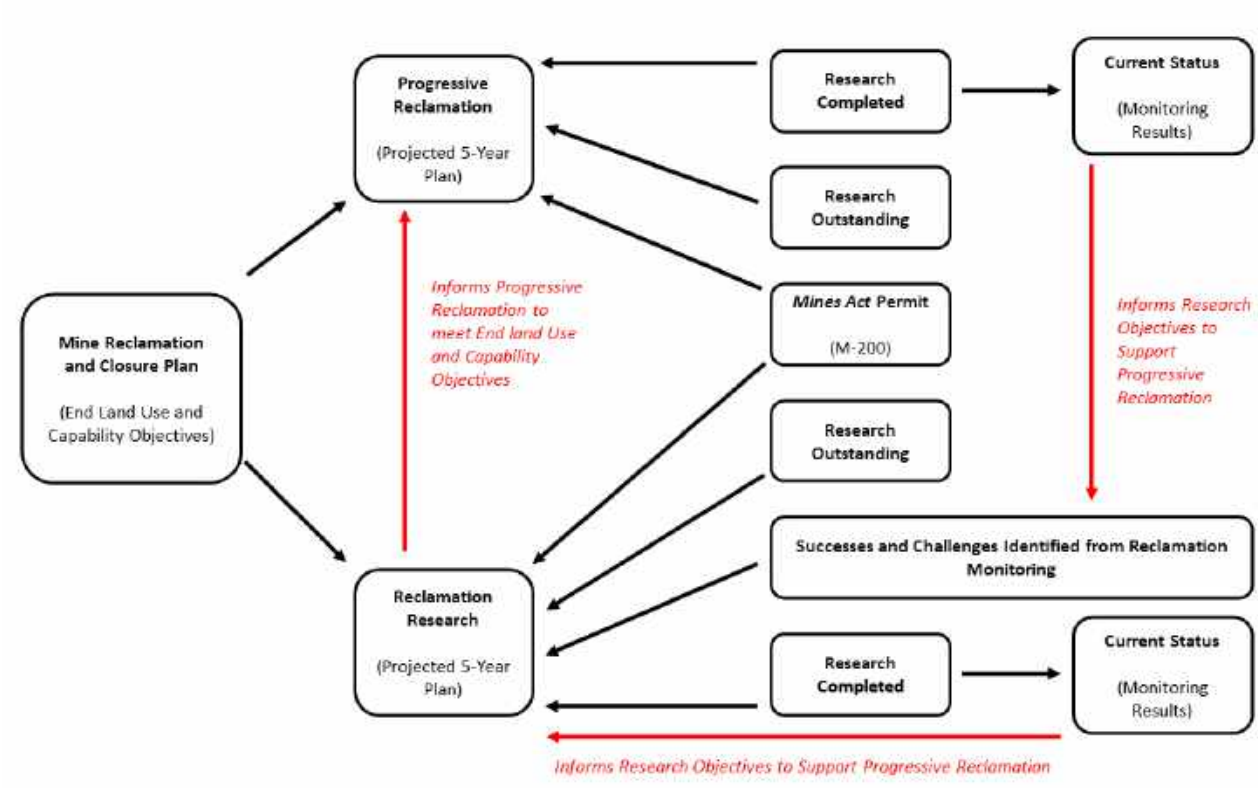

Figure 5.1 Mine reclamation activities and their relationships, under the 2021 Reclamation Research Program

In 2023 water management including long-term planning, passive treatment, and distributed discharge was a focus for reclamation research. Information on ongoing and past reclamation research can be found in

the MPMC AERRs and AERs from 2010 to 2022. Additional information can be found in MPMC's biannual Water Treatment and Discharge Program Progress Reports from 2018-2023. The *Mine Plan and Reclamation Program Update 2022* further builds on concepts outlined in the 2017 *RCP* (MPMC, 2017) and includes an adaptive management and planning framework. As part of adaptive management, results from research programs will be incorporated where opportunities exist. MPMC relies upon experience, topic specific experts, and research findings to identify methods for achieving reclamation and closure activities. Figure 5.2 shows the Adaptive Management Cycle.

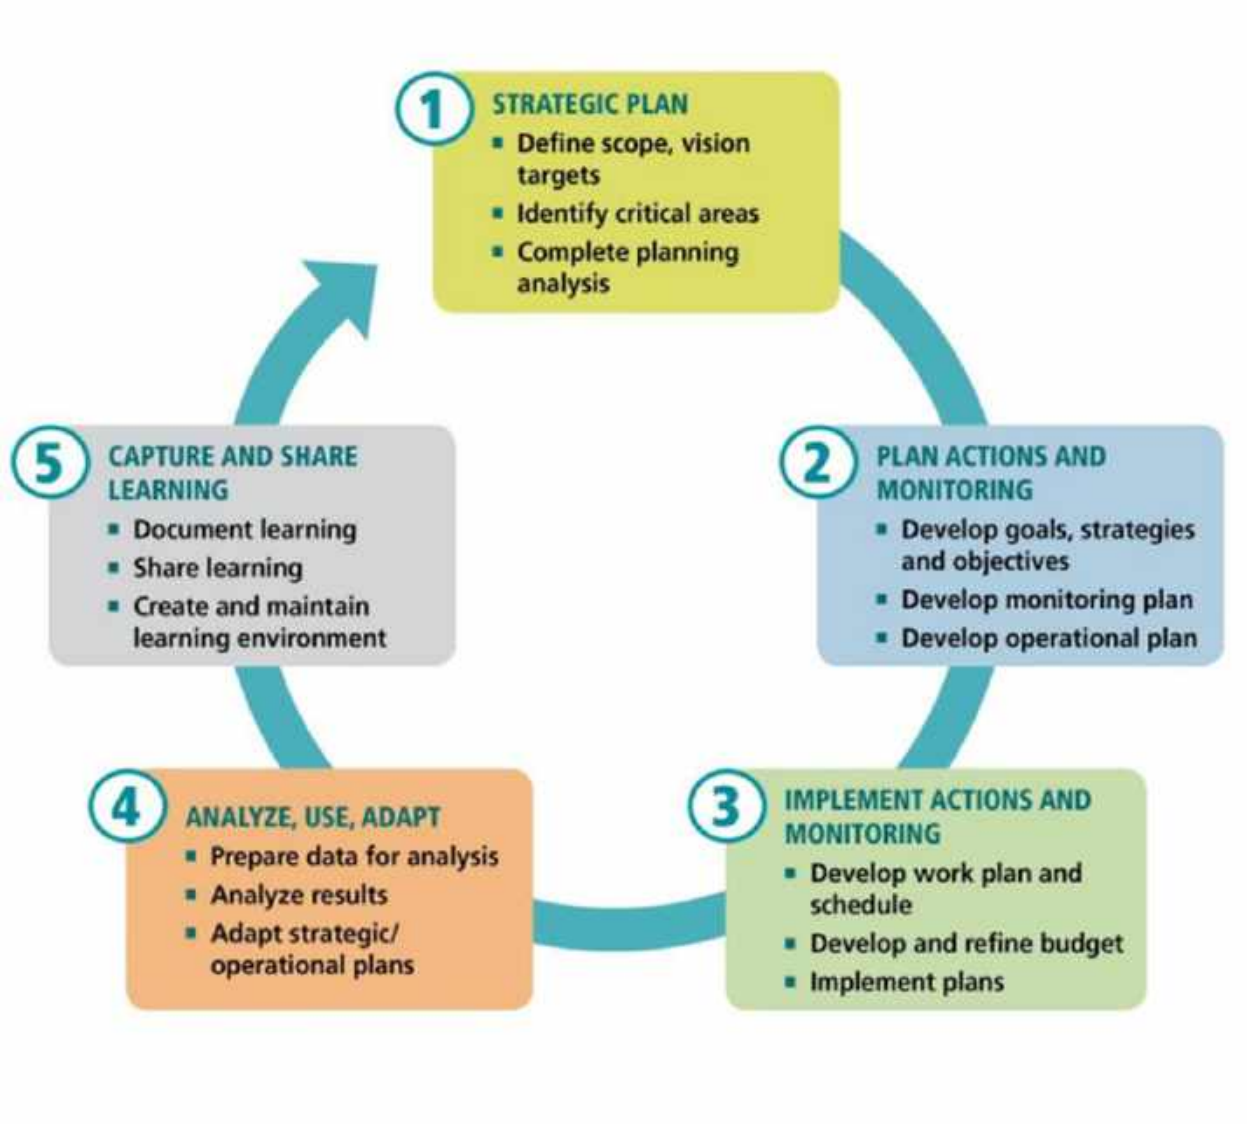

Figure 5.2 Adaptive Management Cycle, under the Mine Plan and Reclamation Program Update 2022

5.10.1 Biosolids

In 1999, the ENV issued MPMC a permit to import biosolids from the Greater Vancouver Regional District (now Metro Vancouver) for the purpose of mine site reclamation (*EMA* Permit 15968). After initial receipt

and stockpiling of the biosolids shipments in 2000, the program was suspended due to the temporary closure of the Mine; biosolids shipment recommenced in 2007. In 2014, *EMA* Permit 15968 was amended to include:

- An increase in the maximum rate of land application from 150 dry tonnes (dt)/ha to 165 dt/ha;
- An increase in the maximum cumulative discharge from 90,000 dt to 99,000 dt;
- Revised references to MPMC land claims and an updated site plan; and
- The allowance of two designated storage facilities.

Currently there is only one biosolids stockpile on site, located near the TSF. Table 5.3 provided by Metro Vancouver, summarizes biosolids deliveries and applications at Mount Polley from 2000 to 2014. No biosolids were used on site in 2023 and no changes to storage facility volumes have been made since 2014. Results from the annual storage facility sample can be found in ***Appendix U***.

Table 5.3 Metro Vancouver biosolids deliveries and applications at Mount Polley (2000 – Present)

Mt Polley Inventory, Updated: Mar. 7, 2018

5.10.1 Water Treatment Technology Development

Multiple water treatment technologies continue to be investigated for the operational, closure and post-closure phases of the mine. Details of the development of these technologies can be found in the bi-annual Water Treatment and Discharge Program Progress Reports that are prepared in compliance of Section 2.12 of Permit 11678. Progress Reports #12 (January 1 to June 30, 2023) and #13 (July 1 to December 31, 2023) can be found in ***Appendix W***. Additional details can be found in the *Mine Plan and Reclamation Program Update 2022* (MPMC, 2022), which will be submitted under a separate cover.

Geomorphic Slope Guidance

A Geomorphic Slope Guidance (Golder, 2017b) document was developed to provide guidelines for site slope recontouring and stream rehabilitation at and around the Mount Polley Mine and will also provide guidance for engineering works that would result in a natural looking slope upon closure. This guidance document will aid in long-term water management.

Soil Cover Test Plot Design

The Soil Cover Test Plot (Golder, 2018a) work, when completed may provide guidance to determine a reclamation cover soil design that reduces infiltration of water into and mass loading of constituents from waste rock disposal sites. This work may also become part of long-term water management.

5.11 Five Year Reclamation Plan

MPMC has an updated *Mine Plan and Reclamation Program Update 2022* (MPMC, 2022) which outlines the development of further reclamation planning. It should be noted that several areas have been identified as candidates for progressive reclamation but there are no immediate plans for completing the work. Work in the next five years will focus on monitoring of progressive reclamation and research projects. Table 5.4 outlines the tentative schedule for Reclamation Research as outlined in the Reclamation Research Plan (MPMC 2021e).

Table 5.4 Tentative schedule for research projects in the projected 5-year Reclamation Research Plan

Task	Duration	Start	Finish	Year 1	Year 2	Year 3	Year 4	Year 5	Year 6	Year 7	Year 8	Year 9	Year 10 (mine closure)
Water Management Strategies and Post-Closure Maintenance and Contingency Requirements: Research Requirement (c)	Year 1-Year 10	Year 1	Year 10[1]	Dependent on water management system									
Species-Specific Planting Trials: Research Requirement (d)	Year 1 - Year 10	Year 1	Year 10	Establish New Test Plots	Continue Current Monitoring			Establish Test Plots surrounding the TSF	Monitor				
Methods for Reducing High Competing Grass Cover: Research Requirement (g)	5 year period	Any year	5 years from initiation	As required									
Soil Replacement Plan: Research Requirement (i) **does not include TSF	5 year periods	Year 1	Year 10	Establish Test Plots within areas that do not have plots	Monitor								
Management for Invasive Plants: Research Requirement (i)	As needed	Year 1	Year 10	Survey & Treat	Monitor treatment effectiveness, retreat as required								
Reclamation Prescription for the TSF: Research Requirement (j)	5 year period	5 years prior to mine closure	Year 10					Establish Test Plots	Monitor				
Assessment of Soil Decompaction Methodologies: Research Requirement (k)	5 year period	5 years prior to mine closure	Year 10					Determine Areas of Severe Compaction & Establish Test Plots	Monitor				
Cumulative Effects of Fertilization and Biosolids Application: Research Requirement (o)	Up to 30 days	Prior to application of fertilizer/biosolids	Up to 30 days post-treatment	As required									

Note: current mine closure date estimated to be 2031.

[1]Passive water treatments and watercourse restorations may not have a finish date.

Notice of Departures

BRITISH COLUMBIA

File: 11678

March 14, 2019

Dale Reimer
Mount Polley Mining Corporation
Suite 200 – 580 Hornby St
Vancouver BC V6C 3B6

Dear Mr. Reimer:

RE: Amendment of the November 9, 2018 Approval of the August 15, 2018 Comprehensive Environmental Monitoring Plan (CEMP) – Mount Polley Mine Permit #11678

The August 15, 2018 CEMP was approved in my letter of November 9, 2018 (see attached).

On December 6, 2018, the Mount Polley Mining Corporation (MPMC) met with the Ministry of Environment & Climate Change Strategy (ENV) and the Government to Government Technical Working Group (G2G TWG) via phone conference to receive some clarification on the CEMP approval conditions in the November 9, 2018 letter.

On January 7, 2019, MPMC submitted to ENV a letter requesting clarification and changes to some of the November 9, 2018 CEMP Approval letter conditions.

The January 7, 2019 request by MPMC has been reviewed by the G2G TWG and comments have been provided to ENV based on this review.

Based on the recommendations from the G2G TWG, this letter provides clarification and revisions to the November 9, 2018 approval letter. The conditions of the November 9, 2018 approval letter are revised as follows:

Condition 3) is replaced by the following wording:
Sampling at Quesnel Lake operational surface water monitoring stations (stations identified in Table 6.6 of the August 15, 2018 CEMP) must occur while the discharge to Quesnel Lake is occurring, for those sites where water quality monitoring happens less frequently than monthly (i.e., four times per year or semi-annually). In the event of an unexpected shutdown of the water treatment plant, MPMC must extend reasonable efforts to re-sample within the timeframe of the quarterly or other specified time period sampling upon restart of effluent discharge to Quesnel Lake.

Condition 4) is replaced by the following wording:
For this condition, samples include both water chemistry samples and depth profile samples.

Ministry of Environment and Climate Change Strategy
Mining Operations
Environmental Protection Division
Mailing Address:
Suite 400-640 Borland Street
Williams lake BC V2G 4T1
Telephone: 250 398-4542
Facsimile: 250 398-4514
Website: www.gov.bc.ca/env

Samples from HAD-3 must be collected on the same day as samples are collected at any Quesnel Lake sample location (i.e. QUL-58, -57, or -59) in order for comparisons to be made between water quality in the lake and in the discharge. QUL-57, QUL-58 and QUL-59 must all be sampled within a one-week period. Sampling at QUL-57 and QUL-59 must include consistent sample depths with QUL-58. The profiling depths at each Quesnel Lake sample location must be matched to the water chemistry sample depths to allow comparisons over time and between sites.

The sample depths shall be the following:
a) if plume is detected samples must be collected mid plume, 5m above plume and 5m below plume; and
b) if plume is not detected samples must be collected from surface, 1m above thermocline and 1m below thermocline (or mid-depth if no thermocline exists), and from bottom

Condition 8) is replaced by the following wording:
MPMC must report in the Quarterly and Annual Reports the results of all toxicity testing conducted as required in the permit and by the Metal and Diamond Mine Effluent Regulation (MDMER).

Condition 9) is replaced by the following wording:
Phytoplankton community composition and chlorophyll a often vary significantly from month to month during the summer. To ensure representative and meaningful data, three samples of phytoplankton community and chlorophyll a samples must be collected in Polley and Quesnel Lakes between June and September. These samples must be collected at least 30 days apart.

Condition 11) is replaced by the following wording:
To help understand what caused the discrepancy between the copper concentration in overlying water in the test and the DGT results, MPMC must continue to conduct monitoring in the shallow areas of Polley and Quesnel Lakes using DGTs. The DGTs must be deployed in a manner and frequency that will allow for monitoring of mobile metals. If the results of DGT monitoring indicate a significant increasing trend between years and potential effects to aquatic receptors are reasonably anticipated, MPMC must submit to the Director for approval a monitoring plan to assess the potential effects of increased metal concentrations detected by the DGTs.

MPMC must conduct toxicity tests with Hyalella azteca using sediment of shallow habitat from Polley and Quesnel Lakes for at least one year to determine potential effects. During 2019, five replicates of sediment samples each must be collected from shallow areas of Polley and Quesnel Lakes where tailings and breach materials were deposited to be used for a 14-day sediment toxicity test on Hyalella azteca and for sediment chemistry analysis. If no effect to Hyalella

azteca is detected in these tests, Hyalella azteca toxicity testing in Polley and Quesnel Lakes may be discontinued upon approval by the Director following submission of a summary report.

Conditions 14) and 15) are rescinded.

Condition 17) remains as approved in the November 9, 2018 CEMP approval letter.

Submission date for an updated CEMP that is to include all items as listed under a) to m) of Approval Condition 20) of the November 9, 2018 CEMP approval letter, is hereby changed to October 31, 2019.

All other conditions in the November 9, 2018 CEMP approval letter remain in effect.

If you have any questions regarding this letter, please contact Gabi Matscha at 250-371-6296 or Gabriele.Matscha@gov.bc.ca.

Sincerely,

Douglas Hill, P. Eng.

BRITISH COLUMBIA

July 15, 2019 Authorization Number: 11678

Dale Reimer
Mount Polley Mining corporation
Suite 200 – 580 Hornby St.
Vancouver BC V6C 3B6

Dear Mr. Reimer:

RE: Amendment of the November 9, 2018 and March 14, 2019 Approval of the August 15, 2018 Comprehensive Environmental Monitoring Plan (CEMP) – Mount Polley Mine Permit #11678

The August 15, 2018 CEMP was approved in my letter of November 9, 2018 (see attached). My letter of March 14, 2019 (see attached) provided a few amendments to the original approval letter of November 9, 2018.

On May 29, 2019, we received a request for changes to Section 6.14 of the approved CEMP via e-mail. The requested changes were outlined in a letter of May 28, 2019 by Minnow Environmental Inc. to the Mount Polley Mining Corporation (MPMC), which recommends changes to the Mount Polley zooplankton and phytoplankton monitoring programs.

The request by MPMC has been reviewed by the Government to Government Technical Working Group (G2G TWG).

Based on the recommendations from the G2G TWG, this letter provides the following revisions to the November 9, 2018 and March 14, 2019 approval letters and Section 6.14 of the approved August 15, 2018 CEMP:

- **For phytoplankton (community and biomass), zooplankton (community, biomass and tissue chemistry) and chlorophyll *a* from Quesnel Lake, Polley Lake and Bootjack Lake, three samples must be collected between June 15 and September 15. These samples must be collected at least 30 days apart. During the 2nd of the three sampling events (preferably in July), 5 replicate samples are to be collected at each site. One sample is to be collected at each site during the 1st and 3rd sampling event.**
- **Zooplankton and phytoplankton samples from a given lake must be collected on the same day.**

.../2

Ministry of Environment and Climate Change Strategy
Mining Operations
Environmental Protection Division
Mailing Address:
Suite 400-640 Borland Street
Williams Lake BC
V2G 4T1
Telephone: 250 398-4530
Facsimile: 250-398-4514
Website: www.gov.bc.ca/env

- **Sample sites for the above zooplankton and phytoplankton program must include:**
  - **In Quesnel Lake, one exposed area (QUL-ZOO-1, west of the mouth of Hazeltine Creek) and one reference area (QUL-ZOO-7, east of Horsefly Bay);**
  - **In Polley Lake one exposed area at P2;**
  - **In Bootjack Lake one reference area at B1.**
- **Sampling methods must include the following:**
  - **50-micron mesh zooplankton nets must be used at all sample sites. At sites where a 150-micron mesh net had been used so far, sampling must occur with both mesh sizes, the 50-micron mesh size and the 150-micron mesh size, in 2019 to enable an assessment of the difference in results and to allow comparisons of historical results with data collected in the future.**
  - **Zooplankton sample nets must have a mouth diameter that is larger than 0.5 metres and must be equipped with a flow meter. The zooplankton collection must be conducted using a modified horizontal tow method.**
  - **The phytoplankton collection must be conducted using a depth-integrated methodology. This can be achieved by collecting water from at least four discrete depths per station (surface, one-third Secchi depth, two-thirds Secchi depth, and total Secchi depth) using a sampler such as a Kemmerer or Van Dorn sampler, by using a length of flexible tubing modified for this purpose with or without a peristaltic pump.**
    - **In order to determine if results of historic surface collection of phytoplankton is comparable to the depth integrated method going forward, additional phytoplankton surface samples must be collected at and analysed for each site in 2019.**
  - **Secchi-depth and in situ water-chemistry supporting data should be collected at each station within each area (n = 5 in July, n= 1 in June and August) during all three sampling seasons and recorded.**
- **Sample Analysis:**
  - **Laboratory analysis should be completed by a single lab for all zooplankton community monitoring (as opposed to one lab for Quesnel Lake and a different one for Polley Lake).**
  - **Laboratory QC reanalysis of 10% of all samples shall be completed for zooplankton and phytoplankton community samples.**
  - **Biomass shall continue to be measured for zooplankton and phytoplankton samples from Quesnel Lake, as well as the addition of biomass estimates for Polley Lake.**

All other conditions in the November 9, 2018 and the March 14, 2019 CEMP approval letters remain in effect.

If you have any questions regarding this letter please contact Gabi Matscha at 250-371-6296 or Gabriele.Matscha@gov.bc.ca.

Sincerely,

Douglas Hill, P. Eng.

1 INTRODUCTION

The Mount Polley Mine is located eight kilometres (km) southwest of Likely and 56 km (100 km by road) northeast of Williams Lake, British Columbia (BC; Figure 1.1). On November 29, 2015, Mount Polley Mining Corporation (MPMC), which operates the mine, received an amendment to Permit 11678 (herein referred to as the Permit) issued by the BC Ministry of Environment and Climate Change Strategy (ENV; previously known as the Ministry of Environment) pursuant to the *Environmental Management Act* (EMA; SBC 2003, Chapter 53) for a short-term water management strategy to discharge treated mine effluent into Quesnel Lake via Hazeltine Creek. The most recent amendment of the Permit was granted April 7, 2017 for a long-term water management strategy to discharge treated mine effluent directly to Quesnel Lake. Section 3.2 of the amended Permit requires MPMC to develop and implement a Comprehensive Environmental Monitoring Plan (CEMP) for the Mount Polley Mine site and surrounding receiving environment that combines pre-existing monitoring programs into an integrated plan as follows:

> *"The Permittee must continue to develop, submit, and implement an ongoing Comprehensive Environmental Monitoring Plan (CEMP) to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas.*
>
> *The CEMP will consolidate and integrate all of the pre-existing monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.*
>
> *The CEMP must at minimum address a three year time span, as well as at a minimum include all sampling sites, frequency of sampling, variables to be analysed, method detection limits, sampling methods, sample analysis methods, and data analysis methods."*

The June 23, 2016 version of the CEMP was approved in the April 7, 2017 Permit amendment. Subsequently, in 2017, MPMC submitted several versions of a CEMP to ENV for review, however, a plan for 2017 was not approved. This CEMP covers the 2018 to 2020 time period and was developed based on the approved updated Terms of Reference (TOR) included as Appendix A. Based on the requirements of the permit, the next CEMP will be submitted in March 2020.

This CEMP is a unique and integrated monitoring plan that has been developed to capture a number of independent and interdependent monitoring programs, including; site monitoring, water discharge, *Metal and Diamond Mining Effluent Regulations* (MDMER) requirements, and Tailings Storage Facility (TSF) embankment breach response and remediation. Monitoring programs are normally developed by requirements of sector-specific regulations (e.g., MDMER of the federal *Fisheries Act* [Government of

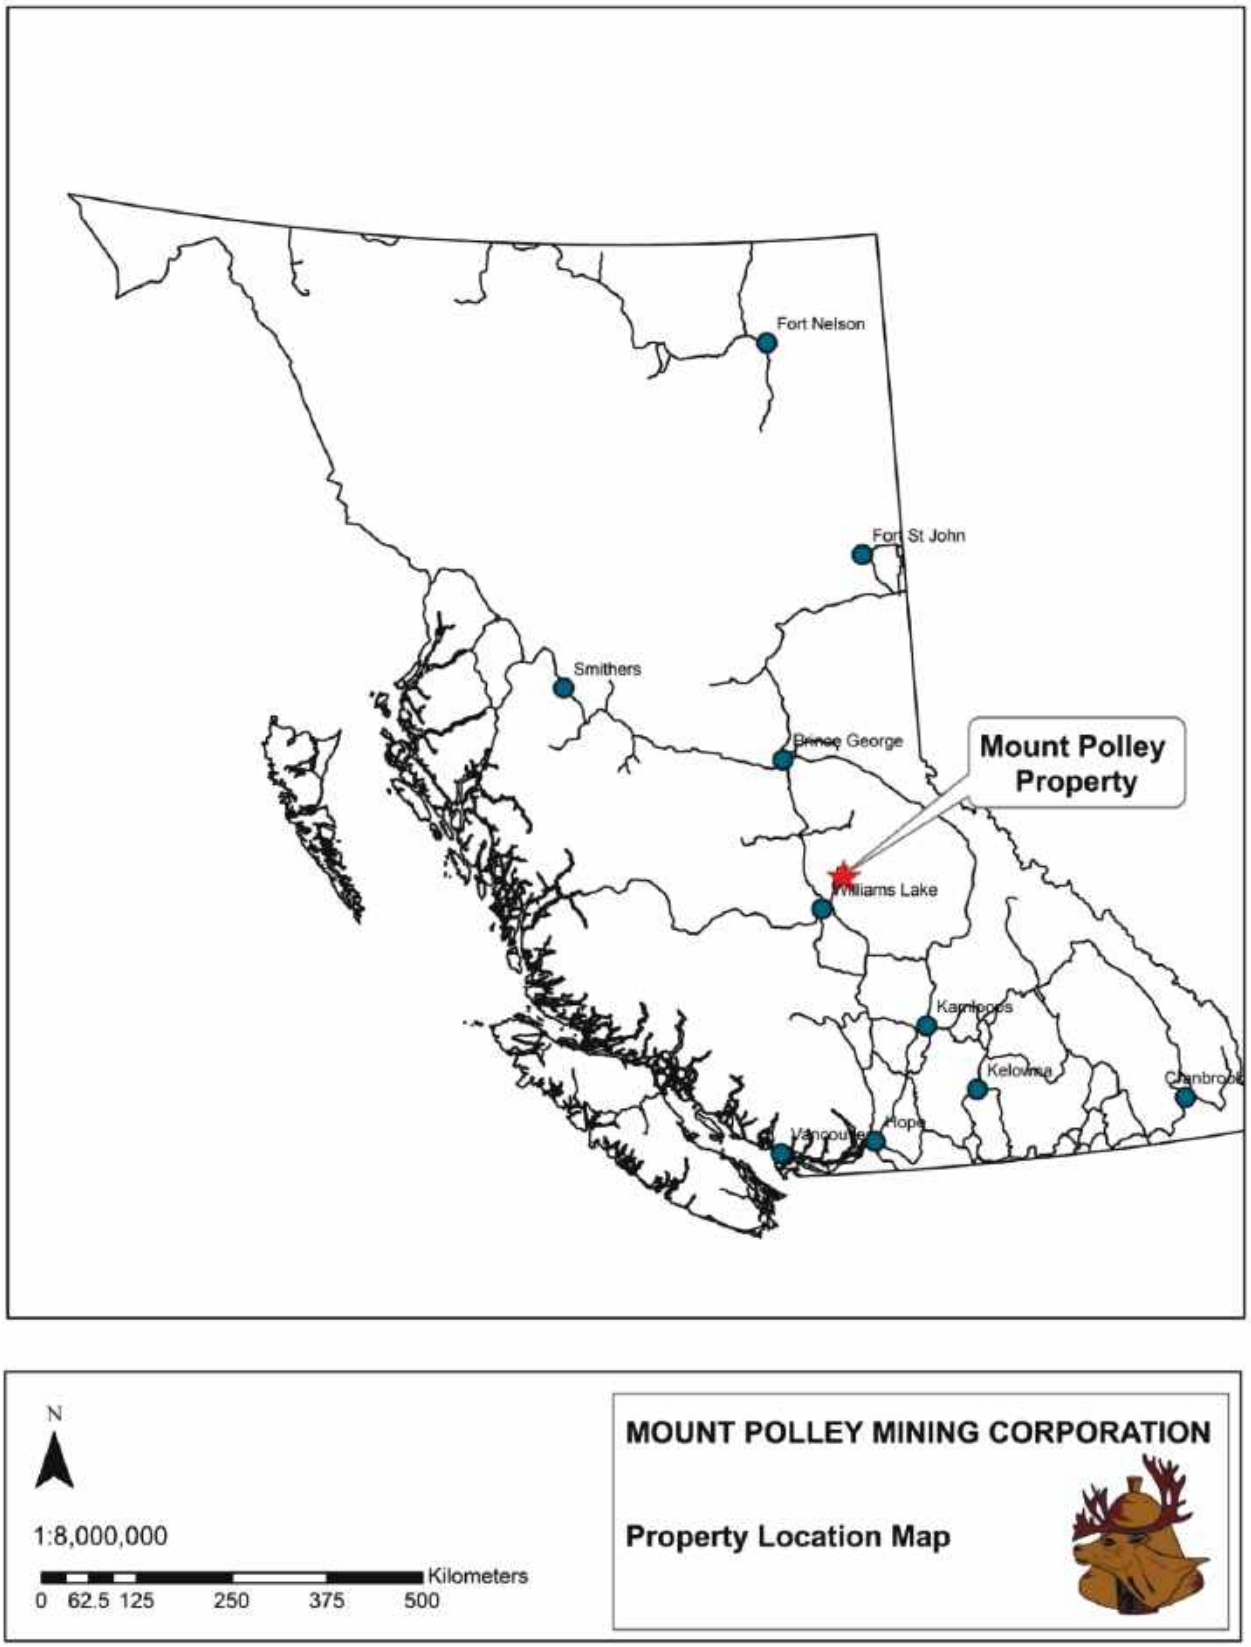

Figure 1.1 Mount Polley Mine property location

Canada 2018]) or by conditions in a permit with a specific monitoring plan that ties together permit-required and MDMER-required monitoring. As there is no ENV Technical Guidance document for this type of plan, this CEMP has been developed through an extensive consultative process that encompasses a number of permitting and other regulatory processes. Through these efforts, it has been suggested by various parties that all of the monitoring programs (e.g., water discharge monitoring, MDMER, TSF embankment breach response, etc.) be combined into one overarching program that takes advantage of the broader data set. This integrated monitoring plan offers the additional benefit of facilitating more efficient monitoring plan review by regulatory agencies, First Nations, and stakeholders. A constraint on this CEMP is where there are specific programs compelled by regulation such as the Environmental Effects Monitoring (EEM) Program that is required under the MDMER. In such instances, transparency of objectives and best efforts will be required to consolidate these different programs to the extent possible.

The CEMP is structured as follows:

- **Section 1:** Describes the CEMP objectives, a brief summary of the monitoring programs that have been integrated into the CEMP, and regulatory requirements.
- **Section 2:** Provides an overview of the integration of the various environmental monitoring programs being undertaken at the mine. Conceptual Site Models (CSMs) for the mine site and the TSF breach affected areas have also been provided, along with further details of the monitoring plans that have been integrated into the CEMP.
- **Section 3:** Provides an overview of First Nations and Stakeholders.
- **Section 4:** Provides a summary of the mine operations and the receiving environment.
- **Section 5:** Describes the environmental management practices in place, including water management.
- **Section 6:** Describes all monitoring components, including climate, surface water, hydrology, groundwater, contact water, seepage water, effluent, sediment quality, benthic invertebrate, plankton and chlorophyll *a*, periphyton, fish, wildlife, amphibian and reptile, soil, soil invertebrate, vegetation, and biosolids.
- **Section 7:** Describes the process for CEMP revisions and updates, along with a summary of changes made since the approved plan was submitted on June 23, 2016.
- **Section 8:** Summarizes relevant components of the post-TSF breach reclamation and remediation plans and interactions with CEMP components.
- **Section 9:** Provides an overview of the reporting of CEMP results.
- **Section 10:** Provides an overview of the future outlook.

The appendices attached to the CEMP are summarized below:

- **Appendix A:** Approved CEMP TOR (April 28, 2017).
- **Appendix B:** Contains the Detailed Study Designs for CEMP components, as referenced in document.
- **Appendix C:** Sample of Monthly Monitoring Schedule, which is a sample of the monthly environmental monitoring schedule provided to environmental department staff.

- **Appendix D:** Site Matrix, which describes all water sample locations in the CEMP, including site descriptions, site locations, access or safety concerns, and rationale for monitoring.
- **Appendix E** Declarations of Competency forms for Qualified Professionals contributing to the CEMP

1.1 OBJECTIVES

As specified in the Permit, the CEMP describes monitoring activities intended to support the evaluation of the potential for effects of mine-related activities on the physical, chemical, and biological characteristics of Bootjack Lake and Morehead Creek in the Springer Pit area, the Hazeltine and Edney Creek drainages, Polley Lake, Quesnel Lake, and Quesnel River, and associated riparian and upland areas. Specifically, the CEMP objectives are:

1. To evaluate if pollution[1] is occurring in the receiving environment as a result of the existing water discharge or mine-related activities;
2. To evaluate the environmental impacts of the August 2014 TSF embankment breach, to inform the rehabilitation plan, as well as to evaluate the effects of mitigation measures that are implemented as part of the rehabilitation strategy;
3. To integrate, to the extent feasible, the requirements of the MDMER; and
4. To inform reclamation and closure (*Mines Act* Permit M-200).

This CEMP includes monitoring of: effluent, surface water, groundwater, sediment, periphyton, plankton, benthic invertebrates, and fish in the aquatic environments; and soil, floodplain and upland vegetation, and wildlife in the terrestrial environments. Specific objectives for individual monitoring program components are stated in the subsequent sections. Supporting summary tables and maps are also provided.

Since the original integration of these plans and submission of the CEMP on March 31, 2016, many iterations of the CEMP have been reviewed, revised, and submitted in 2016 and 2017. Pre-existing monitoring plans that were integrated into the initial CEMP and have subsequently been revised within CEMP revisions (instead of individually) are:

- The *Monitoring Plan for Discharge of Treated Effluent to Quesnel Lake via Hazeltine Creek* (MPMC 2016a);
- The *Annual Monitoring Plan* for surface water and groundwater (MPMC 2015a);
- The *Biological Monitoring and Lake Sampling Plan* (MPMC 2015b); and
- The *Post-TSF Breach Monitoring Plan – 2015 Revision 1* (MPMC 2015c), which references the *Post Breach Fish Tissue Collection Plan – 2015* (MPMC 2015d) and the *Sampling and Analysis Plan: Detailed Site Investigation and Human Health and Ecological Risk Assessment* (Golder 2015a).

[1] Pollution as defined in the BC EMA (S.1(1)) means "*…the presence in the environment of substances or contaminants that substantially alter or impair the usefulness of the environment*".

Previous results were used to inform and structure this version of the CEMP and are summarized below in their respective sections or provided in Appendix B, as appropriate. A summary of results along with a discussion is provided in each relevant section. Throughout the CEMP, references are made to semi-x monitoring. This refers to monitoring that occurs twice per unit time, for example semi-annual monitoring indicates twice per year, and semi-monthly monitoring indicates twice per month.

It is expected that monitoring will be updated from time to time, consistent with an adaptive monitoring program (see Section 2.3). When changes are made to the monitoring, this amended plan (or relevant replacement pages) will be resubmitted to the Director and MPMC's Implementation Committee.

Work plans will be developed for all future monitoring programs and submitted to the ENV at least 30 days prior to commencing the program. These programs will be developed by a Qualified Professional (QP) and will consider linkages and dependencies with existing programs using previous data and review of the CSMs, which are presented in Section 2.2.

2 INTEGRATION OF MONITORING ACTIVITIES

The CEMP integrates environmental monitoring programs being carried out at the mine to meet multiple requirements which have different drivers and, therefore, objectives. Figure 2.1 shows the linkage between these drivers and associated monitoring objectives, as well as the resulting monitoring components that addresses those objectives. Further discussion is provided on these linkages in the sections following.

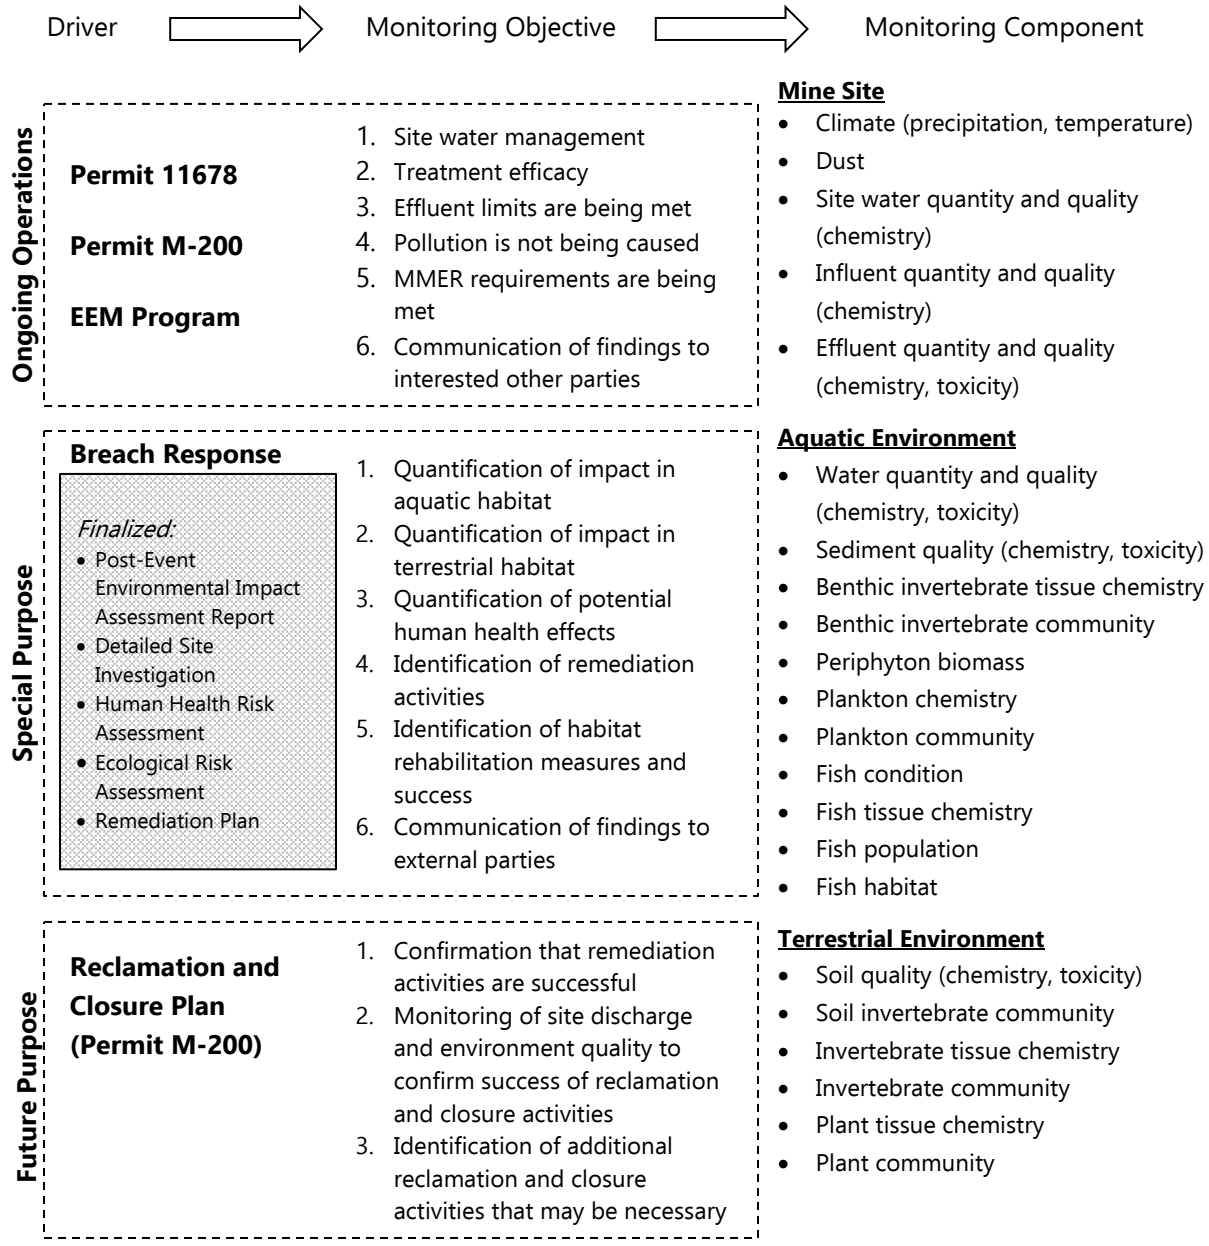

Figure 2.1 CEMP integration framework

2.1 MONITORING DRIVERS AND OBJECTIVES

There are three different drivers for current monitoring activities: ongoing operations, the TSF embankment breach response (special purpose program distinct from normal mine operations monitoring), and reclamation and closure planning (future purpose; note that some progressive reclamation has been done to date). These drivers and their associated monitoring objectives are described below. Previous monitoring results are continually reviewed to inform and structure the monitoring as well.

2.1.1 ONGOING OPERATIONS

Mount Polley Mine is an operational facility that is governed by provisions of the provincial EMA and *Mines Act* and the federal MDMER (a sector-specific regulation of the *Fisheries Act*). These permits and regulations contain specific requirements for on-going monitoring of site activities and downstream aquatic receiving environments. The objectives of ongoing operations monitoring are to:

1. Evaluate and plan for site water management.
2. Evaluate treatment efficacy to provide information for the ongoing management of the water treatment system installed at the time.
3. Verify that effluent limits are being met.
4. Verify that pollution is not being caused.
5. Verify that MDMER requirements are being met.
6. Communicate the findings to all interested parties.

Monitoring in accordance with conditions contained within BC *Mines Act* Permit M 200 is also summarized in the CEMP. This monitoring is only described in the CEMP for completeness purposes. Monitoring is summarized and future changes will be presented in CEMP revisions, but changes to this monitoring are subject to BC *Mines Act* Permit M-200 and not Section 7 in the CEMP or Section 5 in the CEMP TOR (Appendix A). This permit requires monitoring for metal leaching and acid rock drainage (ML/ARD) characteristics, water quality of on-site contact water (Section 6.11), and water quality of seeps from open pits and waste rock piles (Section 6.10). Permit M-200 also contains conditions related to reclamation and closure planning and monitoring. Results of monitoring conducted under the M-200 permit will continue to be reported annually, along with the monitoring results directed under the CEMP, in a combined AERR (Annual Environmental and Reclamation Report) that is submitted to ENV and the BC Energy, Mines, and Petroleum Resources (EMPR; formerly Ministry of Energy and Mines). Refer to Section 9 for information on reporting associated with the CEMP.

MPMC is also subject to the conditions of the BC *Water Sustainability Act* (which replaced the *Water Act* in 2016) that includes provisions related to sediment and erosion control and working around water. MPMC holds conditional water licences and is subject to Order 76930-40 following the TSF embankment breach, both of which were issued under the former *Water Act*.

2.1.2 SPECIAL PURPOSE

On August 4, 2014, a foundation failure of the Mount Polley TSF perimeter embankment occurred. ENV issued a Pollution Abatement Order (PAO) that specified the need for specific impact studies and monitoring to address impacts of the breach event, inform remedial measures, and evaluate changes over time. These studies are referred to as "special purpose" studies (now primarily monitoring) because they relate to a unique event with program objectives that differ considerably from an operating mine. The objectives of the special purpose monitoring are to:

1. Monitor and assess impact to aquatic habitat.
2. Monitor and assess impact to terrestrial habitat.
3. Monitor and assess potential human health risks.
4. Identify remediation activities needed to address identified impacts.
5. Identify habitat rehabilitation measures and related works as well as the success of those works.
6. Communicate findings of the impact assessment and ongoing monitoring to external parties.

2.1.3 FUTURE PURPOSE

As an operating mine, MPMC is required to plan for eventual closure. Reclamation and closure monitoring takes place after the closure plan is implemented. Although progressive reclamation and reclamation research have already been initiated at the site, the Reclamation and Closure Plan (RCP) continues to be refined during operations in preparation for closure and is not yet finalized. However, in the context of a CEMP, future monitoring needs are appropriate to start considering. Because this CEMP is intended to be an adaptive plan, these will be updated as reclamation and closure planning progresses and greater certainty of locations, measurement endpoints, etc. are available.

The objectives of the future monitoring program are to:

1. Confirm that mine site reclamation activities are successful in achieving their stated objectives.
2. Monitor site discharge quality and receiving environment quality as appropriate to confirm that reclamation and closure works have been successful in preventing pollution and that discharges are compliant with applicable requirements.
3. Identify additional reclamation and closure activities that may be necessary.

Additional and more specific objectives will be developed as the reclamation and closure planning process progresses.

2.2 MONITORING COMPONENTS AND CONCEPTUAL SITE MODEL

Figure 2.2 provides an overview of the Mount Polley Mine, in particular the CEMP study areas along with their respective monitoring components. Figure 2.3 and Figure 2.4 show greater detail of the TSF area and the mine site, respectively, of the sources of mine-contact water to the surrounding aquatic receiving environment and areas of ground disturbance. The measurement endpoints are detailed in the applicable sections later in this plan.

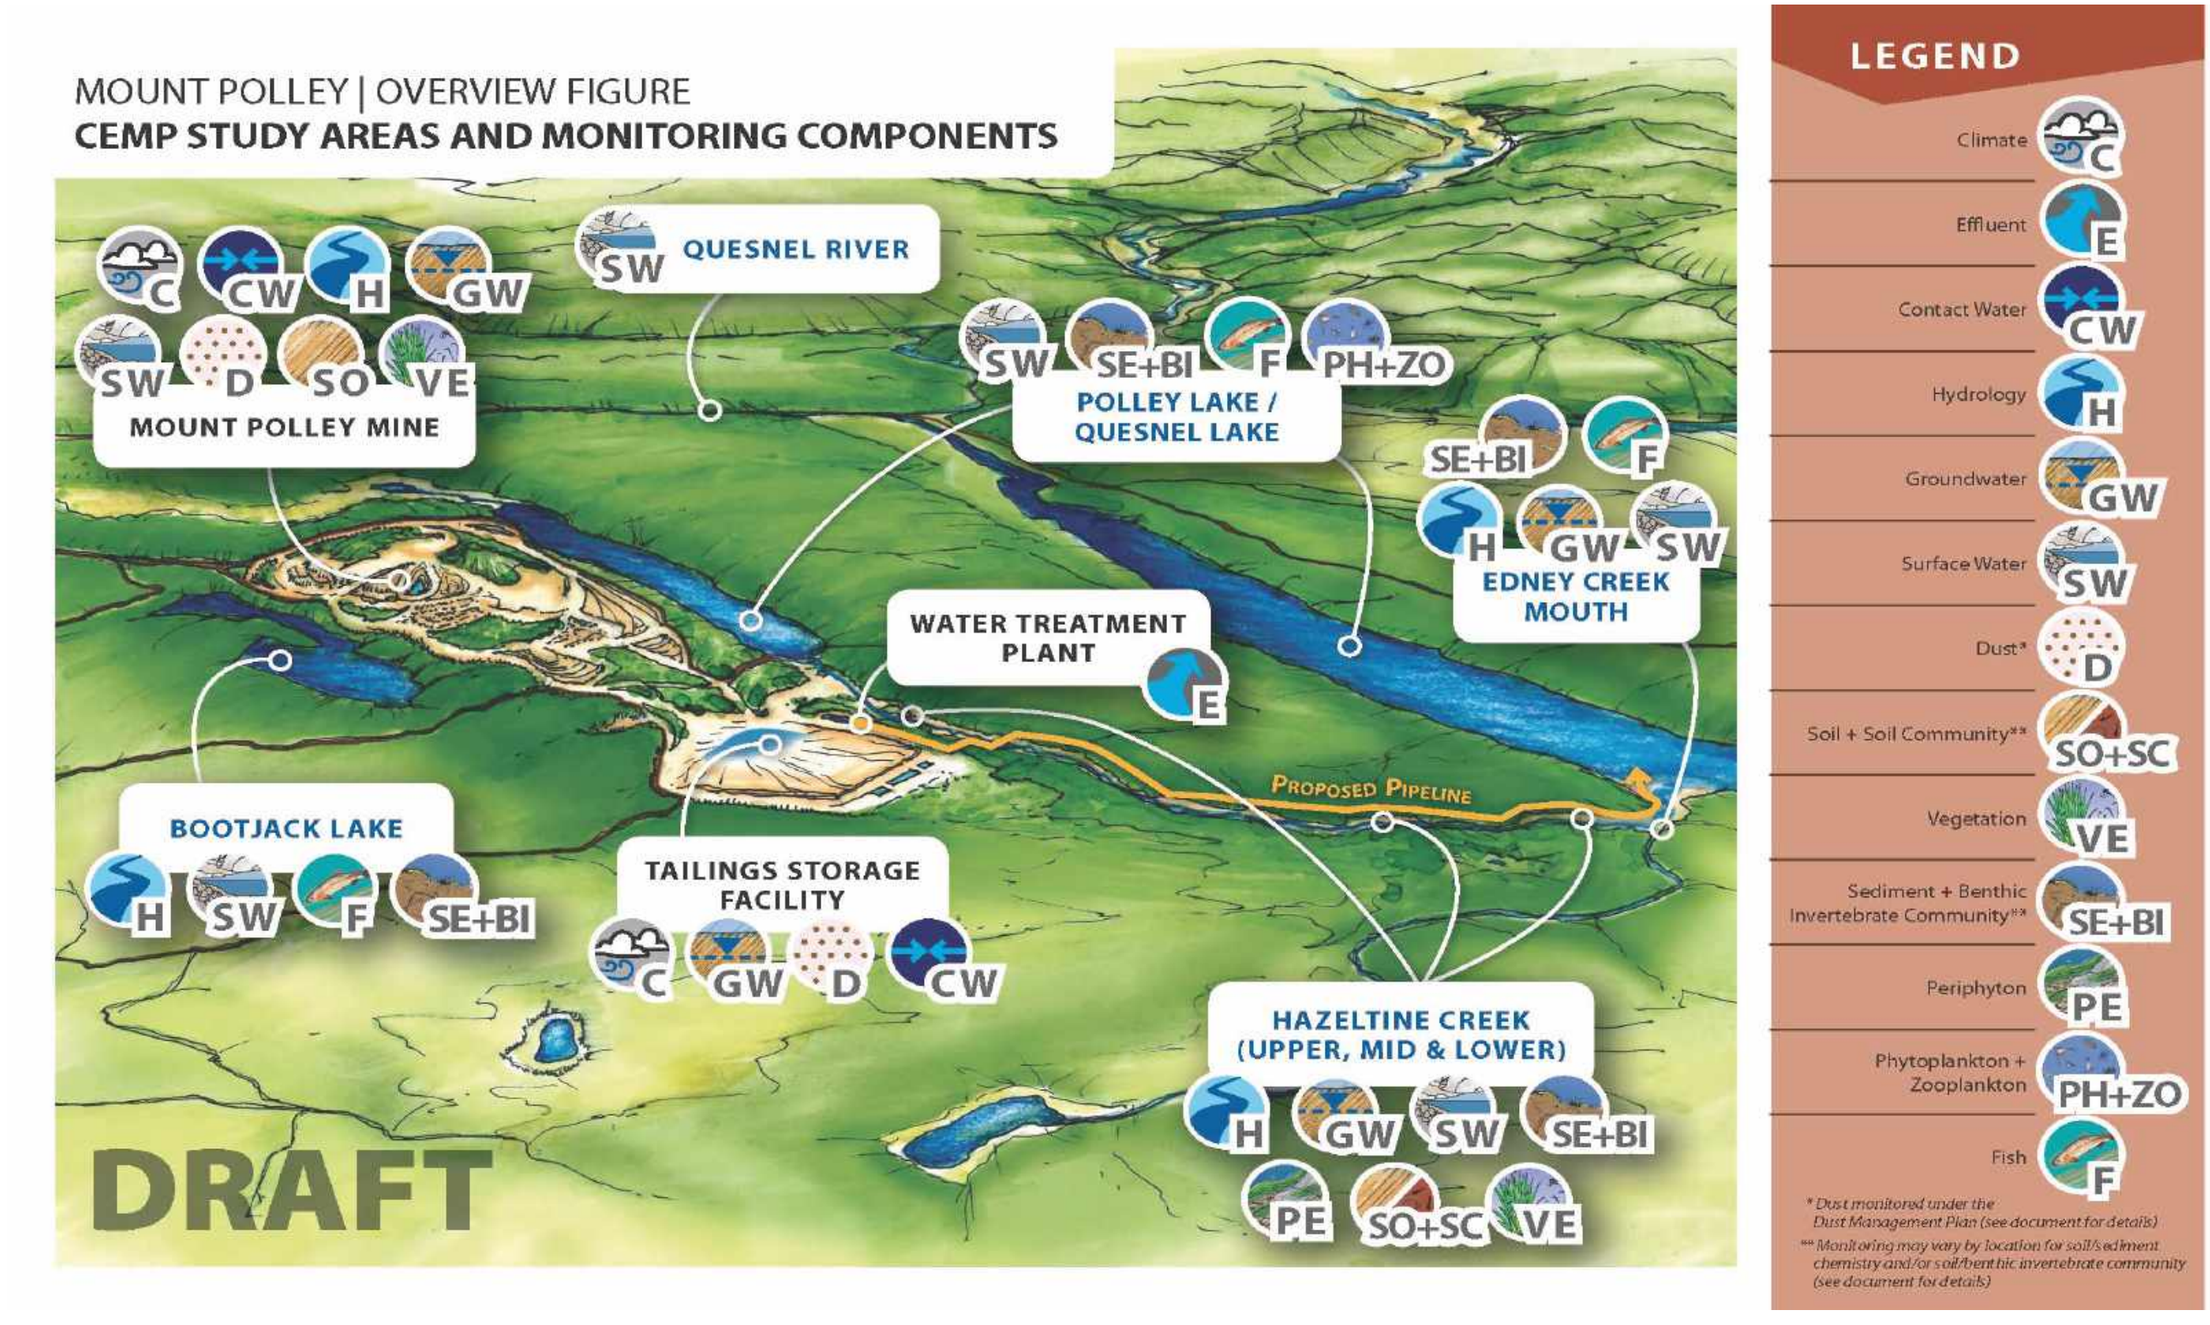

Figure 2.2 CEMP Study Areas and Monitoring Components

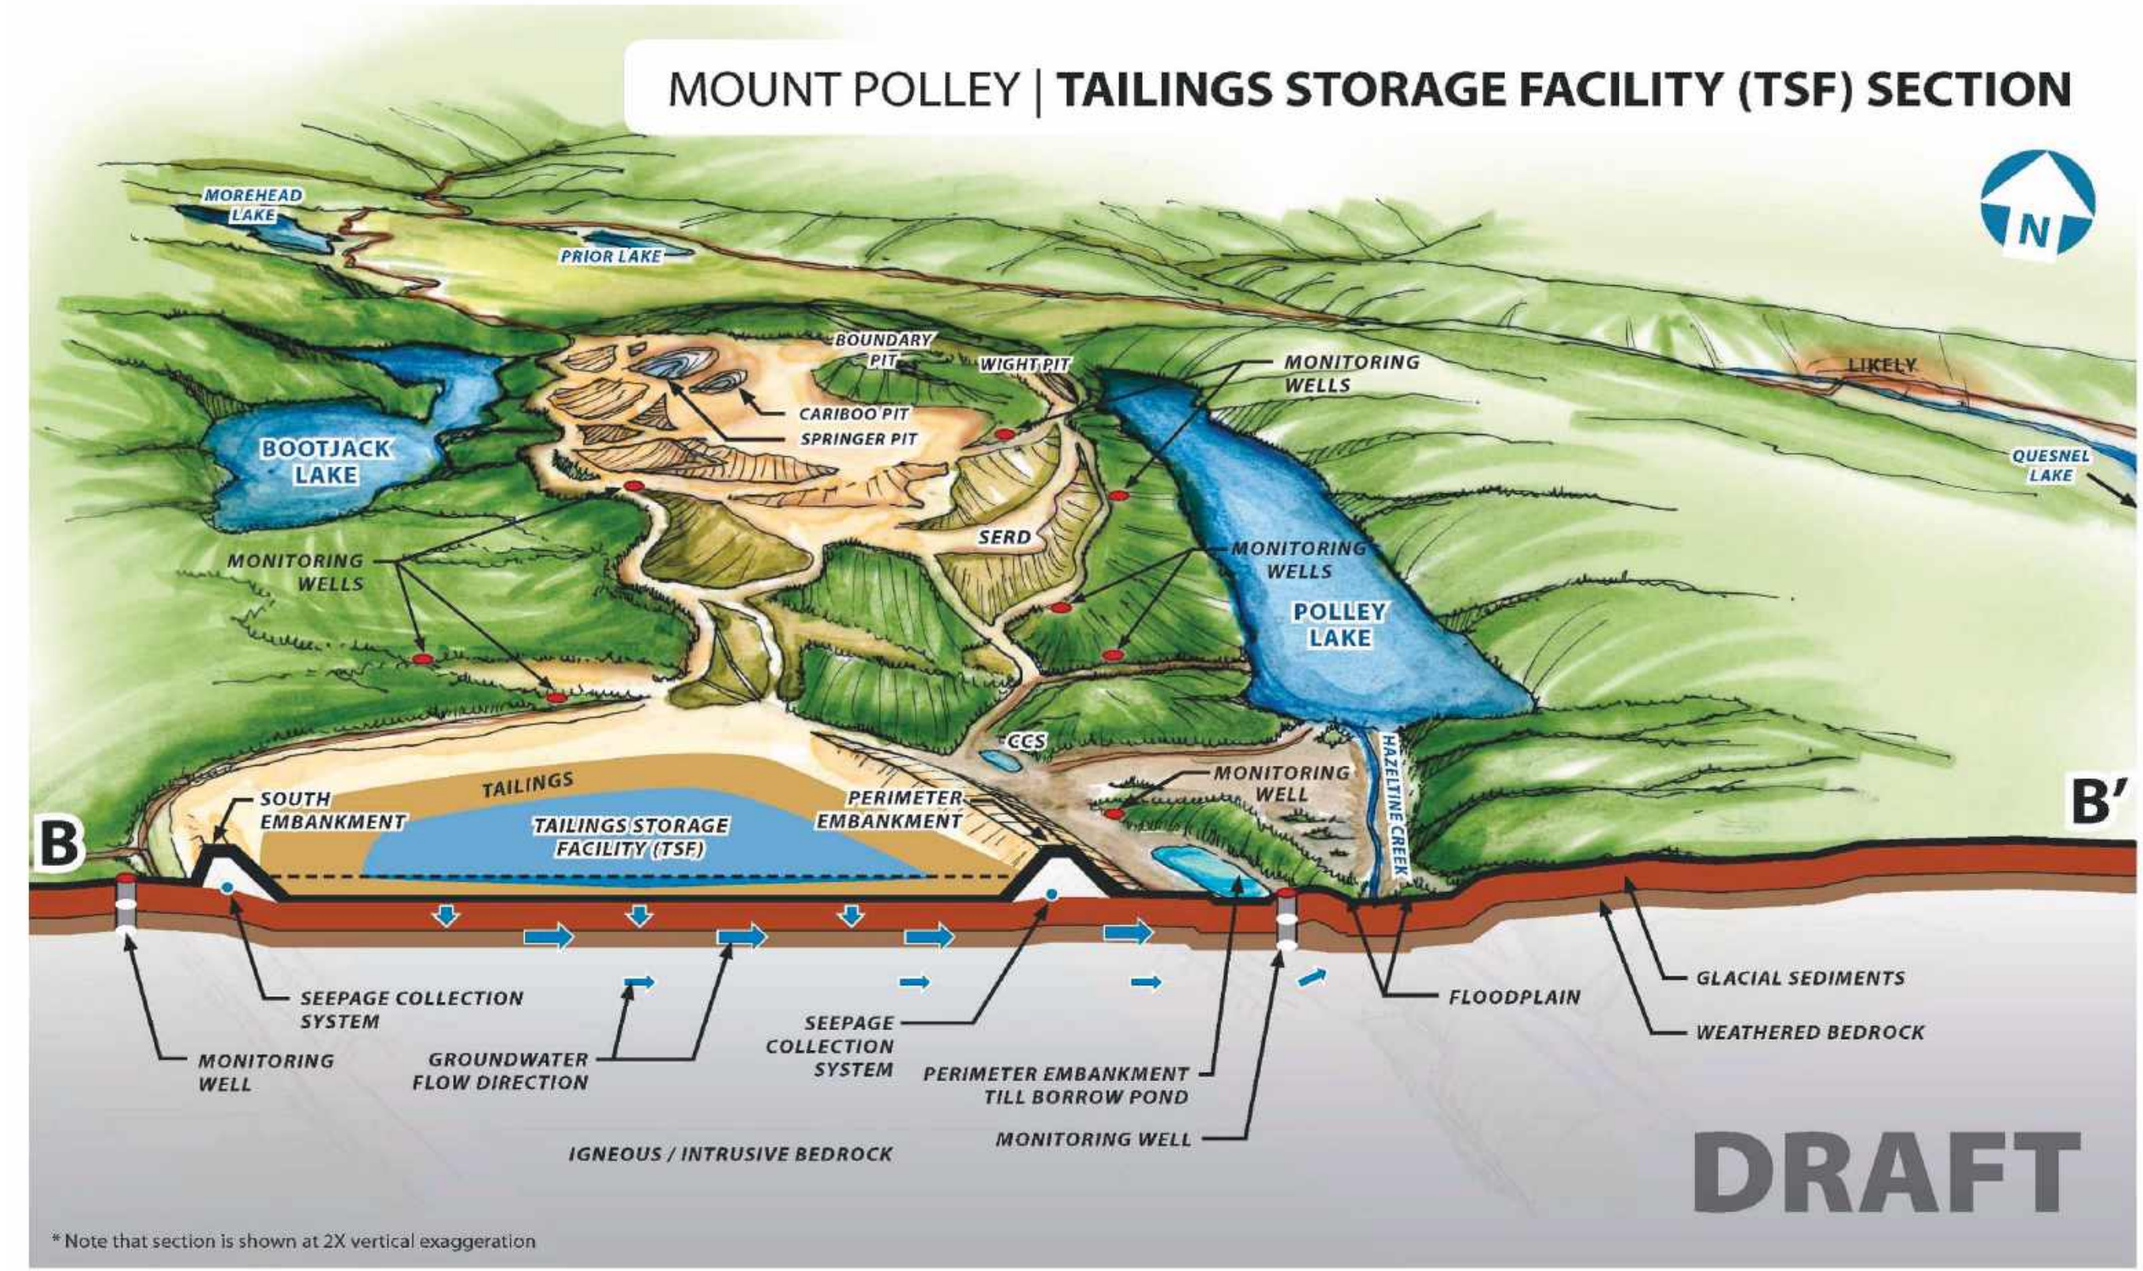

Figure 2.3 Tailings Storage Facility Section

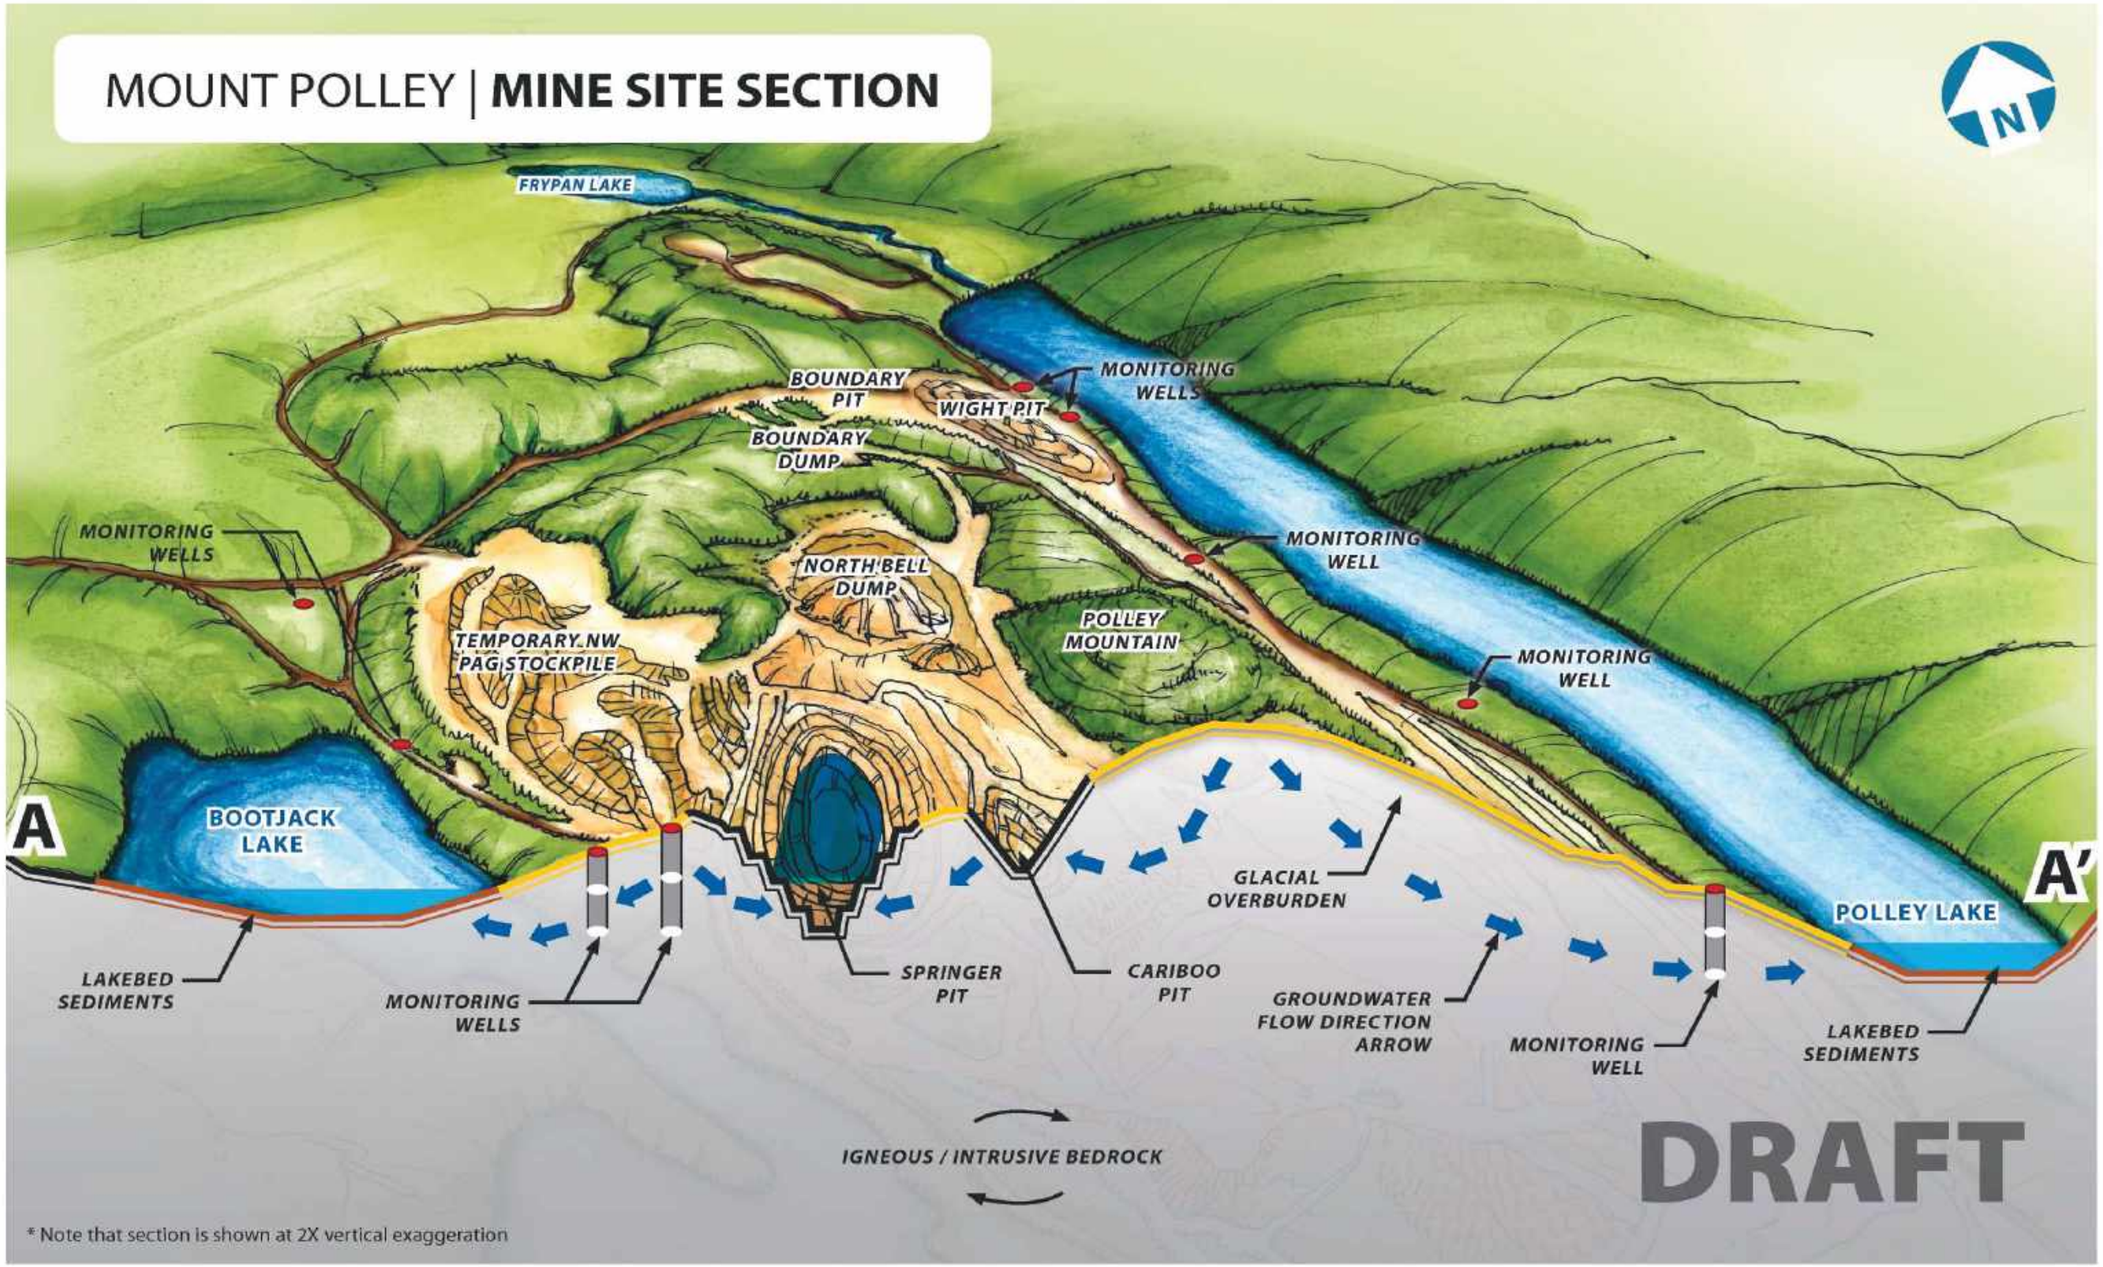

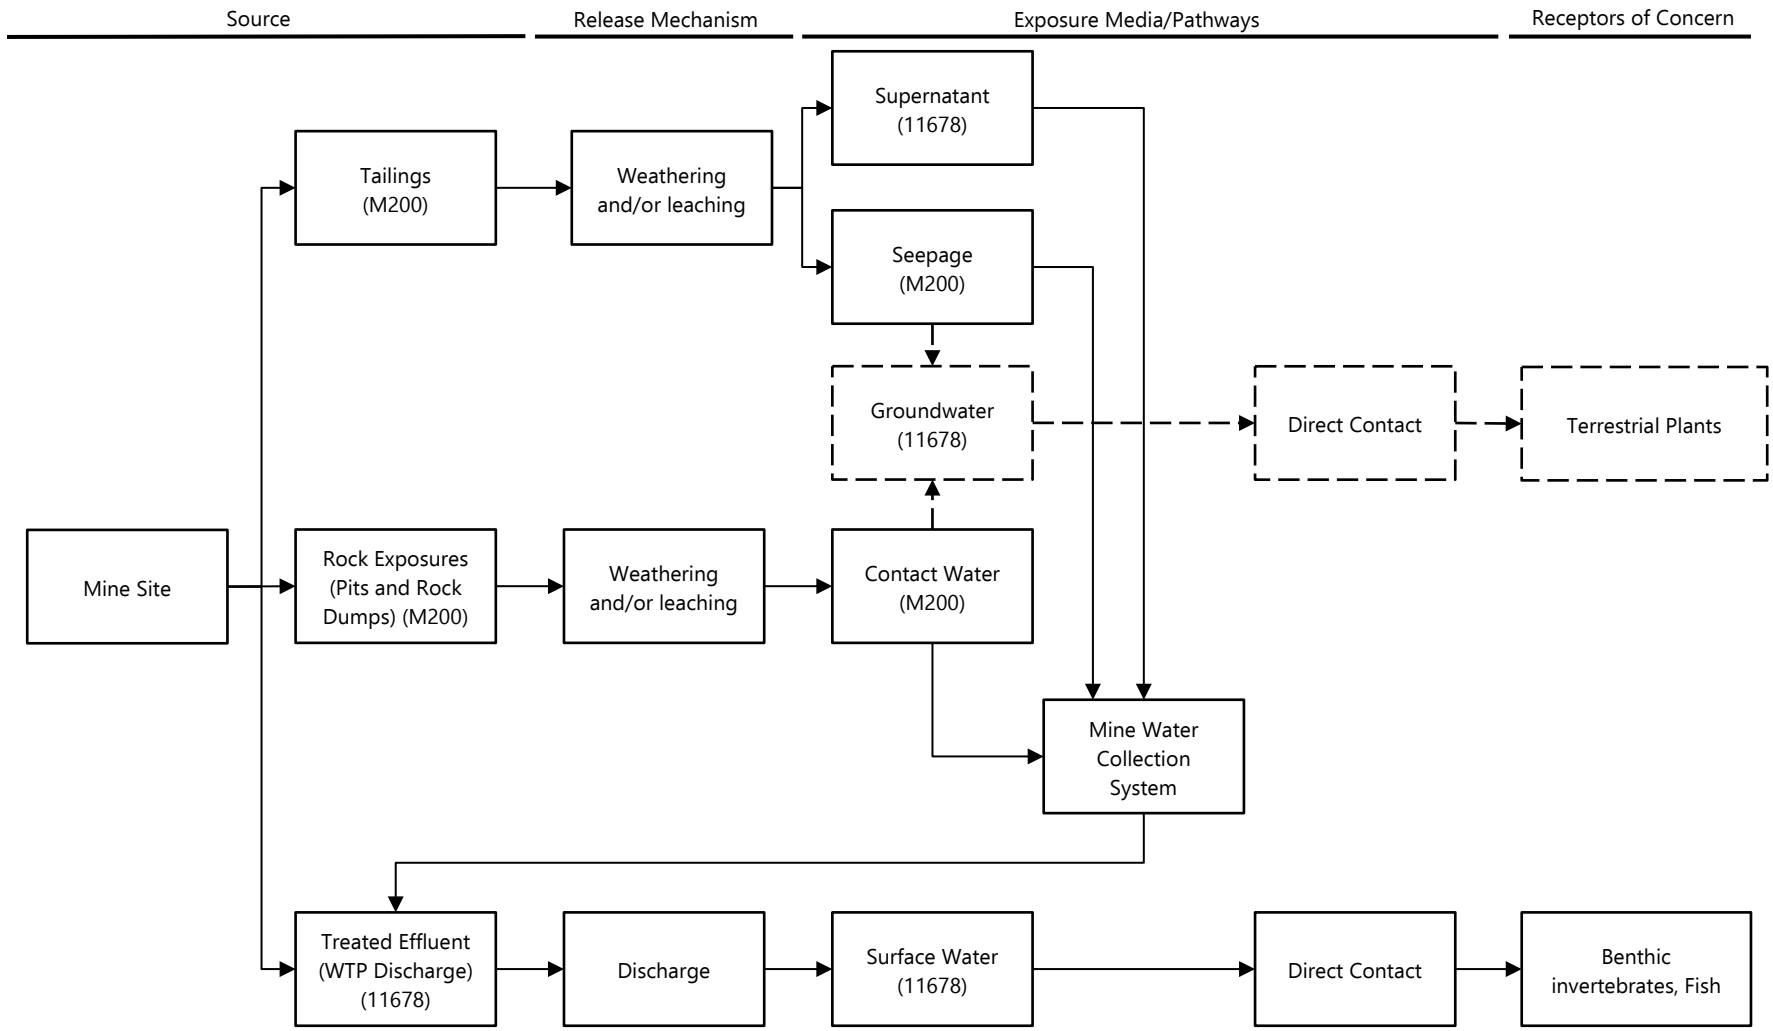

Figure 2.4 Mine Site Section

A CSM helps provide the basis for selecting appropriate monitoring components and suitable locations for those measurements. A CSM provides a graphical articulation of the understanding upon which the CEMP is based including movement of substances, pathways by which organisms (receptors) might become exposed to and interact with those substances in the environment. CSMs are often used in risk assessments to communicate similar concepts; however, in this CEMP, the focus of the study on specific constituents of potential concern (COPCs) has not been an objective because the monitoring program includes broader purposes and will include, for example, the full commercial analytical package for elemental analysis (frequently called "metals analysis"). Groups of substances that will be analyzed for, however, are those related to the potential sources. A CSM specific to the mine site was developed and is shown in Figure 2.5. A CSM for the TSF breach affected areas was developed for the Ecological Risk Assessment (ERA; Golder 2017) and is shown in Figure 2.6.

As discussed in Section 2.1.1, the mine has ongoing operational monitoring needs that centre on permit compliance that include management of site water and ultimately treated water discharges. The mine also needs to address disturbed ground through dust management in the short term. The measurable characteristics or components that contribute information to the stated monitoring objectives can then be identified as variables such as: precipitation and temperature (i.e., climate); dust; mine contact water, groundwater, and surface water quantity and quality; and influent and effluent quantity and quality. These are considered "Site" monitoring components (Figure 2.1). This information contributes to understanding the site water balance, function of site water collection systems, and management of the water treatment plant (WTP; e.g., capacity and treatment efficacy). This information is also useful in understanding the groundwater and seepage flow pathways to Bootjack and Polley lakes.

Ongoing operational activities at the site also have the potential to influence aquatic receiving environments related to effluent discharges. Under the long-term water management plan effluent is discharge from the WTP to Quesnel Lake. Relevant monitoring components for "Aquatic Habitat" include receiving water and sediment chemistry and toxicity, as well as biotic (e.g., plankton, benthos, fish) communities and tissue chemistry as summarized in Figure 2.1.

Following the TSF embankment failure in 2014, the environmental monitoring program was expanded to either incorporate additional monitoring components or increase the frequency of sampling. Many of the same existing operational monitoring components applied to this program and others were added. Additional measurements, related to physical impacts from the event, were collected to contribute to the Post-event Environmental Impact Assessment Report (PEEIAR) and to contribute to the Human Health Risk Assessment (HHRA) and the ERA. This "special purpose" monitoring information is relevant to the Remediation Plan for which an annotated table of contents has been submitted to ENV. As noted in the Risk Monitoring Considerations section of the ERA, further sample collection and evaluation of monitoring data will be done to further refine toxicity reference values for wildlife and confirm bioavailability of copper continues to be low and does not present a risk to wildlife.

Notes:
Solid lines indicate pathways that are likely to be complete or operative.
Dotted lines indicate pathways that are likely to be incomplete or inoperative.

Figure 2.5 Conceptual Site Model for the mine site

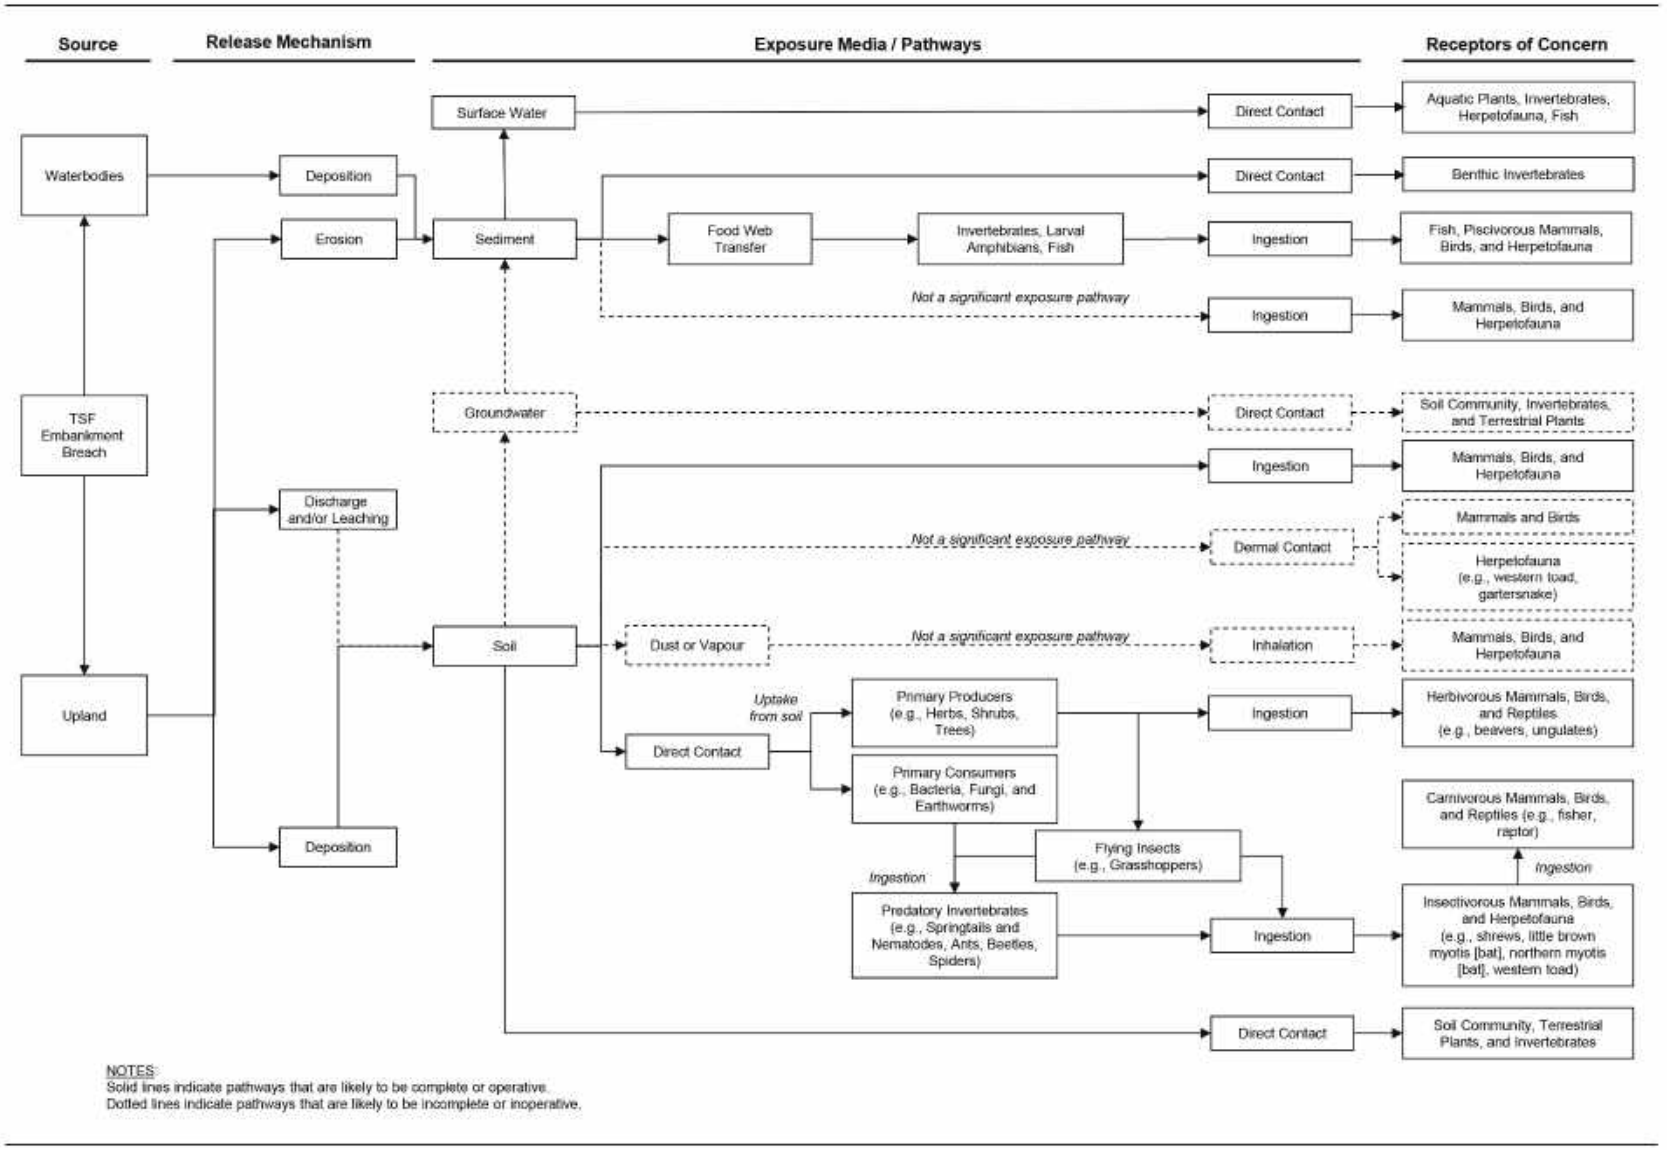

Figure 2.6 Conceptual Site Model for TSF breach affected areas, as developed for the ERA (from Golder 2017)

2.3 Adaptive Management Framework

The CEMP will be adaptive based on the results of ongoing operational and special purpose monitoring (illustrated in Figure 2.7) and based on the developing RCP. The adaptive framework recognizes that studies and monitoring can lead to new information that should be used to inform future monitoring. The framework provides feedback of this new information into the decision-making process that links monitoring and management actions that may need to be implemented to keep MPMC in compliance. For example, more immediate management actions may need to be undertaken in response to pre-defined triggers for unexpected changes in condition. The progressive implementation of the adaptive management framework will also include an annual review of the monitoring program to determine the potential need for revisions to planned sampling and analysis tasks. This review could include cessation of monitoring components that data show may no longer be necessary, or increase of monitoring based on changing conditions or monitoring results. Recommendations for monitoring related to the findings of post-breach-related studies have been included in this CEMP with the intention of forecasting monitoring that may be undertaken in the next three years. Monitoring for a specific year will be verified in monitoring program work plans following the adaptive management framework.

Figure 2.7 Adaptive Management Framework

3 FIRST NATIONS AND STAKEHOLDERS

3.1 FIRST NATIONS ENGAGEMENT

First Nations with recognized claimed traditional territory for the Mount Polley Mine are the T'exelc (Williams Lake Indian Band; WLIB) and the Xatśūll First Nation (Soda Creek Indian Band; SCIB). In 2011 and 2012, MPMC executed Participation Agreements with the WLIB and the SCIB, respectively. Through these respective Participation Agreements, Implementation Committees were formed to facilitate open dialogue between each of the First Nations and MPMC, providing a formalized and regular venue to discuss environmental, social, and economic matters related to mine development, operation, reclamation, and closure (e.g., mine updates, permitting, environmental protection, reclamation, employment opportunities, and potential joint ventures). Meetings with the WLIB have taken place since March 16, 2012 and since July 19, 2012 with the SCIB. Effective October 18, 2012, Joint Implementation Committee meetings have been held with representatives from MPMC, the WLIB, and the SCIB, replacing the previous MPMC/SCIB and MPMC/WLIB Implementation Committee meetings. Joint Implementation Committee meetings are held at minimum quarterly, but typically more frequently. These meetings and associated documentation (TOR, minutes, and action items) provide a well-defined, constructive forum in which issues, reviews, and comments relating to the current and anticipated future operations of the Mount Polley Mine may be discussed. This CEMP and the AERR will be provided in their current form to the SCIB and the WLIB for review, and discussion regarding any comments or concerns will be facilitated through the Joint Implementation Committee.

3.2 PUBLIC LIAISON COMMITTEE

The Public Liaison Committee (PLC) for the Mount Polley Mine was formed in 1999, and meetings have been maintained through the operating years of the Mine. Meetings were historically scheduled in conjunction with updates on proposed developments and projects, with a minimum frequency of one meeting per year. An annual PLC meeting became a requirement of the Permit in 2013 and quarterly meetings became a requirement in 2015. The PLC is intended to provide an opportunity for MPMC to share information about mine activities and the results of monitoring programs with its members, and for members to share such information with their respective membership. The PLC does not replace or diminish the use of other communication procedures that MPMC will use regularly to inform the public, including but not limited to: public meetings, newsletters, emails, and internet websites. The PLC is seen as a medium to add value to parties with interest in the Mount Polley Mine, including, but not limited to: MPMC and its personnel, the public and public interest groups, local communities, First Nations, and regulators.

3.3 COMMUNICATION PLAN

The Permit requires a Communication Plan between MPMC and the WLIB, SCIB, Cariboo Regional District, and the Community of Likely to be in place. The original Communication Plan was submitted to the Director (ENV Statutory Decision Maker) on March 20, 2016 and was approved by the Director on May 11, 2016. The amended Permit required that an updated Communication Plan be submitted by June 30, 2017. The final Communication Plan was submitted to ENV on March 20, 2016.

4 MOUNT POLLEY MINE PROJECT OVERVIEW

4.1 PROJECT HISTORY

Mount Polley Mine, operated by MPMC (a wholly-owned subsidiary of Imperial Metals Corporation), is an open pit copper/gold mine with an underground component, and has the capacity to process 20,000 to 22,000 tonnes per day (tpd) of ore. The Mount Polley property covers 18,892 hectares (ha), which consist of seven mining leases totaling 2,007 ha, and 43 mineral claims encompassing 16,855 ha, as of March 2018.

Clearing of the site and construction of the entire facility began in 1995, with the mill being commissioned in June 1997. In May 1997, the Mine received an ENV (known as the Ministry of Water, Land and Air Protection at that time) Effluent Permit, issued under the provisions of the provincial EMA. This permit authorized the discharge of concentrator tailings, mill site runoff, mine rock runoff, open pit water, and septic tank effluent to a tailings impoundment. Approval of the "Mount Polley Mine Reclamation and Closure Plan" by the EMPR resulted in the issuance of Permit M-200 in July 1997. The first full year of mining and milling at Mount Polley Mine took place in 1998. The mine suspended operations in October 2001 due to low metal prices, then reopened in December 2004 with mill production commencing again in March 2005. A summary of Permit 11678 amendments is provided in Table 4.1.

Table 4.1 Summary of Permit 11678 amendments

Date	Scope of Amendment
30-May-1997	Original permit
20-Oct-1997	Amended authorized tailings discharge rate (10,000 tpd increase)
12-Jun-1998	Amended reporting requirements
08-Sep-1999	Amended monitoring requirements
01-Feb-2000	Amended authorized tailings discharge rate (4,500 tpd increase)
07-Feb-2002	Approval to discharge effluent from the PESCP and MESCP; approval to store TSF supernatant and Mine Site contact water in the Cariboo and Bell Pits
04-May-2005	Amended authorized tailings discharge rate (5,000 tpd increase); discharge of groundwater to Polley Lake; updates to reference analytical procedures and monitoring program
17-Apr-2009	Amended monitoring, water level and supernatant characteristic requirements for the Cariboo and Bell Pits
07-Nov-2012	Approval to discharge to Hazeltine Creek
07-Jun-2013	Sulphate guidelines
09-Jul-2015	Tailings discharge to the Springer Pit
29-Nov-2015	Approval to discharge to Hazeltine Creek
04-Apr-2016	Discharge of additional tailings to the Springer Pit
09-Sep-2016	Hazeltine Creek discharge total suspended solids limit change
07-Apr-2017	Approval to discharge directly to Quesnel Lake

Notes: tdp: tonnes per day; PESCP: Perimeter Embankment Seepage Collection Pond; MESCP: Main Embankment Seepage Collection Pond; TSF: Tailings Storage Facility

As a result of a foundation failure of the perimeter embankment of the TSF on August 4, 2014 (see Section 2.1.2), the mine was placed in care and maintenance until August 5, 2015, when restricted operations under a short-term permit commenced. This restricted operations permit allowed processing of up to 4 million tonnes of ore over a one-year period, with tailings deposition into the Springer Pit.

The Mount Polley Mine became subject to the MDMER on April 10, 2014, following a planned discharge of mine effluent into Hazeltine Creek. The MDMER are also applicable to the long-term discharge approved for the Mount Polley Mine.

4.2 CURRENT OPERATIONS

MPMC was granted full restart permits on June 23, 2016 and has been operating at full capacity since June 27, 2016. The Mount Polley Mine site includes a crusher and mill (includes office spaces), a TSF, waste rock disposal sites, seepage collection ponds, haul roads, access roads, and various small buildings and storage areas (Figure 4.1). Concentrate is transported by truck from the site to the Port of Vancouver, where it is shipped to smelters overseas.

4.3 ENVIRONMENT

4.3.1 TOPOGRAPHY AND CLIMATE

The Mount Polley property is located on the eastern edge of the Fraser Plateau physiographic sub-division, characterized by rolling topography and moderate relief. Elevations range from 920 metres above sea level (masl) at Polley Lake to 1266 masl at the summit of Mount Polley. Volcanic rocks generally underlay this part of the plateau with inclusions of intrusive rocks. Most of the area is covered by a deposit of unconsolidated till which contains fluvial, lacustrine, and colluvial deposits. Some patches of organic soils are present in poorly drained areas (i.e., wetlands). The property is located in an alkali porphyry copper-gold deposit hosted in the Central Quesnel Belt along the Intermontaine Belt of BC.

The site is located within the Interior Cedar Hemlock biogeoclimatic zone. Local forests consist of Western red cedar, Douglas-fir, hybrid spruce, and subalpine fir, with a lesser presence of trembling aspen, black cottonwood, and paper birch. Much of the area has been harvested in commercial logging operations and is also used for cattle grazing.

Average annual precipitation in the study area is 670 millimetres (mm). Precipitation typically occurs as snowfall from November through March, with an average maximum of snowpack of 178 mm snow water equivalent occurring at the end of March (Golder 2015b). Average monthly temperatures at the Mount Polley Mine range from -6.0 degrees Celsius (°C) in January to 15.3°C in July and August (MPMC 2016b). Prevailing winds are from the north-north-east and from the south-south-west near the TSF, and from the northwest (and to a lesser extent the southeast) near the mill, with a predominance of winds designated as calm (below 3 metres per second; Golder 2015b).

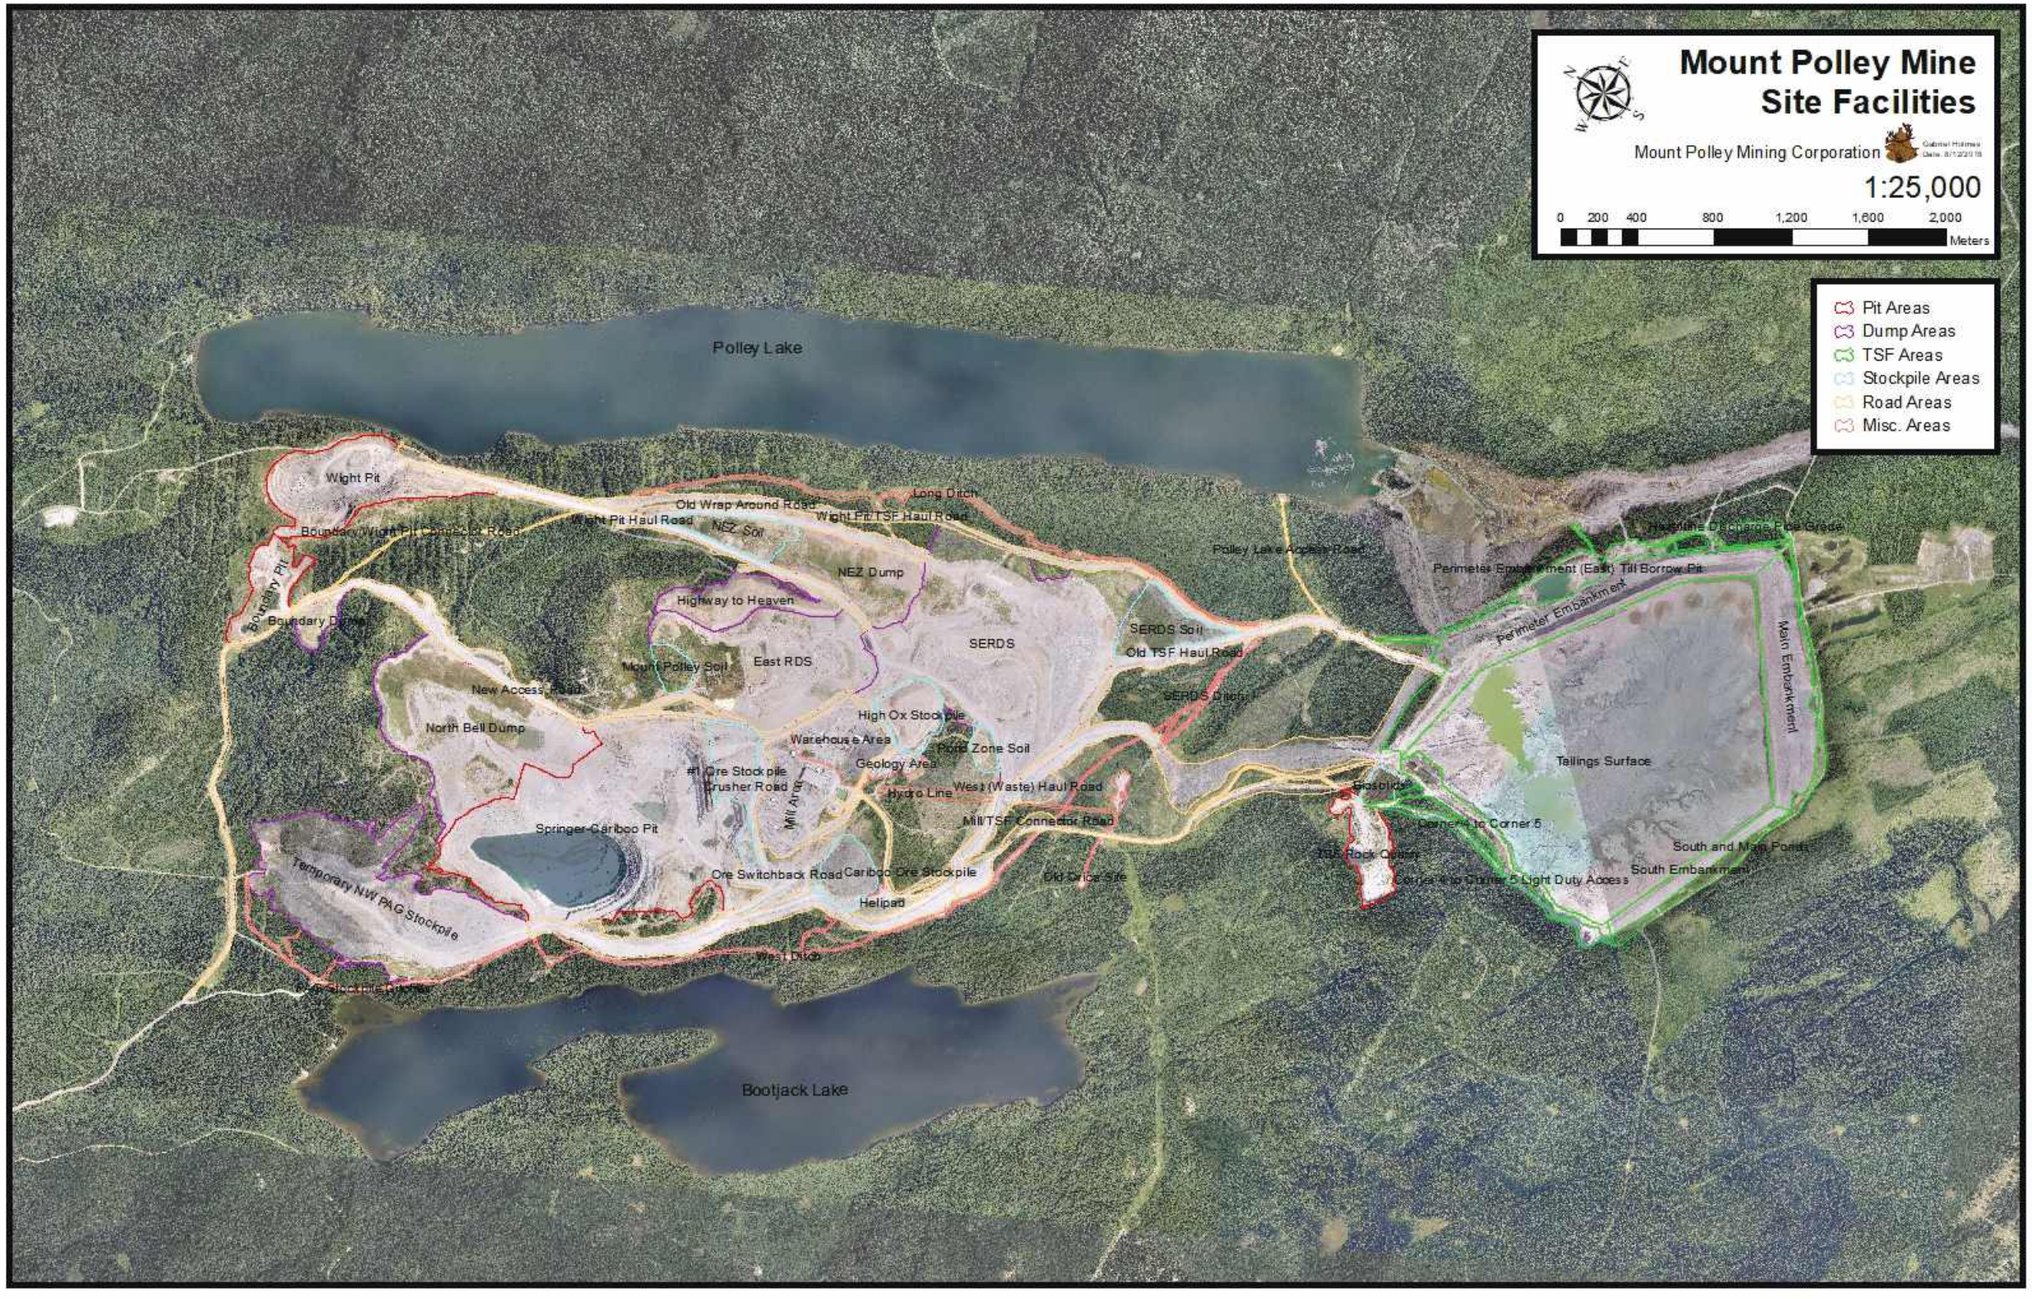

Figure 4.1 Mount Polley Mine site facilities

4.3.2 HYDROGEOLOGY

The groundwater flow at the site occurs primarily in the bedrock units in response to recharge from precipitation in the area between Polley Lake and Bootjack Lake. Flow in the overburden is less significant due to its limited thickness and discontinuous nature. Prior to mining, the water table at the site generally followed the surface topography, but the water table was deeper below the topographic heights and shallower in the low areas. At that time, the direction of groundwater flow was inferred to be from the top of the ridge between the Polley Lake and the Bootjack Lake towards the low lying areas associated with these lakes northeast and southwest from the ridge.

Mine dewatering has altered the groundwater flow pattern at the site, with the open pit and underground workings acting as sinks for groundwater flow. Mine dewatering lowered the water table elevation and created radial patterns of groundwater flow towards these facilities. Following the formation of the pit lake in the Cariboo Pit, seepage from this pit started to provide a contribution to groundwater inflow to the Springer Pit. At present, Springer Pit and Cariboo Pit continue to act as groundwater sinks. The currently available information suggests that some seepage from the Springer Pit lake towards Bootjack Lake occurred when the pit lake level exceeded 1030 m elevation in 2016 (Golder 2016b).

4.3.3 DRAINAGE AND HYDROLOGY

The mine is located on the divide of two sub-watersheds within the Quesnel Lake watershed. Quesnel is a large, deep fjord lake with a surface area of 255 square kilometres (km^2), and is composed of East, West, and North Arms. It is the deepest fjord-type lake in the world, with a maximum depth of more than 511 m in the East Arm (Laval et al. 2008). The West Basin is a shallower (113 m maximum depth) portion of the west arm that is demarcated in the east by a shallow sill near Cariboo Island that is approximately 35 m deep (Laval et al. 2008). The lake drains to the west via the Quesnel River to the Fraser River. The Horsefly River, Mitchell River, and Niagara Creek are the main tributaries to Quesnel Lake, entering from east of the sill.

The western watershed, which includes drainage from Bootjack Lake, Trio Lake, and Morehead Lake, discharges to Quesnel River via Morehead Creek and drained approximately 60% of the Mount Polley area prior to mine construction.

The eastern watershed includes Polley Lake (surface area of 3.8 km^2), which discharges to the east via Hazeltine Creek and then to the western arm of Quesnel Lake. The Hazeltine Creek and Edney Creek watershed areas at Quesnel Lake are currently approximately 30.2 km^2 and 87.4 km^2, respectively. Approximately 10.5 km^2 that historically reported to this watershed is now within the mine contact water runoff collection system catchment.

Bootjack Creek is a small tributary that previously flowed into Hazeltine Creek downstream of Polley Lake. Following the TSF embankment breach, Bootjack Creek was re-routed to Polley Lake; fish access is currently restricted. Historically, Bootjack Lake (surface area of 1.2 km^2) discharged into Hazeltine Creek via Bootjack Creek, but in 1913 a dam was constructed at the south end of Bootjack Lake and the flow direction was reversed in order to direct water into Morehead Lake for hydropower production. This resulted in 14 km^2

being diverted from the Hazeltine Creek catchment. The Morehead Creek watershed, including the Bootjack Lake catchment area, is approximately 11.2 km^2. Approximately 2.3 km^2 that historically reported to this watershed is now within the mine contact water runoff collection system catchment.

Pre-mining watersheds are shown in Figure 4.2. In general, the hydrology of the Mount Polley area is snowmelt driven, with the majority of annual runoff occurring in April and May during snowmelt (i.e., freshet; Knight-Piésold 2014).

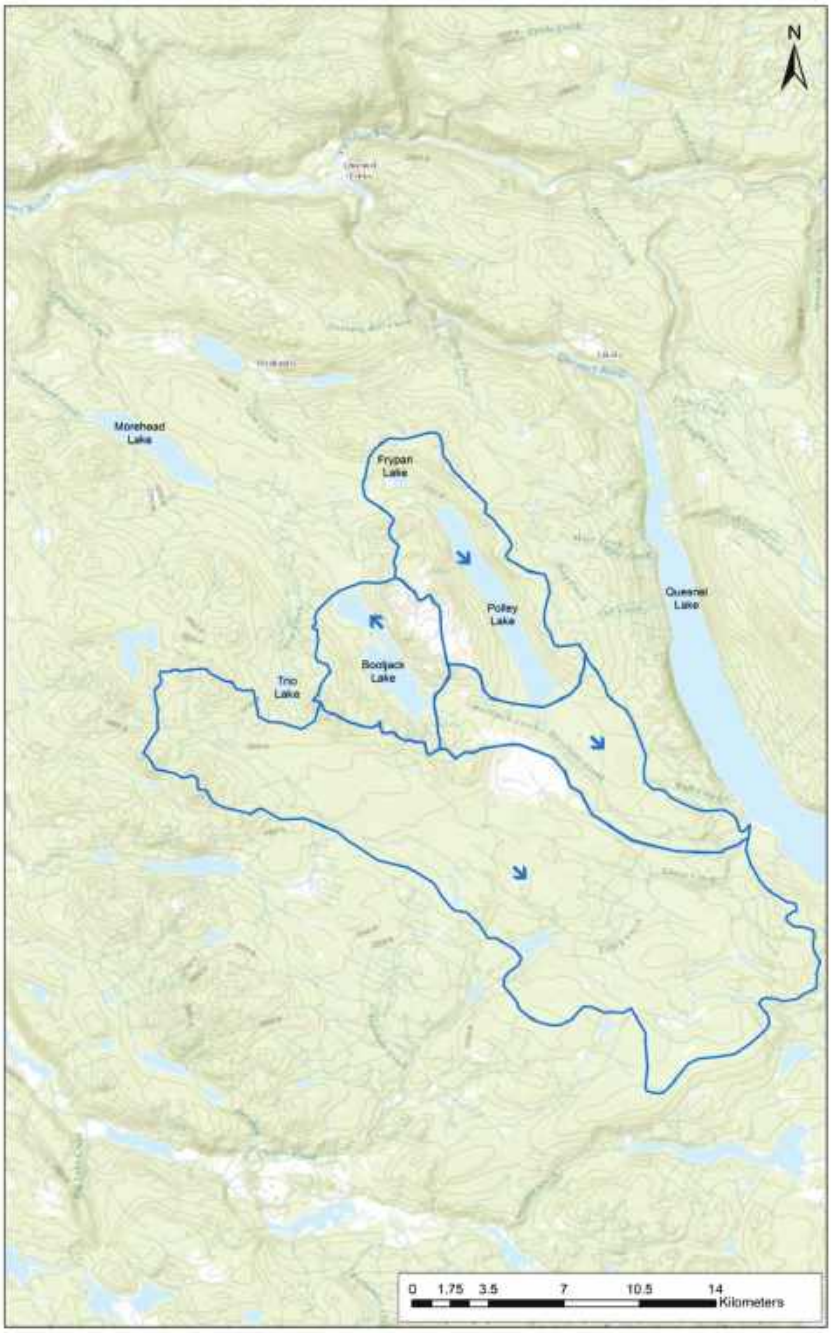

Figure 4.2 Mount Polley area pre-mining watersheds

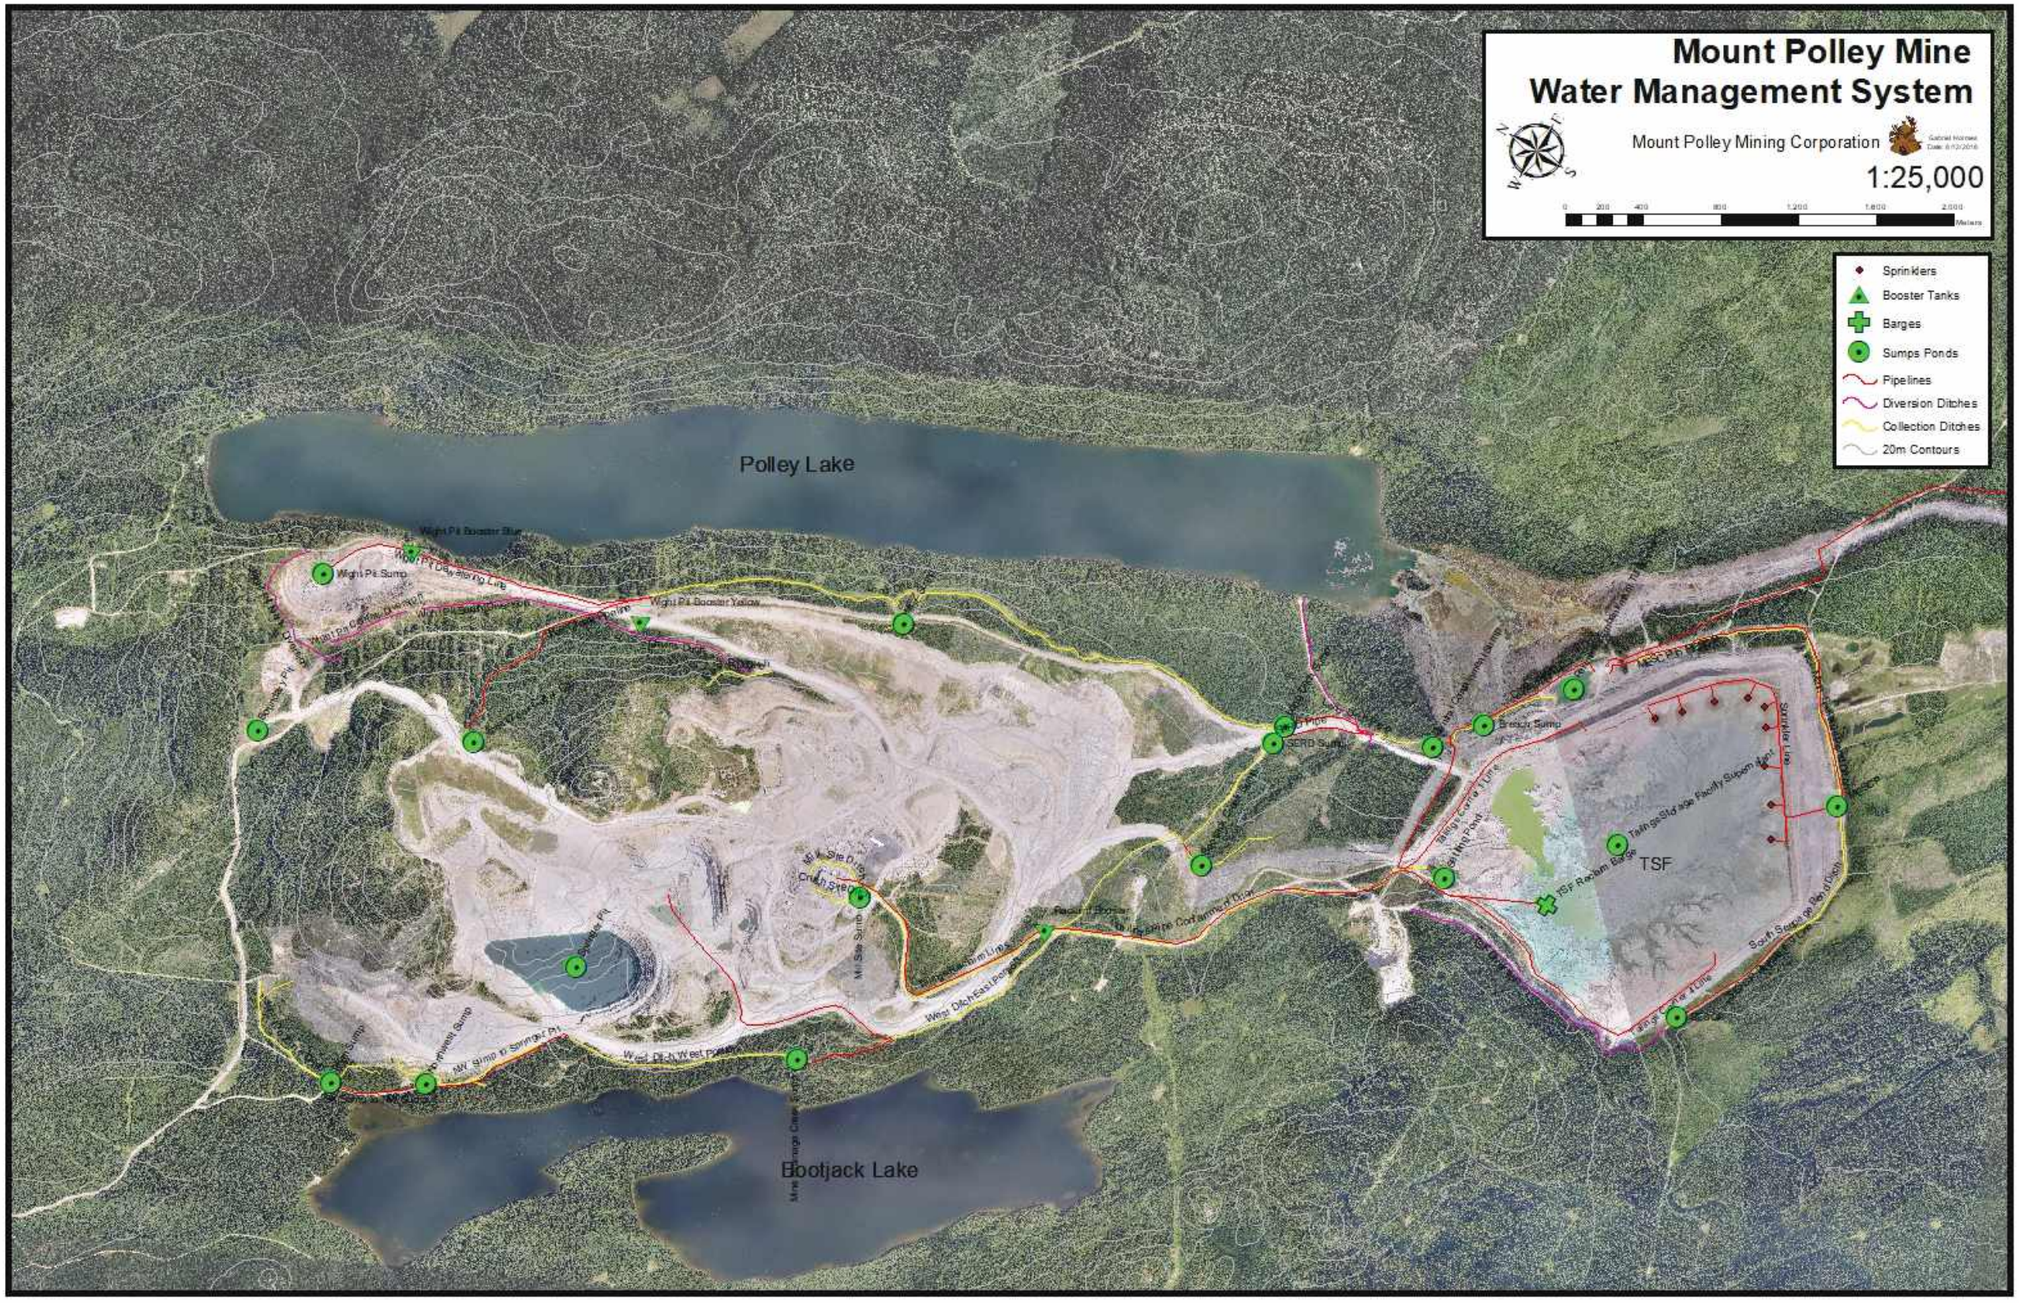
5 ENVIRONMENTAL MANAGEMENT

5.1 WATER MANAGEMENT

To protect natural watercourses from mine-influenced contact water from roads, haul roads, waste rock piles, and other Mine areas, water is collected in a system of ditches and sumps located around the Mine site. Based on site water management objectives, site contact water is either pumped directly to the TSF or reports to the gravity-driven sections of the West Ditch or Long Ditch, the latter two of which both flow to the Central Collection Sump (CCS). Water in the CCS is currently allowed to overflow to the Perimeter Embankment Till Borrow Pond (PETBP) where it is pumped to the WTP or can be returned to the TSF. Pumping infrastructure also exists at the CCS such that it can be directed to the TSF. Water from the TSF is primarily pumped to the Mill via the Booster Station to meet process requirements, but can also be diverted to the CCS. A map of water collection infrastructure, including site collection ditches (including flow direction) and sumps, is shown in Figure 5.1. All water, primarily rain and snow melt, ultimately reports to the PETBP from which it is pumped to the WTP. At the time of writing, any contact water that requires temporary storage on site (i.e., when flows exceed those able to be treated and discharged) is pumped to the TSF. Tailings and process water from the Mill reports by gravity from the Mill to the TSF.



The Mount Polley site has a positive water balance, and a permit for a long-term water discharge system was received on April 7, 2017. Treatment is conducted for removal of suspended solids and associated metals using a Veolia ACTIFLO® system, which is described in detail in Section 5.1.2. Under the long-term water management strategy, treated mine effluent is discharged to Quesnel Lake via a direct pipeline to the submerged diffusers installed in the lake. A continuous discharge of up to 0.6 m^3/s, with an annual average of 0.33 m^3/s is currently permitted until December 31, 2022.

5.1.1 ANNUAL DISCHARGE PLAN

Permit 11678 requires the yearly submission of an Annual Discharge Plan (ADP). The intent of the plan is to identify the specific sources and quantities of water that will be discharged; however, the discharge system (which is described in Section 5.1.2) at Mount Polley is not designed to be able to solely discharge from specific sources and it is not realistic for MPMC to estimate the volumes of precipitation that will occur from year to year. The overall water management at the mine is described in detail in the Long-Term Water Discharge Technical Assessment Report (TAR) that was submitted to ENV October 17, 2016 (Golder 2016e).

5.1.2 DISCHARGE SYSTEM

The WTP sources water from the PETBP. During treatment, the feed water of the WTP undergoes suspended solids removal using Veolia ACTIFLO® water treatment technology. The WTP doses the raw water with coagulant to a tank where a polymer is injected to create floc particles. Microsand is added to ballast the flocculants, which move on to another tank that allows them to swell and mature. The water flows to the next stage, which uses lamella to clarify the water and promote fast settling of the microsand ballasted sludge. The clarified water is discharged and the sludge is separated from the microsand, which is reused.

An on-line turbidity meter measures the turbidity every ten seconds, where the WTP human-machine interface calculates the total suspended solids (TSS) using a calibrated factor based on a site-specific correlation between turbidity and TSS for the treated effluent. If the calculated on-line TSS is greater than 13 mg/L for 10 minutes, or greater than 14 mg/L instantaneously, an alarm sounds to alert the operator and the WTP automatically goes into recirculation mode and ceases discharge.

Treated water from the WTP is discharged, by gravity, to Quesnel Lake via a pipeline (installed as of November 2017) connected to two submerged diffusers. Effluent discharge to the Hazeltine Creek channel ceased as of September 30, 2017.

5.2 Sediment and Erosion Control Management Plan

MPMC has developed a RCP that has been submitted to EMPR under the *Mines Act* Permit M-200. This plan includes several Environmental Management Plans including a Sediment and Erosion Control Plan.

5.3 Invasive Plant Management Plan

MPMC developed an Invasive Plant Management Plan in 2010 and has regularly updated this plan to include newly disturbed areas and to follow the Cariboo Regional District Strategic Plan for Invasive Plant Management. This plan is included in the RCP.

5.4 Dust Management Plan

MPMC maintains a Dust Management Plan that is also included in the RCP.

5.5 Project Environmental Monitoring Plans

MPMC develops a project specific Environmental Monitoring Plans (EMPs) for any development project that has potential to impact the environment. The requirement for these EMPs is outlined in the Erosion and Sediment Control Plan (Section 5.2).

5.6 Waste Management

MPMC recognizes the value of responsible waste management and recycling. MPMC Recycling and Waste Management Awareness presentations are given to Mount Polley employees annually and MPMC promotes several recycling programs for used materials including waste oil, scrap steel, batteries, plastic pails, electronic waste, light bulbs and associated fixtures, paper, cardboard, and beverage containers. Waste management information is also presented to employees and contractors during site orientation. Each year, Mount Polley donates the funds generated by its beverage container recycling program to local charities.

In the course of its ongoing operations, Mount Polley utilizes potentially hazardous chemicals, reagents, and other products. Sumas Environmental Services Ltd. routinely removes and disposes of these waste products in an environmentally safe manner compliant with all relevant waste management legislation. Products removed include: aerosol cans; contaminated gasoline and diesel; waste oil (in drums); waste oil filters; waste grease fuel or oil soaked rags, debris, and floor dry; and leachable liquid toxic waste, such as

glycol/anti-freeze mix. The site waste oil tanks are emptied and the oil removed from site by a third party contractor. MPMC is registered (BCG-01559) with the ENV under the *Hazardous Waste Regulation* for generation and temporary storage of these materials.

5.7 INCIDENT REPORTING

All non-compliance incidents are reported to the Director or to Emergency Management BC. All incidents are recorded and tracked, and are included in the AERR. As outlined in the Communication Plan (see Section 3.3) and required by Section 2.5 of the permit, incidents or emergencies that have the potential to have adverse impacts on the environment will be reported to the SCIB, WLIB, Cariboo Regional District and community of Likely.

5.8 INSPECTIONS

MPMC Environmental Department staff conduct weekly inspections on the site with a focus toward regulatory compliance and waste management (Section 5.6). These inspections are documented and communicated regularly to the site management and their respective departments. Guidance is provided by the Environmental Department for proper internal reporting and follow-up. The goal of these inspections is to provide all departments the capability to engage in proper environmental management practices and open lines of communication with the Environmental Department.

6 MONITORING

The subsections below outline general procedures at MPMC for scheduling of environmental monitoring and data review and management. Field methods, laboratory analysis, data quality control and objectives, as well as data analysis methods are included in the following sections with their respective monitoring components. Note that frequencies may change due to weather conditions or construction work and will be dependent on accessibility and, most importantly, safety of the field crews. Declarations of Competency for relevant Qualified Professionals are provided in Appendix E.

6.1 SCHEDULING

To coordinate sampling and schedule all planned monitoring, as per the CEMP, MPMC prepares internal monthly sampling schedules. An example monthly sampling schedule has been included as Appendix C.

6.2 FIELD METHODS

Monitoring procedures that will be used in carrying out the CEMP are consistent with the *BC Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples* (2013 or most recent version, herein referred to as the "BC Field Sampling Manual"; MoE 2013a). As appropriate, monitoring procedures will also be consistent with the *Metal Mining Technical Guidance for Environmental Effects Monitoring* (Environment Canada 2012) and the *Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators* (MoE 2012). MPMC's procedures are also consistent with applicable sections of the *British Columbia Environmental Laboratory Manual* (MoE 2015), such as sample collection and preservation requirements.

Quality assurance/quality control (QA/QC) methods will follow procedures outlined in the *MPMC Environmental Department QA/QC Manual* (most recent version: MPMC 2016c, herein referred to as the "QA/QC Manual", developed for the Mount Polley Mine. This manual provides detailed Standard Operating Procedures (SOPs) and Work Methods (WMs) of the protocols for environmental monitoring at MPMC and is a requirement of the Permit (April 7, 2017: Section 3.8). Procedures described in the manual are consistent with the BC Field Sampling Manual (MoE 2013a). The QA/QC Manual is reviewed and updated as appropriate (at minimum annually) to reflect changes to the ENV procedures and recommendations, and industry best practices. Should the manual be updated, the ENV Environmental Protection Division will be notified within 30 days of implementation as required by the Permit.

The QA/QC Manual protocols include collection of samples by trained personnel using standardized procedures, and use of field notebooks and chain of custody forms for sample documentation and tracking. These protocols are summarized for the different CEMP monitoring components below, where appropriate.

6.3 LABORATORY ANALYSIS

Sample analysis will be conducted at a laboratory registered for the designated parameter under the *Environmental Data Quality Assurance Regulation*. MPMC will participate in QA audits as required by the regulation.

6.4 Data Quality Review and Data Management

A data quality review of results will be conducted, including screening of laboratory QA/QC data, sample integrity issues, detection limits achieved, and metadata accuracy, as well as potential outliers/extreme values. This information will be catalogued in the MPMC sample tracking spreadsheets and the laboratory is contacted if any problem is identified. Water, soil, sediment, and tissue chemistry data as well as weather station data will be uploaded into the MP-5 database using files generated by the analytical laboratory. Accompanying field data will be manually entered and uploaded into the MP-5 database. Original laboratory-produced results files are filed on the MPMC network by date, and are linked to the data stored in the MP-5 database. Field data undergo a QC screening prior to upload and parameter restrictions are in place to reduce the likelihood of a typographical or laboratory reporting error being uploaded.

Non-chemistry data, including toxicity testing results, benthic invertebrate and plankton taxonomy data, and hydrology data (logger downloads and FlowTracker exports) are filed according to year and site on the MPMC network.

6.5 Climate Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.5.1 Section Authors and Study Component Design Professionals

This section was written by MPMC and is guided by Section 3.6 of the Permit (April 7, 2017).

6.5.2 Monitoring Objectives

The objective of the climate monitoring program is to track site weather data to support maintenance of the site water balance, water flow and accumulation predictions, and the design of water management infrastructure. Climate data are also considered important basic site characterization information that inform a number of other activities, such as reclamation revegetation prescriptions or building snow load requirements. Climate monitoring is also required under the Permit Section 3.6 (April 7, 2017).

6.5.3 Monitoring Overview

MPMC maintains two automated HOBO weather stations. Both stations are connected via telemetry allowing real time viewing of weather conditions. Four snow course sites are located around the mine site to target different exposure conditions. Table 6.1 provides an overview of the climate monitoring. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.1 shows monitoring locations of the meteorological monitoring locations.

Table 6.1 Climate monitoring overview

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
Weather Station #1	N/A	Continuous monitoring weather station beside tree plots near Mill Site	Logged every 5 minutes	Temperature, wind speed and direction, solar radiation, relative humidity, rainfall	N/A
Weather Station #2	N/A	Continuous monitoring weather station adjacent to the TSF	Logged every 5 minutes	Temperature, wind speed and direction, solar radiation, relative humidity, rainfall	N/A
JCP	N/A	Snow course site located east of the start of the Long Ditch in a clearing	End of month and after major snowfall and melting events	Snow depth, snow volume	N/A
Weather Station #1	N/A	Snow course site located near Weather Station #1	End of month and after major snowfall and melting events	Snow depth, snow volume	N/A
PAG Stockpile	N/A	Snow course site located beside the NW sump	End of month and after major snowfall and melting events	Snow depth, snow volume	N/A

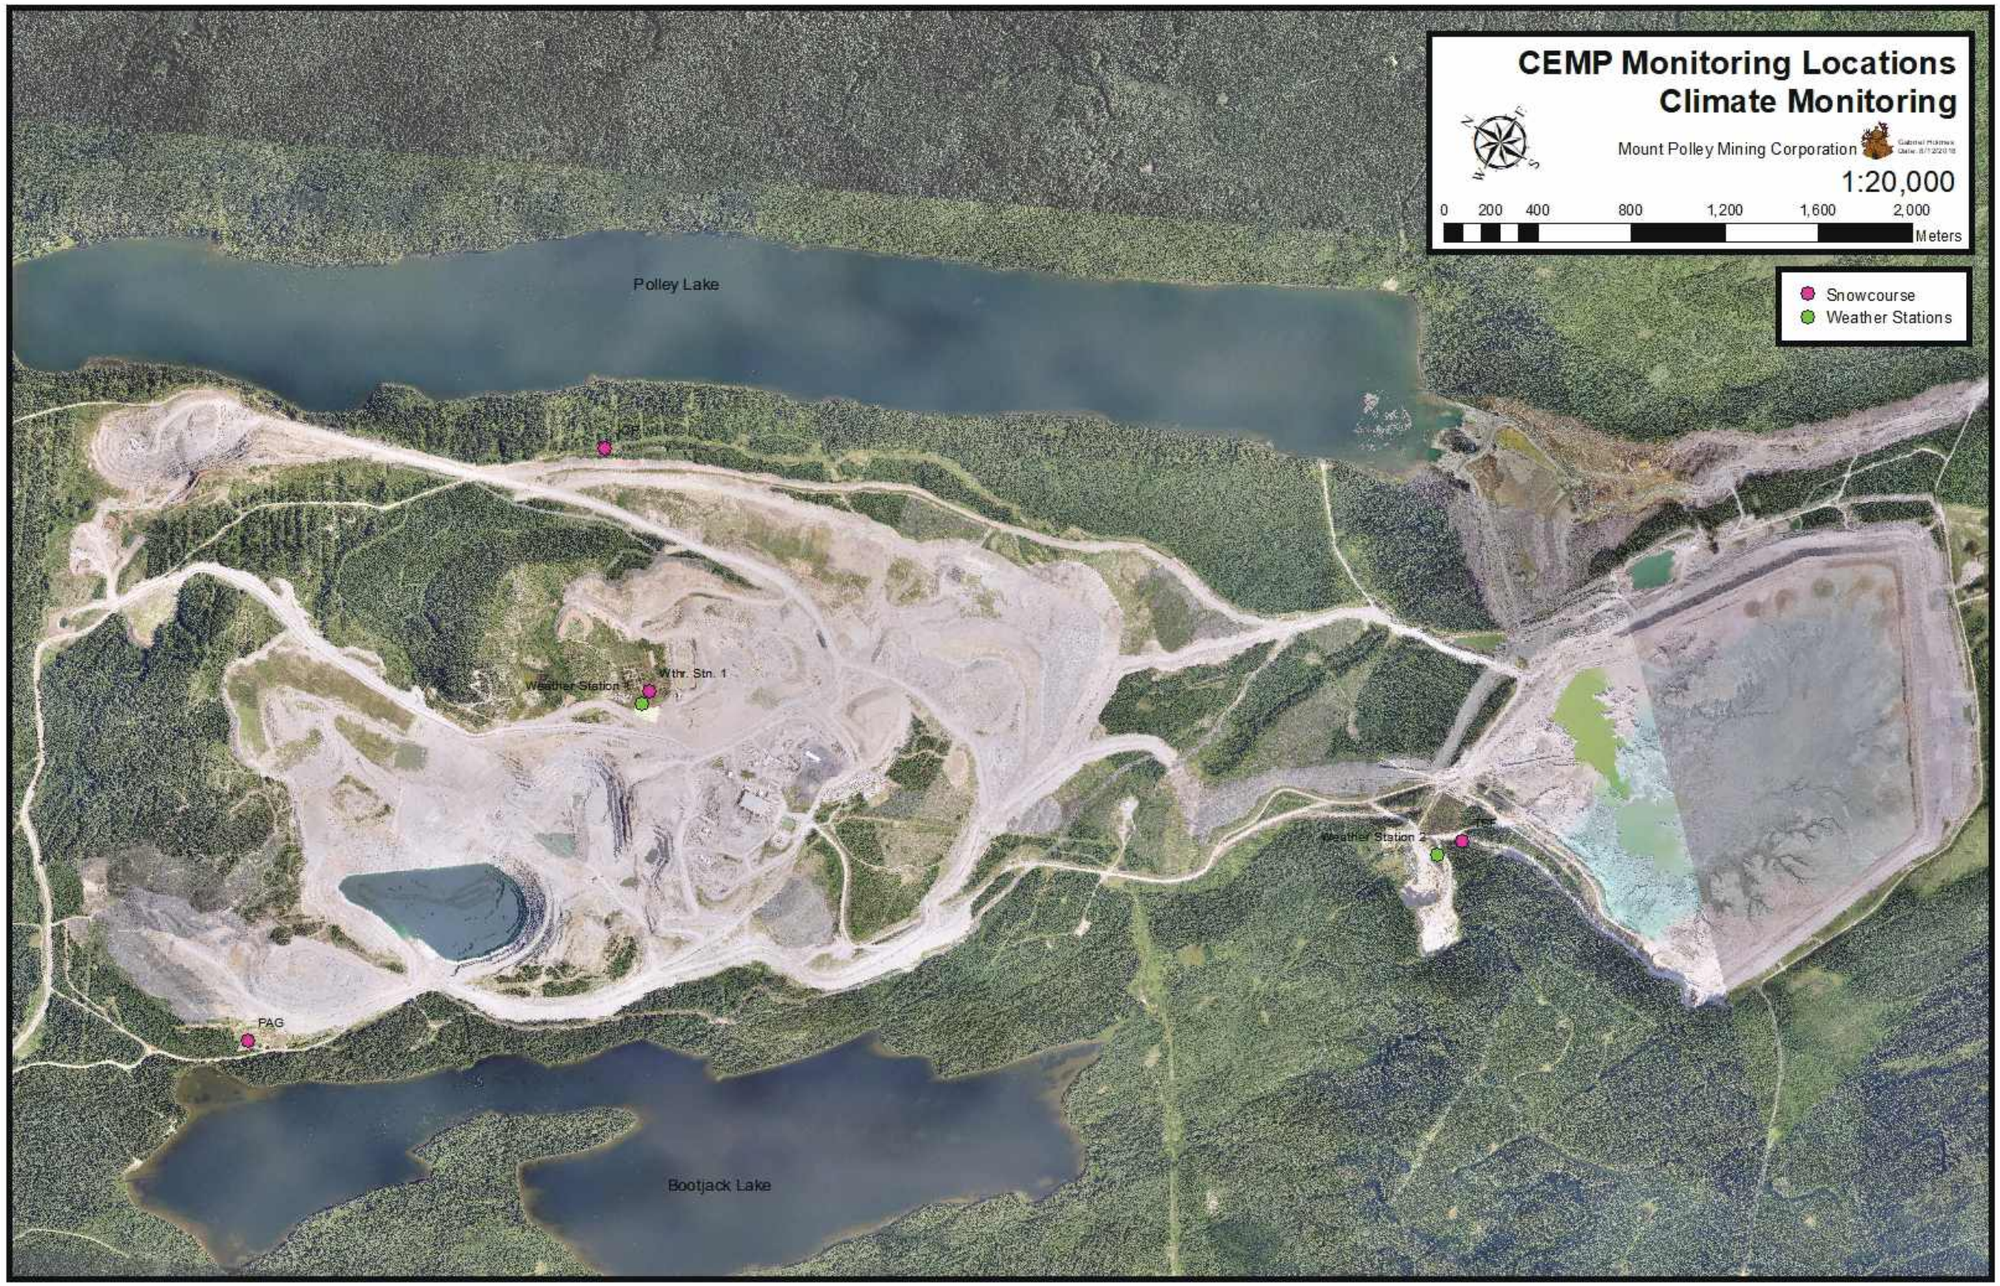

Figure 6.1 CEMP monitoring locations: Climate monitoring

6.5.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Meteorological monitoring will occur as per the SOPs and WMs for Meteorological Data Collection and Snowpack Measurements in the QA/QC Manual. There are two automated HOBO weather stations located on the mine site that continuously record wind speed and direction, precipitation, solar radiation, relative humidity, and temperature. Evaporation is calculated based on data collected from these stations. The data are downloaded from the automated weather stations monthly or as required by remote radio telemetry. If necessary, data are also stored for 30 days on the weather logger and can be downloaded manually using a data shuttle.

The snowpack measurement method will change in 2018 to align with the *Snow Survey Sampling Guide* written by ENV (MoE 2016). A workshop will be given to the Environmental Staff at first snowfall in fall 2018. The SOP and WM for Snowpack Measurements will be updated at this time and submitted to ENV for review.

Table 6.2 is a summary of previous climate monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.2 Summary of climate monitoring

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Two weather stations collect temperature, wind speed and direction, solar radiation, and precipitation data. Snowpack data was collected at four representative snow course sites. The weather and snow course stations are situated to encompass the topographical and geographic range of the mine site.	N/A	N/A
Summary of findings	Weather data collected were compared to site averages. Evaporation was calculated using measured parameters.	N/A	N/A
Recommendations for 2018-2020 monitoring	The snowpack measurement method will be changed to align with the *Snow Survey Sampling Guide*. The program will otherwise continue unchanged because the two current weather stations and snow course sites provide adequate information for the conditions on site.	N/A	N/A

Notes: N/A – not applicable

6.5.5 Data Quality Control, Objectives, and Review

Data ranges are set in the MP-5 database to detect erroneous data collected during station malfunctions. Weather station data that are erroneous (e.g., sensor malfunctions) will be investigated.

6.5.6 Laboratory Analysis

No laboratory analysis is required for climate monitoring.

6.5.7 Data Analysis and Reporting

Climate statistics, including mean, minimum, and maximum temperature, will be calculated and reviewed monthly. Daily evaporation is calculated using the Penman-Monteith equation for open water in the WaSIM software (developed by Cranfield University), based on data collected from the weather stations and site-specific factors, such as weather station elevation. These data are reported annually in the AERR.

6.6 Surface Water Monitoring

Surface water monitoring is characterised below into the following locations: Hazeltine Creek, streams and creeks adjacent to the mine site (receiving environment of the mine site), Bootjack Lake, Polley Lake, Edney Creek, Quesnel Lake, and Quesnel River.

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.6.1 Section Authors and Study Design Professionals

The mine site environmental monitoring was developed during the Environmental Assessment process in 1995, which included input from several QPs. For the purpose of the CEMP, MPMC will continue to monitor with the understanding that this program is well-established to monitor any mine-related effects. The mine site monitoring described below was written by MPMC.

6.6.2 Monitoring Objectives

The objective of water chemistry monitoring in Hazeltine Creek is to evaluate the Hazeltine Creek aquatic environment following the TSF embankment breach and track changes to the aquatic environment over time and/or as a result of implementation of rehabilitation and sediment and erosion control work.

The objective of water chemistry monitoring in streams and creeks adjacent to the mine site, as well as Bootjack Lake and Polley Lake, is to identify water quality changes in waterbodies that run through or are adjacent to the mine site to assess efficacy of the mine water management systems and to stimulate applicable management actions.

The objective of water chemistry monitoring in Polley Lake, Quesnel Lake, and Quesnel River is to support ongoing evaluation of water chemistry following the TSF embankment breach in the downstream environments.

The objective of water chemistry monitoring in Quesnel Lake at the boundary of the initial dilution zone (IDZ) is to verify that the discharge of treated effluent is not causing an exceedance of the applicable ambient BC Water Quality Guidelines at the edge of the IDZ, as required by the Permit, and to verify the discharge model, as described in the ADP.

Monitoring of the far-field receiving environment in Quesnel Lake in the West Basin will be carried out downstream and upstream (for reference) of the mouth of Hazeltine Creek for the verification of the discharge model as described in the ADP.

6.6.3 MONITORING OVERVIEW

Table 6.3 summarizes the parameters analysed for surface water quality. The lake field parameters are measured at each sampling depth and for each limnological profile (excluding Secchi depth, which is taken from the surface of each lake sampling point). Table 6.4 provides an overview of the surface water monitoring. The location "Mine Site" refers to the streams and creeks adjacent to the mine site. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.2 shows monitoring locations of the surface water sampling locations.

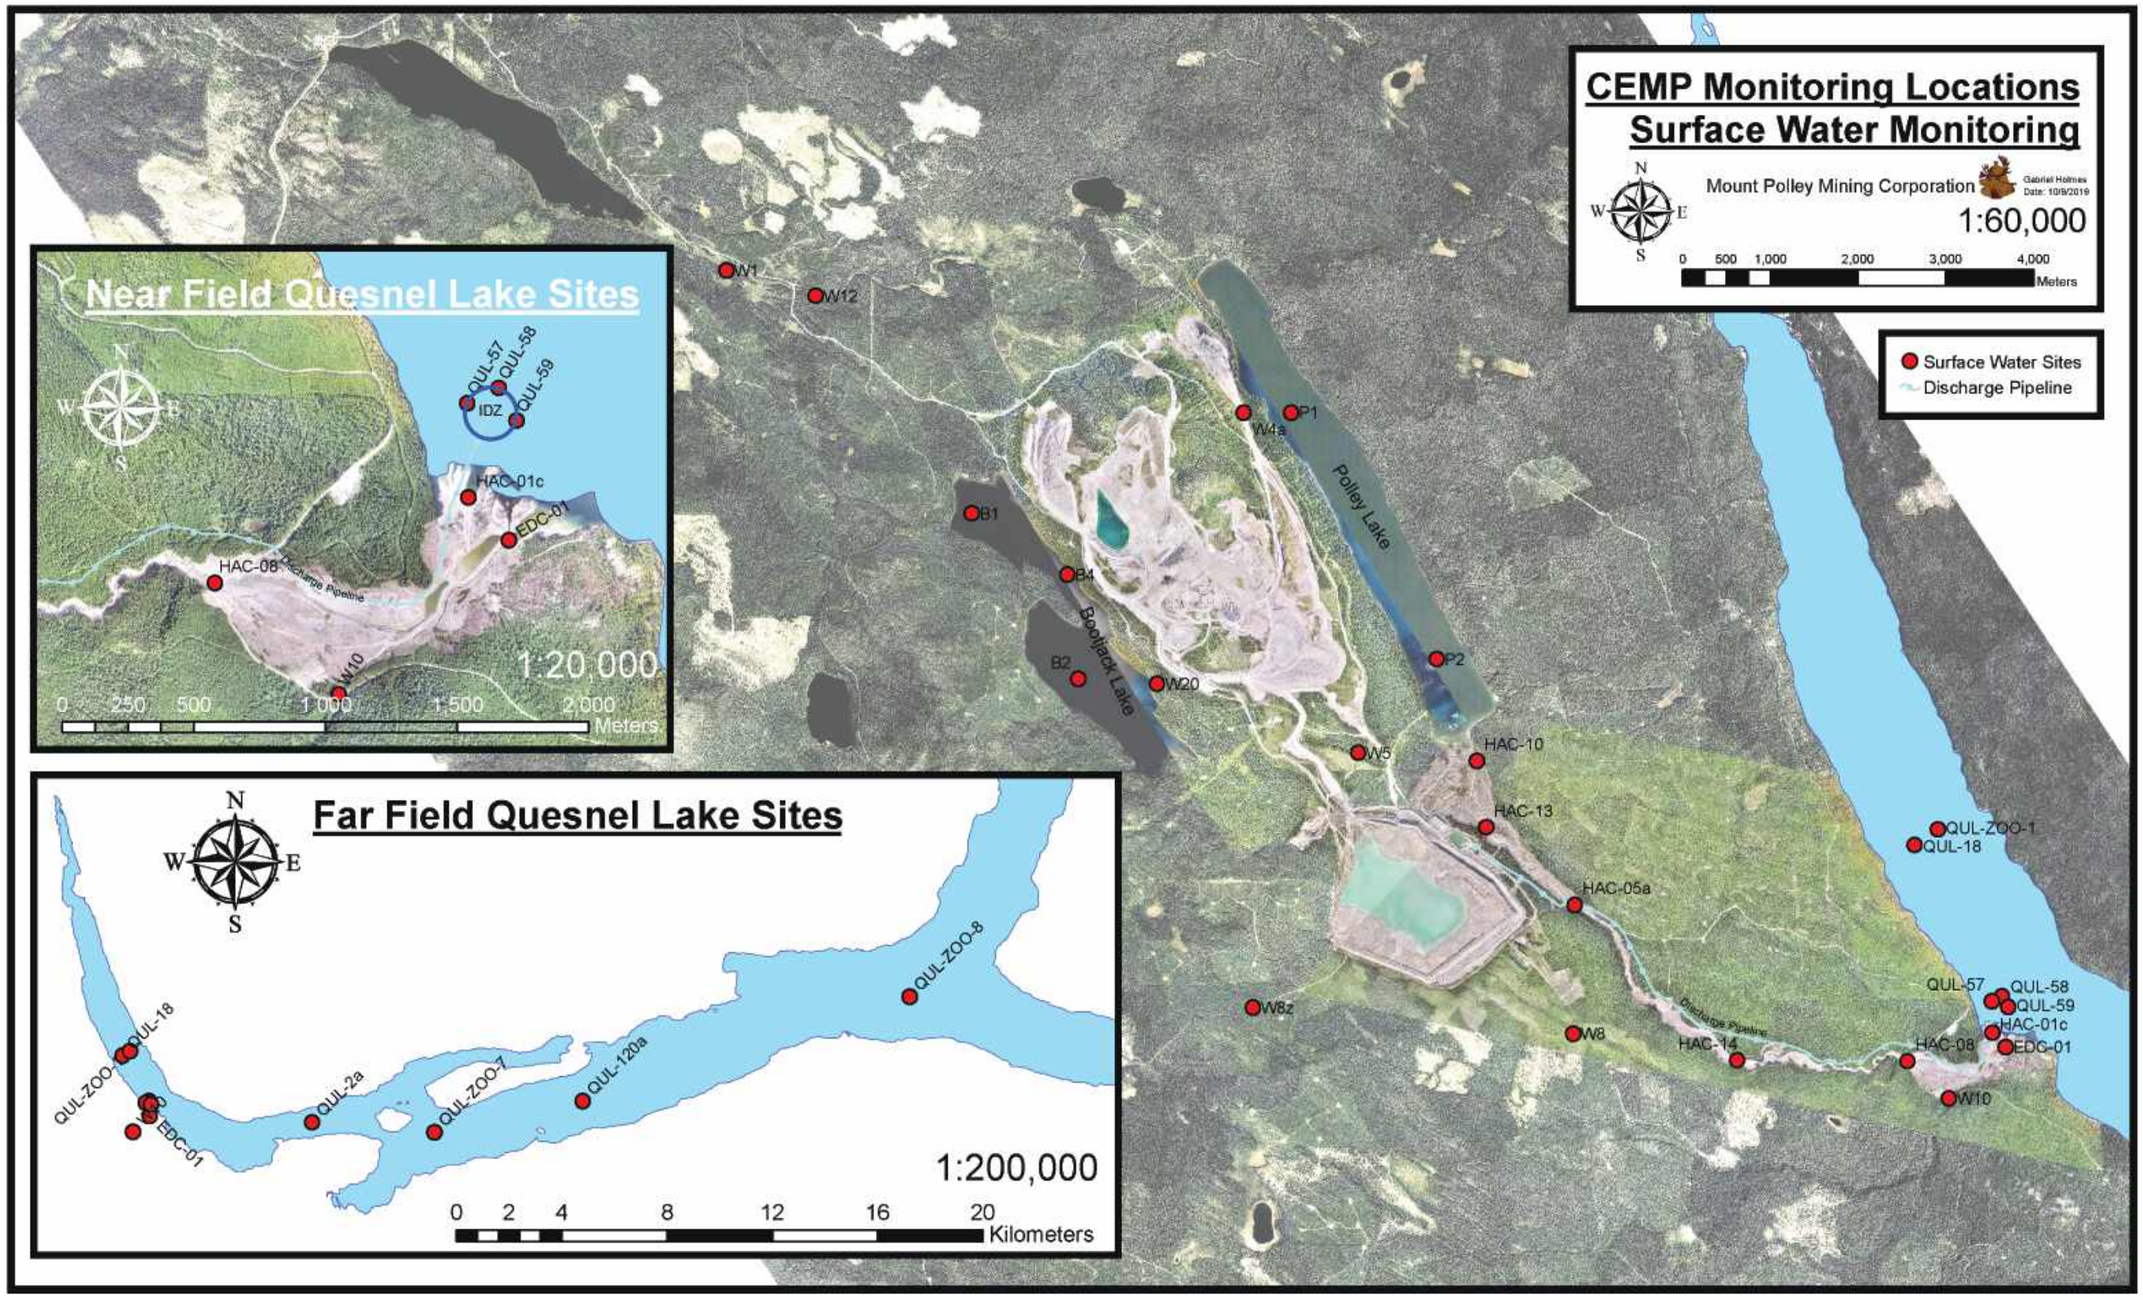

Figure 6.2 CEMP monitoring locations: Surface water monitoring

6.6.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Field parameter collection, sample collection, preparation, and shipping will be conducted following the SOPs and WMs for the associated field meters, Surface Water Quality Monitoring and Lake Water Monitoring, as appropriate as described in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.6.3. Limnological profiles of field parameters will be conducted where described in Table 6.4.

For the edge of the IDZ sampling, limnological profiles of field parameters (specific conductance, temperature, and turbidity) will be carried out in an attempt to identify the location of the plume from the outfall (i.e., direction of flow). MPMC is committed to spending a reasonable level of effort and time to detect the plume and direction of flow. The reasonable level of effort and time will vary depending on the health and safety risks associated with the weather conditions and season. Vertical profiles of field measurements and water chemistry samples will be taken at the inferred centerline of the plume at the edge of the IDZ (station QUL-58).

A plume dispersion model was developed by Golder for the nearfield (i.e., in the vicinity of the IDZ), and a hydrodynamic model of Quesnel Lake has been developed and calibrated by Tetra Tech EBA to predict effluent transfer throughout the West Basin of Quesnel Lake and potential for buildup (Golder 2015b). Monitoring at the near-field station, along with monitoring of other Quesnel Lake receiving environment stations, will be used to verify the near-field and lake-wide hydrodynamic models. It should be noted that the nearfield and the hydrodynamic models, as described in the Long Term Water Management Plan, serve as the basis for the Trigger Response Plan incorporated into the 2018 ADP.

Table 6.5 is a summary of previous surface water monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.5 Summary of surface water monitoring

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Monitoring included streams adjacent to the mine site to determine if there are any changes in water quality. Bootjack and Polley lakes were monitored as receiving environment of the mine. Bootjack Lake was monitored to evaluate potential for exfiltration from Springer Pit. The monitoring sites in Bootjack Lake were moved to two deeper monitoring locations in 2017, as described in the 2016 AERR. For the discharge receiving environment, Quesnel Lake and Quesnel River were monitored.	Post-breach monitoring overlapped with operational monitoring in Polley Lake, Quesnel Lake, and Quesnel River. Monitoring occurred at sites selected to capture major inputs and mixing of Hazeltine Creek. Supplemental sampling of 3 stations flowing into Hazeltine Creek in the Polley Flats area was undertaken to support a geochemical conceptual model in 2016 (SRK and Minnow 2016).	N/A
Summary of findings	The results for the creeks and lakes from 2016-2017 identified no significant trends. No indication of exfiltration from the Springer Pit was found in Bootjack Lake.	Results from Quesnel River show no indications of further effects post-breach since 2016. The 2016 and 2017 results showed that the lower sedimentation pond was effective at decreasing the TSS concentration of Hazeltine Creek. The modelling concluded that 93 to 99% of copper was organically complexed and generally not bioavailable.	N/A
Recommendations for 2018-2020 monitoring	A summary of all changes from the 2016 CEMP is provided in Section 6.6.4.1.	A summary of changes from the 2016 CEMP is provided in Sections 6.6.4.1 and 6.6.4.2.	N/A

Notes: AERR: Annual Environmental and Reclamation Report; N/A: not applicable; TSS: total suspended solids

6.6.4.1 OPERATIONAL MONITORING

Table 6.6 summarizes all changes in operational surface water monitoring form the 2016 CEMP.

Table 6.6 Operational monitoring changes since the 2016 CEMP

Sample Site(s)	Change from 2016 CEMP	Purpose/Justification
W1	Reduced frequency from monthly to quarterly	W1 monitors water quality in Morehead Creek, the outflow of Bootjack Lake. As of time of writing, Springer Pit water level is below 990 masl and no indication of exfiltration from the Springer Pit was found in Bootjack Lake. The monitoring frequency will be reviewed by a QP if Bootjack Lake shows any mine-related changes in the future.
W10	Reduced frequency from monthly to semi annually (in June and October)	The monitoring of this site overlaps with Post-Breach Monitoring as it acts as a reference location for the remediated section of Edney Creek. The reduced frequency aligns with frequency of EDC-01 (see Section 6.6.4.2).
W20	Reduced frequency from quarterly to semi-annually	This creek is not directly influenced by mine activities as mine-affected water is diverted away from this creek catchment. Less intense monitoring is required. The frequency will be reviewed by a QP if Bootjack Lake water quality shows any mine-related changes.
QUL-58	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	Monitoring As per the ADP, QUL-58 monitoring is for model verification.
QUL-57	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	As per the ADP, QUL-57 monitoring is for model verification.
QUL-59	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	As per the ADP, QUL-59 monitoring is for model verification.
QUL-18	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	As per the ADP, QUL-18 monitoring is for model verification.
QUL-2a	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month) Considered Quesnel Lake reference site	As per the ADP, QUL-2a monitoring is for model verification and is now considered the Quesnel Lake reference site.

Sample Site(s)	Change from 2016 CEMP	Purpose/Justification
QUL-120a	Reduced from seasonally to semi-annually (taken at evenly spaced time series plus or minus one month) No longer considered Quesnel Lake reference site	As per the ADP, QUL-120a monitoring is for model verification.
QUR-1	Continuous monitoring removed	Continuous monitoring was conducted at this site from August 12, 2014 to May 30, 2016. In consultation with ENV, given the lack of variation in the results, continuous monitoring was deemed to be no longer necessary.
QUR-11	Removed	This site is regularly monitored by the provincial and federal government agencies with financial support from MPMC. An annual side-by-side sample will be collected by MPMC at the request of the regulator.
P1, P2	Reduced sampling from monthly to spring overturn, twice in summer, fall overturn, and once in winter under ice Change in sampling depths	The monitoring of these sites overlap with Post-Breach Monitoring. The reduction in monitoring frequency (both sampling and limnological profiles) is because the water quality in Polley Lake appears to be stable. If changes are observed in water quality reflecting breach- or mine-related impacts, frequency of monitoring will be reviewed by a QP. These sample depths align with pre-breach monitoring as agreed upon with ENV staff biologist.
B1, B2	Reduced monitoring of limnological profile from semi-monthly to monthly Change in sampling depths	The reduction in monitoring frequency is because the water quality in Bootjack Lake appears to be stable. If changes are observed in water quality reflecting mine-related impacts, frequency of monitoring will be reviewed by a QP. These sample depths align with pre-breach monitoring as agreed upon with ENV staff biologist.

Notes: CEMP: Comprehensive Environmental Monitoring Plan; masl: meters above sea level; QP: Qualified Professional; ADP: Annual Discharge Plan

6.6.4.2 POST-BREACH MONITORING

Table 6.7 summarizes all changes in operational surface water monitoring form the 2016 CEMP.

Table 6.7 Post-breach monitoring changes since the 2016 CEMP

Sample Site(s)	Change from 2016 CEMP	Purpose/Justification
HAC-13	Reduced from weekly to monthly	This site used to be upstream of the Hazeltine Creek Discharge and was monitored under the EEM. Currently, this site monitors water quality in Hazeltine Creek after Reach 1. Monitoring frequency has been reduced to align with other Hazeltine Creek samples.
HAC-14	Added	This site was added to monitor effects of remediation activities on Hazeltine Creek water quality. The frequency aligns with other Hazeltine Creek samples.
HAC-12	Removed	In consultation with ENV (C. Danyluk, personal communication, February 8, 2018), this site has been removed as it is no longer necessary with the connection of the pipeline from the WTP to the diffusers.
HAC-01c	Added	This site represents Hazeltine Creek water quality before entering Quesnel Lake. The frequency aligns with other Hazeltine Creek samples.
EDC-01	Reduced from monthly to semi-annually	No significant trends have been identified at EDC-01. Because of reduced site access in winter and stable water quality, sampling frequency has been reduced to semi-annually.

Notes: CEMP: Comprehensive Environmental Monitoring Plan; EEM: Environmental Effects Monitoring; ENV: BC Ministry of Environment and Climate Change Strategy; WTP: Water Treatment Plant

6.6.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all surface water monitoring (i.e., operational, post-breach, reclamation) is summarized in Table 6.8.

Table 6.8 Water chemistry QC sample frequencies for surface water monitoring

QC Samples	Frequency
Duplicate samples	10% of surface water samples
Equipment blanks	Monthly per piece of equipment (when used)
Trip blanks	Twice per month
Field blanks	Twice per month
Filter blanks	Quarterly
Deionized water blanks	Annually
Laboratory replicate[1]	Annually

Note: [1] Split sample

For results greater than five times the method detection limit (MDL), a relative percent difference (RPD) will be used to identify differences between original and duplicate samples. These data quality objectives (DQOs) are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

6.6.6 Laboratory Analysis

Samples will be submitted to and processed by a Canadian Association of Laboratory Accreditation (CALA) accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.6.7 Data Analysis and Reporting

In Hazeltine Creek, data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, maximum, and 95th percentile values over the period of interest) and evaluation of any spatial (e.g., down the creek) and temporal changes or trends. Results will also be compared to the BC aquatic life WQGs.

In the other surface water monitoring sites, statistical analysis will be carried out to compare data to reference sites and to assess trends over time. Results will also be compared to the BC aquatic life WQGs.

6.7 Hydrology Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.7.1 Section Authors and Study Design Professionals

This section was written by MPMC, and is guided by Section 3.4 of the Permit (April 7, 2017).

6.7.2 MONITORING OBJECTIVES

The objective of hydrological monitoring in Hazeltine Creek is to characterize the hydrology of the Hazeltine Creek system, assess fish habitat (only in reaches accessible to fish), interpret water quality and water balance, and evaluate changes over time as rehabilitation works are carried out and system recovery occurs (e.g., establishment of riparian vegetation).

The objective of hydrological monitoring in Edney Creek is to characterize the hydrology of Edney Creek in the remediated section, asses fish habitat, interpret water quality, and evaluate changes over time as rehabilitation works are carried out and system recovery occurs (e.g., establishment of riparian vegetation).

The objective of the hydrological monitoring of the streams and creeks that run through or adjacent to the mine site is to characterize the hydrology of the drainages, interpret water quality, and evaluate any changes over time.

6.7.3 MONITORING OVERVIEW

MPMC maintains eight hydrology stations as required by the Permit. Table 6.9 provides an overview of the hydrology monitoring. No large changes have been made from the 2016 CEMP, but wording has been changed to more align with the wording in Section 3.4 in the Permit. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.3 shows monitoring locations of the hydrology monitoring locations.

Staff gauges will be benchmarked (calibrated) once per year between June 15 and August 31, as defined by the Permit. Staff gauge readings will be recorded during water chemistry sampling events at the associated stations and each manual flow measurement. Note that there is currently no staff gauge installed at station W4a (North Dump Creek), as it is a very low flow creek; however, as recommended by WaterSmith Research Inc. (WaterSmith; Appendix K in MPMC 2016e), MPMC will endeavor to install a staff gauge at this location that provides adequate information. Continuous stage monitoring equipment (pressure transducers) will be installed at hydrometric locations specified in Table 6.9 during non-freezing conditions.

Manual flow gaugings will be conducted at all sites during high, moderate, and low flows in non-freezing conditions. These measurements will be conducted at minimum three times per year for validation of the stage-discharge rating curves. If stage-discharge stability is not demonstrated, the frequency of monitoring will be increased to five times per year during the non-freezing period (across the spectrum of high to low flows) to meet Resources Information Standards Committee Grade A standards for hydrometric monitoring (MoE 2009). Due to site characteristics and difficult operating conditions, often the sites meet Grade B/C standards. MPMC will continue to work with a QP to move toward meeting Grade A standards for all hydrological stations. A stage discharge curve that encompasses the non-freezing period flows will be maintained for all hydrological stations with staff gauges.

Table 6.9 Hydrology monitoring overview

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
H4	-	Upper Hazeltine Creek at Polley Lake outlet	Continuous[1]	Water head pressure, temperature	N/A
			Weekly (daily during high runoff periods)	Stage (staff gauge)	Permit 11678
			Monthly[1]	Manual flow gauging	
H1	-	Upper Hazeltine Creek hydrometric station (at Gavin Lake FSR Bridge)	Continuous[1]	Water head pressure, temperature	Permit 11678
			Monthly[1]	Stage (staff gauge)	
			Monthly[1]	Manual flow gauging	
H2	-	Lower Hazeltine Creek hydrometric station (downstream of the Ditch Road Bridge)	Continuous[1]	Water head pressure, temperature	Permit 11678
			Monthly[1]	Stage (staff gauge)	
			Monthly[1]	Manual flow gauging	
W1b	E291449	Morehead Creek	Water quality sample and when flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated)	
W4a	E298551	North Dump Creek below Wight Pit Road	Monthly[1]	Manual flow gauging	Permit 11678
W5	E208039	Bootjack Creek Above Hazeltine Creek	Water quality sample and when flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate, and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated); only when sufficient flow	

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
W12	E216744	6 km Creek at Road	Water quality sample; when flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated)	
H3	-	Lower Edney Creek	Continuous[1]	Water head pressure, temperature	N/A
			When flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated)	

Notes: [1] In non-freezing conditions; N/A: not applicable

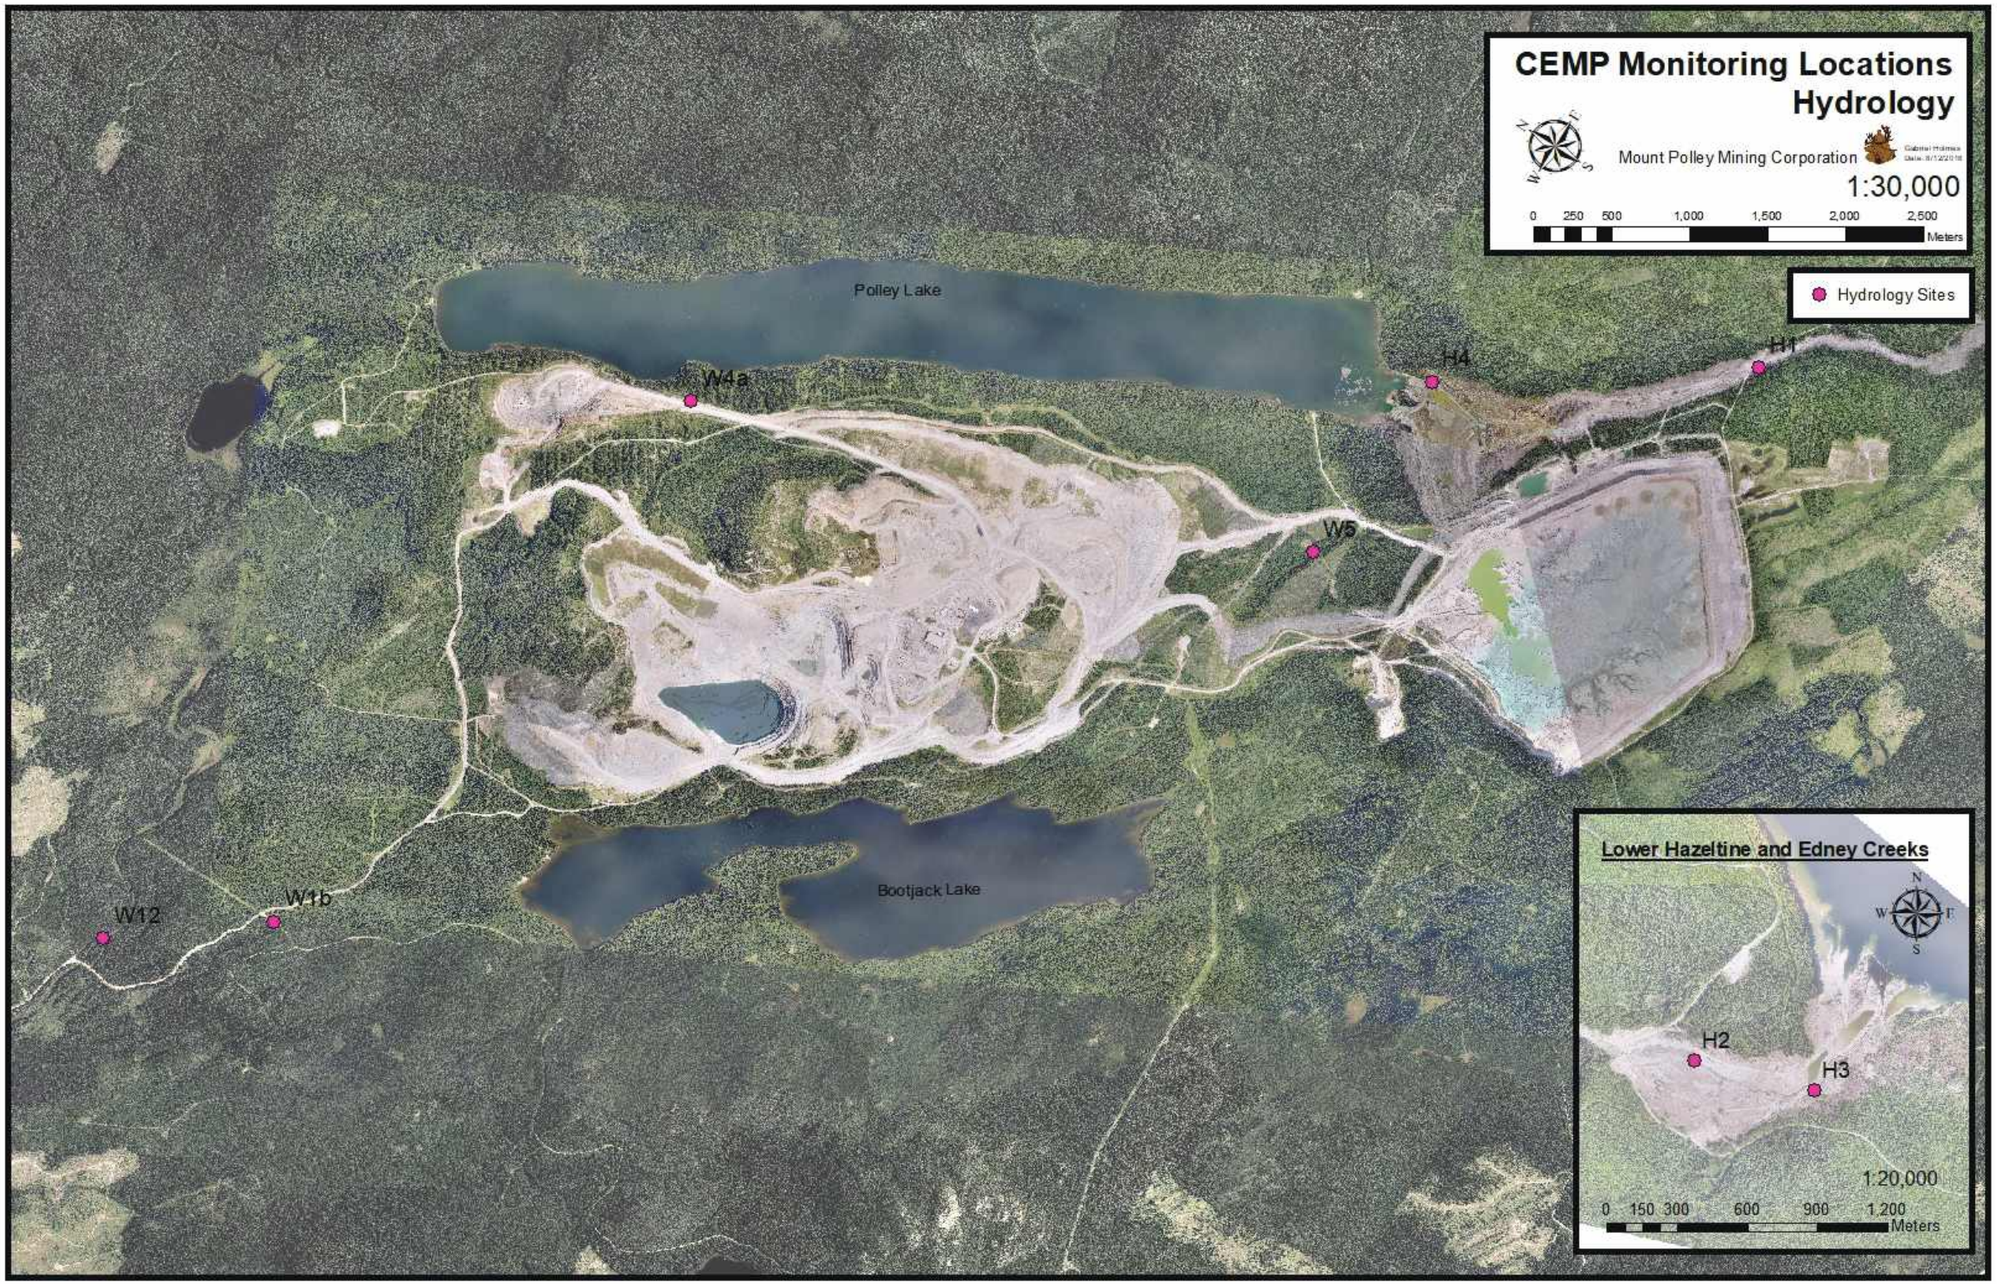

Figure 6.3 CEMP monitoring locations: Hydrology monitoring

6.7.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Hydrological monitoring will be conducted as per the SOPs and WMs for Hydrological Monitoring (which includes installing and downloading continuous loggers) and Benchmarking, as well as the specific WM for operating the FlowTracker acoustic Doppler velocity meter.

Note that some streams do not flow year-round; if there is no flow and a sample or measurement cannot be taken as scheduled, the attempt will be documented in the field notebook.

To verify the accuracy of established rating curves (i.e., confirm that the channel morphology at the station and outflow control point have not changed) and, where possible, extend the upper and lower bounds of the curves, manual flow gaugings will be taken according to Table 6.9 in non-freezing conditions. Manual flow monitoring requirements will be re-evaluated each year, following refinement of the stage-discharge rating curves.

Table 6.10 is a summary of previous hydrology monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.10 Summary of hydrology monitoring and findings

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	W1b, W5, and W12 were established prior to 2014. W4a was established in 2014. More detail for each site is provided in Section 6.7.4.1.	H1 and H2 hydrology sites were established in 2015, when channeling of Hazeltine Creek was completed. H4 hydrology site was established in 2016 in the remediated section of upper Hazeltine Creek. H3 hydrology site in the remediated section of Edney Creek was established in 2015. More detail of each station is provided in Section 6.7.4.2.	N/A
Summary of findings	Manual measurements were used to confirm and refine rating curves.	Manual measurements confirmed the rating curves for H1, H2, and H3. Increased manual measurements for H4 will confirm the ratings curve.	N/A

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	Post-Breach	Reclamation
Recommendations for 2018-2020 monitoring	Manual measurements will be collected to confirm the rating curves. One hydrology station is not configured for staff gauge and its establishment will be explored.	Continuous monitoring of levels will continue using the established rating curve. Manual measurements will be collected to confirm the rating curves.	N/A

Notes: N/A: not applicable

6.7.4.1 Operational Monitoring

Table 6.11 summarizes the operational hydrology sites. Flows around the MPMC site are freshet driven; therefore, many hydrology stations are low flow during the rest of the year and cannot be measured. No continuous monitoring devices are installed at these sites due to the very low flow nature of the creeks.

Table 6.11 Summary of operational hydrology sites

Site	Comment
W1b	Site W1b was established in 2012. Benchmarking of this station has occurred annually. In 2016, WaterSmith made significant changes to the site and a new stage-discharge curve was developed. MPMC will continue to conducted manual measurements to confirm the rating curve.
W4a	Site W4a was established downstream, and replaced site W4 in 2014. Only manual bucket flow measurements are recorded from a constructed pipe weir at this site and will continue until recommendations for installation of a staff gauge are explored.
W5	Site W5 at Bootjack Creek was re-established in 2008. Benchmarking of this station has occurred annually. A new staff gauge was installed in 2016 by WaterSmith and a new stage-discharge curve was developed. MPMC will continue to conducted manual measurements to confirm the curve.
W12	Site W12 was established in 1990. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. MPMC will continue to conducted manual measurements to confirm the curve.

Notes: WaterSmith: WaterSmith Research Inc.; MPMC: Mount Polley Mining Corporation

6.7.4.2 Post-Breach Monitoring

Table 6.12 summarizes the post-breach hydrology sites.

Table 6.12 Summary of post-breach monitoring hydrology sites

Site	Comment
H1	Site H1 was established in upper Hazeltine Creek in 2015. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the rating curve.
H2	Site H2 was established in upper Hazeltine Creek in 2015. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the rating curve.
H3	Site H3 was established in the remediated area of lower Edney Creek in 2015. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the curve.
H4	Site H4 was established in upper Hazeltine Creek at the Polley Lake Weir in 2016. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the curve.

Notes: MPMC: Mount Polley Mining Corporation

6.7.5 Data Quality Control, Objectives, and Review

The FlowTracker has built in error messages associated with measurements that are outside of set QC bounds, and reports an International Standard Calculation error and statistical (US Geological Survey calculation) error output following each discharge measurement as a QC measure.

Benchmarking, as described above and as per the protocol in the QA/QC Manual, will occur annually between June 15 and August 31 as per the Permit, or as described by the Permit.

Routine monitoring includes inspections of equipment, including stilling wells and loggers (e.g., to identify sedimentation inside the stilling well or debris build up in logger ports). Identification of potential station changes or issues also occurs through data analysis when data are inconsistent or unusual in comparison with previously collected data.

6.7.6 Laboratory Analysis

No laboratory analysis is required for hydrology monitoring.

6.7.7 Data Analysis and Reporting

Data analysis will include building and validating the stage-discharge rating curves, as well as production of annual hydrographs. These will be presented in the AERR.

6.8 GROUNDWATER MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.8.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC.

6.8.2 MONITORING OBJECTIVES

The primary objective of the groundwater monitoring program on the mine site is to determine the direction, volume, and quality of groundwater flow from the mine site and other disturbed areas to receiving environment.

6.8.3 MONITORING OVERVIEW

Groundwater monitoring wells around the mine site are installed in the area around the TSF, the Springer Pit, downstream of waste rock dumps and haul roads, and in other areas on or surrounding the mine. The monitoring program was developed on the recommendation of the groundwater program review by Golder conducted in March 2016. This review was submitted to ENV on March 31, 2016. An annual review of the groundwater monitoring program was also conducted by Golder in March 2017 and was submitted as Appendix F in the 2017 AERR (MPMC 2018). Recommendations from the 2017 review have been incorporated into the monitoring program outlined below. Sampling events at times of maximum and minimum hydrologic conditions to account for seasonal variability will be conducted when appropriate (i.e., spring and late summer/fall). Static water level (SWL) of all wells will be monitored on the same day at minimum once annually to allow for comparison across the site.

Groundwater monitoring wells were also installed along the Hazeltine Creek in 2015 and 2016. From Golder (2017), groundwater "was not screened for the terrestrial risk assessment because wildlife do not consume groundwater". Monitoring of surface water in Hazeltine Creek captures the potential effects of groundwater discharged to the Hazeltine Channel system (Golder 2017; see Section 6.6). No further monitoring is planned at these groundwater wells.

Table 6.13 summarizes the parameters analysed for groundwater quality. Table 6.14 provides an overview of the groundwater monitoring. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.4 shows monitoring locations of the groundwater sampling locations.

Table 6.13 Groundwater chemistry parameters

Parameter	LOR	Unit

Notes: [1] Wells show stable chemistry. If an unexpected change in SWL is observed, well water will be sampled; [2] Wells provide domestic water for personnel; BC WQG – British Columbia water quality guideline; SWL: static water level; CSR: Contaminated Sites Regulations; AL: aquatic life; [3] Leveloggers have been removed from GW15-1a and 1b as wells are dry. Leveloggers will be reinstalled once water is above well screen.

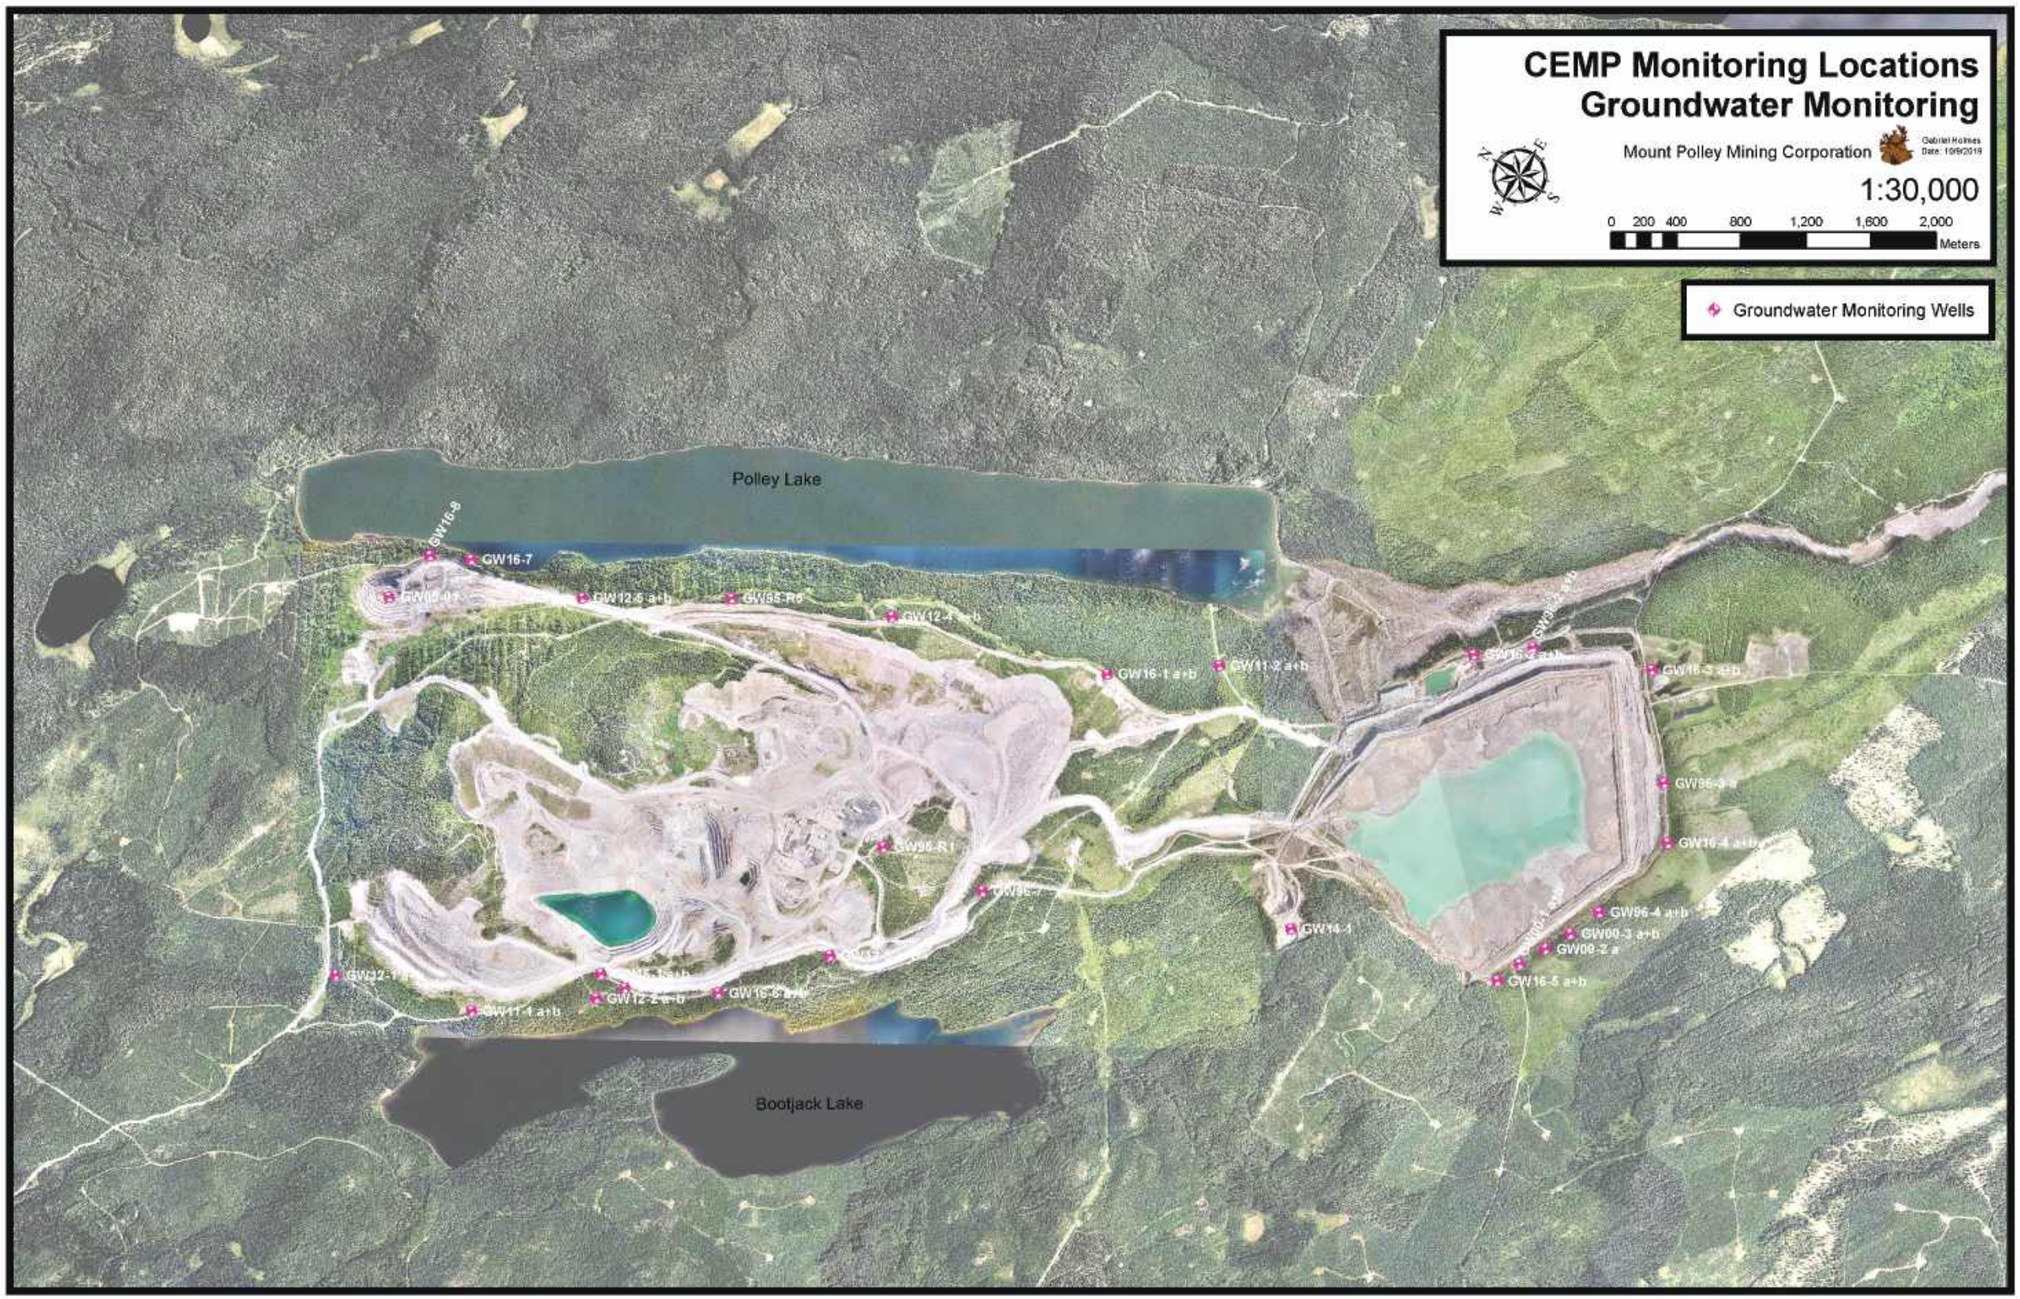

Figure 6.4 CEMP monitoring locations: Groundwater monitoring

6.8.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

As outlined in the SOPs, groundwater monitoring involves use of an automated depth to water meter to measure SWL and a submersible pump powered by a generator for sampling. These protocols also require routine inspections of the well housing.

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Groundwater Monitoring and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.8.3.

Table 6.15 is a summary of previous groundwater monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.15 Summary of groundwater monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Groundwater locations in both shallow and deep bedrock downstream of mine activities. Higher frequency monitoring occurred at wells near the Springer Pit in 2015, 2016, and 2017 because the pit water level was above 1025 masl. Dredging of the Springer Pit commenced in 2017, and the water level in the pit is less than 1000 masl at the time of writing.	An updated groundwater program was implemented for the ERA (Golder 2017). Wells installed in 2015 were resampled and additional wells were installed along the creek in 2016. Groundwater was analyzed for dissolved metals, TSS, pH, anions, nutrients, hardness and acidity.	N/A
Summary of findings	Monitoring of the groundwater wells near the Springer Pit showed exfiltration from the Springer Pit towards Bootjack Lake occurred during 2016. This exfiltration was reversed after the Springer Pit was dewatered, which was confirmed by continued monitoring of these wells. No groundwater leakage from Springer Pit to Bootjack Lake in 2107 was inferred based on the levels measured. No significant changes to groundwater quality were identified in the 2017 annual groundwater review (MPMC 2018).	Although copper was the primary metal of concern in the tailings outwash material deposited in Hazeltine Creek, groundwater copper concentrations were lower than the CSR standard. Other substances that exceeded CSR standards are believed to be associated with natural conditions and were not derived from the tailings.	N/A
Recommendations for 2018-2020 monitoring	New groundwater wells were drilled at the end of 2016 as per recommendations in the Groundwater Program Review. These wells were incorporated into the current program in 2017. One pair of wells was removed due to likely contamination and were replaced (see Golder 2016c). See Section 6.8.4.1 for more detail on the recommendations for future monitoring.	No further sampling is planned for groundwater in Hazeltine Creek. If the water quality declines in the creek, monitoring of these wells will be reviewed and considered.	N/A

Notes: masl: metres above sea level; CSR: Contaminated Sites Regulation; ERA: ecological risk assessment; TSS: total suspended solids

6.8.4.1 OPERATIONAL MONITORING

The monitoring frequencies of the Springer Pit wells were decreased from monthly to quarterly due to the ongoing dewatering at Springer Pit, which has resulted in a significant drop in water levels in some of these wells. For example, dataloggers have been removed from GW15-1a and b as these wells are now dry (J. Foley, personal communication, August 10, 2018). According to J. Foley, "due to the ongoing dewatering at Springer Pit, Golder would consider it acceptable to move to quarterly monitoring, if groundwater is present within the wells." Once dewatering stops and the pit is refilled, consideration to move back to monthly monitoring for a period of time will be given.

A further change to the recommendations put forth in Appendix F of MPMC (2018) is that "quarterly groundwater monitoring should continue at GW16-6 a and b, but semi-annual monitoring can be completed at the remaining GW16 well series. Note that some of the remaining 2016 well series (other than GW16-6 a/b) were monitored one to three times in the 2017 calendar year" (J. Foley, personal communication, August 10, 2018).

6.8.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all the groundwater monitoring is summarized in Table 6.16.

Table 6.16 Water chemistry QC sample frequencies for groundwater water monitoring

QC Samples	Frequency
Duplicate samples	10% of groundwater samples
Equipment blanks	Quarterly per piece of equipment (when used)
Trip blanks	Quarterly/semi-annually[1]
Field blanks	Quarterly/semi-annually[1]

Notes: [1] Quarterly for quarterly groundwater samples, semi-annually for semi-annual groundwater samples (i.e., six per year)

For results greater than five times the MDL, an RPD will be used to identify differences between original and duplicate samples. These DQOs are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

6.8.6 LABORATORY ANALYSIS

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC for chemistry samples, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.8.7 Data Analysis and Reporting

Data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, maximum, and 95th percentile values over the period of interest) and evaluation of water chemistry or water level changes and/or trends. Groundwater chemistry will be compared to the Schedule 3.2, Column 3 (Aquatic Life) standards in the ENV Contaminated Sites Regulation (CSR) under the EMA, and BC WQGs per Technical Guidance 15 (MOE 2017a). These data will also be used by a third party qualified professional for the three-year groundwater monitoring program review, and updates to hydrogeological models, including the Springer Pit groundwater model. Hazeltine Creek groundwater data will be used to support the geochemical characterization of materials in the Hazeltine Creek corridor.

6.9 Contact Water Quality Monitoring

Monitoring in this subsection falls under BC *Mines Act* M-200 and is only described here for completeness. Monitoring is summarized and changes will be presented in the CEMP, but changes to this monitoring are subject to BC *Mines Act* Permit M-200 and not Section 7 in the CEMP or Section 5 in the CEMP TOR (Appendix A).

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.9.1 Section Authors and Study Design Professionals

This section was written by MPMC.

6.9.2 Monitoring Objectives

The objective is to monitor trends in contact water quality on site, including runoff and mill process water, specifically at locations that represent the WTP source water. These data are applied to understand trends in site water chemistry and inform water management planning, including water discharge strategies.

6.9.3 Monitoring Overview

Table 6.17 summarizes the parameters analysed for contact water quality. Table 6.18 provides an overview of the contact water monitoring. Figure 6.5 shows monitoring locations of the contact water sampling locations.

These clean water ditches are monitored to ensure water quality is maintained; N/A: not applicable; TSF: Tailings Storage Facility; PAG: potentially acid generating

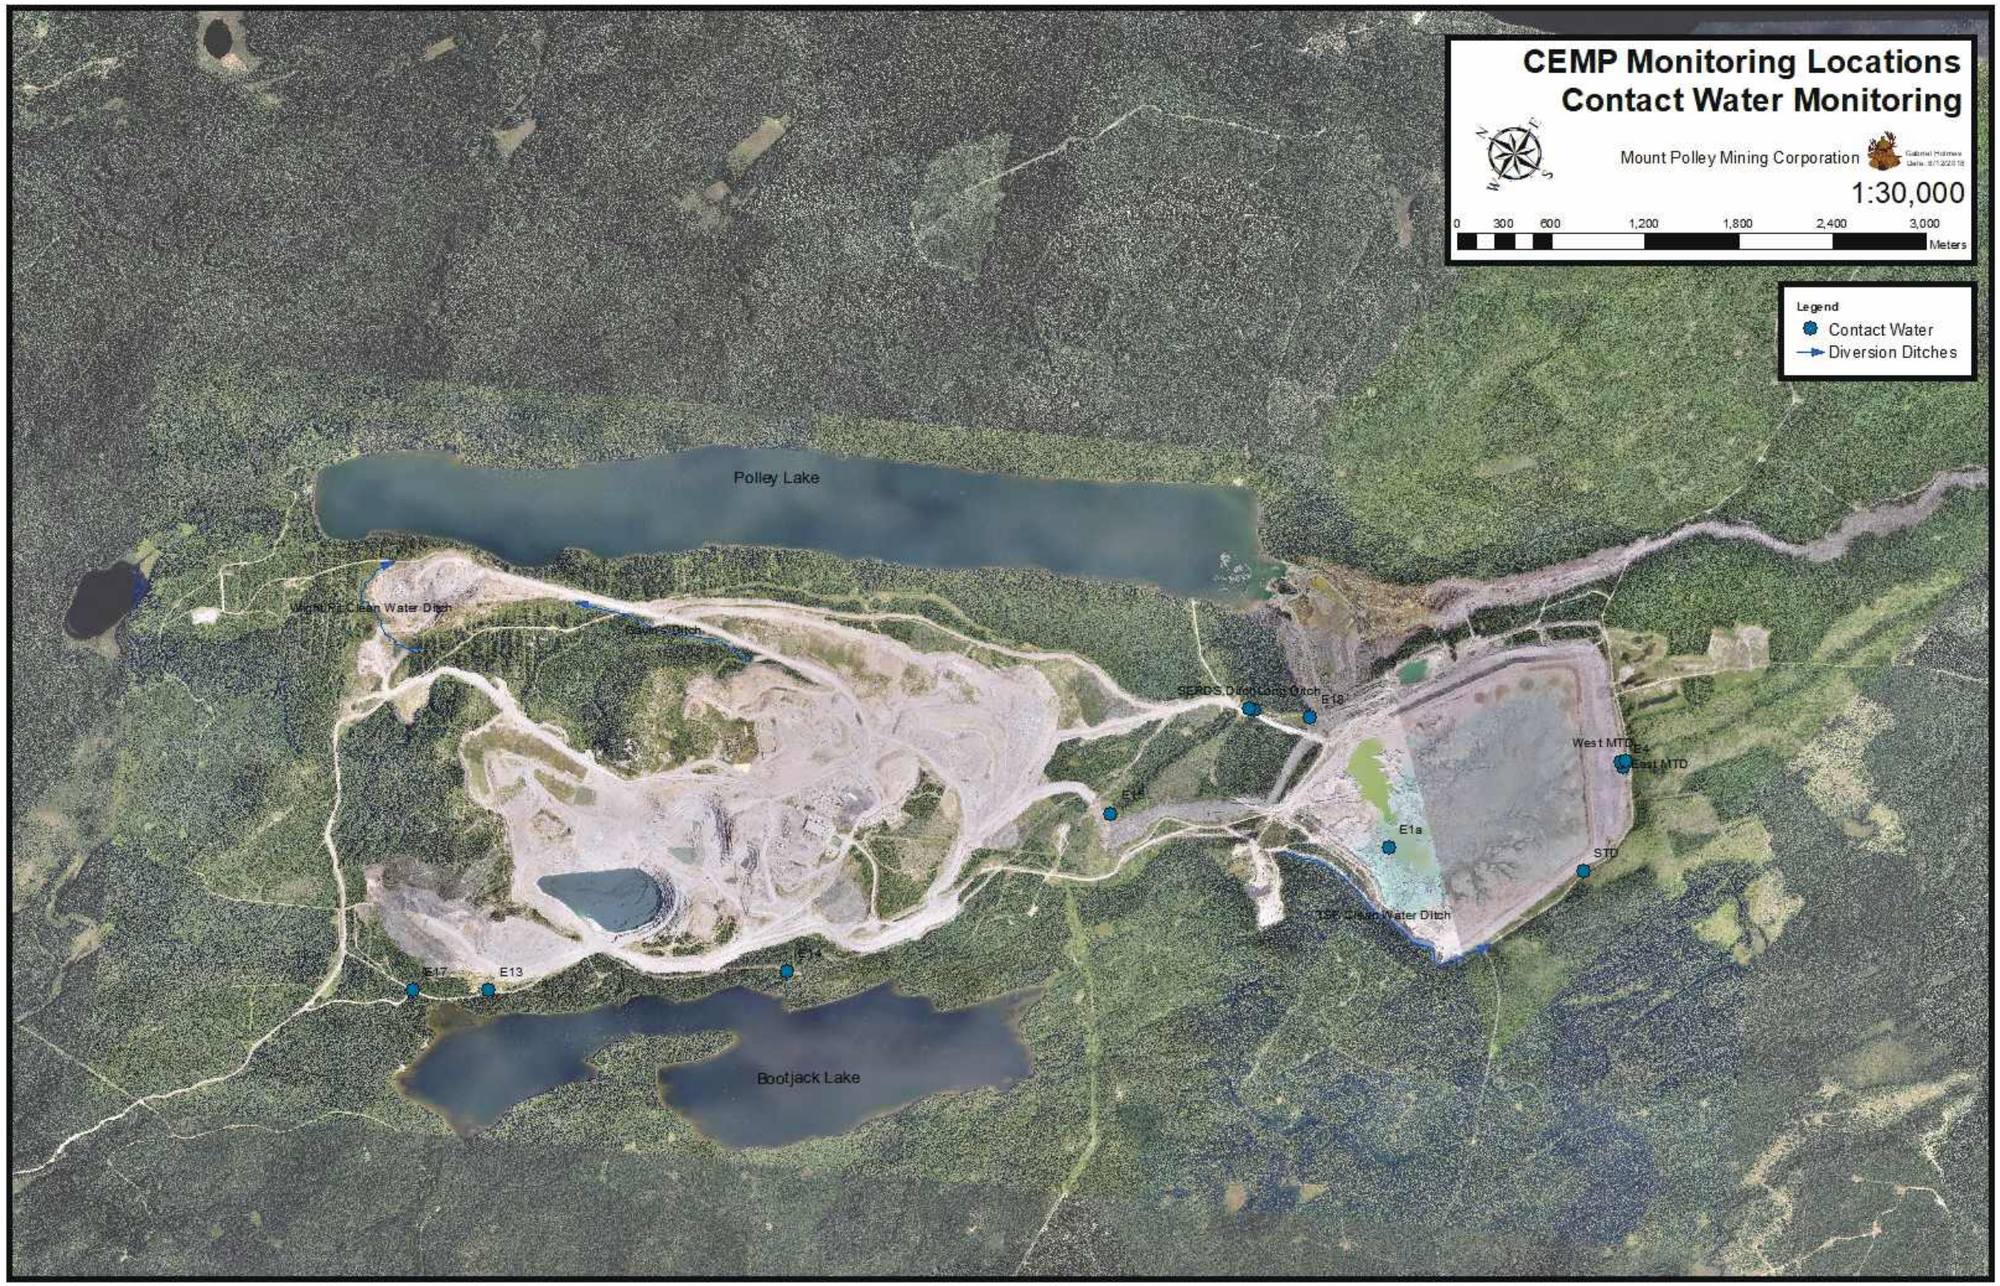

Figure 6.5 CEMP monitoring locations: Contact water monitoring

6.9.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Surface Water Quality Monitoring, and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.9.3.

Table 6.19 is a summary of previous contact water monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.19 Summary of contact water monitoring and findings

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Sumps that collect and temporarily store water as well as ditches that convey water from many different sources were monitored.	N/A	N/A
Summary of findings	There were no notable trends in 2017 contact water monitoring that suggested the monitoring program needs to be changed.	N/A	N/A
Recommendations for 2018-2020 monitoring	The Springer Pit Sump (E11) is no longer representative of the pit lake water quality and has not been the source of influent for the WTP since 2016. Tailings supernatant (E1a) is also not the source for the WTP. Therefore, these sites has been removed from monitoring under the Permit; E11 continues to be monitored under the *Mines Act* Permit M-200 (see Section 6.10).	N/A	N/A

Notes: N/A: not applicable; WTP: Water Treatment Plant

6.9.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all contact water monitoring is summarized in Table 6.20. For results greater than five times the MDL, an RPD will be used to identify differences between original and duplicate samples. These DQOs are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

Table 6.20 Water chemistry QC sample frequencies for contact water monitoring

QC Samples	Frequency
Duplicate samples	10% of contact water samples
Trip blanks	Combined with surface water QC schedule
Field blanks	Combined with surface water QC schedule

6.9.6 Laboratory Analysis

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.9.7 Data Management and Analysis

Data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, maximum, and 95th percentile values over the period of interest). These data, including spatial and temporal trends in relation to mine features and their geochemistry, will be used in long-term water management planning (Section 5.1).

6.10 Seep Monitoring

Monitoring included in this subsection fall under BC *Mines Act* Permit M-200 and is only described here for completeness. Monitoring is summarized and changes will be presented in the CEMP, but changes to this monitoring are subject to BC *Mines Act* Permit M-200 and not Section 7 in the CEMP or Section 5 in the CEMP TOR (Appendix A).

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.10.1 Section Authors and Study Design Professionals

This section was written by MPMC.

6.10.2 Monitoring Objectives

An important component in determining and monitoring long-term chemical stability of drainage from the pits and waste rock dumps is water quality monitoring. The seep sampling is conducted under the BC *Mines Act* Permit M-200.

6.10.3 MONITORING OVERVIEW

Under the BC *Mines Act* Permit M-200 seepage monitoring program, monitoring of waste rock dump seepages is conducted under a bi-annual seep survey program of all waste rock dumps on site, with representative seeps being monitored more frequently when possible (numerous seeps stop flowing during dry periods). Table 6.21 summarizes the parameters analysed for seepage water quality. A list of dumps and pits that are sampled, along with the representative sample locations, is provided in Table 6.22 and Table 6.23, respectively. Figure 6.6 shows monitoring locations of the seepage sampling locations.

6.10.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Surface Water Quality Monitoring, and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.10.3.

Table 6.24 is a summary of previous seep monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.24 Summary of seep monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	N/A	N/A	Seeps were sampled at the toe of waste rock piles and from pits that are not storing water from other locations.
Summary of findings	N/A	N/A	The results are used to inform long-term planning for reclamation and closure. It has been identified that two seeps from the NEZ Dump have elevated metal concentrations. See Section 6.10.4.1 for more detail.
Recommendations for 2018-2020 monitoring	N/A	N/A	The program will continue unchanged because bi-annual monitoring (i.e., in spring and fall) captures representative conditions.

Notes: N/A: not applicable; NEZ: North-East Zone

6.10.4.1 RECLAMATION AND CLOSURE MONITORING

NEZ Seep 1 and NEZ Seep 2 have elevated metal concentrations compared to other seeps on site. To address this, research into the source of the elevated metals has been launched, as well as possible treatment options. A new collection system for these two seeps has been constructed to isolate the water from the mine site collection infrastructure; this water will be pumped to the mill for the short-term while the research is conducted.

6.10.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all seep monitoring is summarized in Table 6.25.

Table 6.25 Water chemistry QC sample frequencies for seep monitoring

QC Samples	Frequency
Duplicate samples	10% of seep monitoring samples
Trip blanks	Quarterly/Semi-annually[1]
Field blanks	Quarterly/Semi-annually[1]

Notes: [1] Quarterly for quarterly sampling events; semi-annually for semi-annual sampling events

For results greater than five times the MDL, an RPD will be used to identify differences between original and duplicate samples. These DQOs are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

6.10.6 Laboratory Analysis

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.10.7 Data Analysis and Reporting

Collection of this data is used in long-term effluent water quality predictions. These results are presented in the AERR and are applied to understand long-term ML/ARD potential, develop site source terms, and inform water management planning.

6.11 Effluent Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.11.1 Section Authors and Study Design Professionals

This section was written by MPMC.

6.11.2 MONITORING OBJECTIVES

The objective of the effluent monitoring program is to verify the water chemistry complies with the applicable regulatory limits at the point of discharge (MDMER Schedule 4 and the Permit limits in Table 6.26; see Section 1.2.3 in the Permit), and that the discharge flow rate does not exceed the permitted rates of a maximum of 52,000 m^3/day and an annual average of 29,000 m^3/day (see Section 1.2.1 in the Permit). The influent is also sampled to allow for analysis of treatment efficacy.

6.11.3 MONITORING OVERVIEW

The flow rate, temperature, and TSS of the effluent will be continuously monitored and recorded in the Veolia WTP HMI. MPMC may consider less frequent sampling (MDMER minimum is quarterly) if the monthly mean concentrations of parameters are <10% of the MDMER guidelines for 12 months, as described Section 13 (1) of the MDMER. To make this change if these conditions are met, MPMC will follow the process outlined in Section 7. Table 6.27 summarizes the parameters analysed for effluent quality and Table 6.28 provides an overview of the effluent monitoring. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.7 shows monitoring locations of the effluent sampling locations. Reporting of the monitoring data is outlined in Section 9.

Table 6.26 Permit 11678 and MDMER Schedule 4 treated effluent compliance limits for direct discharge to Quesnel Lake

		Permit Limit		MDMER Schedule 4: Authorized Limits	
Constituent	**Units**	**Interim [1]**	**Final [2]**	**MAX Monthly Mean**	**MAX Grab Sample**

Selenium	mg/L	0.06	0.075	-	-
Silver	mg/L	0.00024		-	-
Zinc	mg/L	0.059		-	-
Dissolved Metals					
Aluminum	mg/L	0.75		-	-
Cadmium	mg/L	0.00034		-	-
Iron	mg/L	0.35		-	-
Acute Toxicity Testing Results					
96h LC50 Rainbow Trout	Mortality in 100% effluent	50%		-	LC50 >100%
48h LC50 *D. magna*		50%		-	LC50 >100%

Notes: [1] Maximum discharge limits until toxicity testing on final effluent concentrations is conducted; [2] Maximum discharge limits applicable after ENV is satisfied that toxicity testing demonstrates that the final effluent will not cause mixture toxicity. This requirement has been met; [3] MDMER requirement only; if cyanide is not used in the mining/milling process, then it does not have to be analysed. Since cyanide is not used in the mining/milling process at Mount Polley, the effluent is not analysed for cyanide; [4] MDMER requirement only; if 10 consecutive samples show radium 226 as less than 0.037 Bq/l then frequency of sampling for radium 226 can be reduced to once a quarter. This has been satisfied, and radium 226 analysis is currently conducted quarterly.

Table 6.28 Effluent monitoring overview

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
E19	E305050	WTP influent	Weekly[1]	Field parameters, physical tests, anions and nutrients, DOC, total and dissolved metals	N/A
HAD-3	E304230	WTP treated effluent	Continuous[1]	TSS (calculated), temperature, flow rate	Permit 11678
			Weekly[1]	Field parameters, physical tests, anions and nutrients, DOC, total and dissolved metals, radium 226[2], total mercury[3]	Permit 11678; MDMER; EEM
			Monthly	Acute toxicity tests: - Rainbow trout: *Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Rainbow Trout* (Reference Method EPS1/RM/13) - Daphnia Magna: *Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Daphnia magna* (Reference Method EPS1/RM/14) - or most recent methods, as per MDMER	Permit 11678; MDMER[4]
			Semi-annually[5]	Chronic toxicity tests: - Biological Test Method: *Toxicity Tests Using Early Life Stages of Salmonid Fish* (Rainbow Trout) (Reference Method EPS 1/RM/28) - Invertebrate species: *Biological Test Method: Test of Reproduction and Survival Using the Cladoceran Ceriodaphnia dubia* (Report EPS 1/RM/21) - Plant species: *Biological Test Method: Test for Measuring the Inhibition of Growth Using the Freshwater Macrophyte, Lemna minor* (Reference Method EPS 1/RM/37) - Algal species: *Biological Test Method: Growth Inhibition Test Using Freshwater Alga Selenastrum capricornutum* (Report Method EPS 1/RM/25)	MDMER

Notes: [1] Only when discharging; [2] MDMER requirement only; if 10 consecutive samples show radium 226 as less than 0.037 Bq/l then frequency of sampling for radium 226 can be reduced to once a quarter. This has been satisfied and radium 226 analysis is currently conducted quarterly; [3] EEM requirement only; can be discontinued if concentration is less than 0.10 µg/L in 12 consecutive samples. This has been satisfied and mercury analysis has been discontinued; [4] MDMER June 2018 Part 2 Division 2 16 (1): frequency may be reduced to quarterly if discharge is determined not to be acutely lethal for 12 consecutive months; [5] Chronic/sub-lethal toxicity tests are conducted semi-annually for 3 years. MDMER June 2018 Schedule 5, 6 (1-3): after 3 years, frequency will be increased to once per calendar quarter on the sub lethal species whose results of sub lethal tests produce the lowest geometric mean, taking into account the inhibition concentration that produces a 25% effect or effective concentration of 25%; N/A: not applicable; TSS: total suspended solids; DOC: dissolved organic carbon; MDMER: Metal and Diamond Mining Effluent Regulations; EEM: Environmental Effects Monitoring

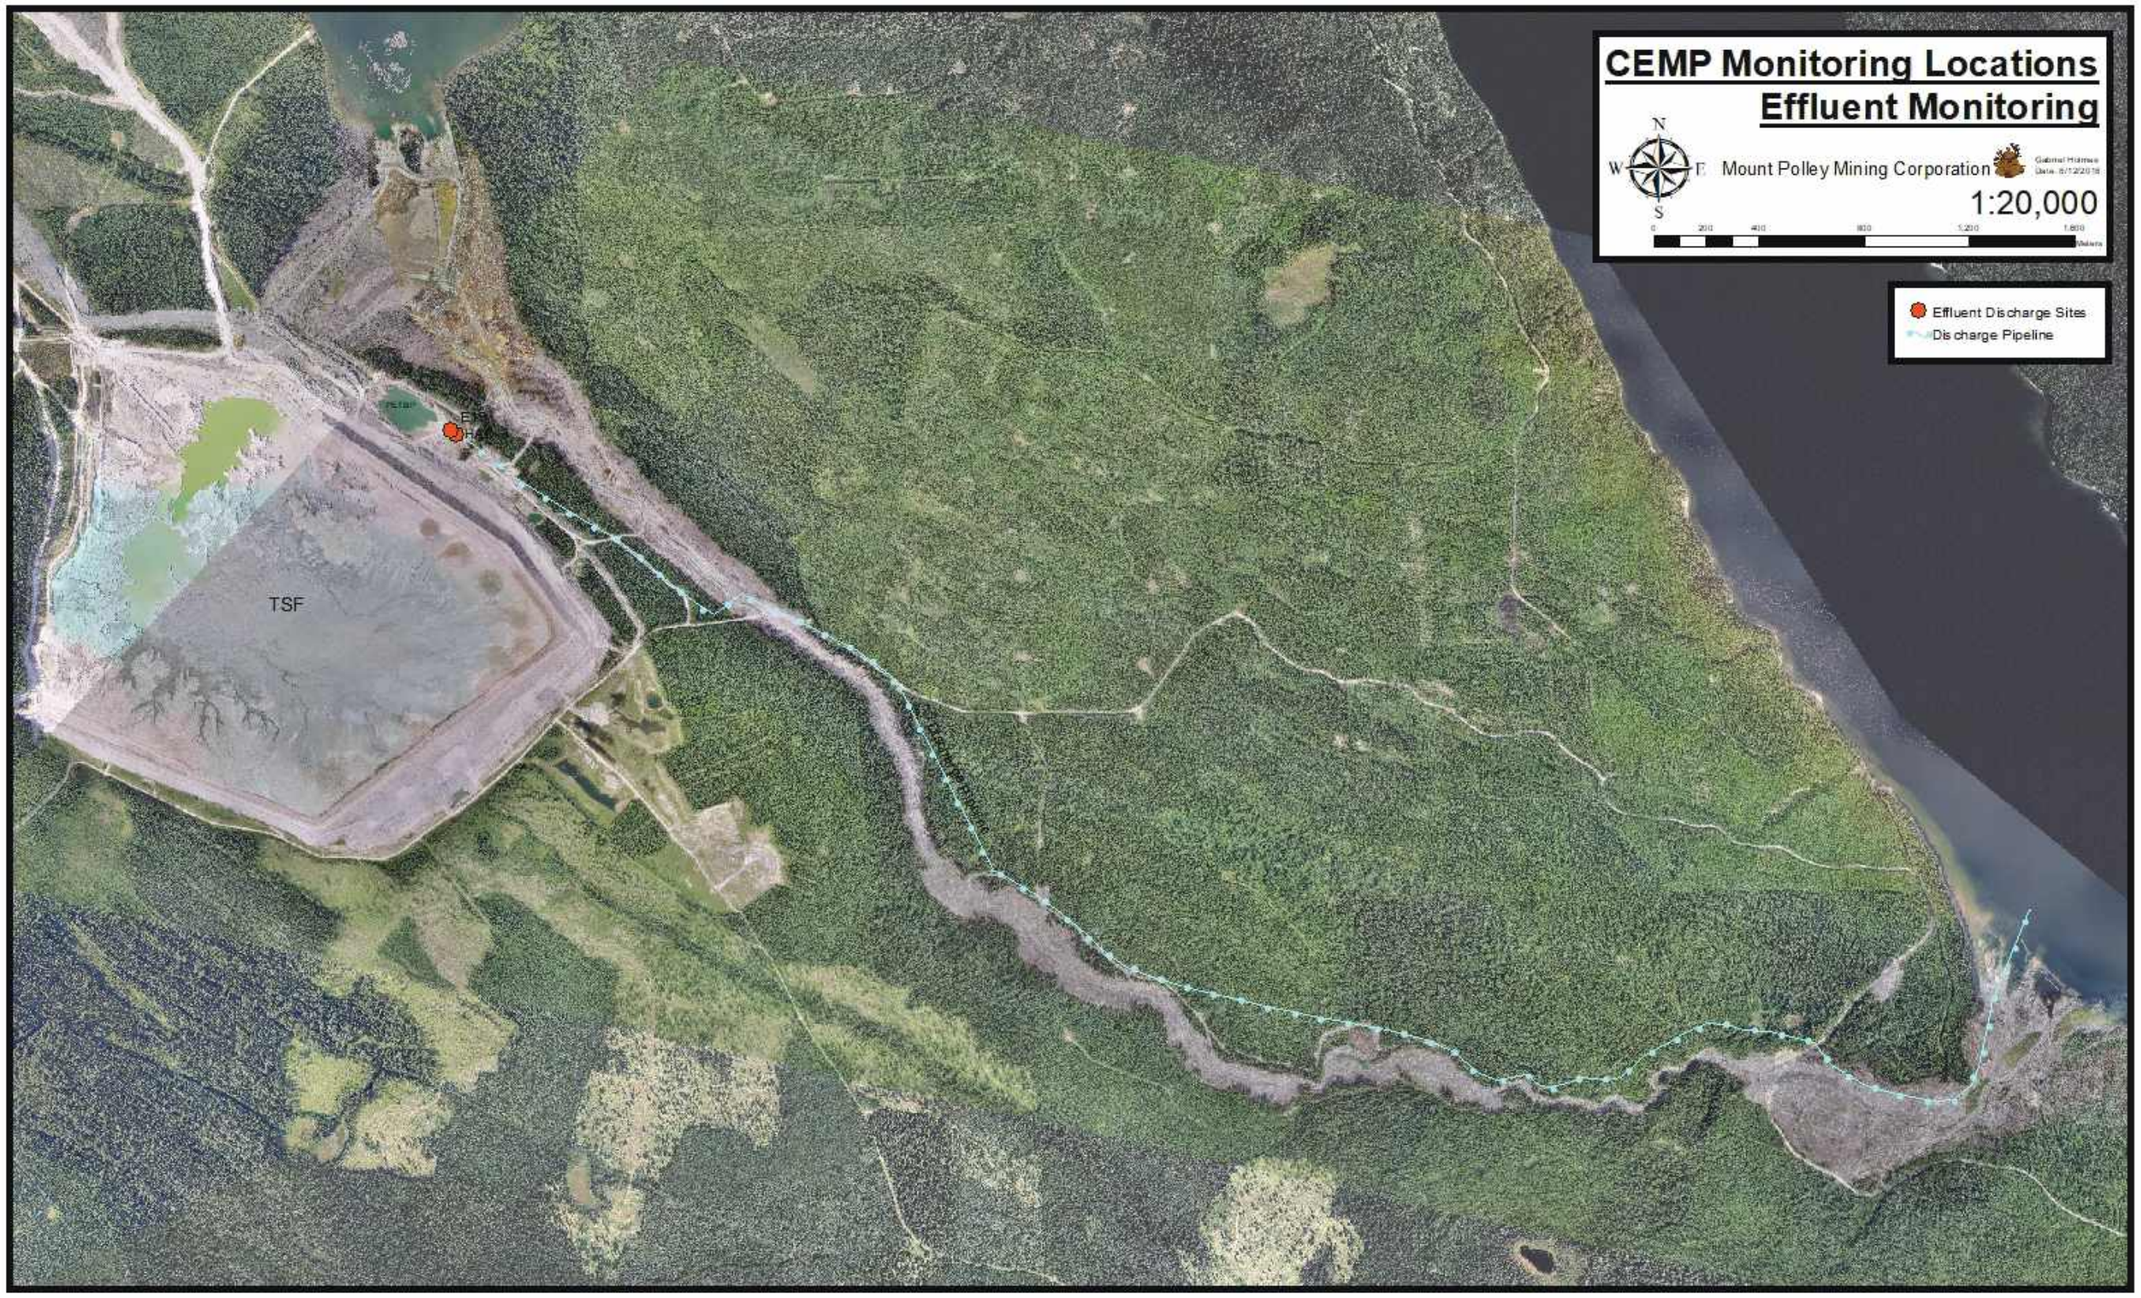

Figure 6.7 CEMP monitoring locations: Effluent monitoring

6.11.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Surface Water Quality Monitoring, and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed for the parameters described in Section 6.11.3.

Table 6.29 is a summary of previous effluent monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.29 Summary of effluent monitoring and findings

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Discharge monitoring included the influent and treated effluent.	N/A	N/A
Summary of findings	All samples were at or below permit limits for the treated effluent in 2017; in 2016, the majority of samples were at or below the permit limits. When samples did not meet permit limits, ENV was notified and an investigation into the cause was undertaken. Comparing the influent concentrations to treated effluent concentrations verified reduction in parameters interest. See Section 6.11.4.1 for more details.	N/A	N/A
Recommendations for 2018-2020 monitoring	Monitoring of the influent (E19) will be increased from monthly to weekly to align with monitoring of HAD-03 for better efficiency analysis of the WTP.	N/A	N/A

Notes: N/A: not applicable; ENV: Ministry of Environment and Climate Change Strategy; WTP: water treatment plant

Should there be an extreme weather event or equipment failure in the WTP that could affect water quality in the effluent, MPMC has the ability to request rush analysis from the analytical lab (ALS). MPMC maintains an Emergency Response Plan for the effluent discharge as required by the MDMER and the Permit.

6.11.4.1 OPERATIONAL MONITORING

Figure 6.8 shows total copper concentrations and Figure 6.9 shows TSS in the influent (E19) and effluent (HAD-03) in 2017. No exceedances were recorded in 2017 in the effluent.

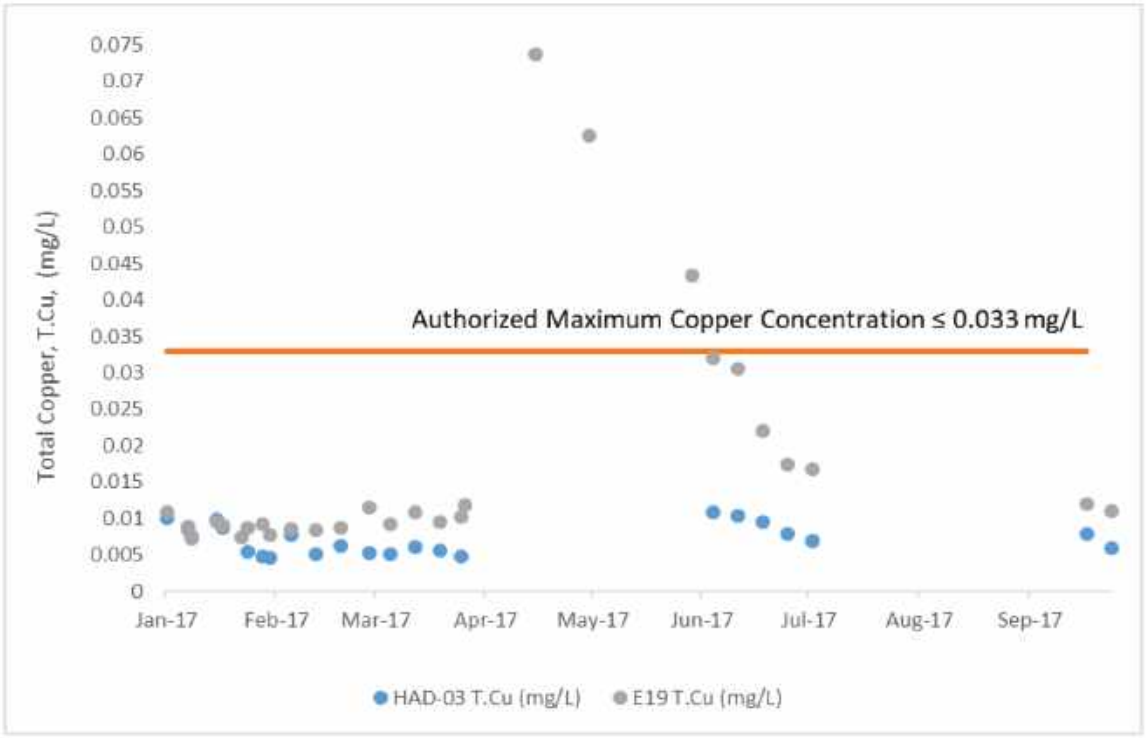

Figure 6.8 Total suspended solids concentrations in influent (E19) and effluent (HAD-03) in 2017

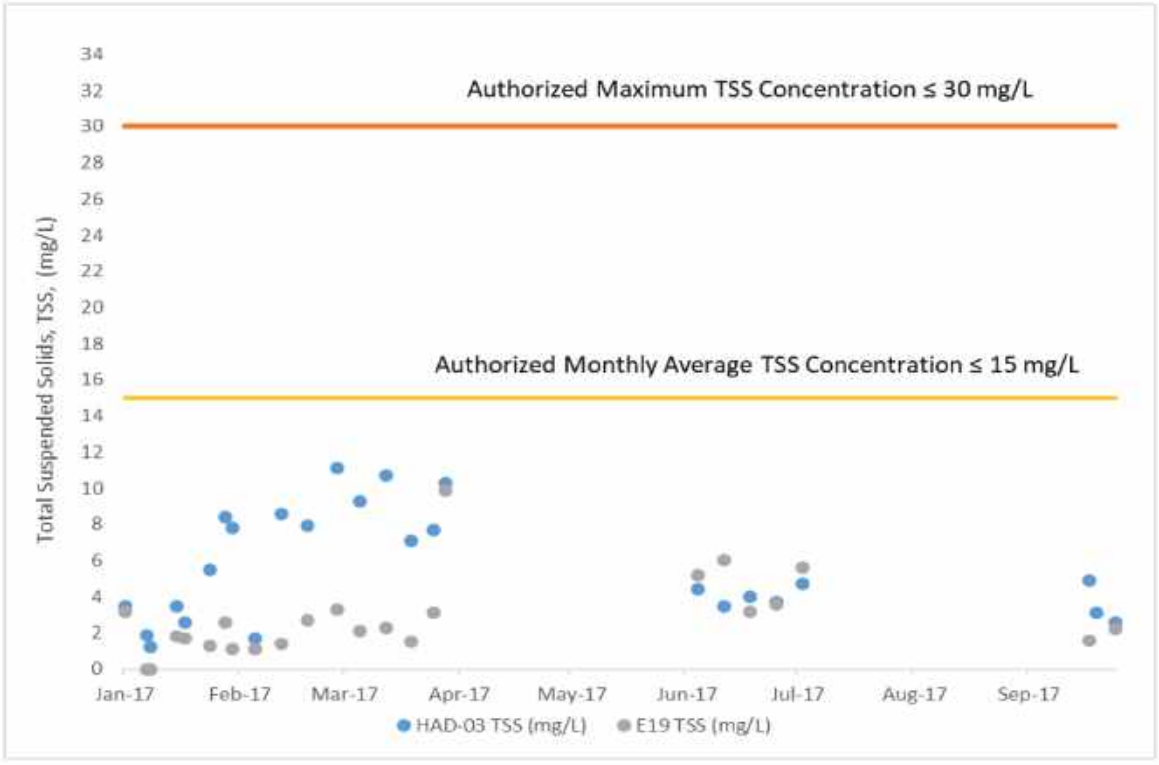

Figure 6.9 Total copper concentrations in influent (E19) and effluent (HAD-03) in 2017

MPMC conducts acute toxicity tests monthly for LC50 Rainbow trout and LC50 *Daphnia magna*. Under the new MDMER, *D. magna* is now a compliance parameter. MPMC will continue to conduct these acute lethality tests as required.

MDMER has changed the frequency of acute toxicity tests for effluent discharge. In accordance with Part 2, Division 2, paragraph 16 (1), acute lethality tests at the final discharge point (HAD-3) will become quarterly if the effluent is determined to be non-lethal for 12 consecutive months (Government of Canada 2018). Effluent at HAD-3 since discharge has started (December 2015) has been shown to be non-lethal.

MPMC has conducted chronic toxicity tests on the effluent discharge since December 7, 2015 on a quarterly and semi-annual basis. Under MDMER requirements, after three years (after December 2018 at HAD-3), the chronic toxicity tests results will be reviewed by a QP and will be streamlined to one test only. This test will be based on the most sensitive organism to the effluent according to historical geometric means and will be tested quarterly. The reduction of frequency from the 2016 CEMP for the chronic toxicity tests, as described in Table 6.28, aligns with the MDMER, as no actionable effects have been recorded at HAD-03 and the MDMER protocol is established to characterise the impacts on the most sensitive aquatic life.

6.11.5 Data Quality Control, Objectives, and Review

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. Effluent monitoring samples are combined in the surface water QC schedule (see Section 6.6.5), as laid out in Table 6.8.

6.11.6 Laboratory Analysis

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC for chemistry samples and Nautilus Environmental in Burnaby, BC for toxicity testing, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015) and the MDMER (where applicable; i.e., discharge water toxicity testing).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

QC monitoring for toxicity testing will be carried out at the laboratory, as per the test methods, with requirements to meet criteria such as test organism health history, and control acceptability. Uncertainty associated with test results will be described by the standard deviation around the mean and/or the confidence limits around the point estimate.

6.11.7 Data Analysis and Reporting

Data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, max, and 95th percentile values over the period of interest) and screening of results

against applicable regulatory benchmarks (see Table 6.26). Screening will include evaluation of results at the treated effluent discharge against MDMER and the Permit limits. Alerts are set up in the MP-5 database so that MPMC Environmental Department staff receives an email if specified benchmarks are exceeded.

6.12 SEDIMENT QUALITY MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.12.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow Environmental Inc. (Minnow). The detailed study design is provided in Appendix B.1. Golder prepared the study design for selecting an alternate reference lake for Polley Lake (Appendix B.7).

6.12.2 MONITORING OBJECTIVES

As outlined in Appendix B.1, the objectives of sediment quality monitoring are to:

- "Evaluate the influence of mine activities on the receiving environments (e.g., Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions";
- "Determine potential implications to aquatic life by applying a variety of interpretive tools";
- "Provide data to support exposure assessment as part of the ERA and HHRA";
- "Provide supporting information for benthic invertebrate community monitoring"; and,
- "Advance technical understanding of the stability or mobility and potential bioavailability of metals and metalloids in lake sediments affected by the TSF Breach".

6.12.3 MONITORING OVERVIEW

Sediment quality monitoring under the CEMP is proposed to meet the combined needs of:

1) Operational monitoring (including the discharge of treated effluent to Quesnel Lake);
2) Monitoring of the impact of the 2014 perimeter embankment failure; and
3) Monitoring of response to reclamation activity following the perimeter embankment failure.

An overview of the proposed sediment quality monitoring program is provided in Table 2 and Figures 5 and 6 of Appendix B.1. Sediment quality monitoring is focused on Polley Lake, Hazeltine Creek, and Quesnel Lake, with reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake for Polley Lake, unaffected areas of Quesnel Lake for impacted areas of Quesnel Lake). Table 3 in Appendix B.1 summarizes the analytes and laboratory reporting limits for the sediment quality monitoring program.

The monitoring program is divided into lake monitoring and creek monitoring and will include physical and chemical characterisation of deposited sediments. Sediment quality sampling will be supported by

measurements of temperature, dissolved oxygen, pH, and specific conductance near the sediment-water interface at all sampling stations. Some additional monitoring of the stability and potential bioavailability of metals associated with sediments impacted by the TSF Breach may be undertaken (e.g., deployment of Diffusive Gradients in Thin Films [DGT] devices to monitor labile metal concentrations; toxicity testing using *Hyalella azteca*). More detail is provided in Appendix B.1.

6.12.4 High-Level Monitoring Design Description

Appendix B.1 provides a summary of sediment monitoring history previously conducted in the vicinity of the mine in the surrounding lakes and creeks, including baseline, and pre- and post-breach monitoring. The sample collection methods are also summarized in Appendix B.1 for lake sediment sampling, creek sediment sampling, and DGT sampling. A study design for evaluating alternate reference lakes for Polley Lake is provided in Appendix B.7.

6.12.5 Data Quality Control, Objectives, and Review

Appendix B.1 summarizes the QAQC program for the sediment monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. As described in Appendix B.1, "comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD <40% for concentrations that are >5 times the detection limit, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective detection limits." See Appendix B.1 for more details.

6.12.6 Laboratory Analysis

Chemical analyses will be completed at a CALA accredited analytical laboratory and will include moisture content, pH, particle size distribution, total organic carbon (TOC), total nitrogen, total sulphur, and total metal concentrations, as summarized in Table 3 in Appendix B.1.

Toxicity testing will be conducted at a CALA accredited testing laboratory using a 10 day test of the survival and growth of *Chironomus dilutus.* DGT analysis is described in detail in Appendix B.1 in Section 4.3.

6.12.7 Data Analysis and Reporting

As described in Appendix B.1, data will be provided to the QP and summarized by calculating mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile for each analyte for all replicated data. Appendix B.1 describes how "sediment quality data will then be evaluated in comparison to British Columbia Working Sediment Quality Guidelines for the protection of aquatic life (WSQGs; MOE 2017b) and reference concentrations. Reference 95th percentile values will be used to screen exposed-area mean concentrations to efficiently identify analytes with concentrations that are beyond the range of reference.

"The overall interpretation of sediment quality data will include integration of a weight-of-evidence that includes other components of the MPMC CEMP (e.g., benthic invertebrate community data). Thus, within

the CEMP, sediment quality data interpretation will specifically include the integration of data on sediment quality, the results of specialized evaluations (e.g., DGT results), and the results of bio-assessment (e.g., sediment toxicity testing and benthic invertebrate communities).

"An interpretive report based on the sediment quality data will be prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an Appendix and will include the data quality review, the results of the screening against BCWSQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots."

6.13 BENTHIC INVERTEBRATE MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.13.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow. The detailed study design is provided in Appendix B.2. Golder prepared a study design for selecting an alternate reference lake for Polley Lake (Appendix B.7).

6.13.2 MONITORING OBJECTIVES

As outlined in Appendix B.2, the objectives of benthic invertebrate monitoring are to:

- "Evaluate the influence of Mount Polley Mine activities on benthic invertebrate communities, productivity, and tissue quality in receiving environments (e.g., Polley Lake, Hazeltine Creek, Edney Creek, and Quesnel Lake) in comparison to baseline and/or reference conditions";
- "Determine potential implications to aquatic life (e.g., through assessment of benthic invertebrate community and productivity endpoints, and comparison of benthic tissue quality results to available guidelines; MoE 2014) and to aquatic ecosystem health by providing supporting information for the assessment of potential effects to higher trophic levels (e.g., fish and fish habitat quality; Section 6.16)"; and,
- "Provide data to support exposure assessment as part of the ERA and HHRA."

Benthic invertebrate community monitoring is also required as part of EEM under the MDMER. The objective of the MDMER EEM benthic invertebrate monitoring identified in Appendix B.2 is to "evaluate whether there are effects to benthic invertebrate community characteristics between the area of Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012)."

6.13.3 MONITORING OVERVIEW

Benthic invertebrate monitoring under the CEMP is designed to meet the combined needs of:

1) Operational monitoring (including the discharge of treated effluent to Quesnel Lake);
2) Monitoring of the impact of the 2014 TSF embankment breach; and
3) Monitoring of the response to reclamation activity following the TSF embankment breach.

An overview of the proposed benthic invertebrate monitoring program is provided in Table 3 of Appendix B.2, and includes benthic invertebrate community, productivity, and tissue quality. Benthic invertebrate monitoring is focused on Polley Lake, Hazeltine Creek, lower Edney Creek, Quesnel Lake, and associated reference areas (Figures 6 and 7 of Appendix B.2). Table 4 in Appendix B.2 summarizes the analytes and laboratory reporting limits for the benthic invertebrate monitoring program. The sampling frequency at this time is once every three years.

6.13.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Appendix B.2 provides a summary of benthic invertebrate monitoring history previously conducted in the vicinity of the mine in the surrounding lakes and creeks, including baseline, and pre- and post-breach monitoring. The sample collection methods are also summarized in Appendix B.2 for community and productivity sampling, and tissue quality sampling. A study design for evaluating alternate reference lakes for Polley Lake is provided in Appendix B.7.

6.13.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Appendix B.2 summarizes the QAQC program for the benthic invertebrate monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. As stated in Appendix B.2, "for benthic invertebrate tissue quality samples, comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD <25% for concentrations that are >5 times the detection limit, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective detection limits.

"For benthic invertebrate community samples, reanalysis for quality control endpoints (organism sorting efficiency, subsampling precision and accuracy error, and taxonomic identification error) will be performed on 10% of samples, and results of quality control measures will be evaluated relative to pre-established DQOs." See Appendix B.2 for more details.

6.13.6 LABORATORY ANALYSIS

As described in Appendix B.2, "taxonomic identification of benthic invertebrate community samples will be completed by a qualified laboratory certified under the Taxonomic Certification Program of the Society for Freshwater Science (SFS). Benthic invertebrate tissue quality samples will remain frozen until overnight shipment on ice with completed COCs to ALS Environmental, Burnaby BC, which is an analytical laboratory accredited by the CALA."

6.13.7 DATA ANALYSIS AND REPORTING

As described in Appendix B.2, data will be provided to the QP and summarized by calculating mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile for each endpoint for all replicated data. Data analysis will be completed for each monitoring component (community, productivity, and tissue quality). More detail for each monitoring component is provided in Section 4.5 of Appendix B.2.

As stated in Appendix B.2, "an interpretive report based on the benthic invertebrate data will be prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an appendix and will include the date quality review, the results of the screening against BCWQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots."

6.14 PLANKTON AND CHLOROPHYLL *A* MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.14.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC.

6.14.2 MONITORING OBJECTIVES

The objective of phytoplankton and zooplankton monitoring at lake stations is to assess potential changes in plankton community abundance and diversity, as well as temporal and special changes in zooplankton metal concentrations. Chlorophyll *a* sampling will be conducted and analyzed to provide support data that can be interpreted with other biological monitoring and water chemistry data in a broader analysis of lake productivity.

This monitoring will be conducted to aid in assessing lake productivity following the TSF embankment breach (Post-Breach Monitoring: Polley Lake and Quesnel Lake) and to identify any changes related to the chemistry of the discharged treated effluent (Operational Monitoring: Quesnel Lake).

6.14.3 MONITORING OVERVIEW

Table 6.30 summarizes the parameters analysed for plankton and chlorophyll *a* monitoring. Chlorophyll *a*, phytoplankton taxonomy and biomass, and zooplankton taxonomy and metal tissue samples will continue to be collected concurrently with water chemistry samples (including field parameters) three times per year to capture early and late growing seasons as outlined in Table 6.31. Growing seasons were determined after monthly sampling was conducted in 2015; data analysis of zooplankton community is presented in Golder (2016d). Further details of monitoring sites, including site access descriptions, access or safety concerns,

and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.10 shows monitoring locations of the plankton and chlorophyll *a* sampling locations.

Table 6.30 Plankton and chlorophyll *a* parameters

Parameter	LOR	Unit
Taxonomy		
Phytoplankton	-	-
Zooplankton	-	-
Total Metals in Tissue		
Aluminum (Al)	2	mg/kg
Antimony (Sb)	0.01	mg/kg

Table 6.31 Plankton and chlorophyll *a* monitoring overview

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
P2	E307975	Polley Lake deepest area at south end	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A
B2	E215897	Bootjack Lake deepest area at south end	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A
QUL-ZOO-1	E306455	Quesnel Lake zooplankton station at Hazeltine	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A
QUL-ZOO-7	E306456	Quesnel Lake zooplankton station at Horsefly	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A

Notes: N/A: not applicable; IDZ: initial dilution zone

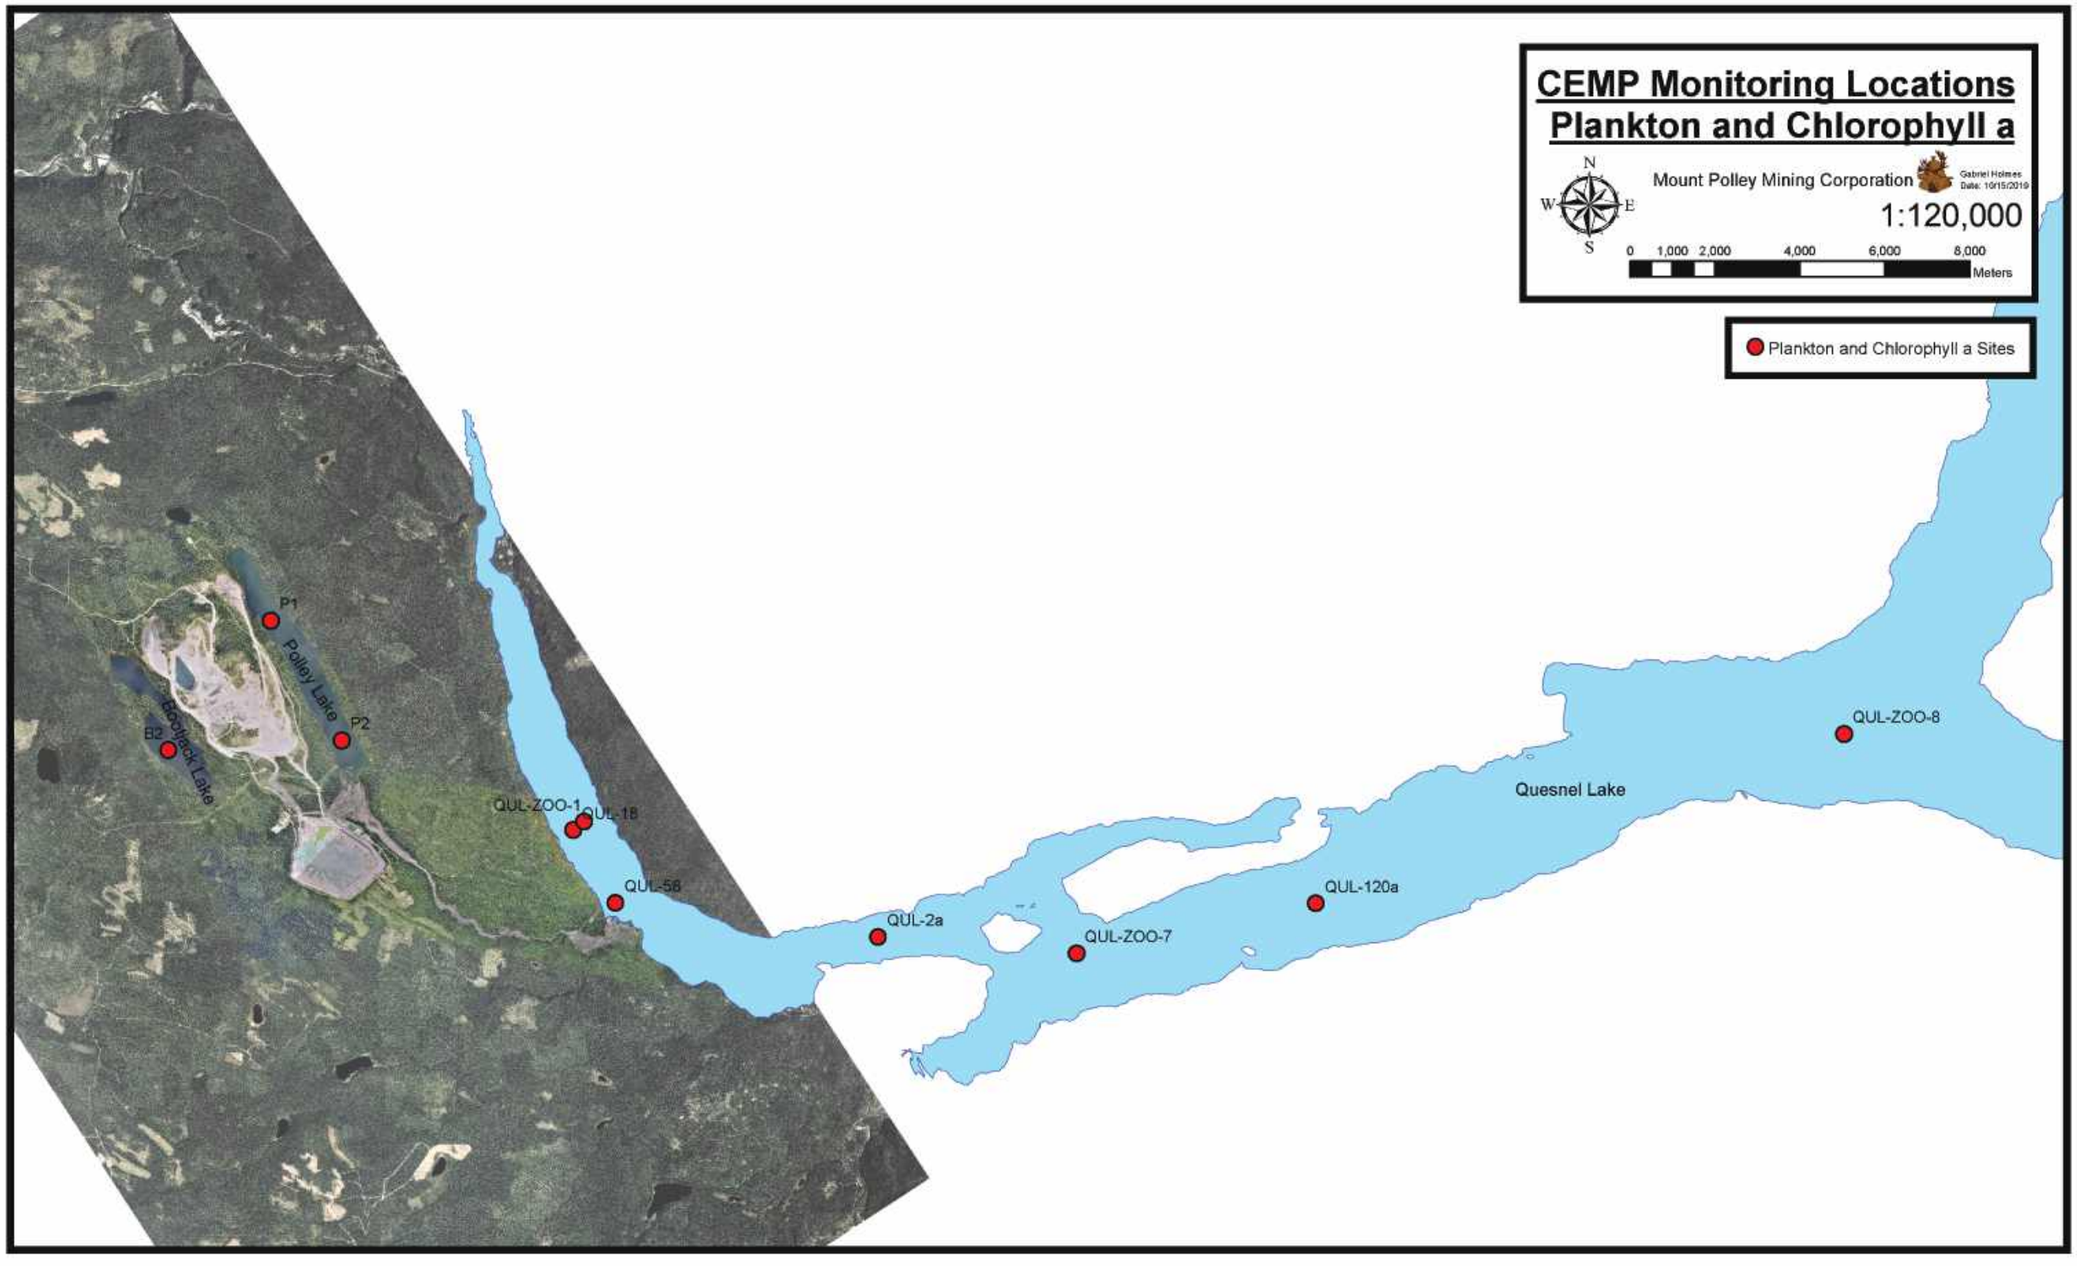

Figure 6.10 CEMP monitoring locations: Plankton and chlorophyll *a* monitoring

6.14.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following procedures outlined in the SOPs and WMs on Lake Water Monitoring and Zooplankton Sampling in the MPMC QA/QC Manual.

In brief, sampling at all stations will be conducted as follows:

- Zooplankton samples:
  - will be collected using 50 µm mesh nets with a mouth diameter ≥0.5 m, and equipped with a flow meter. In 2019, for stations previously sampled with a 150-µm mesh net, samples will be collected with both a 50- and a 150-µm mesh net to enable an assessment of the difference between the two net mesh sizes and to facilitate comparison with historical data.
  - will be collected using a modified horizontal tow.
  - for taxonomy/biomass will be transferred to a Nalgene container and preserved with buffered formalin.
  - for tissue chemistry will consist of a composite of multiple tows to achieve a minimum required tissue mass for analysis (i.e., 1.5 g).
- Phytoplankton samples
  - will be collected as a depth-integrated sample. Water will be collected from at least four discrete depths at each station (surface, one-third Secchi depth, two-thirds Secchi depth, total Secchi depth), with a grab sampler (e.g., Kemmerer, Van Dorn) or with a length of flexible tubing modified for this purpose, with or without a peristaltic pump.
  - will be collected as surface and depth-integrated samples in 2019 to allow for an assessment of the difference between the two methods and to facilitate comparison with historical data.
  - for Chlorophyll *a* analysis will be transferred to a container wrapped in aluminum foil.
  - for taxonomy/biomass will be preserved with Lugol's solution

One replicate will be collected in each of June and August, and five replicates will be collected during the July sampling event, and samples for zooplankton and phytoplankton will be collected on the same day for each lake. Secchi depth and *in situ* water-chemistry supporting data will be collected concurrently at each station.

Table 6.32 is a summary of previous plankton and chlorophyll *a* monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable. Monitoring for plankton and chlorophyll *a* overlaps with operational monitoring in Quesnel Lake, as described in Section 6.14.2.

Table 6.32 Summary of plankton and chlorophyll *a* monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Plankton (phyto and zoo) taxonomy and chlorophyll *a* sampling frequency was semi-annually in 2016 and 2017 (June/July and August) at two stations in Polley Lake and three stations in Quesnel Lake. Some sampling events were missed in 2017 due to safety concerns.		N/A
Summary of findings	Zooplankton and phytoplankton results will be analysed in the three-year interpretive report (see Section 9.4) and recommendations for changes may be made, if required, in this report. Some chlorophyll *a* data were collected prior to the TSF breach. Results from 2013 – 2017 are shown in Section 6.14.4.1.		N/A
Recommendations for 2017-2020 monitoring	The sampling program outlined in Table 6.31 will be repeated annually.		N/A

Notes: N/A: not applicable

6.14.4.1 POST-BREACH MONITORING

Figure 6.11 shows chlorophyll *a* data collected from Polley Lake from 2013 – 2017. Data from P2 will continue to be collected to analyse potential trends.

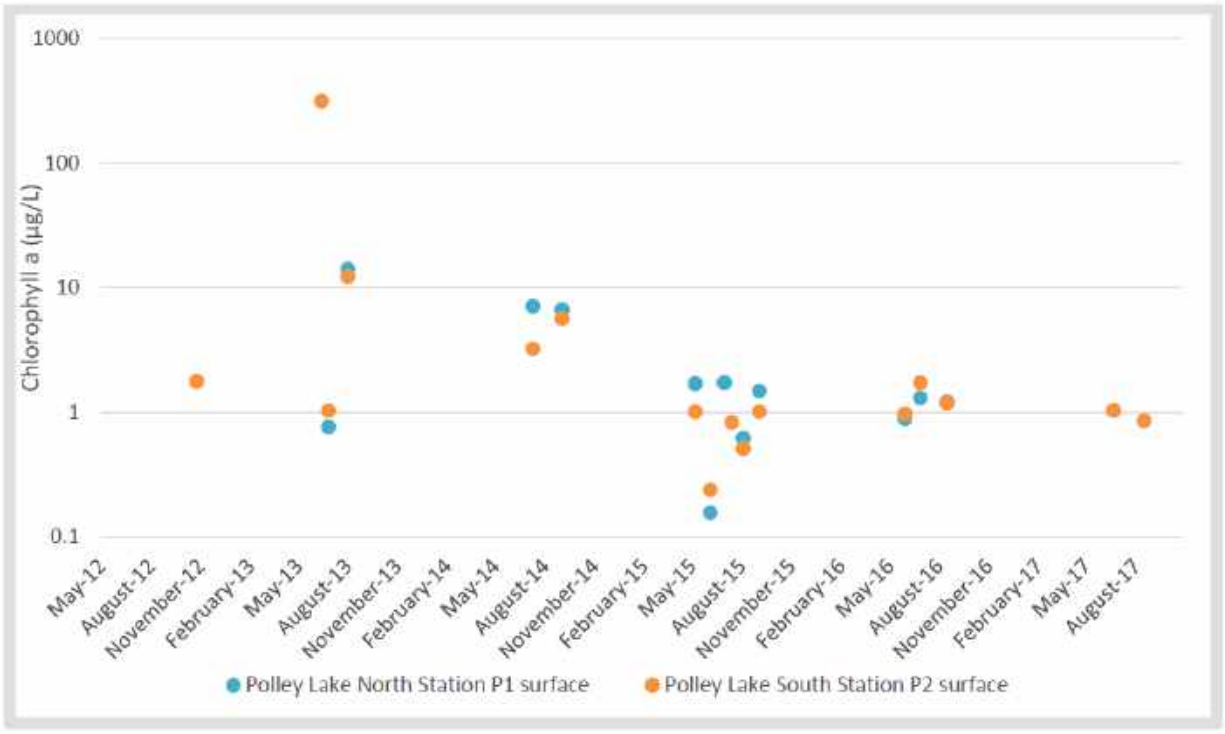

Figure 6.11 Chlorophyll *a* data collected from Polley Lake from 2013 - 2017

6.14.5 Data Quality Control, Objectives, and Review

QA/QC procedures will consist of re-analysis of 10% of phytoplankton and zooplankton taxonomy samples, and analysis of a duplicate metals sample for tissue chemistry once annually. For taxonomy, replicate counts should meet the DQO of within 20% of the original count. For metals, the RPD data quality of greater than 40% for concentrations greater than or equal to five times the MDL will be used to identify differences between original and duplicate samples for metals.

6.14.6 Laboratory Analysis

Plankton taxonomy samples will be shipped to the following laboratories for processing[2]:

- Biologica environmental Services Ltd., Victoria, BC: plankton taxonomy.
- ALS Environmental Inc., Burnaby, BC[3] – chlorophyll *a* and zooplankton tissue chemistry.

6.14.7 Data Analysis and Reporting

Statistical analysis will be carried out to evaluate trends over time by comparing results with data collected annually. In Quesnel Lake, near-field data will be compared with far-field and reference data to evaluate

[2] No accreditation program exists for plankton taxonomy

[3] Accredited by the Canadian Association of Laboratory Accreditation (CALA)

potential mine impact and spatial trends. These data will also be used to assess implications for lake productivity and fish populations.

6.15 PERIPHYTON MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.15.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow. The detailed study design is provided in Appendix B.3.

6.15.2 MONITORING OBJECTIVES

As outlined in Appendix B.3, the objectives of periphyton monitoring are to:

- "Evaluate the influence of mine activities (related to mine operations, the TSF breach, and/or rehabilitation activities) on Hazeltine Creek (the creek receiving environment directly influenced by mine activity) and lower Edney Creek (a creek environment directly influenced by the TSF breach)";
- "Serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (benthic invertebrates and fish; Sections 6.13 and 6.16, respectively)";
- "Provide supporting information for the assessment of benthic invertebrate tissue quality, benthic invertebrate community condition, and fish habitat productivity"; and,
- "Provide data to support exposure assessment as part of the ERA and HHRA".

Periphyton monitoring will include assessment of productivity, community composition, and tissue quality, with comparison to previous and/or reference conditions, to applicable guidelines (i.e., chlorophyll *a*; MoE 2018), and to literature-based criteria (or classification ranges) for productivity.

6.15.3 MONITORING OVERVIEW

Periphyton monitoring under the CEMP is proposed to meet the combined needs of:

1) Operational monitoring (including the previous discharge of treated effluent to Hazeltine Creek);
2) Monitoring of the impact of the 2014 TSF breach; and
3) Monitoring of the response to reclamation activity following the TSF breach.

An overview of the proposed periphyton monitoring program is provided in Table 1 and Figure 4 of Appendix B.3. Periphyton monitoring is focused on Hazeltine Creek and lower Edney Creek with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and an unaffected area of lower Edney Creek for rehabilitated areas of lower Edney Creek

and lower Hazeltine Creek). Table 2 in Appendix B.3 summarizes the analytes and laboratory reporting limits or the periphyton monitoring program.

6.15.4 High-Level Monitoring Design Description

Appendix B.3 provides a summary of periphyton monitoring history previously conducted in the vicinity of the mine in the surrounding creeks, including pre- and post-breach monitoring. The sample collection methods are also summarized in Appendix B.3 for biomass and chlorophyll *a* sampling, community sampling, and tissue quality sampling.

6.15.5 Data Quality Control, Objectives, and Review

Appendix B.3 summarizes the QAQC program for the periphyton monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. As stated in Appendix B.3, "comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD < 25% for concentrations that are > 5 times the detection limit, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective detection limits. Specific QC sampling and associated reporting will for tissue quality and periphyton productivity endpoints be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). QC reporting will also be requested of the laboratory performing taxonomic analysis of the periphyton community samples, including organism enumeration checks for a minimum of 10% of samples." See Appendix B.3 for more details.

6.15.6 Laboratory Analysis

The laboratory responsible for the physical or chemical analyses will be accredited by the CALA for these analyses.

6.15.7 Data Analysis and Reporting

For all replicated data (typically based on a sample size of five or eight stations per area), data will be provided to the QP and summarized by calculating mean, median, standard deviation, minimum, and maximum for each analyte. Data analysis will be completed for each monitoring component (productivity, community, and tissue quality). More detail for each monitoring component is provided in Section 4.5 of Appendix B.3.

As outlined in Appendix B.3, "an interpretive report based on the periphyton monitoring data will be prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an appendix and will include the data quality review, the results of the screening against BCWSQG and other guidelines or classification schemes, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots."

6.16 FISH MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.16.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow. The detailed study design is provided in Appendix B.4.

6.16.2 MONITORING OBJECTIVES

As outlined in Appendix B.4, the objectives of fish monitoring are to:

- "Evaluate the influence of Mount Polley Mine activities on fish communities, populations, and tissue quality in receiving environments (Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions";
- "Determine potential implications to aquatic ecosystem health and human health (e.g., relative to available fish tissue quality guidelines [MoE 2014; CFIA 2015])";
- "Provide data to support exposure assessment as part of the ERA and HHRA"; and,
- "Document fish habitat utilization in creek and lake areas that were physically impacted by the TSF breach (most notably Hazeltine Creek and the lower segment of Edney Creek), thereby documenting the effectiveness of fish habitat rehabilitation efforts".

From Appendix B.4, the objective of the MDMER EEM fish monitoring is to "evaluate whether there are differences in population endpoints (survival, growth, and reproduction) of sentinel fish species between the area of Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012)." Evaluation of selenium in fish tissues is also triggered under the MDMER on the basis of current selenium concentrations in effluent.

6.16.3 MONITORING OVERVIEW

Fish monitoring under the CEMP is designed to meet the combined needs of:

1) Operational monitoring (including the discharge of treated effluent to Quesnel Lake);
2) Monitoring of the impact of the 2014 TSF embankment breach; and
3) Monitoring of the response to remediation following the TSF embankment breach.

As previously indicated, fish monitoring includes fish tissue quality monitoring, sentinel fish population monitoring, fish habitat characterization and fish usage monitoring, and fish community monitoring. An overview of the proposed fish monitoring program is provided in Table 8 and Figures 5 and 6 of Appendix B.4. Table 9 in Appendix B.4 summarizes the fish tissue analytes and laboratory reporting limits for the fish monitoring program.

6.16.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Appendix B.4 provides a summary of fish monitoring history previously conducted in the vicinity of the mine in the surrounding creeks, including baseline monitoring, and pre- and post-breach monitoring. The sample collection methods and monitoring are also summarized in Appendix B.4 for tissue sampling, sentinel fish population monitoring, fish community monitoring, and fish habitat characterization and usage monitoring.

In addition to the monitoring outlined in Appendix B.4, visual spawning surveys of upper Hazeltine Creek to evaluate the success of re-introduction of spawning access by Polley Lake rainbow trout, and at the mouth of Hazeltine/Edney Creek to confirm access to that stream reach following a monitoring program developed in conjunction with the Habitat Remediation Working Group (HRWG). The surveys consisted of two field staff walking the bank of the creek channel and documenting visual observations of species, life stage, and behaviour of fish in the creek, and in lower Hazeltine/Edney, the presence of redds was noted. In upper Hazeltine Creek 25 surveys were conducted through the 2018 ice-free period and in the Hazeltine/Edney Creek mouth, 12 surveys were conducted. Spawning surveys were conducted in Hazeltine/Edney again in 2019.

6.16.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Appendix B.4 summarizes the QAQC program for the fish monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. For fish tissue samples, comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD <25% for concentrations that are >5 times the detection limit, then the duplicate sample results will be considered acceptable. Specific QC samples will include laboratory blanks, laboratory replicates, and laboratory accuracy samples (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). The QC sample results will be assessed as part of the data quality review. See Appendix B.4 for more details.

6.16.6 LABORATORY ANALYSIS

All chemical analyses will be completed by a laboratory that is accredited by CALA, and will be required to include specific QC samples and report associated results.

6.16.7 DATA ANALYSIS AND REPORTING

Catch-per-unit-effort and summary statistics for meristic measurements taken in the field will be calculated. Although community and population data is collected during every phase or component of the fish monitoring program, the sample size will be defined by the study objectives and may be insufficient to address corollary questions. For example, the sample size required for tissue quality analyses (n = 8) is not large enough to support formal contrasts of population endpoints. To this end, evaluation of fish community data will rely on qualitative comparisons, and conclusions regarding fish populations will be supported by non-lethal measurements and sampling under the MDMER EEM (with larger sample size), as described in Appendix B.4. Analysis methods for the MDMER EEM fish population data, as described in Appendix B.4 will be "consistent with EEM technical guidance (Environment Canada 2012). Summary statistics, including mean, median, minimum, maximum, standard deviation, standard error, and sample

size, will be calculated for fish age, fork length, total length, body weight, condition, liver weight, gonad weight, and fecundity; calculations will be completed according to species and area. All data sets will be assessed for normality and equality of variance in order to determine the suitability of parametric statistical procedures. An effect on the fish population will be evaluated for each of these measures and is defined as a statistically significant difference between the effluent-exposed area and the reference area (Environment Canada 2012). For each endpoint, statistically significant differences between effluent-exposed and reference areas (by species and sex) will be assessed using ANOVA, Analysis of Covariance (ANCOVA), or non-parametric equivalents, as appropriate, following technical guidance (Environment Canada 2012).

"For the fish tissue data sets, statistical comparisons of age, length, weight, and concentrations of metals in fish tissues (n = 8) will be completed among years and locations. The sample size, mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile will be calculated for each analyte. Means will be calculated using the Kaplan-Meier (K-M) method. The standard deviation and the median for each analyte will also be calculated using the K-M method. When a standard deviation cannot be estimated (i.e., when an analyte has a high proportion of censored values), it will be reported as "not calculated".

"Results of the fish habitat characterizations for Upper Hazeltine, Lower Hazeltine, and Lower Edney creeks will be summarized, along with fish usage results, according to season (spring, summer, and fall) and year. Fish habitat characterization measures will be summarized by season, reach, and area (rehabilitated and reference), with summary statistics (mean and standard deviation) calculated for all numerical parameters."

More detail for each monitoring component is provided in Section 4.5 of Appendix B.4.

An interpretive report based on the fish monitoring data was prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an appendix and will include the data quality review, the results of the screening against BCWQGs, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

With respect to the spawning surveys, rainbow trout were observed spawning in upper Hazeltine Creek, confirming that the fish were successfully re-introduced to the reconstructed channel. A majority of spawning activity occurring from May 10 to 25, 2018, when 488 rainbow trout redds were counted, and emergence of young-of-year trout began in late June (Minnow 2019). In 2018, rainbow trout, longnose sucker and redside shiner were observed lower Hazeltine/Edney (Minnow 2019) and in fall 2019, sockeye salmon were observed using the reconstructed habitat (data will be reported in 2020).

6.17 WILDLIFE MONITORING

Wildlife monitoring described below includes observational monitoring and monitoring using wildlife cameras. A study design for wildlife monitoring in the Hazeltine Creek corridor will be provided in 2020. This subsection will be updated accordingly.

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.17.1 Section Authors and Study Design Professionals

This section was written by MPMC (wildlife observations) and Golder (tissue collection and food chain model – related to follow up tasks for the ERA).

6.17.2 Monitoring Objectives

The current objective of the wildlife monitoring is to document the presence of mammals and birds using or migrating through the mine site and adjacent areas. This information is used for land use planning and to monitor the potential for effects of mine-related activities on animals in the area.

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017).

6.17.3 Monitoring Overview

Operational Monitoring - Wildlife occurrences will be recorded throughout the year by MPMC Environmental Department staff, and by other MPMC employees and contractors, when possible. Observations will include wildlife sightings and evidence of wildlife, such as tracks and droppings. Documentation will include the date, initials of the observer, location of the observation, wildlife observed, and comments (such as size of group, sex, or activity of an animal).

Data files from wildlife cameras installed in three locations (Hazeltine Creek, Mine Site, Reference site) are downloaded and reviewed monthly. Any changes to the location of the cameras are documented. Details including frequency of use by wildlife near each camera and variety of wildlife are documented. These details will be included in the AERR.

Supplemental Tasks - A tiered approach was been recommended, as outlined in Appendix B.5. Only Tasks 1A, 2A, 2B and 3 will be undertaken as part of the current CEMP. If risks are found to be unacceptable at the end of Step 2, further investigation following the proposed tiered approach described in Appendix B.5 will be conducted, which may include a development of a study design.

6.17.4 High-Level Monitoring Design Description

Table 6.33 is a summary of previous wildlife monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.33 Summary of wildlife monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	General wildlife observations (animals, scat, and tracks) documented.	N/A	N/A
Summary of findings	734 observations of wildlife were documented in 2017.	N/A	N/A
Recommendations for 2018-2020 monitoring	General wildlife observations will continue to be made per Permit requirements. A study design for wildlife monitoring in the Hazeltine Creek corridor will be provided in 2020.	Reconnaissance-level field surveys to support updated food chain modelling for potential bioaccumulation in wildlife.	N/A

Notes: N/A: not applicable

6.17.4.1 Operational Monitoring

This section will be updated when a study design is submitted in 2020.

6.17.4.2 Post-Breach Monitoring

In 2018, a reconnaissance-level survey was undertaken to support an update of the food chain model first presented in the ERA. Soil sampling is presented in Section 6.19, soil invertebrate sampling in Section 6.20, and vegetation monitoring in Section 6.21. An additional component considered in the food chain model was flying insects.

Samples of flying invertebrates (bees/wasps [order Hymenoptera], moths [order Lepidoptera], and crickets/grasshoppers [order Orthoptera]) were collected from the impacted area and background areas. Information about the tissue chemistry of this important food item for insectivorous birds and bats was not previously available in Golder (2017). The samples were collected through a combination of manual foraging and trapping. Manual foraging generally involved surveying flowering plants for bees or the ground surface for grasshoppers and using a sweep net to capture target invertebrates. Moths were predominantly collected using black light traps. Terrestrial invertebrate trapping was conducted using methods adapted from the RISC guidelines for terrestrial arthropod inventory (RIC 1998), guidance from the Biological Survey of Canada (Marshall et al. 1994; Danks 1996) and the US Department of Agriculture (Schauff 1998). Terrestrial invertebrate trapping methods employed on the Site included malaise traps, black light traps, pan/window traps and Berlese funnels.

Irrespective of the specific capture method, the following steps consistent with the *BC Field Sampling Manual* (BC ENV 2013) were followed to process the flying invertebrate samples:

- Samples were collected using nitrile gloves and transferred to clean Ziploc bags.
- Flying invertebrates of the same order from a single sample location (limited to 25 meters squared [m2]) were composited.
- Flying invertebrates were left in sample containers stored at ambient temperature overnight to allow samples to depurate.
- Flying invertebrate samples were rinsed using DI water and blotted dry with lint-free wipes before being transferred to clean Ziploc bags.
- Samples were transferred to a freezer to kill the invertebrates.
- Samples were kept frozen until they were submitted to the laboratory for analysis.

The invertebrate tissue samples were submitted for analysis of metals and moisture content, and the data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.7.

6.17.5 Data Quality Control, Objectives, and Review

Wildlife observations data will undergo a QC screening prior to upload to the network.

Twelve duplicate flying invertebrate samples were collected and laboratory QC samples consisted of duplicates, method and equipment blanks, and certified reference materials. RPDs exceeded DQOs for most metals in at least one duplicate sample. A higher variability in flying invertebrate samples is expected because the field duplicates are not splits of a composite—they are two composites of different individual organisms. In terms of copper, RPDs of 58 and 86% were noted in two of twelve duplicate pairs for wet weight concentrations and in one of twelve (RPD = 50%) of dry weight concentrations For vanadium, RPDs of 65 to 126% were noted in three of twelve duplicate sample pairs for wet weight concentrations and in zero of twelve duplicate sample pairs for dry weight. The data were considered reliable and suitable for there intended purpose

6.17.6 Laboratory Analysis

Laboratory analyses of the invertebrate tissue samples were undertaken by a CALA-accredited laboratory.

6.17.7 Data Analysis and Reporting

Number of wildlife observations will be tabulated and reported in the AERR.

The flying insect chemistry data (Golder 2019a) and updated food chain model (Golder 2019b) were submitted to ENV as an attachment to the 2018 Annual Report.

The wildlife food chain model presented in the ERA (Golder 2017) provided screening-level risk estimates for receptors exposed to copper and vanadium (the only contaminants of concern identified in the ERA),

which were based on calculated area-weighted hazard quotients (HQs) of <1 to 2.8, and a maximum HQ of 5.1 (for masked shrew in the Polley Flats area). Although the HQs were considered not to represent an unacceptable risk to wildlife, the food chain model was refined in 2018 by:

- Adding bats (*Myotis* sp.) as a receptor.
- Improving the quality of information with respect to tissue concentrations in invertebrates and plants by expanding the existing bioaccumulation sampling (as part of the reconnaissance-level survey conducted in 2018).
- Replacing the conservative assumption that flying insects have the same tissue concentrations as soil-dwelling insects by collecting site-specific data (as part of the reconnaissance-level survey conducted in 2018).
- Refining the toxicity reference values (i.e., the denominator in the HQ) to consider more than a highly conservative threshold

Revised screening-level risk estimates resulted in lower HQs. Screening-level HQs were <1 for all receptors except robin, shrew, and bat exposed to copper. The aggregate area-weighted HQs for those three receptors ranged from 1.0 to 1.7, and the maximum observed HQ for a sub-area was 2.1 for robin in the Polley Flats area. When a refined TRV was used to provide an additional level of protection to listed species, no HQs greater than 1 were identified and therefore, risks to wildlife associated with copper and vanadium in soils at the site are considered to be acceptable.

6.18 Amphibian and Reptile Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.18.1 Section Authors and Study Design Professionals

This section was written by Golder. The detailed study design concept is provided in Appendix B.6. Note that Appendix B.6 is a study design concept; a study design may be submitted at a later date depending on results of a preliminary review (Steps 1 and 2 as outlined in Figure 1 in Appendix B.6).

6.18.2 Monitoring Objectives

The study design concept in Appendix B.6 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.6, the objectives of amphibian monitoring will be to "continue the risk assessment process by proceeding through tiers to the point needed to support an informed risk management decision". More detail is provided in Appendix B.6.

6.18.3 Monitoring Overview

A tiered approach has been recommended, as outlined in Appendix B.6. Only Steps 1 and 2 will be completed as part of the current CEMP, with Step 1 undertaken in 2018. If risks are found to be unacceptable

at the end of Step 2, further investigation following the proposed tiered approach described in Appendix B.6 will be conducted, which may include a development of a study design.

6.18.4 High-Level Monitoring Design Description

In 2018, Step 1 of the study design concept was undertaken, specifically, a hazard evaluation. Existing soil, sediment and surface water chemistry data were screened for different habitat units against a conservative amphibian-specific screening value, as follows:

1. Review of existing guidelines: the purpose of the review was to determine if existing guidelines, criteria or standards contained sufficient amphibian-specific data to allow their use as a screening value for this assessment.
2. Derivation of screening values: the existing guidelines were determined to be unsuitable for the amphibian hazard assessment, and therefore screening values were developed through the review of scientific literature. Toxicity testing data were compiled, an uncertainty analysis was conducted on the compiled data, and safety factors were applied as applicable to mitigated identified uncertainties.
3. Application of derived screening values to site data: site monitoring data for water, sediment and soils were compared to the screening values for water and hydric soils/sediment.

6.18.5 Data Quality Control, Objectives, and Review

The study was a desktop review of guideline derivation documents and scientific literature.

6.18.6 Laboratory Analysis

No laboratory analysis were undertaken as part of the amphibian hazard assessment.

6.18.7 Data Analysis and Reporting

The amphibian hazard assessment (Golder 2019c) was submitted to ENV as an attachment to the 2018 Environmental and Reclamation Report (the "2018 Annual Report"), prepared in fulfillment of *Mines Act* permit M-200, and *Environmental Management Act* permit 11678. In summary, a toxicity reference value of 0.018 mg/L dissolved copper was derived for evaluating hazards associated with surface water, and 800 mg/kg copper for evaluating hazards associated with hydric soils or sediment. The available surface water and soil data for the Mount Polley site were compared to these conservative screening values, and overall, there was no evidence that environmental concentrations were routinely or notably higher than those screening value on a site-wide basis. Hazards to amphibians as a result of exposure to soil or surface water are considered to be low under these circumstances.

6.19 Soil Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description;

data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.19.1 Section Authors and Study Design Professionals

This section was written by Golder, and the detailed study design concept is provided in Appendix B.5.

6.19.2 Monitoring Objectives

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.5, the objective of soil monitoring will be to "refine site-specific relationships between copper concentrations in soil and copper concentrations in various soil invertebrate and plant tissues". More detail is provided in Appendix B.5.

6.19.3 Monitoring Overview

Monitoring of soil stockpiles on the mine site for reclamation and closure is outlined in the Soil Management Plan included in the RCP. It is covered under BC *Mines Act* Permit M-200.

In 2018, Task 1A of the study design concept was undertaken, specifically, a reconnaissance-level sampling program.

6.19.4 High-Level Monitoring Design Description

Operational Sampling - Monitoring of soil stockpiles on the mine site for reclamation and closure is outlined in the Soil Management Plan included in the RCP. It is covered under BC *Mines Act* Permit M-200.

Supplemental Sampling - Soil samples were collected from 69 locations (co-located with tissue samples – described in Sections 6.20 and 6.21) to refine the exposure estimate for post-breach rehabilitated areas. The soil chemistry data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.

Each sample was a composite of three aliquots of soil collected from within a 5 m radius of the tissue sample. The aliquots were collected from the top 20 cm of soil using a hand shovel, and then homogenized in a stainless-steel bowl prior to transfer to clean, laboratory-supplied 125-mL, glass sample jars with Teflon™ lined lids. Samples were kept on ice in a cooler after collection and kept cool until submitted to ALS for analysis of metals and pH.

6.19.5 Data Quality Control, Objectives, and Review

Supplemental soil sampling was undertaken using methods consistent with those used for the HHRA and ERA. Eight field duplicates were collected and laboratory QC consisted of duplicates, method blanks and matrix spike recovery. Copper and vanadium (the metals of interest for the food chain model) met the field DQOs. The soil sample results met the laboratory DQOs for precision, accuracy, method blanks, duplicate sample analysis and matrix spike recovery, with the exception of a method blank that had a detected

concentration of copper. This could be a potential bias in samples that are near the limit of reporting but was not an issue in the current samples because all copper results were substantially higher than detection limits. Overall, the data were considered representative and suitable for their intended use.

6.19.6 Laboratory Analysis

Laboratory analyses were undertaken by a CALA-accredited laboratory.

6.19.7 Data Analysis and Reporting

The results of the reconnaissance survey (Golder 2019a) were submitted to ENV as an attachment to the 2018 Annual Report. Data from the 2018 soil sampling were integrated with the relevant historical data to update the soil concentrations used in the food chain model. All samples were compared to the applicable CSR standards, and an overview of those findings is provided below for each of the different rehabilitated areas that were sampled in Tables 1 through 3. Overall, the results of the soil chemistry were consistent with results from previous sampling in those areas and no new contaminants of concern were identified. The use of the soil chemistry data is further discussed in Section 17 (vis-à-vis the food chain model update).

6.20 Soil Invertebrate Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.20.1 Section Authors and Study Design Professionals

This section was written by Golder, and the detailed study design concept is provided in Appendix B.5.

6.20.2 Monitoring Objectives

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.5, the objectives of soil invertebrate monitoring will be to:

- "Focus on establishing a long-term trend analysis of soil invertebrate community rather than to support a multitude of pair-wise comparisons that would have limited value for making site management decisions";
- "Refine site-specific relationships between copper concentrations in soil and copper concentrations in various soil invertebrate tissues"; and,
- "Improve the quality of data with respect to tissue concentrations in invertebrates, particularly for flying insects."

6.20.3 Monitoring Overview

In 2018, Task 2A of the study design concept was undertaken, specifically, a reconnaissance-level sampling program.

6.20.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Additional sampling was conducted to improve the spatial coverage of soil invertebrate samples, and to obtain sufficient samples of each main invertebrate type from the range of soil concentrations present at the site. Invertebrate (i.e., ants, beetles, spiders and worm) samples were collected through a combination of manual foraging and trapping. Manual foraging involved surveying the ground surface and searching below woody debris. Sampling was conducted if sufficient volume of soil invertebrates were noted or if a larger soil invertebrate (e.g., a large beetle) was found.

Terrestrial invertebrate trapping was conducted using methods adapted from the RISC guidelines for terrestrial arthropod inventory (RIC 1998), guidance from the Biological Survey of Canada (Marshall et al. 1994; Danks 1996) and the US Department of Agriculture (Schauff 1998). These documents guided the selection of the trapping method, locations of samples, sampling design and trapping protocols. Terrestrial invertebrate trapping methods employed on the Site included pitfall traps and Berlese funnels. Irrespective of the specific capture method, the following steps consistent with the *BC Field Sampling Manual* (BC ENV 2013) were followed to process the soil invertebrate samples:

- Samples were collected using nitrile gloves and transferred to either clean, laboratory supplied glass jars or clean Ziploc bags.
- Invertebrates of the same order from a single sample location (limited to 25 m^2) were composited.
- Soil invertebrates were left in partially open sample containers stored at ambient temperature overnight to allow samples to depurate.
- Invertebrate samples were rinsed using DI water and blotted dry with lint-free wipes before being transferred to clean Ziploc bags.
- Samples were transferred to a freezer to kill the invertebrates.
- Samples were kept frozen until they were submitted to the laboratory for analysis.

The soil invertebrate tissue samples were submitted for analysis of metals and moisture content, and the data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.

6.20.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Soil invertebrate sampling were undertaken using methods consistent with those used for the HHRA and ERA. Eight field duplicates were collected and laboratory QC consisted of duplicates, method blanks and certified reference materials. RPDs were greater than 50% for most metals in at least one duplicate sample. A higher variability in soil invertebrate samples is expected because the field duplicates are not splits of a composite—they are two composites of different individual organisms. In terms of copper, an RPD of 65% was noted for the wet weight concentration in one duplicate pair, but the dry weight data had an acceptable RPD (48%). There was less variability in copper results than most other metals, and Golder concludes that the data are reliable and suitable for its intended purpose. RPDs of 55 to 106% were noted in four of eight duplicate sample pairs for wet weight concentrations and in two of eight duplicate sample pairs for dry

weight with respect to vanadium. However, this variability does not impact the overall conclusion that vanadium bioaccumulation is limited, nor does it change the conclusion that vanadium risks to wildlife from consumption of dietary items was low. The tissue samples met the laboratory DQOs with respect to copper and vanadium (the parameters of interest for the food chain model).

6.20.6 Laboratory Analysis

Laboratory analyses were undertaken by a CALA-accredited laboratory.

6.20.7 Data Analysis and Reporting

The results of the reconnaissance survey (Golder 2019a) were submitted to ENV as an attachment to the 2018 Annual Report. The use of the soil chemistry data is further discussed in Section 17 (vis-à-vis the food chain model update).

6.21 Vegetation Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.21.1 Section Authors and Study Design Professionals

This section was written by MPMC, and is a summary of the study design concept provided by Golder. The detailed study design concept is provided in Appendix B.5. Note that Appendix B.5 is a study design concept; a study design will be submitted in Q1 2019 after completion of tasks outlined in Figure 2 in Appendix B.5.

6.21.2 Monitoring Objectives

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.5, the objectives of vegetation monitoring will be to:

- "Focus on establishing a long-term trend analysis of plant community rather than to support a multitude of pair-wise comparisons that would have limited value for making site management decisions"; and,
- "Refine site-specific relationships between copper concentrations in soil and copper concentrations in various plant tissues."

More detail is provided in Appendix B.5.

6.21.3 Monitoring Overview

In 2018, Task 2A of the study design concept was undertaken, specifically, a reconnaissance-level sampling program.

6.21.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Samples of the edible portions of plants (were collected following the same approach used in 2015 and 2016. The focus of plant sampling was on rehabilitated areas to increase sample density in these areas and to provide more information about plants growing in soils that have lower copper concentrations than the non-reclaimed areas. The following plant tissue samples were collected in 2018:

- Berry—Berry samples were collected from raspberry [*Rubus occidentalis]*, high bush cranberry [*Viburnum trilobum*], and thimbleberry [*Rubus parviflorus*]) plants that were rooted in soil.
- Leaf—Willow (*Salix* sp.) and alder (*Alnus crispa*) leaf samples were collected from shrubs planted in the impacted area. Only shrubs planted in the floodplain before spring 2016 were sampled. Plants sampled included willow planted in lower Hazeltine Channel in early 2015, above the canyon in late 2015, and in upper Hazeltine Channel late 2015 (near Gavin Lake Bridge).
- Grass— Slender wheatgrass *(Elymus trachycaulus*) samples were collected from a variety of areas. The objective of the sampling was to reduce the uncertainty in the existing soil-to-grass bioaccumulation relationship, and therefore, sampling was limited to a single species which was commonly found across the entire site. Only the edible, above-ground portion of grass was collected.

Sampling methods were consistent with the *BC Field Sampling Manual* (MoE 2013) and consisted of the following steps:

- Plant tissue was hand-picked by field staff using nitrile gloves from an area of 25 m^2 or less. Plant tissue was composited from multiple plants within the area if sufficient volume could not be collected from one plant.
- Plant samples were rinsed using DI water and blotted dry with lint-free wipes before being transferred to clean Ziploc bags.
- Samples were placed in a cooler containing ice until they could be transferred to a freezer for storage prior to shipping to the laboratory for analysis.

The plant tissue samples were submitted for analysis of metals and moisture content, and the data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.

6.21.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Vegetation sampling was undertaken using methods consistent with those used for the HHRA and ERA. Five replicate plant samples were collected and laboratory QC consisted of duplicates, method blanks and certified reference materials. Data quality objectives were met for copper and vanadium (the parameters of interest for the food chain model) in vegetation samples for both field and laboratory QC samples.

6.21.6 Laboratory Analysis

Laboratory analyses were undertaken by a CALA-accredited laboratory.

6.21.7 Data Analysis and Reporting

The results of the reconnaissance survey (Golder 2019a) were submitted to ENV as an attachment to the 2018 Annual Report. The use of the soil chemistry data is further discussed in Section 17 (vis-à-vis the food chain model update).

6.22 Biosolids Monitoring

MPMC is in possession of an EMA permit (15968) for the use of biosolids. This permit requires that MPMC retain the services of a qualified professional to develop a monitoring plan for the biosolids application program. MPMC will submit this plan to ENV and EMPR prior to receiving any additional shipments of biosolids to the mine site.

7 CEMP UPDATES AND REVISIONS

When possible, MPMC will provide written notice of planned changes to the CEMP to the ENV Director a minimum of 30 days prior to implementation to allow for review and feedback on the revision. Proposed changes will be shared with First Nations and stakeholders, as per MPMC's Communication Plan (MPMC 2016d). Additionally, changes that occur but are unplanned, such as the collection of additional samples, will be discussed with the ENV Director as soon as possible after the sampling occurs. When changes are made to the monitoring, this amended plan (or relevant replacement pages) will be resubmitted to the Director.

Given the dynamic nature of environmental investigation, rehabilitation, and water management plan development at Mount Polley Mine, it is anticipated that the CEMP will evolve in alignment with site activities and findings, as described in Section 2.3, and will be updated as required. It is anticipated that larger CEMP revisions in response to these activities and findings will be made with consideration of maintaining continuity in spatial and temporal coverage to meet the global objectives of the CEMP, as described in Section 1.1.

As required by the Permit, following the three-year detailed monitoring program interpretive report to the Director, MPMC will submit a summary of proposed changes to the CEMP to the Director by April 30 of that year (one month following the interpretive report deadline). In order to incorporate recommended changes in a timely fashion, MPMC would appreciate feedback on the proposed changes from the ENV by May 31 of that year.

8 RECLAMATION AND REMEDIATION

Rehabilitation of the aquatic and terrestrial receiving environments that were impacted by the TSF embankment breach and associated remediation activities is continuing as outlined in the Rehabilitation Strategy (November 2015 update; MPMC 2015f), as required by the PAO 107461. Under this broader Rehabilitation Strategy:

- Terrestrial rehabilitation works are being conducted as per the *Planning Concepts for Rehabilitation of Terrestrial Ecosystems at Mount Polley* technical memorandum prepared by Golder (2015e). The reclamation and monitoring steps described in this memorandum are based on the TSF embankment breach environmental impact assessment results to date.
- Rehabilitation of aquatic systems is being conducted under guidance of the Habitat Remediation Working Group, which includes representatives of DFO, ENV, the BC Ministry of Forest, Lands and Natural Resource Operations, the SCIB, and the WLIB. This group provides recommendations and feedback on aquatic ecosystem rehabilitation plans developed by MPMC's consultants.

Monitoring associated with the Hazeltine Creek channel rehabilitation construction activity is undertaken under the *Post-Breach Rehabilitation Work Environmental Management Plan* (Golder 2015f), which pertains to monitoring of any construction works and associated construction specifications. While the lower reaches of Hazeltine Creek remain non-fish bearing (with the exception of the lower sedimentation pond), the *MPMC Fish Exclusion and Response Plan* (MPMC 2015f) is in effect. MPMC will conduct monthly visual inspections for fish in the non-fish bearing areas of the creek when the creek is free of snow and ice (in case any fish have evaded the barriers), as well as weekly inspections of fish exclusion structures. The plan outlines response actions in the event that fish are observed.

As Hazeltine Creek is rehabilitated and returned to fish-bearing status, this environmental management plan will be phased out and be replaced by routine monitoring for evaluating performance of the works as a component of the CEMP.

The Habitat Remediation Working Group made up of provincial and federal regulators, qualified professionals and First Nations representatives, agreed upon a monitoring plan for the return of rainbow trout in Hazeltine Creek in 2018. This plan includes week fish surveys, detailed habitat usage surveys, benthic, sediment, water (quality and quantity), and fish tissue sampling. Reporting on these results will be included in the AERR.

The steps in the aforementioned terrestrial rehabilitation plan include establishment of permanent monitoring plots for ongoing assessment, feedback (to inform adaptive management) and demonstration. As terrestrial rehabilitation works progress, monitoring to this end will be implemented.

A Conceptual Remediation Plan (CRP) was submitted to ENV on January 31, 2018 (Golder 2018) and following receipt of comments on the CRP, a Remediation Plan submitted on March 29, 2019 (Golder 2019d). The Remediation Plan identifies remedial options for the sites impacted by the TSF breach, including creek habitats, lake habitats, and terrestrial habitats, as well as proposed monitoring components to verify the success of the planned remediation. The Remediation Plan was approved by ENV on July 3, 2019.

9 REPORTING

9.1 MONTHLY REPORTING

As required by Section 3.9 in the Permit (April 7, 2017) a monthly report will be submitted to the Director in each month that discharge occurs. The report will summarize the volume of treated effluent discharged, a summary of continuous turbidity readings of the treated effluent discharged, and the most recently available water quality results for the effluent discharged, including a summary of acute and/or chronic toxicity testing results.

9.2 QUARTERLY REPORTING

All data and information collected under the CEMP will be provided to the Director, in electronic format, on a quarterly basis or as required by the Permit.

Under the most recent version of PAO 107461 (June 9, 2017) Section 6.0, a quarterly report detailing the implementation status of requirements of the order, a summary of communications with stakeholders and public relating to the breach, and any remediation activities undertaken in Hazeltine Creek, Polley Lake and Quesnel Lake for the previous and upcoming three months must be submitted to the director.

9.3 ANNUAL REPORTING

As required by the Permit Section 3.9, MPMC will continue to submit an AERR on or before March 31 of each year. This report is combined with the Annual Reclamation Report prepared for the EMPR, with the combined document submitted to both agencies. These reports will include the details required by the permit, as well as an analysis of the linkages between program components, where appropriate. MPMC will refer to *Technical Guidance 4, Environmental Monitoring under the Environmental Management Act* such that the ENV's expectations for reporting are achieved.

The AERR will continue to be in a format suitable for public release and will be deposited at the Cariboo Regional District Library as well as submitted to the SCIB and WLIB within 30 days of being submitted to the ENV.

As required by the Permit (April 7, 2017) Section 2.5, MPMC will continue to submit an annual Environmental Emergency Response Plan and will include updated procedures and notification protocols. MPMC will also continue to submit an Annual Discharge Plan on or before April 15 of each year and include the details required by the Permit Section 2.7.

9.4 THREE-YEAR REPORTS

Under the Permit, a detailed monitoring program interpretive report is required every three years with the first report due on March 31, 2019 and every three years thereafter. The March 2019 interpretive report will include data collected in 2016, 2017, and 2018. This report will be completed by one or more qualified professionals and will be more comprehensive than the synoptic review of data presented in the annual reports. It will include recommendations for changes to the CEMP.

In addition, a groundwater monitoring program review including, but not limited to, sampling, well locations, site water balance, interpretation of data trends, and suitable recommendations is required every three years, with the first presented in March 2016. The next report will be submitted on March 31, 2019. Monitoring data and the analysis of those data presented in the report will be reviewed by a third party qualified professional.

10 FUTURE OUTLOOK

This CEMP represents a unique and specialized variation of a typical mine environmental monitoring plan. This plan seeks to integrate all environmental monitoring programs that are carried out on the Mount Polley mine site and in the local area related to:

(a) Ongoing mine operations (including EMA and *Mines Acts* permit requirements and MDMER requirements of the *Fisheries Act*);
(b) TSF embankment breach-related impacts and remediation; and,
(c) Reclamation and closure planning (*Mines Act* permit requirement).

The overall goals of this CEMP are to provide science-based evidence: for evaluation of environmental impacts of mine operations; for evaluation of the effects of any ongoing impacts of, and remediation measures undertaken in response to, the TSF embankment breach; and to inform ongoing reclamation and closure planning. These goals are guided by an intent to return the impacted areas of the mine site and its surroundings to viable and diverse ecosystems that reflect pre-breach land uses, or those identified by Communities of Interest as representing values of importance. These values of importance are identified through ongoing consultation with local Communities of Interest.

Mount Polley fosters a culture of research and innovation. In addition to the extensive monitoring and research work that was undertaken as part of the impact and risk assessments of the TSF embankment breach, there are a number of research projects underway (and several recently completed) that the mine has supported. The results of these projects may contribute directly to improving the mine's understanding of breach impacts (Cuervo et al, 2017; Garris et al, 2018; Byrne et al, 2018), new approaches to remediation, reclamation and closure (McMahen, PhD in progress, UBC; Litke MASc in progress, UBC), and to mitigating environmental impacts of ongoing operations.

With respect to mitigating environmental impacts of ongoing operations and planning for reclamation and closure, Mount Polley is embarking on passive water treatment research and pilot projects to test the suitability of constructed wetland water treatment systems for dispersed water treatment and discharge on the mine site. These research projects will include lab and site testing, monitoring of water quality, vegetation, and microbial communities, and will be reported annually in the AERR or in a technical memo.

As the results of monitoring programs and environmental research projects are generated, analyzed, and interpreted, this CEMP will be reviewed and updated where warranted. MPMC will aim to review the requirements of the CEMP on a quarterly basis and will submit a list of proposed changes based on the review to the Director within 45 days from the end of the quarter.

Terms of Reference

Comprehensive Environmental Monitoring Plan – 4 July 2017

1 BACKGROUND AND CONTEXT

Mount Polley Mining Corporation (MPMC) is the owner and operator of the Mount Polley Mine, a property comprising, among other things, a copper-gold mine and mill complex located near Likely, British Columbia (BC).

MPMC is authorized by the BC Ministry of Environment (MoE) to discharge effluent to the land and to surface water from the Mount Polley Mine, subject to the terms and conditions of *Environmental Management Act* (*EMA*) Permit 11678. *EMA* Permit 11678 was originally issued to MPMC by the MoE on 30 May 1997, and has been the subject of numerous amendments since.

As is typical of owners of mines in BC, MPMC undertakes extensive environmental monitoring for a variety of purposes and objectives. In many instances, data collected as part of one monitoring program are beneficial to other programs, even though programs may have been established specifically for unique purposes.

Under Section 3.2 of *EMA* Permit 11678, MPMC is required to implement a Comprehensive Environmental Monitoring Plan (CEMP). In previous versions of *EMA* Permit 11678, MPMC was required to implement a number of individually defined monitoring plans for various aspects of Mount Polley Mine operations to which this MoE authorization was subject. As stated in Section 3.2 of *EMA* Permit 11678, the CEMP is intended to consolidate and integrate all such pre-existing monitoring programs.

2 OBJECTIVES AND DRIVERS

As described in Section 3.2 of *EMA* Permit 11678, the objective of the CEMP is to evaluate the effects of mining-related activities on the physical, chemical and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas.

Environmental monitoring has the broad objective of verifying that environmental controls are in place that protect the environment and are sufficient to confirm compliance with applicable statutory requirements to which operations are subject. Environmental monitoring also has the broad objective of providing data to support evidence-based communication to parties who might be affected by the Mount Polley Mine.

For the Mount Polley Mine, the main drivers (which govern the objectives) are:

- Regulatory Drivers;
    - Federal (e.g., *Metal Mining Effluent Regulation* [MMER])
    - Provincial (e.g., *EMA, Mines Act*)
- MPMC Commitments:
    - The respective Participation Agreements (PAs) that MPMC have in place with the Soda Creek Indian Band (SCIB; Xatśūll First Nation) and the Williams Lake Indian Band (WLIB).

Subject to the requirements of the various drivers, the CEMP is intended to be an adaptive plan. This means that the CEMP is anticipated to change over time, as it is informed by findings obtained from preceding stages of work.

3 SCOPE AND CONTENT

The scope of the CEMP will be built around the Objectives and Drivers, will provide an appropriate level of scientific robustness, and will utilize provincially and federally acknowledged methodology. It is noted that failing to utilize methods common to the various objectives undermines the value of a comprehensive monitoring program. The scope of the CEMP will not include studies of general research (e.g., academic), nor will it include collection of regional data that are not directly linked to the Objectives and Drivers.

As per Section 3.2 of *EMA* Permit 11678, the scope of the CEMP must be such that it consolidates and integrates monitoring programs that are being conducted in the vicinity of the Mount Polley Mine site. At minimum, the CEMP must consider programs addressing surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.

As described in Section 3.2 of *EMA* Permit 11678, the CEMP must address, at minimum, a three-year time span, as well as, at minimum, include all sampling sites, frequency of sampling, variables to be analyzed, method detection limits, sampling methods, sample analysis methods, and data analysis methods.

As noted in the Background and Context of this Terms of Reference, environmental monitoring is a tool used by mining companies (and others) to inform them (and other parties), of the adequacy of their source control efforts. The content of the CEMP will be reflective of its use as such a monitoring tool. The CEMP will serve as the document that provides the context and linkages demonstrating how the monitoring program developed provides an appropriate mechanism by which to meet the Objectives and Drivers of the CEMP. In providing this purpose, the CEMP's content is anticipated to provide: a statement of its objectives; an overview of its subject (the Mount Polley Mine); a discussion of the various components that comprise environmental management in the context of the Mount Polley Mine; presentation of monitoring procedures and considerations (e.g., previous data) specific to each environmental monitoring component; and, an outline for control of the CEMP (e.g., updating and revising) and its reporting outputs.

A comprehensive monitoring plan requires a response framework as the monitoring program is the linkage between monitoring plan design, implementation, and effective use. The level and urgency

of response will have due regard to the level of potential risk to the environment (which includes people). The CEMP response framework will be updated in parallel with the CEMP, or as otherwise appropriate.

4 DEPENDENCIES AND ASSUMPTIONS

The CEMP is intended to support an interdependent program. The dependencies across the monitoring programs will be evaluated with the benefit of a conceptual site model (CSM). The CSM will aid in understanding and addressing the dependencies by allowing a visual representation of release and transport mechanisms (e.g., sources and water flow) and exposure by environmental receptors. The CEMP is predicated on the understanding that people (i.e., humans) are part of the environment. The CEMP response framework will have due regard to linkages and dependencies, and the CSM.

The CSM will be reviewed for dependencies in the context of:

- The Objectives and Drivers and Scope for the CEMP, as described in this Terms of Reference.
- The basal understanding of sources, pathways, contaminants of potential concern (COPC), and receptors.
- An analysis of the linkages between program components, in a tabular format.
    - Linkages will include a rationalization of methods used across program components to make the methodology as consistent as possible.
- Current and planned activities at the Mount Polley Mine site, especially how those activities might impact on the CSM.

The following assumptions guide the continued development and implementation of the CEMP required under Section 3.2 of *EMA* Permit 11678:

- The CEMP is developed, reviewed and revised by Qualified Professionals (QPs), QPs being as defined by the Province of BC (e.g., R.P.Bio.).
    - MPMC notes that there are certain aspects of CEMP scoping (particularly in defining the objectives and drivers), where a QP is not necessary. For example, the reasonable study questions from members of the public are outside of the domain of expertise for a QP who would develop a CEMP; however, the scientific approach by which those questions would be answered are within the QP's domain of expertise.
- The CEMP will be based on information that is available, verifiable and can be relied upon by a QP.
- With the exception of regulatory requirements, a pattern of decrease or stasis in environmental condition is a suitable basis for gradual decrease in monitoring locations, frequencies, or parameters.

5 REVISION

The Mount Polley Mine is an operating site, changes to which are anticipated to transpire as development and closure activities co-occur; thus, an adaptive approach is both necessary and appropriate for documents such as the CEMP. Review of the CEMP content is an integral aspect of its effectiveness. In this application, 'effectiveness' means that the CEMP delivers on the regulatory drivers, some of which have rigid statutory obligations (e.g., MMER), satisfies the Objectives and Drivers for the CEMP, and undertakes that work with due regard to financial impact (without limiting the ability to meet the Objectives and Drivers established) and the adaptive nature of the CEMP.

To fulfill the adaptive approach, the CEMP will be reviewed and revised considering data collected in previous years (as interpreted by QPs). Such data will include that collected and interpreted directly under the CEMP, or as may be available from other assessments, studies or reports commissioned by MPMC as relating to the Objectives and Drivers for the CEMP. In the case of the latter, the CEMP will be modified, as appropriate, in consideration of the results and recommendations of such assessments, studies or reports. Based on collected data (and subsequent interpretation by QPs), the CEMP will include rationale for existing monitoring as well as any changes to the monitoring plan. It is anticipated that larger CEMP revisions in response to these activities will be made with consideration of maintaining continuity in spatial and temporal coverage to meet the Objectives and Drivers of the CEMP.

When possible, MPMC will provide written notice of planned changes to the CEMP to the MoE Director a minimum of 30 days prior to implementation to allow for review and feedback on the revision. Such written notice shall describe the planned changes as well as the rationale for the changes, including a summary of relevant data considered.

Under Section 3.2 of *EMA* Permit 11678, MPMC must submit a three-year detailed monitoring program interpretive report and updated CEMP to the MoE Director, for approval, by 31 March 2019, and every three years thereafter. Following the three-year detailed monitoring program interpretive report to the Director, MPMC will submit a summary of proposed changes to the CEMP to the MoE Director by April 30 of that year (one month following the interpretive report deadline).

A key component of the CEMP will be the monitoring program itself. The monitoring program will be designed, reviewed and revised by QPs such that, in their professional opinion, it satisfies the Objectives of the Drivers for the CEMP and allows MPMC to be informed of the adequacy of their source control efforts. Changes to the monitoring program that occur but are unplanned, such as the collection of additional samples, will be formally submitted with the MoE Director as soon as possible after the sampling occurs. Such written notice shall describe the planned changes as well as the rationale for the changes.

Notification of any CEMP or CEMP monitoring program changes must be provided to the MoE Director in writing for approval.

Notwithstanding the above, as per Section 3.2 of *EMA* Permit 11678, the MoE Director may require revisions to the CEMP or monitoring program based on review of monitoring data and/or any other relevant information.

6 CONSTRAINTS AND PROJECT RISKS

In the context of the CEMP and the content of this Terms of Reference, the following constraints and project risks have been identified by MPMC:

- The Mount Polley Mine, and by it, MPMC as owner and operator of the mine, is constrained to comply with applicable laws and statutory requirements.
- The health and safety of persons engaged in the monitoring work is a paramount consideration. Samples that cannot be obtained safely, using practical methods, will not be obtained. Certain seasonal conditions may preclude safe sampling.
- MPMC has voluntarily entered into (respective) PAs with the SCIB and the WLIB. MPMC will honour the respective PAs in full, and expects the SCIB and WLIB to reciprocate. Certain aspects of the CEMP pertain to subjects that fall within the bounds of the PAs.

7 ROLES AND RESPONSIBILITIES

In the context of the CEMP and the content of this Terms of Reference, the following roles and responsibilities are established:

- The MPMC Environmental Superintendent (or designate) will be responsible for implementing the CEMP, and revising it as appropriate.
    - Deliverables will be prepared by, or under the direct supervision of, QPs.
- Monitoring that is part of the CEMP will be coordinated by MPMC.
- All parties' reviewers of technical elements of the CEMP are required to be QPs if they are providing recommendations on the content or implementation of its subject matter.
- Participants involved in the design and review of the CEMP acknowledge that study designs, monitoring methods, and interpretation will be carried out in accordance with federal and provincial laws, policy and guidance.

Appendix B

Detailed Study Designs for CEMP Components

Appendix B - Addendum

Subsequent to the Issuance of the August 2018 CEMP, the following changes were made to study programs described in Appendix B:

Study	Change
Appendix B.1: Diffusive Gradient in Thin Film (DGT) sampling and toxicity testing with *Hyalella azteca*.	Sampling was conducted in 2019 and laboratory results are pending. When received, the data will be reviewed and recommendations for additional sampling, if any, will be presented to ENV in 2020.
Appendix B.2: Replication of tissue samples at Edney Creek location E1	Eight replicates of periphyton and benthic invertebrate tissues for chemistry were collected from E1 in 2019. The results are pending from the analytical laboratory.
Appendix B.4: Monitoring frequency	Monitoring frequencies applicable from 2018 to 2019, will be reviewed following data interpretation and modifications may be made in response to QP recommendations, subject to approval by the Director.
Appendix B.4: Spawning surveys	Visual spawning surveys (counts of adults and redds) were conducted in Upper Hazeltine Creek (2018) and lower Hazeltine/Edney Creek (2018 and 2019) per a monitoring plan developed in conjunction with the Habitat Remediation Working Group.

1 INTRODUCTION

1.1 Background

Sediment is an important sink and potential source of metals, metalloids, and nutrients[1] in aquatic environments (e.g., Horowitz 1991; Ingersoll et al. 1997; Simpson and Batley 2016). Sediment quality of receiving environments adjacent to mine sites can be influenced by the direct input of solids as well as by the introduction of dissolved constituents (e.g., metals) into water that subsequently associate with reactive materials on sediment surfaces (e.g., oxides, organic carbon) by surface complexation (Santschi et al. 1990; Stumm and Morgan 1996; Sposito 2004). Sediment also represents a pathway for the exposure of aquatic life to metals and other substances (e.g., nutrients, organic substances). Therefore, sediment quality is an important component of the CEMP.

The influence of the Mount Polley Mine on sediment quality can occur (or, at some locations, has occurred) by several key mechanisms: 1) general mine influence from physical impingement, dustfall, and/or uncontained surface or groundwater flows: 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to December 2017, and directly since January 2018]); 3) the TSF embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Sediment quality in waterbodies adjacent to the Mount Polley Mine has been monitored since baseline investigations in 1989, 1995, and 1996 (Imperial Metals 1990; HKP 1996, 1997). Results of sediment quality monitoring are reviewed in Section 2 and provide context for a CEMP sediment quality monitoring program that is guided by a combination of historical findings, representative locations downstream of Mount Polley Mine operations, representative reference locations, and considerations for a statistically-based design that will facilitate the detection of spatial and temporal differences in addition to providing data to evaluate concentrations relative to effects-based guidelines (e.g., British Columbia Working Sediment Quality Guidelines [BCWSQG]; BCMOE 2017). In addition to sediment quality monitoring required as part of the Mount Polley CEMP, sediment quality monitoring is required to support benthic invertebrate community monitoring conducted as part of Environmental Effect Monitoring (EEM) under the Metal Mining Effluent Regulations (MDMER) of the federal *Fisheries Act*.

The following sections of the CEMP Sediment Quality Monitoring Plan provide the objectives of sediment quality monitoring, a summary of historical sediment quality findings, an overview of the CEMP study design and associated rationale (including sampling locations, replication,

[1] Through the remainder of this section, the term “metals” will be used to include metals, metalloids, and nutrients for ease of communication

frequency, and analytes), and detailed methodology for sediment quality monitoring (quality assurance/quality control [QA/QC], sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting).

1.2 Monitoring Objective

The objective of sediment quality monitoring is to evaluate the influence of Mount Polley Mine activities on receiving environments (Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions, and to determine potential implications to aquatic life by applying a variety of interpretive tools (e.g., Working Sediment Quality Guidelines [BCMOE 2017], biological assessment). Sediment quality monitoring also provides supporting information for benthic invertebrate community monitoring, and to support exposure assessment as part of ecological risk assessment (ERA) and human health risk assessment (HHRA). An additional objective is to advance the technical understanding of the stability or mobility and the potential bioavailability of metals in lake sediments affected by the TSF embankment breach.

2 SUMMARY OF HISTORICAL FINDINGS

Sediment has been monitored in the vicinity of the Mount Polley Mine since 1989, with most of the sediment quality samples collected in Polley Lake, Bootjack Lake, Hazeltine Creek, and Edney Creek (Table 1). Hazeltine Creek and Edney Creek are primarily comprised of erosional habitat, with few locations of sediment deposition. This has made sediment sampling challenging relative to lake environments, and some unconventional methodologies were applied in baseline studies.

Sediment quality sampling in the vicinity of the Mount Polley Mine has spanned four distinct time periods:

1. Baseline monitoring (1989, 1995, 1996);
2. Pre-breach operational monitoring (1999, 2009, 2012);
3. Post-breach operational monitoring (2014, 2015); and
4. Post-breach and post-discharge monitoring (2016).

Data collected prior to the breach were summarized in an Aquatic Environmental Description Report prepared concurrent with an application for water discharge to Polley Lake in 2014 (Minnow 2014), and general findings of the historical sampling, as well as sediment monitoring data collected from 2014 to present, are provided, by sampling area to support the design of the sediment quality monitoring plan.

2.1 Polley Lake

Baseline sediment quality of Polley Lake was characterized by concentrations of a number of metals that were naturally elevated above sediment quality guidelines, including arsenic, chromium, copper, iron, manganese, nickel, and selenium (Minnow 2014). Concentrations of copper, iron, and manganese were particularly elevated, with concentrations naturally exceeding upper sediment quality guidelines (also known as probable effect levels) in some samples (HKP 1996, 1997).

Sediment quality monitoring in Polley Lake during operations but before the TSF embankment breach in 2014 indicated that concentrations of most of the elevated analytes remained similar to baseline. One apparent exception was selenium, which increased from 1.7 – 2.6 mg/kg dry weight (dw) in baseline to 2.5 – 3.7 mg/kg dw in 2009, and 5.0 to 6.9 mg/kg dw in 2012 (Minnow 2014). This increase was considered to be due to uncontrolled surface runoff from a north waste rock dump which reported to Polley Lake via North Dump Creek. This runoff contained elevated concentrations of selenium from 2006 until control in 2009 with the construction of the Long Ditch.

Table 1: History of Sediment Quality Monitoring in Waterbodies in the Vicinity of the Mount Polley Mine

A) Lakes

2015	Sedimentation Pond	Minnow 2015b
2016	Sedimentation Pond	Minnow 2016

Following the TSF embankment breach, sediment quality monitoring in Polley Lake indicated that concentrations of arsenic, copper, and iron were elevated at one or more monitoring locations relative to guidelines and baseline concentrations (Minnow 2015a). Changes in sediment quality were greatest for copper, with concentrations increasing from a baseline range of 262 – 370 mg/kg dw to 630 – 722 mg/kg dw in September 2014 (Minnow 2015a). Due to very low organic content of the breach-derived materials, sediment organic carbon content was also lower following the breach (Minnow 2015a). Sediment quality monitoring completed in 2015 and 2016 indicated very similar sediment quality from 2014 to 2016 (Minnow 2015b; 2016a; Figures 1 and 2). Evaluation of sediment deposition rates have indicated relatively low rates of sediment deposition in Polley Lake (average 0.66 mm/yr; 15 years for the accumulation of 1 cm of sediment; Minnow 2018). Sediment toxicity testing completed in 2014 and in 2016 indicated no effects to survival or growth of *Chironomus dilutus* and *Hyalella azteca* in standard tests completed on sediments from the Polley Lake basins (the deepest locations of the lake, known as P1 and P2), but a moderate reduction in growth of *H. azteca* at mid-depth areas (Minnow 2015a; Minnow 2017a). The benthic invertebrate community of the two deep basins in Polley Lake showed consistent recovery from 2014 to 2016 to a condition similar to the reference area in terms of density and richness in 2016 (Minnow 2017b). Lastly, a variety of sediment quality investigations conducted to characterize the potential mobility and bioavailability of sediment-associated metals (humidity cell tests, shake flask tests, selective extractions, ratios of simultaneously extracted metals to acid volatile sulphides [SEM/AVS], porewater chemistry, and Diffusive Gradients in Thin Films [DGT] devices) have all supported low mobility and bioavailability of sediment-associated metals (e.g., SRK 2015a,b; Minnow 2015a, 2016c, 2016d, 2017c, 2017d)

2.2 Hazeltine Creek

Baseline sediment quality of Hazeltine Creek was characterized in 1995 and 1996 (HKP 1996, 1997), but the latter included suspected errors (i.e., sampling in 1996 yielded unusually high concentrations of some metals [e.g., up to 2.2% copper] that were not observed in 1995 and have not been observed since). Based on the sampling conducted in 1995 (HKP 1996) and consistency with sampling conducted in 1999 (Beak 2000), concentrations of arsenic, copper, iron, and manganese (although reported as much lower than in 1996) were naturally elevated above lower sediment quality guidelines (Minnow 2014).

Sediment quality monitoring in Hazeltine Creek during operations but before the TSF embankment breach in 2014 indicated that concentrations of most of the elevated analytes remained similar to baseline. One possible exception was selenium, which, despite some uncertainty associated with different sampling methods and locations, had concentrations that were slightly greater than the sediment quality guideline of 2 mg/kg dw (i.e., up to 3.14 mg/kg dw

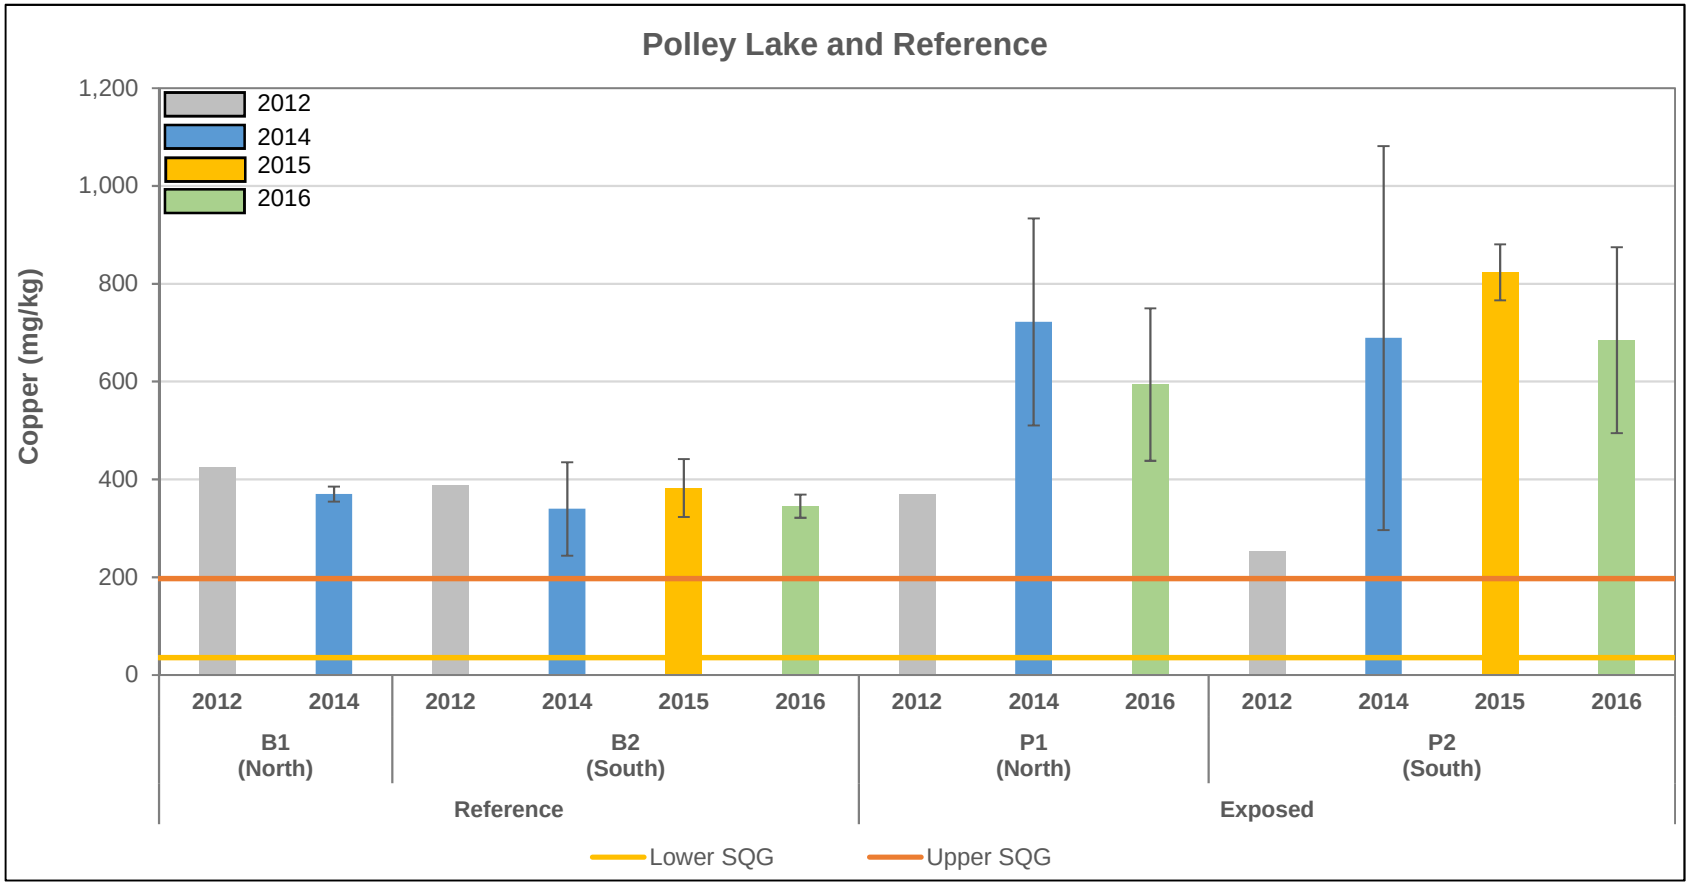

Figure 1: Concentrations of Copper in Polley Lake and Reference Sediment, 2012 to 2016

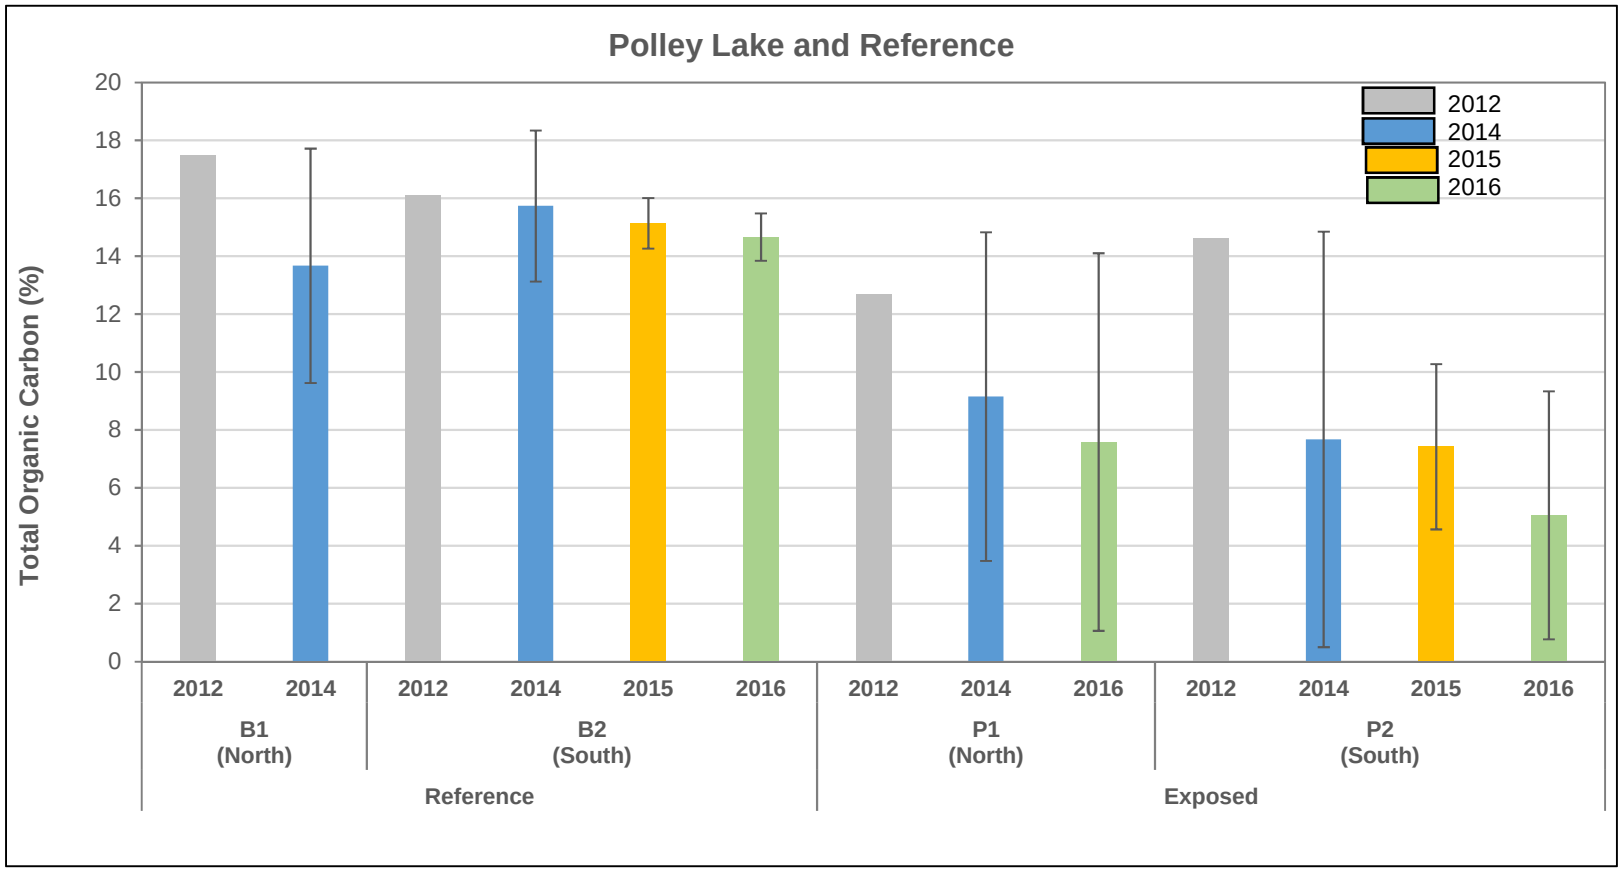

Figure 2: Concentrations of Total Organic Carbon in Polley Lake and Reference Sediment, 2012 to 2016

in a beaver pond in the fall of 2013; Minnow 2014). It is uncertain whether this difference was associated with the uncontrolled surface runoff that occurred from 2006 to 2009 (as described in Section 2.1) or if it was associated with the exclusive availability of fine sediment (that would naturally be expected to have higher metal concentrations) at a beaver pond sampled in 2013.

Following the TSF embankment breach, sediment quality monitoring was conducted in Hazeltine Creek in 2014. This sampling was prior to substantial rehabilitation from 2015 to 2017 and represented breach-material, believed to be mostly tailings. Accordingly, these "sediments" had very low organic carbon content, concentrations of copper and iron greater than upper sediment quality guidelines, and concentrations of arsenic and nickel greater than lower sediment quality guidelines (Minnow 2015a). Sediment quality monitoring of the Hazeltine Creek upper sedimentation pond completed in 2015 and 2016 indicated that concentrations of arsenic and nickel occurred at concentrations greater than reference and lower sediment quality guidelines, and concentrations of copper and iron occurred at concentrations greater than reference and upper sediment quality guidelines (Minnow 2015b; 2016).

2.3 Quesnel Lake

Sediment quality data for Quesnel Lake collected prior to the TSF embankment breach are limited to a few samples collected in the north arm near the mouth of the Mitchell River in 2012. These data documented a mean selenium concentration of 0.37 mg/kg dw (Minnow 2015a).

Following the TSF embankment breach, sediment quality monitoring in Quesnel Lake was completed at impacted areas and reference areas. A total of 121 sediment samples were collected from deep habitat of Quesnel Lake and 60 sediment samples were collected from shallow habitat of Quesnel Lake between 2014 and 2016 to characterize sediment quality (Minnow 2015a, 2015b, 2016). These sediment quality investigations indicated that the majority of breach-derived material was deposited to deep habitat. As with other habitats (i.e., Polley Lake and Hazeltine Creek), the chemical influence of the breach was most evident in copper concentrations greater than reference and upper sediment quality guidelines in impacted areas. Arsenic, iron, and manganese were elevated to concentrations greater than lower sediment quality guidelines, but concentrations of these metals were not elevated relative to reference or far-field concentrations. The influence of the breach was also evident in very low organic carbon content in impacted areas relative to reference. Sediment quality monitoring completed in 2015 and 2016 indicated very similar sediment quality from 2014 to 2016 (Figures 3 and 4; Minnow 2015b; 2016b), although the repositioning of two stations in area PNF in 2016 resulted in higher mean concentrations and lower variability. Some sediment consolidation (i.e., compaction) appears to be occurring in Quesnel Lake. Temporal change is expected to be primarily associated with deposition (i.e., covering of impacted sediment with non-impacted

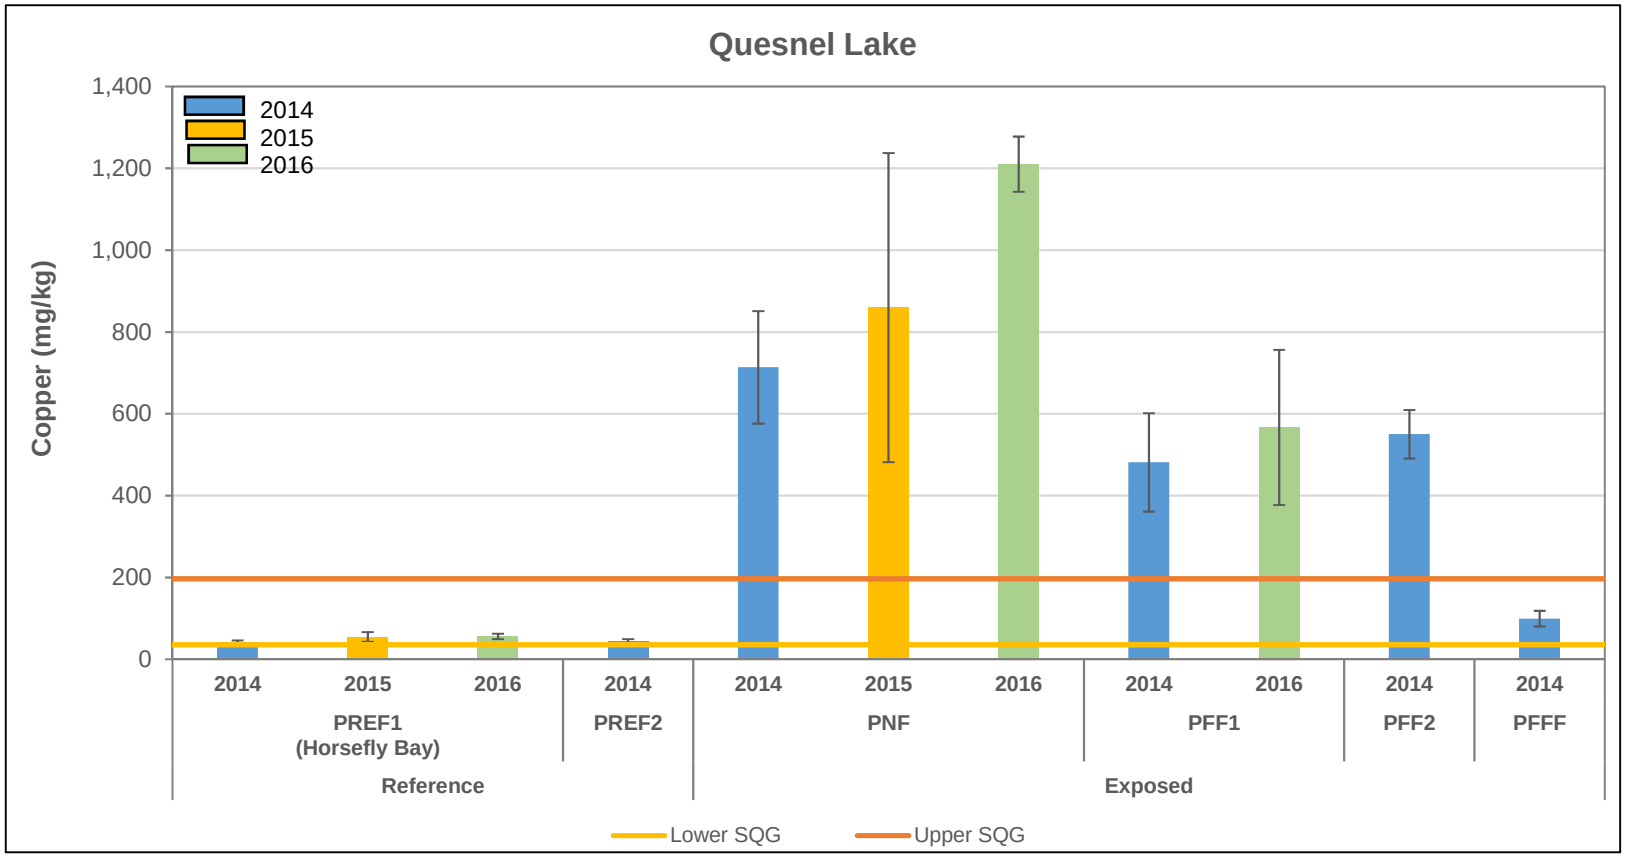

Figure 3: Concentrations of Copper in Quesnel Lake Sediment, 2014 to 2016

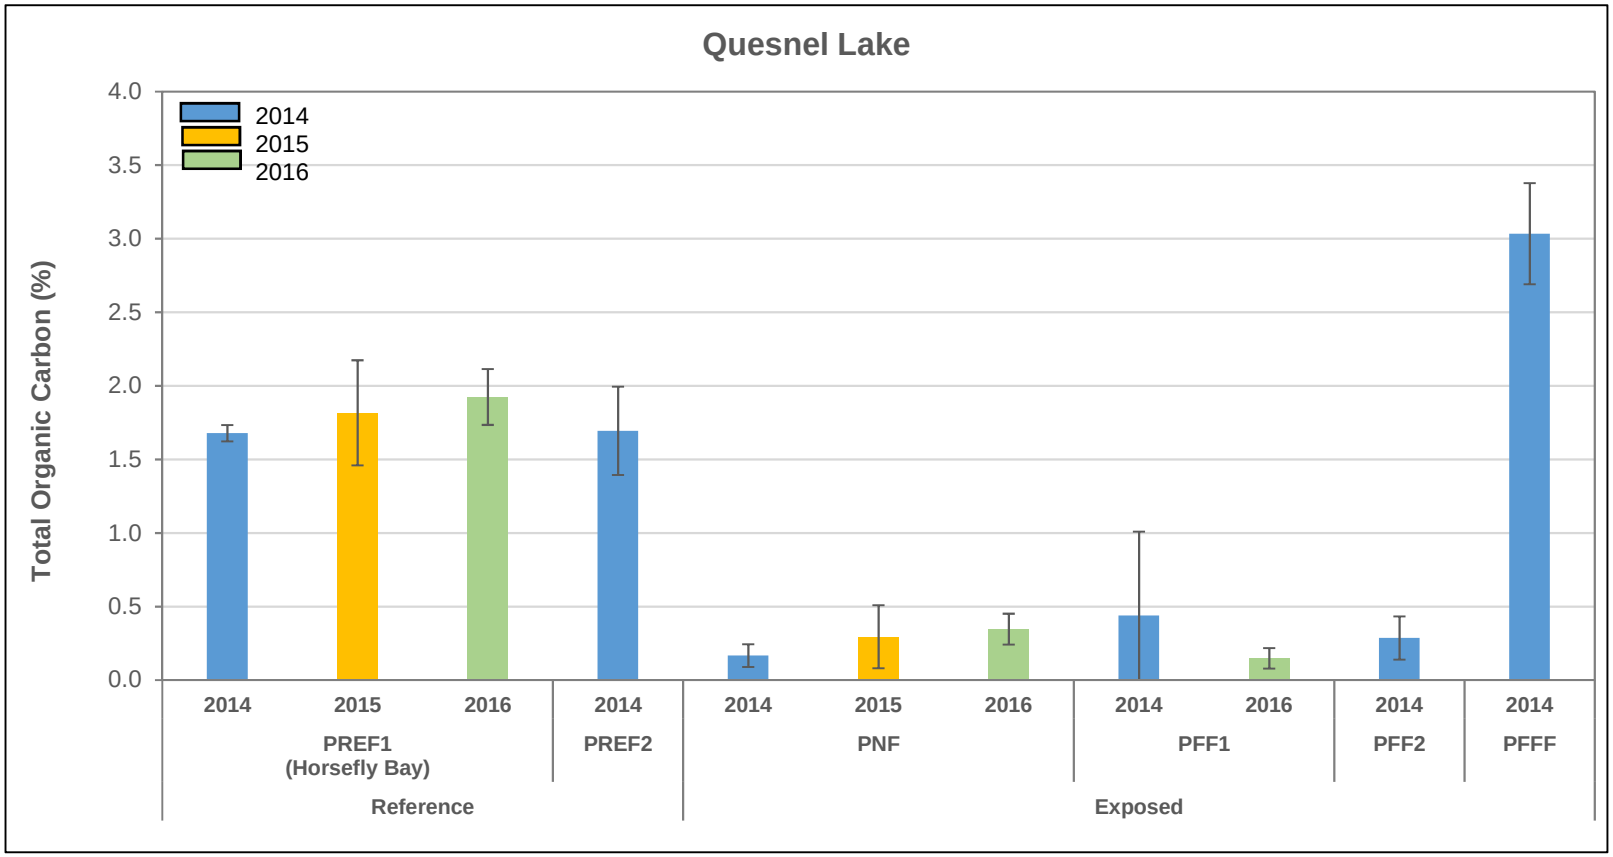

Figure 4: Concentrations of Total Organic Carbon in Quesnel Lake Sediment, 2014 to 2016

sediment), and evaluation of sediment deposition rates have indicated relatively low rates of sediment deposition in Quesnel Lake (range 1.4 to 1.7 mm/yr; 6 to 7 years for the accumulation of 1 cm of sediment; Minnow 2018).

Sediment toxicity testing completed in 2014, 2015, and 2016 indicated no responses to *C. dilutus* survival, but clear reductions in growth (Minnow 2017a). Clear responses to *H. azteca* survival and growth were observed, but *H. azteca* has low site-relevance as it is not present in deep areas of local lakes. Evaluation of relationships between observed responses and sediment quality indicated that combinations of high copper concentrations and low sediment organic carbon content were the best determinants of the observed responses (Minnow 2017a). Despite the observed responses in sediment toxicity tests, benthic invertebrate community monitoring, which is considered to be a measure of greater ecological relevance than toxicity testing (due to the fact that it evaluates in-situ habitat use by site organisms), indicated consistent recovery of organism density and taxon richness from 2014 through 2016. Although these endpoints remain lower than reference and the exposed area communities are not identical to reference, the observed increases are indicative of continued recolonization of these impacted areas. Lastly, a variety of sediment quality investigations conducted to characterize the potential mobility and bioavailability of sediment associated metals (humidity cell tests, shake flask tests, selective extractions, ratios of simultaneously extracted metals to acid volatile sulphides [SEM/AVS], porewater chemistry, and DGT devices) have supported low mobility and bioavailability of sediment-associated metals (e.g., SRK 2015a,b; Minnow 2015a, 2016c, 2017c).

3 STUDY DESIGN OVERVIEW AND RATIONALE

Sediment quality monitoring under the CEMP is designed to meet the combined needs of: 1) operational monitoring (including the discharge of treated effluent to Quesnel Lake); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to reclamation activity following the TSF embankment breach. An overview of the proposed sediment quality monitoring program is provided in Table 2 and Figures 5 and 6. Sediment quality monitoring is focused on Polley Lake, Hazeltine Creek, and Quesnel Lake, with reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake [and Jacobie Lake in 2018] for Polley Lake, unaffected areas of Quesnel Lake for impacted areas of Quesnel Lake). In Polley Lake, sediment sampling will focus on the two basins (deepest locations in Polley Lake, representing locations of sediment accumulation/fate), with the deepest location in Bootjack Lake (and Jacobie Lake in 2018) serving as reference. In Quesnel Lake, sediment quality monitoring for MDMER EEM will focus on the area near the point of effluent discharge (per Minnow 2016b) with two reference areas serving as reference (one unaffected by the breach and one affected by the breach but outside of the influence of effluent discharge). Additional sediment sampling in Quesnel Lake will focus on the deep areas that were previously monitored as near-field areas, with concurrent sampling of suitable reference areas. Hazeltine Creek is an erosional creek, and sediment sampling will be opportunistic, focussed on the collection of fines deposited on the declining hydrograph. All sediment quality monitoring includes sediment physical condition and sediment chemistry at all proposed sampling locations, as well as supporting sediment toxicity testing at a subset of areas (Table 2). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) concentrations relative to sediment quality guidelines for the protection of aquatic life (BCMOE). Accordingly, five stations per area are proposed for each to provide replication for the statistical contrasts.

Sediment quality monitoring will include physical and chemical characterization of deposited sediments, including particle size distribution, organic matter content, nutrients, and metals (see Section 4.2 below for greater detail). In accordance with BCMOE (2016) and in consideration that lake samples analyzed at the <63 µm fraction and <2.0 mm fraction yielded similar results (Minnow 2015a), sediment organic matter content, nutrients, and metals will be determined in the <63 µm fraction (silt and clay). Sediment toxicity testing (at Polley Lake, Quesnel Lake deep habitat, and associated references) will focus on larvae of the non-biting midge *Chironomus dilutus*. This organism is an ideal test organism for these sediments due to the ubiquitous presence of Chironomidae in these areas (Minnow 2015a) and the in-benthic habit of these organisms (in contrast to the epi-benthic habitat of other test organisms such as the amphipod

Table 2: Mount Polley CEMP Sediment Quality Monitoring Program Overview

A) Lakes

Water Body	Sampling Area	Type	Components [1]	Replication [2]	Rationale
Polley Lake	POL - P1 (Northwest Basin)	Exposed	C, T	5	immediately adjacent to mine and breach-influenced
	POL - P2 (Southeast Basin)	Exposed	C, T, D	5	immediately adjacent to mine and breach-influenced

Hyalella; Wang et al. 2004). Lastly, DGT devices will be deployed above the sediment water interface in areas most impacted by the TSF embankment breach (Polley Lake and Quesnel Lake deep areas) to provide annual feedback on whether there has been any change in the concentrations and/or proportion of labile metals above the sediment water interface (which would be suggestive of the potential instability or the temporal stability of sediment-associated metals).

Sediment quality and toxicity sampling will be supported by measurements of temperature, dissolved oxygen, pH, and specific conductance near the sediment-water interface at all sampling stations. Additional information to be collected includes GPS coordinates of each station and supporting photographs of the sampling location and samples. Some additional monitoring of the stability and potential bioavailability of metals associated with sediments impacted by the TSF embankment breach will be undertaken (e.g., deployment of Diffusive Gradients in Thin Films [DGT] devices to monitoring labile metal concentrations), as recommended by a QP and approved by ENV.

Sediment sampling will be completed in August or September consistent with previous data collections (HKP 1996, 1997; Beak 2000; Minnow 2015a,b; 2016). The frequency of sediment quality monitoring at the federal EEM sampling areas (where sediment is collected to support a benthic invertebrate community survey to evaluate potential effects of effluent discharge) is initially at a prescribed frequency of every three years, subject to modification based on the findings of at least two EEM phases (Environment Canada 2012). The frequency of sediment sampling at the lake areas is also guided by the results of sediment quality monitoring undertaken from 2014 to 2017. Evaluation of sediment deposition rates have indicated relatively low rates of sediment deposition in Polley Lake (average 0.66 mm/yr; 15 years for the accumulation of 1 cm of sediment) and Quesnel Lake (range 1.4 to 1.7 mm/yr; 6 to 7 years for the accumulation of 1 cm of sediment; Minnow 2018). This is consistent with limited change in sediment quality of these lakes which were sampled annually from 2014 to 2016 (e.g., Figures 1 to 4; Minnow 2016). Therefore, sediment sampling in lakes will be completed in 2018 and then every three years concurrent with EEM (2018, 2021, etc.). It is anticipated that a three-year frequency will be sufficient to track recovery associated with the deposition of approximately 2.0 mm of new sediment in Polley Lake and approximately 4.7 cm of new sediment in Quesnel Lake over the three-year period. As sediment samples are composed of the top 3 cm (30 mm) of deposited sediment (to represent exposure to benthic organisms and consistent with technical guidance; BCMOE 2016), this is equivalent to approximately 6.6% and 16% of the sample volume being comprised of new material. Water quality above the sediment water interface will be monitored in 2018-2020, including the deployment of Diffusive Gradients in Thin Films (DGTs). If monitoring of labile metal concentrations using DGT devices indicate increases above the sediment-water

interface, design modification (e.g., changes to monitoring frequency or locations) will be made in response to QP recommendations in future interpretive reports.

The initial frequency of sediment quality monitoring at the creek areas (Hazeltine and Edney Creeks) is annual. This is because post-breach / post-rehabilitation conditions have not been established. Frequency should be reviewed following interpretation of the data collected in 2020, with particular consideration of whether sediment, which is quantitatively rare in these erosional creeks, provides value as an independent monitor given the intensive monitoring of water, periphyton, and benthic invertebrates.

Sediments will be sampled, processed, analyzed, and associated data interpreted using methodology consistent with previous assessment at Mount Polley (e.g., Minnow 2015a,b; 2016), which is also consistent with technical guidance (e.g., Environment Canada 2012; BCMOE 2013, 2016). Detailed methodology is provided in Section 4, including: quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting.

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be performed by qualified field staff experienced in the implementation of sediment quality monitoring programs. Quality assurance and quality control measures will be consistent with requirements outlined in the BC Field Sampling Manual (BCMOE 2013), and will include program review prior to implementation, adequate resources for all field teams including field checklists and field data sheets, the availability and maintenance of clean sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination.

Quality control (QC) samples will be collected to support the sediment quality monitoring program. Five replicate samples (samples from 5 separate stations to represent the sampling area) will be collected from each sampling area in order to capture within-area variability. Specific field QC samples will include duplicates (i.e., splits) collected at a frequency of 10% of the total number of samples to assess field precision as part of the Data Quality Review (DQR; Section 4.4). Duplicate water samples will be collected at a frequency of 10% to assess field precision associated with the water samples that support DGT monitoring. In addition to field QA/QC, any laboratory conducting the physical or chemical analyses will be accredited by the Canadian Association for Laboratory Accreditation (CALA) for these analyses. Specific QC sampling and associated reporting will be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). These results will be assessed as part of the DQR (Section 4.4).

All raw field data will be transcribed from field sheets into an electronic spreadsheet. Data will then checked by a separate individual for data entry errors as part of routine Quality Assurance/Quality Control (QA/QC) procedures.

4.2 Sample Collection Methods

4.2.1 Lakes

Sampling of lake sediments will be consistent with previous monitoring (Minnow 2015a,b; 2016a). In Polley Lake (and the associated reference – Bootjack Lake [and Jacobie Lake in 2018]), sediments will be collected at five replicate stations per area, with sediments for the analysis of total organic carbon, total sulphur, total nitrogen, and metals collected using a Kajak-Brinkhurst corer or a Tech Ops corer in accordance with technical guidance for gravity coring outlined in the BC Field Sampling Manual (BCMOE 2013) and the Metal Mining Technical Guidance for EEM

(Environment Canada 2012). Sediment samples for particle size distribution will be collected using a Petite Ponar grab sampler. Briefly, the KB corer is a gravity corer that collects samples in 2" (5.08 cm) diameter core tubes. Core collection relies on a combination of surface tension within the core and suction supplied by a plunger that seals the top of the core tube after being deployed by a messenger. The Tech Ops corer is a gravity corer that collects samples in 4" (10.16 cm) diameter core tubes. Core collection relies on a combination of surface tension within the core and suction supplied by an automatic seal (plunger assembly) that shuts in response to sampler retrieval (upward pull). Success rates for each of the core devices tend to vary with sampling location in accordance with sediment characteristics and both devices may be used in the program.

Collection of sediment by coring requires careful application and experience to obtain good quality sediment samples (i.e., sediment samples that capture an undisturbed sediment-water interface). During coring, care will be taken to control the rate at which the coring device is lowered, to maintain the corer in a vertical position during descent, and to allow the corer to penetrate the sediment with minimal sediment disturbance. The corer will then be carefully retrieved to surface. At surface, an extruder head-piece will be inserted into the bottom of the core tube to prevent sediment slippage. Core samples will be rejected if there was evidence of slippage, that the core did not penetrate the substrate vertically, or that the sediment-water interface was disturbed within the core. Accepted samples will then be processed by removing the core tube from the corer and using the extruder to push the sediment upwards towards the top of the core tube in a controlled fashion with care taken to minimize suspension of fines. In the event of suspension, momentum will be stopped, allowing the suspended solids to re-settle. Once the sediment is extruded to near the top of the tube, an extrusion collar marked in 1-cm intervals will be carefully aligned on the top of the tube and the sediment will be extruded upwards into the extrusion collar to the 3-cm mark. A core slicer will then be carefully inserted between the tube and the collar to collect the top 3-cm of sediment, which will then be transferred into a 250 mL glass sampling jar labeled with the project number, sample location, and collection date. The procedure will then be repeated twice more (at minimum) in order to provide a composite sample of sufficient volume for the required analyses. All sampling equipment will be rinsed between stations using site water. As indicated above, duplicate (split) sediment samples will be collected at a target frequency of 10% for quality assurance/quality control (QA/QC) purposes (associated composite samples will be composed of twice the number of grabs to support the split samples). In addition, supporting information will be collected at each sampling site as outlined below. Immediately after collection, sediment samples will be placed into a cooler with ice packs, where they will be maintained cool prior to transport to the field laboratory where they will then be transferred to a refrigerator and held until shipment to the analytical laboratory.

Sediment samples for particle size analysis in Polley Lake, Bootjack Lake, and Jacobie Lake will be collected using a stainless steel Petite Ponar grab sampler in accordance with technical guidance outlined in the BC Field Sampling Manual (BCMOE 2013) and the Metal Mining Technical Guidance for EEM (Environment Canada 2012). Briefly, the Petite Ponar is a 6" x 6" (15.24 cm x 15.24 cm) grab sampler with jaws that can be held open by shear-pressure on a spring-loaded pin. The grab sampler is lowered to the substrate at which point shear-pressure is eliminated and the pin springs out. Upon upward pull at the initiation of retrieval, the jaws of the ponar close to grab surficial sediment. As with coring, care must be taken to control the rate at which the ponar is lowered to allow appropriate sediment penetration and to minimize sediment disturbance. The ponar will then be carefully retrieved to surface and each grab will be placed into a plastic tote and observed for completeness and any unusual characteristics. If the sample is deemed acceptable (i.e., the sampler is full to each end and is representative of surface sediment), surficial material to a depth of 3 cm will be transferred to a second tote using a stainless steel spoon, and the remaining sediment discarded. At each station, composite samples of the top 3 cm of surficial sediment of three acceptable grabs will be collected. The sediment within the tote will then be homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars labeled with the project number, sample location, and collection date. Sampling equipment will be rinsed between stations using site water.

Sediment samples for toxicity testing of *Chironomus dilutus* will also be collected using a Petite Ponar grab sampler. The same methodology as above will be applied, with the exception that, at stations that require both sediment chemistry and toxicity testing, a composite sample will be composed of a minimum of five grabs and will be placed into a 250 mL glass sampling jar for chemical analysis (as above) and another 500 mL jar for toxicity testing. As noted above, all jars will be labelled with the project number, sample location, and collection date.

In Quesnel Lake, all sediment samples (for total organic carbon, total sulphur, total nitrogen, and metals) will be collected using a stainless steel Petite Ponar (15.24 cm x 15.24 cm; 0.023 m^2 sampling area) or a stainless steel standard ponar (22.86 cm x 22.86 cm; 0.052 m^2 sampling area) in accordance with federal and provincial technical guidance (Environment Canada 2012; BCMOE 2013). Attempts to collect sediment from Quesnel Lake by gravity coring have yielded poor success rates due to the substantial depth of sampling (approximately 100 meters) and the non-cohesive nature of the sediment. Samples will be retrieved with the assistance of a coMDMERcial line hauler (Ace Line Hauler - Brutus Plus 40) using methodology consistent with that described above for collection of the Polley Lake (and Bootjack Lake) sediment particle size samples. Composite samples of the top three centimeters of surficial sediment of a minimum of three acceptable grabs (i.e., full to each edge of the sampler) will be collected at stations where toxicity testing is not required, and composite samples of the top three centimeters of surficial

sediment of a minimum of five acceptable grabs (i.e., full to each edge of the sampler) will be collected at stations where toxicity testing is required (Table 2 and Figure 5). Sediment homogenization and transfer to sampling jars will be as described above. All sampling equipment will be rinsed between stations using site water. Duplicate (i.e., split) sediment samples will be collected at a target frequency of 10% for quality assurance/quality control (QA/QC) purposes (associated composite samples will be composed of twice the number of grabs to support the split samples). In addition, supporting information will be collected at each sampling station as outlined below. Immediately after collection, sediment samples will be placed into a cooler with ice packs, where they will be maintained cool prior to transport to the field laboratory where they will be placed in a refrigerator and held until shipment to the analytical laboratory.

Supporting information collected at each of the lake sediment monitoring stations will include GPS (Geographic Positioning System) coordinates, sampling depth, Secchi depth, field meter measurements of temperature, specific conductance, dissolved oxygen and pH, photographs of sediment samples, notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). In addition, one full vertical profile of the field meter measurements will collected at one station per area.

4.2.2 Creeks

Hazeltine Creek and the associated reference creek (Edney Creek) are predominantly erosional (HKP 1996, 1997; Minnow 2007) and there are few locations of true sediment deposition. The limited sediment within these creeks tends to wash through during spring freshet and deposit as a thin layer of fines in quiescent areas on the lowering hydrograph. Thus, collection of true sediment (i.e., fines in the silt and clay size category) cannot be completed by conventional grab sampling as applied in lakes (as described above) and typically applied in depositional creeks (i.e., due to the dominant presence of sand, gravel, and cobble). An alternative method will therefore be applied – sampling by spoon. This sampling will target the fine sediment fraction (i.e., silt and clay). Sampling will be undertaken in late suMDMER when low flows support some sediment deposition, even if only as a thin layer over sand, gravel, or cobble. As with lake sampling, sediments will be collected at five replicate stations per area. However, due to the non-uniform nature of sediment deposition in erosional creeks, the actual sampling stations will be determined opportunistically with each field sampling campaign and may vary slightly over time (i.e., a priority will be placed on the quality of the five replicate sediment samples collected within each area rather than the precise location of each sample within each area).

Sediment samples from creeks will be collected using a clean stainless steel spoon. All samples will be collected from wetted sampling stations that support the accumulation of fine materials (i.e., small pools or backwaters). Sampling locations will be approached by foot in a manner that

does not disturb sediment prior to sampling. At locations of sediment deposition, surficial sediment will be carefully collected by slowly placing the spoon on the sediment surface in a manner that minimizes disturbance. The spoon will then be inserted into the sediment to capture sediment to a depth of no greater than 3 cm and moved horizontally to fill the spoon. In reality, the collection depth may be much less than 3 cm, as fines often settle in a thin layer over coarser material (and sampling seeks to avoid coarse material as indicated above). The spoon will then be slowly retrieved to surface to avoid sample washout. The content of the spoon will then be inspected to ensure that it represents fine sediment (i.e., is predominantly silt and clay) and, if accepted, will be placed into a 250 mL glass sampling jar labeled with the project number, sample location and collection date. This procedure will be repeated a minimum of four more times to form a composite sample representative of the sampling station. Sampling equipment will be rinsed between stations using site water. Duplicate sediment samples will be collected at a target frequency of 10% for quality assurance/quality control (QA/QC) purposes (associated composite samples will be composed of twice the number of spoons to support the split samples). In addition, supporting information will be collected at each sampling site as outlined below. Immediately after collection, sediment samples will be placed into a cooler with ice packs, where they will be maintained cool prior to transport to the field laboratory where they will then be transferred to refrigerator and held until shipment to the analytical laboratory.

Supporting information collected at each of the creek sediment monitoring stations will include GPS (Geographic Positioning System) coordinates, average water depth at the sample locations, average sediment depth collected, field meter measurements of temperature, specific conductance, dissolved oxygen and pH, photographs of sediment samples, notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.).

4.2.3 DGT Sampling

Diffusive Gradients in Thin Films (DGT) sampling devices (DGT model C-LSNX; DGT Research, Lancaster, UK) as described in Minnow (2017a) will be installed in the lower water column at one sediment sampling area in Polley Lake (POL-P2; with an area in Bootjack Lake [BOL-2] as reference) and at one sediment sampling area in Quesnel Lake (QUL-PNF; with an area in Quesnel Lake [QUL-PREF1] as reference; Table 2). Five replicate DGT devices will be placed in exposed areas and three replicates will be placed in reference areas. The purpose of the DGT device monitoring is to provide data on the concentrations of DGT-labile metals above of the sediment-water interface, and most importantly to monitor DGT-labile metals above the sediment-water interface to determine if those concentrations are changing over time. Low and unchanging concentrations of DGT-labile metals would be indicative of stability of metals and metalloids in

lake sediments affected by the TSF embankment breach. Conversely, increasing concentrations of DGT-labile metals would be indicative of instability of metals and metalloids in lake sediments.

The DGT devices will be installed in the lower water column approximately one meter above the sediment surface. This will be achieved by placing a line with anchor and float at each sample location. The DGT devices will be deployed with care (including not touching the DGT window) while wearing metal free disposable nitrile gloves and will be left in place for a total period of 35 to 50 days. Upon retrieval, DGT devices will be handled with care while wearing metal free disposable nitrile gloves. Upon retrieval, each DGT device will be gently rinsed with metal free water (provided by the laboratory) and placed into a labelled glass soil jar with a few drops of metal free water to prevent desiccation. Jars will then be placed into clean Ziploc™ bags and then into a dedicated cooler with ice packs, where they were maintained cool prior to transport.

Supporting information collected at each DGT deployment location will include GPS (Geographic Positioning System) coordinates, sampling depth, field meter measurements of temperature, specific conductance, dissolved oxygen and pH, site photographs (including photographs of the DGT devices), and notes on the presence or absence of any fouling of the DGT devices. Supporting water samples will also be collected from each sampling area, including samples for total and dissolved constituents (including metals), the latter prepared by field filtration using a 0.45 µm syringe filter. Water samples will be placed into a dedicated cooler with frozen ice packs, and kept cool prior to transport to the field laboratory.

4.3 Sample Handling and Laboratory Analysis

At the termination of the field program or at intervals of no more than seven days, sediment samples will be shipped in coolers with ice packs to the analytical laboratory and/or toxicity testing laboratory. Shipment transit time will be less than one day.

Chemical analyses will be completed at an analytical laboratory accredited by the Canadian Association for Laboratory Accreditation (CALA) using methods that are consistent with those specified in the British Columbia Environmental Laboratory Manual (BCMOE 2015) and will include moisture content, pH, particle size distribution, total organic carbon (TOC), total nitrogen, total sulphur, and total metal concentrations (Table 3). All analyses except for particle size distribution will be completed on the silt/clay fraction (<63 µm diameter) in accordance with recent recommendations by BCMOE (2016) and because sediment quality characterization conducted in 2014 indicated similar results in <63 µm and <2 mm sediments (Minnow 2015a). Analysis of metals will be based on the BC Strong Acid Leachable Metals digestion (SALM; BCMOE 2016). Analyses of pH will be completed by electrode, particle size analysis will be completed by sieve and pipette, total organic carbon will be completed by combustion and titration (total carbon minus total inorganic carbon), total nitrogen and total sulphur will be completed by combustion, metals

Table 3: Analytes and Laboratory Reporting Limits for Mount Polley CEMP Sediment Quality Monitoring

[2] British Columbia Sediment Quality Guidelines; from British Columbia Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture (BCMOE 2017)

[a] approximately 2%

[b] approximately 4%

will be completed by collision reaction cell inductively coupled plasma – mass spectrometry (ICP-MS [USEPA Method 6020A; USEPA 1998]), and mercury will be completed by cold vapor atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (USEPA Method 245.7; USEPA 2005).

Toxicity testing will be completed at a testing laboratory accredited by CALA. Testing will be completed using a standard 10 day test of the survival and growth of *Chironomus dilutus* (a midge larva; Environment Canada 1997). In accordance with recent recommendations for toxicity testing, test replicates (n = 5) will be field-collected replicates. In addition to the exposed area field replicates and the reference area field replicates, a laboratory control (beach sand in accordance with the standard biological test methods) will also be included (also to be set up with five laboratory replicates).

At the termination of the DGT device collections or at intervals of no more than four days, DGT devices will be shipped in coolers with ice packs to the analytical laboratory. Laboratory analysis of the DGT devices will involve dismantling the devices followed by digestion of the resins to determine total metal concentrations in the resin by ICP-MS (USEPA Method 6020A; USEPA 1998). DGT-labile metal concentrations will subsequently be calculated by the analytical laboratory based on total metal in the resin, mean water temperature during deployment at each area, total deployment time, and manufacturer-supplied peer-reviewed diffusion coefficients, which, in turn, are based on Fick's first law of diffusion (Zhang and Davison 1995; Panther et al. 2014). Supporting water samples will be treated in a manner identical to the routine water quality samples collected as part of the CEMP (Section 6.6).

Each of the laboratories will provide a sample receipt confirmation when the samples are received and logged. These receipts will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. Upon completion of the analyses, each laboratory will provide a data report in Microsoft (MS) Excel™ and as an Adobe Acrobat Portable Document Format (PDF). Reporting will include the results of the laboratory QC sample results.

4.4 Data Quality Review

Upon receipt of sediment quality data and supporting water quality data from the analytical laboratory, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs have been achieved. The DQR will also include an evaluation of differences between duplicate samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the sediment quality data will ensure timely communication with the laboratory should any issues be identified.

Comparisons between duplicate samples will be made by calculating the relative percent difference (RPD) between concentrations between paired duplicates. If the RPD is <40% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping).

4.5 Data Handling, Interpretation, and Reporting

Upon receipt of data from the analytical laboratories, all laboratory data files will be managed by the Mount Polley Mining Corporation (MPMC) Environment Department. In addition, data provided by the primary analytical laboratories as an Electronic Data Deliverable (EDD) will be imported directly into the MPMC's database following completion of the DQR. Following the completion of the DQR, all sediment quality data and supporting data will be managed in Microsoft (MS) Excel™. For all replicated data (typically based on a sample size of five stations per area), data will be provided to the QP and summarized by calculating mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile for each analyte. Sediment quality data will then be evaluated in comparison to British Columbia Working Sediment Quality Guidelines for the protection of aquatic life (WSQGs; BCMOE 2017) and reference concentrations. Reference 95th percentile values will be used to screen exposed-area mean concentrations to efficiently identify analytes with concentrations that are beyond the range of reference. Analytes with concentrations greater than guidelines and reference will be the focus of more detailed interpretation, which may include, as required for data interpretation: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations and/or over time.

WSQGs are numerical criteria that are protective of sediment-dwelling organisms based on long-term exposure. Most British Columbia WSQGs have been adopted from the CCME (CCME 1999) or from Ontario (OMOE 1993) and have two levels – a Lower WSQG (also known as a Threshold Effect Level [TEL] or a Lowest Effect Level [LEL]) and a Higher WSQG (also known as a Probable Effect Level [PEL] or a Severe Effect Level [SEL]). The Lower WSQG is intended to represent a concentration that will protect aquatic life from adverse effects of a toxic substance in most situations (BCMOE 2017). The Upper WSQG is intended to represent a concentration that, if exceeded, will likely cause severe effects on aquatic life (BCMOE 2017). However, WSQGs – even the Upper WSQGs - are often naturally exceeded in mineralized areas, as was the case for copper, iron, and manganese in Polley Lake (Section 2.1). In addition, SQGs were developed based on co-occurring bulk surficial sediment data and biological effect data (CCME 1995). Bulk

sediment chemistry can differ substantially from the <63 µm fraction, and this discrepancy between measurement (<63 µm fraction) and exposure (to bulk sediment to which SQGs are most applicable) should be considered in interpretation as "caution should be used in interpreting the biological significance of chemical concentrations in sediments for different types based on these guidelines" (CCME 1995).

Multivariate statistical tools may also be applied to assist with sediment quality data interpretation. Specifically, ordination techniques such as Principal Components Analysis (PCA), Correspondence Analysis (CA), or Nonmetric Multidimensional Scaling (NMDS) may be applied to assist in the identification of key spatial or temporal differences in sediment chemistry. Perhaps more importantly, these techniques will be used in the analysis of potential physical and/or chemical causes of differences in biological metrics (e.g., benthic invertebrate community condition) as a means of reducing data to focus on a small list of key components for correlation analysis (see Section 6.13 – Benthic Invertebrate Monitoring).

As indicated above, analytes with concentrations greater than guidelines and reference 95th percentile concentrations will be the focus of more detailed interpretation, which may include, as required for data interpretation: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations and/or over time. This will include the following: graphical plots in relation to all guidelines, reference values, and historical values and examination of relationships to physical variables. Plots of the analytes of interest (those greater than SQG and reference) will be prepared in MSExcel. At a sample size of 5, plots will include of each replicate by area. Available guidelines (BCWSQG), reference concentrations, and background concentrations (as available) will be added to the plots as lines to facilitate comparison of concentrations to these benchmarks.

Relationships between the analytes of interest and physical features (i.e., particle size) and other chemical variables (total organic carbon content) will be evaluated using correlation analysis. Spearman correlation (often referred to a Spearman Rank-Order correlation) will be completed. Following the derivation of correlation coefficients, a Bonferroni-type correction (i.e., p-value [0.05] divided by the total number of correlations examined for independent variables) will be applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected p-value of 0.05. Any significant correlations found at the Bonferroni-adjusted p-value or at a p-value of 0.01 will be further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were "leveraged" by outlying points (or groups of points).

Sediment toxicity test results (survival and growth of *C. dilutus*) will be interpreted based on a combination of effect size and statistical contrasts. Results associated with each exposed area will be contrasted against the matched reference area and against the laboratory control. Results will then be evaluated using a stepwise procedure similar to that of Southern California Coastal Water Research Project (SCCWRP) California Sediment Quality Objectives (CASQO; Bay et al. 2014):

1. mean responses (percent survival and growth [dry weight per surviving organism]) will be expressed as a percentage of the mean laboratory control result and the mean field reference result; and

2. results of the statistical contrasts of mean responses in tests of impacted sediment against the laboratory control and the field reference sediment will be compiled.

Results will then be categorized as follows:

1. no unacceptable response is a mean response within 20% of the mean field reference response (i.e., survival or growth were ≥80% of the field reference);

2. a low to moderate response is a mean response of between 20% and 50% of the mean field reference response (i.e., survival or growth were 50% to 80% of the field reference); and

3. a large response is a mean response of >50% of the mean field reference response (i.e., survival or growth were <50% of the field reference).

Low and moderate responses will be distinguished based on whether the results differ significantly from reference (moderate response) or not (low response). Application of a 20% reduction in survival relative to the field reference to define acceptability is consistent with thresholds used elsewhere (e.g., BCMELP 1998; Government of Canada 2010; Bay et al. 2014). If low, moderate, or high responses are observed in sediment toxicity testing, relationships between the effect endpoint (i.e., survival or growth) and sediment quality will be evaluated in consideration of WSQGs, effect thresholds, and the results of correlation analysis. Although it is recognized that a significant correlation or regression does not indicate causation (e.g., Norton et al. 2015), it is desirable to not only characterize the nature of a response (e.g., reduced survival or growth in sediment toxicity tests), but to also obtain evidence of cause. Correlation / regression analyses are commonly applied tools for identifying potential cause (e.g., Norton et al. 2015). Evidence of causation obtained from correlation or regression analysis will be carefully considered in light of the strength, range, and continuity of the relationships as well as mechanistic knowledge/understanding of potential cause.

The overall interpretation of sediment quality data will include integration of a weight-of-evidence that includes other components of the MPMC CEMP (e.g., water quality data, periphyton data for creeks, benthic invertebrate community data for lakes and creeks). Thus, within the CEMP, sediment quality data interpretation will specifically include the integration of data on sediment quality, the results of specialized evaluations (e.g., DGT results), and the results of bio-assessment (e.g., sediment toxicity testing and benthic invertebrate communities).

An interpretive report based on the sediment quality data will be prepared to be integrated into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWSQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

1 INTRODUCTION

1.1 Background

Benthic invertebrates are excellent biomonitors for assessing potential effects of physical and/or chemical habitat changes in aquatic systems (Barbour et al. 1999; Feltmate and Fraser 1999; Beatty et al. 2006). Due to the complexity of benthic invertebrate community structure and known tolerances and sensitivities to sediment and water quality (e.g., Barbour et al. 1999; Mandaville 2002), benthic invertebrate community analysis is typically a highly sensitive bio-monitor. Benthic invertebrate are sessile, therefore evaluation of benthic invertebrate tissue quality can provide an important measure of localized chemical conditions and of spatial extent of an effect, as well as of potential direct or indirect exposure of fish and wildlife to metals, metalloids, and nutrients[1]. Therefore, benthic invertebrate community and tissue quality monitoring is an important component of the Mount Polley CEMP.

The influence of the Mount Polley Mine on benthic invertebrate communities, productivity, and/or tissue quality can occur by several key mechanisms: 1) general mine influence from dustfall and/or uncontained surface or groundwater flows: 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to December 2017, and directly since January 2018]); 3) the TSF embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Reclamation activities in Hazeltine Creek and lower Edney Creek were initiated in 2014 following the TSF embankment breach, and were completed in lower Edney Creek in August 2015 (Golder 2017a). Construction / rehabilitation in areas of upper Hazeltine Creek (Reaches 1 and 2) were completed between July and September of 2016 and 2017, respectively (Golder 2017b,c). Reach 2 of the rehabilitation works encompassed a sampling area established prior to the TSF embankment breach (UHC; Minnow 2009). In lower Hazeltine Creek, initial channel rehabilitation was completed in 2015, and further rehabilitation has yet to be completed in this area of creek. The geomorphology of Hazeltine Creek was drastically altered as a result of the TSF embankment breach such that Fisheries and Oceans Canada considered it not to be fish habitat (Golder 2015a), and the creek was inaccessible to fish from August 2014 (following the breach) until the spring of 2018 when it was reopened as fish habitat.

Benthic invertebrate communities in waterbodies adjacent to the Mount Polley Mine have been monitored since baseline investigations in 1989, 1995, and 1996 (Imperial Metals 1990; HKP 1996, 1997). Benthic invertebrate tissue quality has been monitored since prior to the TSF

[1] Through the remainder of this section, the term “metals” will be used to include metals, metalloids, and nutrients for ease of communication.

embankment breach (2009, 2010, 2012, and 2013; Minnow 2011, 2013a,b). Results of benthic invertebrate community and tissue quality monitoring are reviewed in Section 2 and provide context for a CEMP benthic invertebrate monitoring program that is guided by a combination of historical findings, representative locations downstream of Mount Polley Mine operations, representative reference locations, and considerations for a statistically-based design that will facilitate the detection of spatial and/or temporal differences in benthic invertebrate productivity, community, and/or tissue quality, in addition to providing data to evaluate tissue quality results (i.e., tissue selenium concentrations) relative to effects-based guidelines (e.g., British Columbia Water Quality Guidelines [BCWQG]; BCMOE 2014). In addition to monitoring required as part of the Mount Polley CEMP, benthic invertebrate community monitoring is required as part of Environmental Effect Monitoring (EEM) under the Metal Mining Effluent Regulations (MDMER) of the federal *Fisheries Act*.

The following sections of the CEMP Benthic Invertebrate Monitoring Plan provide the objectives of benthic invertebrate community and tissue quality monitoring, a summary of historical benthic invertebrate findings, an overview of the CEMP study design and associated rationale (including sampling locations, replication, frequency, and analytes), and detailed methodology for benthic invertebrate community and tissue quality monitoring (quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting).

1.2 Monitoring Objective

The objective of benthic invertebrate monitoring is to evaluate the influence of Mount Polley Mine activities on benthic invertebrate communities, productivity, and tissue quality in receiving environments (Polley Lake, Hazeltine Creek, Edney Creek, and Quesnel Lake) in comparison to baseline and/or reference conditions, and to determine potential implications to aquatic life (e.g., through assessment of benthic invertebrate community and productivity endpoints, and comparison of benthic tissue quality results to available guidelines; BCMOE 2014) and to aquatic ecosystem health by providing supporting information for the assessment of potential effects to higher trophic levels (e.g., fish and fish habitat quality; Section 6.16). Benthic invertebrate monitoring also provides data to support exposure assessment as part of the ecological risk assessment (ERA) and human health risk assessment (HHRA). Benthic invertebrate community monitoring is also required as part of Environmental Effect Monitoring (EEM) under the Metal and Diamond Mining Effluent Regulations (MDMER) of the federal *Fisheries Act* (Government of Canada 2018). The objective of the MDMER EEM benthic invertebrate monitoring is to evaluate whether there are effects to benthic invertebrate community characteristics between the area of

Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012a).

2 SUMMARY OF HISTORICAL FINDINGS

Benthic invertebrate community has been monitored in the vicinity of the Mount Polley Mine since 1989, and benthic invertebrate tissue quality has been monitored since 2009. The majority of benthic invertebrate community and tissue quality samples have been collected from Polley Lake, Bootjack Lake, Quesnel Lake, Hazeltine Creek, and Edney Creek (Tables 1 and 2).

Benthic invertebrate community sampling in the vicinity of the Mount Polley Mine has spanned the four distinct time periods listed below:

1. Baseline monitoring (1989, 1995, 1996);
2. Pre-breach operational monitoring (1999, 2007, 2009, 2010, 2012, 2013);
3. Post-breach operational monitoring (2014, 2015); and
4. Post-breach and post-discharge monitoring (2016, 2017).

Benthic invertebrate tissue quality sampling in the vicinity of the Mount Polley has spanned operational time periods only (time periods 2 to 4). Data collected prior to the breach were summarized in a Technical Assessment Report (MPMC 2009) and an Aquatic Environmental Description Report (Minnow 2014a) prepared concurrently with applications for water discharge in 2009 and 2014, respectively. General findings associated with baseline, pre-breach, post-breach operational, and post-breach post-discharge monitoring are summarized, by sampling area, in the following sections.

2.1 Polley Lake

2.1.1 Community

The benthic invertebrate community of Polley Lake during baseline studies (Table 1; 1995 and 1996; HKP 1996, 1997) and pre-breach operational monitoring (1999; Beak 2000) was characterized by a dominance of Chironomidae (midges) and Oligochaeta (worms) in the two deep basins of the lake (P1 and P2). A temporal increase in density and richness at these stations was observed between baseline period and pre-breach operational monitoring, but due to unavailability of detailed sample collection and laboratory methods for baseline studies (e.g., HKP 1996, 1997) the reason for this difference is not clear (Minnow 2014a).

Following the TSF embankment breach, the benthic community in Polley Lake differed dramatically from conditions prior to the breach (1999; Beak 2000) and from reference in both deep basins of the lake (Figure 1). Specifically, no benthic organisms were present in the south basin (POL-P2) indicating an unequivocal impact, and organism density and taxon richness in the

north basin (POL-P1) was also substantially impacted (9 to 17 organisms/m^2; 1 to 2 taxa, respectively) relative to reference (1,431 to 2,551 organisms/m^2; 4 to 6 taxa, respectively) and pre-breach conditions (300 to 614 organisms/m^2; 10 to 15 taxa; Figure 1; Minnow 2015a). Benthic invertebrate community monitoring completed in 2015 and 2016 indicated substantial recovery of the benthic community in both deep basins of Polley Lake relative to 2014 conditions. Organism density (mean = 686 to 1,360 organisms/m^2) and taxon richness (mean = 7.4 to 8.4 taxa) at both areas in 2016 were similar to reference, and density was similar to pre-breach conditions as determined by Before-After/Control-Impact analysis (1999 and 2016; Minnow 2017a). Some differences in community composition relative to reference were observed in 2015 and 2016 (Minnow 2016b, 2017a); however, the primary difference (lower relative proportion of *Chaoborus* in Polley Lake in comparison to reference) was observed prior to the embankment breach (i.e., Beak 2000).

2.1.2 Tissue Quality

Benthic invertebrate tissue quality in Polley Lake was not assessed as part of baseline studies (1989-1996; Table 2). Selenium-specific aquatic environmental monitoring was initiated in 2009 after an uncontrolled surface runoff event from the north waste rock dump which reported to Polley Lake via North Dump Creek (Minnow 2011; see CEMP Sections 6.12 and 6.16). This runoff started in 2006, was controlled in 2009 with the construction of the Long Ditch, and was characterized by elevated concentrations of sulphate and selenium. Mean selenium concentrations observed during pre-breach operational monitoring (2009 and 2012; 6.0 to 7.8 mg/kg dw) were greater than reference and the interim BCWQG of 4 mg/kg dry weight, and were generally similar among sampling years (Figure 2; Minnow 2011, 2013a).

Following the TSF embankment breach, mean benthic invertebrate concentrations of selenium remained significantly higher than the BCWQG and reference, but were significantly lower in 2016 (5.4 mg/kg dw) relative to 2009 and 2012 indicating no breach-related increase (Figure 2; Minnow 2017b). Benthic invertebrate tissue quality investigations following the TSF embankment breach were also focussed on a suite of analytes identified as indicative of the chemical influence of the breach on sediment quality in the receiving environment (Minnow 2015a): Parameters of Interest (POIs: arsenic, copper, iron, manganese, nickel, and zinc), and Indicator Parameters (IPs: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium). Mean concentrations of a number these POIs and IPs were higher than reference in 2015 (manganese, tin, and titanium), in 2016 (arsenic, iron, and vanadium), and in both 2015 and 2016 (copper and molybdenum; Minnow 2016a, 2017a). In particular, mean benthic invertebrate copper concentrations were approximately 5.8 to 6.9 times higher than reference (Figure 3). These results are not unexpected, given that sediment copper concentrations were approximately

twice reference values (see CEMP Section 6.12). Although whole benthic invertebrate tissue concentrations accurately represent concentrations associated with food for higher trophic level organisms that consume benthic invertebrates, they may not accurately represent metal concentrations in the tissues of benthic organisms due to a known confounding influence of gut content on the determination of tissue metal concentrations in invertebrates, and therefore on the evaluation of potential biological effects associated with these metal concentrations (i.e., Chapman 1985, 2016). Metal concentrations were evaluated in both depurated and non-depurated benthic invertebrate samples in 2016 from Polley Lake in order to minimize the confounding influence of gut content. However, depuration made little difference to results (Minnow 2017a). Due to the uncertainties associated with depositional benthic invertebrate tissue monitoring, and similarities with results of other sampling methods (Diffusive Gradients in Thin Films [DGT] devices), DGTs will be used to monitor temporal changes in labile metal concentrations in Polley Lake (see CEMP Section 6.12).

Ratios of benthic invertebrate tissue metal concentrations to sediment concentration ([benthic invertebrate sample]/[sediment]) are referred to as Biota Sediment Accumulation Factors (BSAFs) and are often used to describe the accumulation of sediment-associated analytes in tissues of ecological receptors (i.e., Burkhard 2009). BSAFs for benthic invertebrate tissues from Polley Lake were generally higher than reference following the TSF embankment breach, however remained stable between 2015 and 2016, as did benthic invertebrate tissue chemistry results (Minnow 2016a, 2017a). The only exception was copper, with BSAF results indicative of greater bioavailability in 2016 versus 2015 (Minnow 2017a). Continued monitoring of potential temporal changes in labile metal concentrations in Polley Lake will be implemented using DGTs, which are not subject to the confounding influences (i.e., gut content) described for benthic invertebrate tissue quality monitoring.

2.2 Hazeltine and Edney Creeks

2.2.1 Community

The benthic invertebrate community of Hazeltine Creek was relatively stable between baseline studies in 1995, 1996 (HKP 1997, 1997), and operational monitoring in 1999 (Beak 2000) and 2007 (Minnow 2009), although unusual methodologies were applied to data collection in the 1996 baseline that appeared to affect results of certain endpoints such as density and the proportions of different taxon groups (MPMC 2009). Overall, benthic communities in both upper and lower Hazeltine Creek (with the exception of 1996 data) had high organism densities (25,000 to 43,000 and 6,000 to 33,000 organisms/m^2, respectively) and taxon richness (36 to 50 and 26 to 46 taxa, respectively) with a high proportion of metal sensitive taxa of the orders Ephemeroptera,

Plecoptera, and Trichoptera (EPT; mayflies, stoneflies, and caddisflies) indicating good ecosystem health (Minnow 2014a).

Monitoring in 2015 following the TSF embankment breach indicated that benthic invertebrate community recovery was incomplete and the community was dominated by pollution tolerant organisms (e.g., blackflies and oligochaete worms), particularly in the upper creek area (Minnow 2016b). In lower Hazeltine Creek, further recovery was documented in 2017, evidenced by taxon richness similar to reference (28 to 40 taxa) and a proportion of sensitive EPT taxa similar to reference and historic conditions despite significantly lower organism density (3,738 to 5,788 organisms/m^2; Figure 4). Productivity monitoring initiated in 2017 corroborated the low organism density, with biomass in lower Hazeltine Creek (0.70 to 2.5 g/m^2 dw) below that of upper Hazeltine Creek (2.9 to 20 g/m^2 dw) and reference (5.5 to 33 g/m^2 dw; Minnow 2018a). In upper Hazeltine Creek, the benthic community documented in 2017 (approximately one year following completion of final rehabilitation activities) was dominated primarily by Trichoptera (caddisflies), and to a lesser degree by Ephemeroptera (mayflies), and Chironomidae. The presence of these sensitive taxa suggests limited chemical effect on recolonization, and total organism abundances similar to reference in 2015 indicate a benthic community supportive of fish habitat productivity (Figure 4; Minnow 2018a).

Similar to Hazeltine Creek, the benthic invertebrate community of Edney Creek was evaluated during baseline studies in 1995, 1996 (HKP 1996, 1997), and during the pre-breach operational time period in 1999 (Beak 2000), 2002 (Morrow/Azimuth 2003), and again in 2007 (Minnow 2009). Benthic invertebrate communities appeared to be relatively stable over this time (with the exception of the 1996 data discussed above), with organism densities of 15,500 to 62,000 organisms/m^2 and taxon richness of 32 to 55 taxa, and a relatively high proportion of metal sensitive EPT taxa (MPMC 2009; Minnow 2014a).

Monitoring following the TSF embankment breach indicated recovery of the benthic invertebrate community between 2015 and 2017 in the rehabilitated area of lower Edney Creek. Specifically, although organism density was lower than reference in 2017 (due mainly to an increase in density at the reference area), taxon richness in 2016 and 2017 was similar to reference (Figure 4), and the relative proportion of Trichoptera increased significantly between 2016 and 2017 while the proportion of Chironomidae decreased, which is indicative of recovery (Minnow 2018a). Initial benthic invertebrate productivity sampling in 2017 indicated that total biomass in the rehabilitated area of lower Edney Creek (0.44 to 3.37 g/m^2 dw) was slightly lower than reference (0.79 to 3.44 g/m^2 dw; Minnow 2018a).

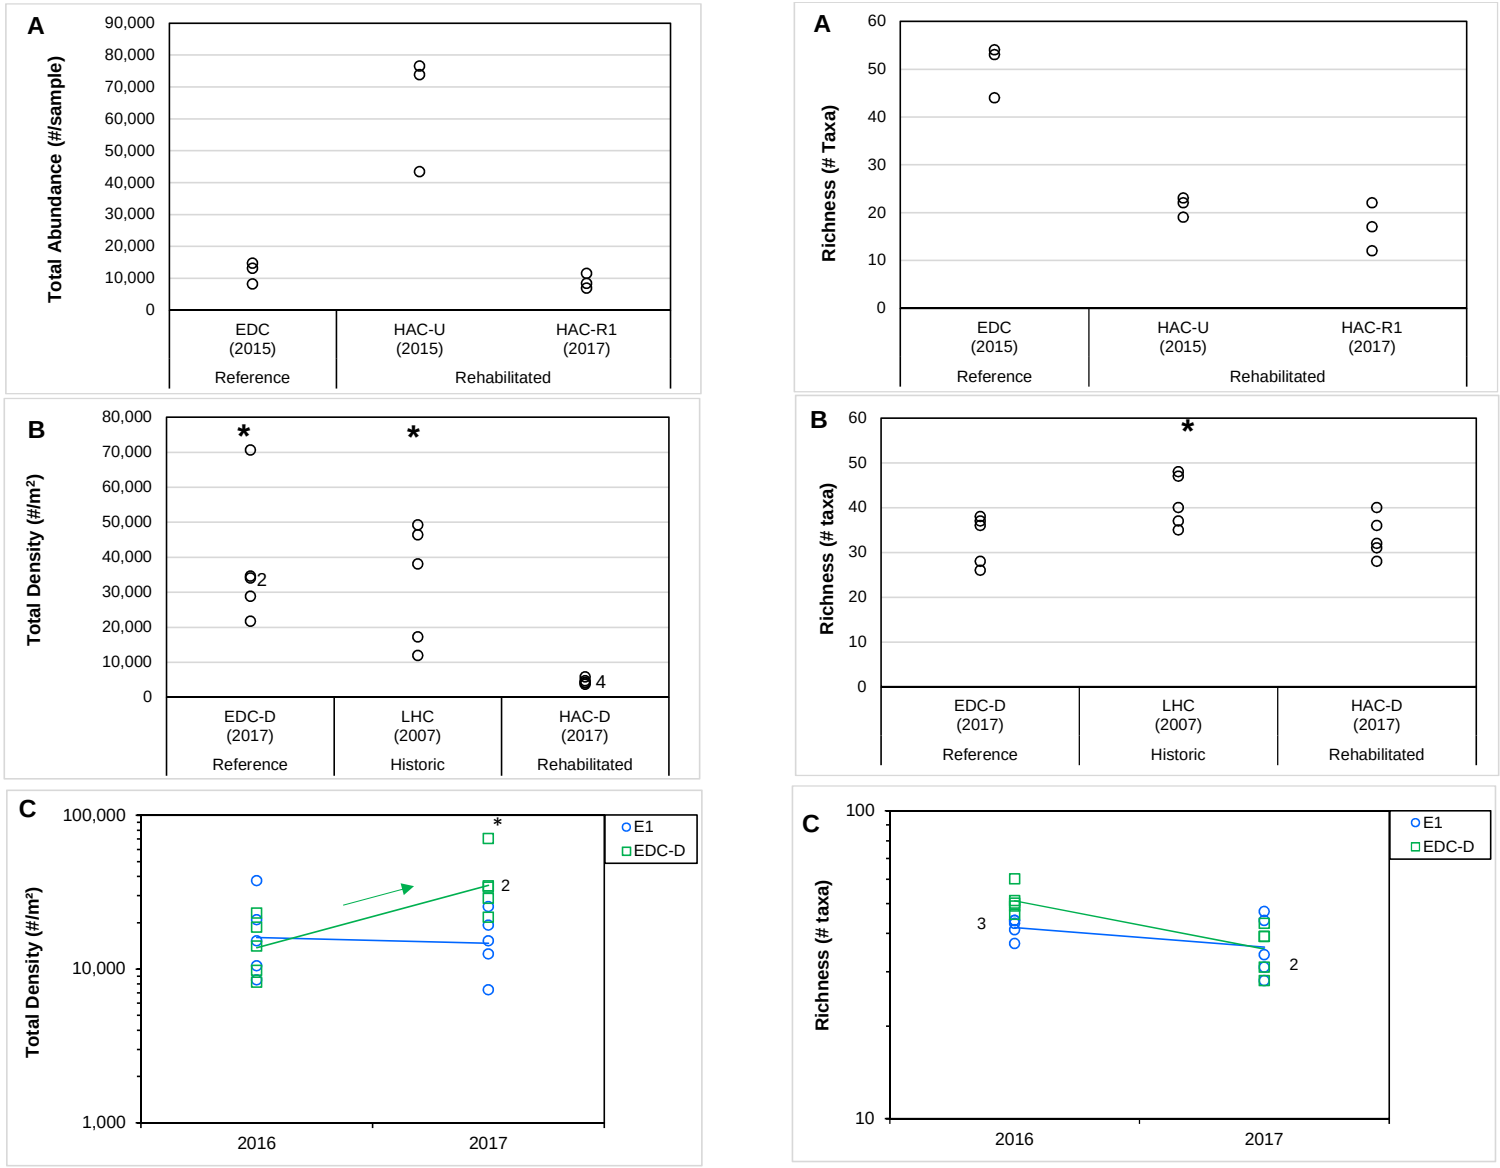

Figure 4: Benthic Invertebrate Community Endpoints for Rehabilitated Areas of A) Upper Hazeltine Creek (Kick-and-Sweep Sampling), B) Lower Hazeltine Creek (250 µm Surber Sampling), C) Lower Edney Creek (250 µm Surber Sampling), and Associated Reference Areas in the Vicinity of the Mount Polley Mine, 2007 to 2017[1]

Notes: For Lower Hazeltine Creek, areas displayed with an asterisk differed significantly from HAC-D (2017, $P < 0.1$). For Lower Edney Creek, statistical comparisons were conducted using a two-way ANOVA with factors Area and Year (* = significant difference ($\alpha = 0.1$) between areas for the given year; ** = significant difference ($\alpha = 0.1$) between areas in 2017 and magnitude of effect is different from ~~2016;~~ ► = significant ($\alpha = 0.1$) year effect ~~for E1~~► = significant ($\alpha = 0.1$) year effect for EDC-D).

[1] Values shown beside data points indicate number of stations sharing a similar result.

2.2.2 Tissue Quality

Benthic invertebrate tissue quality monitoring in Hazeltine Creek was initiated in 2009 as part of the ongoing characterization of selenium incorporation into the aquatic food chain in the vicinity of the Mount Polley Mine. Throughout the pre-breach operational period (2009 to 2013) mean benthic invertebrate tissue selenium concentrations at erosional habitats in upper Hazeltine Creek were higher than the interim BCWQG (4 mg/kg dw; BCMOE 2014) and generally higher than reference, while mean concentrations at erosional habitats in lower Hazeltine Creek were below the BCWQG (Figure 2; Minnow 2011, 2013a,b). In addition, selenium concentrations in benthic invertebrates from exposed erosional habitats were noted to be higher than those from nearby depositional areas (Minnow 2011, 2013b).

Following the TSF embankment breach, data interpretation focused on the POIs and IPs identified in Section 2.1.2 (which included selenium). In 2015 prior to initiation of effluent discharge to Hazeltine Creek, mean tissue concentrations of a number of these POIs and IPs were significantly higher in Hazeltine Creek than reference (arsenic, copper, iron, manganese, nickel, barium, calcium, cobalt, selenium, silver, sodium, strontium, titanium, and vanadium; Minnow 2016a). In addition, concentrations of copper and vanadium were higher in both upper and lower Hazeltine Creek areas relative to pre-breach conditions (3.5 and 8 times for copper, respectively; Figure 3; Minnow 2016a), whereas selenium concentrations were similar to pre-breach conditions (Figure 2). Examination of Bioconcentration Factors (BCFs; which are used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes other than diet; i.e, Arnot and Gobas 2006), indicated suggested that bioavailability did not differ from pre-breach conditions (Minnow 2016a).

Effluent was discharged directly to Hazeltine Creek between December 2015 and November 2017, however Hazeltine Creek was not considered to be fish habitat during this time by Fisheries and Oceans Canada (Golder 2015a) and was inaccessible to fish. Mean selenium concentrations in benthic invertebrates from Hazeltine Creek were higher than the majority of pre-breach results and the BCWQG in 2016 (10 mg/kg dw in both upper and lower Hazeltine Creek; Figure 2; Minnow 2017b), however these tissue concentrations corresponded with elevated mean dissolved selenium concentrations related to the conveyance of effluent that were 143-times higher than reference, and at least 46-times higher than at the same locations prior to the breach (Minnow 2013a, Minnow 2017b). Mean concentrations in 2017 were more similar to pre-breach results and were below the BCWQG in lower Hazeltine Creek (mean = 3.4 to 5.7 mg/kg dw; Figure 2; Minnow 2017b), presumably due to limited effluent discharge in 2017. Tissue concentrations of a number of POIs and IPs at effluent-exposed sampling areas were significantly

higher than reference in 2016[2] (barium, manganese, strontium, titanium), in 2017 (calcium), and in both years (arsenic, cobalt, copper, iron, molybdenum, nickel, selenium, vanadium; Minnow 2017b, 2018b). In particular, copper concentrations during this effluent discharge period (49 to 217 mg/kg dw) were elevated above reference and pre-breach concentrations but were generally similar to 2015 (prior to discharge; 158 to 254 mg/kg dw; Figure 3). Examination of BCFs indicated higher copper bioavailability relative to reference during the effluent discharge period (Minnow 2017b, 2018b), which was consistent with findings of higher labile copper concentration determined by DGTs (Minnow 2017c). Direct effluent discharge to Hazeltine Creek ceased in January 2018 prior to the reopening of upper Hazeltine Creek as fish habitat in spring 2018.

2.3 Quesnel Lake

2.3.1 Community

Benthic invertebrate community data for Quesnel Lake collected prior to the TSF embankment breach are limited to a few samples collected near the mouth of Hazeltine Creek in 2007 (Table 1). These data documented a mean density of approximately 31,100 organisms/m^2 and a mean taxonomic richness of 30 (Minnow 2009).

Benthic invertebrate community monitoring following the TSF embankment breach indicated that impacts to the community in shallow habitats were primarily limited to near-field areas and did not extend to far-field areas (Minnow 2015a). Impacts to the benthic community of the near-field area documented in 2014 included significantly lower mean organism density (159 to 294 organisms/m^2) and taxon richness (5.6 to 10 taxa) than reference (1,400 to 7,900 organisms/m^2 and 19 to 21 taxa, respectively; Minnow 2015a). Further monitoring in 2016 and 2017 confirmed these impacts, and indicated that limited recovery had occurred relative to: 1) a fine substrate reference with aquatic vegetation (2016; Minnow 2017a); and 2) two shallow sandy reference areas which more closely matching the habitat present in the near-field area in 2016 and 2017 (2017; Minnow 2018a). Benthic biomass sampling initiated in 2017 corroborated these results, with significantly lower biomass at the near-field area (mean = 0.28 g/m^2 ww) than reference (mean = 1.0 to 3.6 g/m^2 ww; Minnow 2018a).

Sediment investigations following the TSF embankment breach indicated that the majority of breach-derived material was deposited to deep habitat of Quesnel Lake (Minnow 2015a,b, 2016c). Immediately following the TSF embankment breach (2014), benthic invertebrate communities in deep exposed areas were characterized by particularly low mean organism

[2] Benthic invertebrate tissue quality results reflect single-taxon samples in 2016 and 2017 (caddisflies and/or stoneflies), and composite-taxa samples in 2015.

densities at the exposed near-field (PNF; 39.7 organisms/m^2) and far-field areas (3.4 to 22.6 organisms/m^2) relative to reference (5,840 organisms/m^2), and significantly lower mean taxon richness (0.2 to 2.6 taxa at near-field and far-field areas, 7.8 taxa at reference; Figure 5). Overall, results suggested that the biological effects were breach-related, but it was uncertain whether the effects were physical (due to smothering and/or low dissolved oxygen and low TOC content) or chemical (Minnow 2015a). Monitoring in 2015 and 2016 documented some recovery in mean organism density at the near-field (216 to 588 organisms/m^2 in 2015 and 2016, respectively), and far-field areas (266 organisms/m^2 in 2016; Figure 5), however density remained significantly lower than reference (Figure 5; Minnow 2016b, 2017a). Recovery of taxon richness was also documented (particularly at the near-field area; 4.6 to 6.2 taxa in 2015 and 2016, respectively), although differences in community composition remain (Minnow 2017a). Sediment transplant experiments indicated an increase in organism density and richness in exposed area sediment transplanted to the reference area, suggesting that sediment quality is not prohibitive of re-colonization (Minnow 2016b).

2.3.2 Tissue Quality

Benthic invertebrate tissue quality in Quesnel Lake was not assessed as part of baseline studies (1989-1996) for the Mount Polley mine (Table 2). Monitoring was initiated in 2012 as part of the ongoing characterization of selenium incorporation into the aquatic food chain in the vicinity of the Mount Polley Mine (see Sections 2.1.2 and 2.2.1). Sampling documented mean tissue selenium concentrations below the BCWQG in all areas of Quesnel Lake; 1.7 mg/kg dw near the Hazeltine Creek outlet, and 2.1 mg/kg dw at a reference area in the north arm of the lake (Minnow 2013a).

Following the TSF embankment breach, mean concentrations of all analytes identified as POIs and IPs in benthic invertebrate tissue (see Section 2.1.2) at the exposed shallow and deep areas of Quesnel Lake were similar to reference (including selenium), with the exception of copper which was significantly higher than reference at the deep exposed area in both 2015 and 2016 (147 to 178 mg/kg dw at exposed areas; 40 to 54.9 mg/kg dw at reference; Figure 3; Minnow 2016a, 2017b). As described previously (Section 2.1.2), these elevated benthic invertebrate concentrations could be attributed to higher sediment copper concentrations observed in this area and the confounding influence of gut contents (i.e., Chapman 1985; 2016). BSAFs for copper in the Quesnel Lake deep areas indicated relatively similar bioavailability between the exposed and reference areas (Minnow 2016a, 2017b), which is consistent with results of labile copper concentrations determined by DGTs (Minnow 2016d, Minnow 2017c).

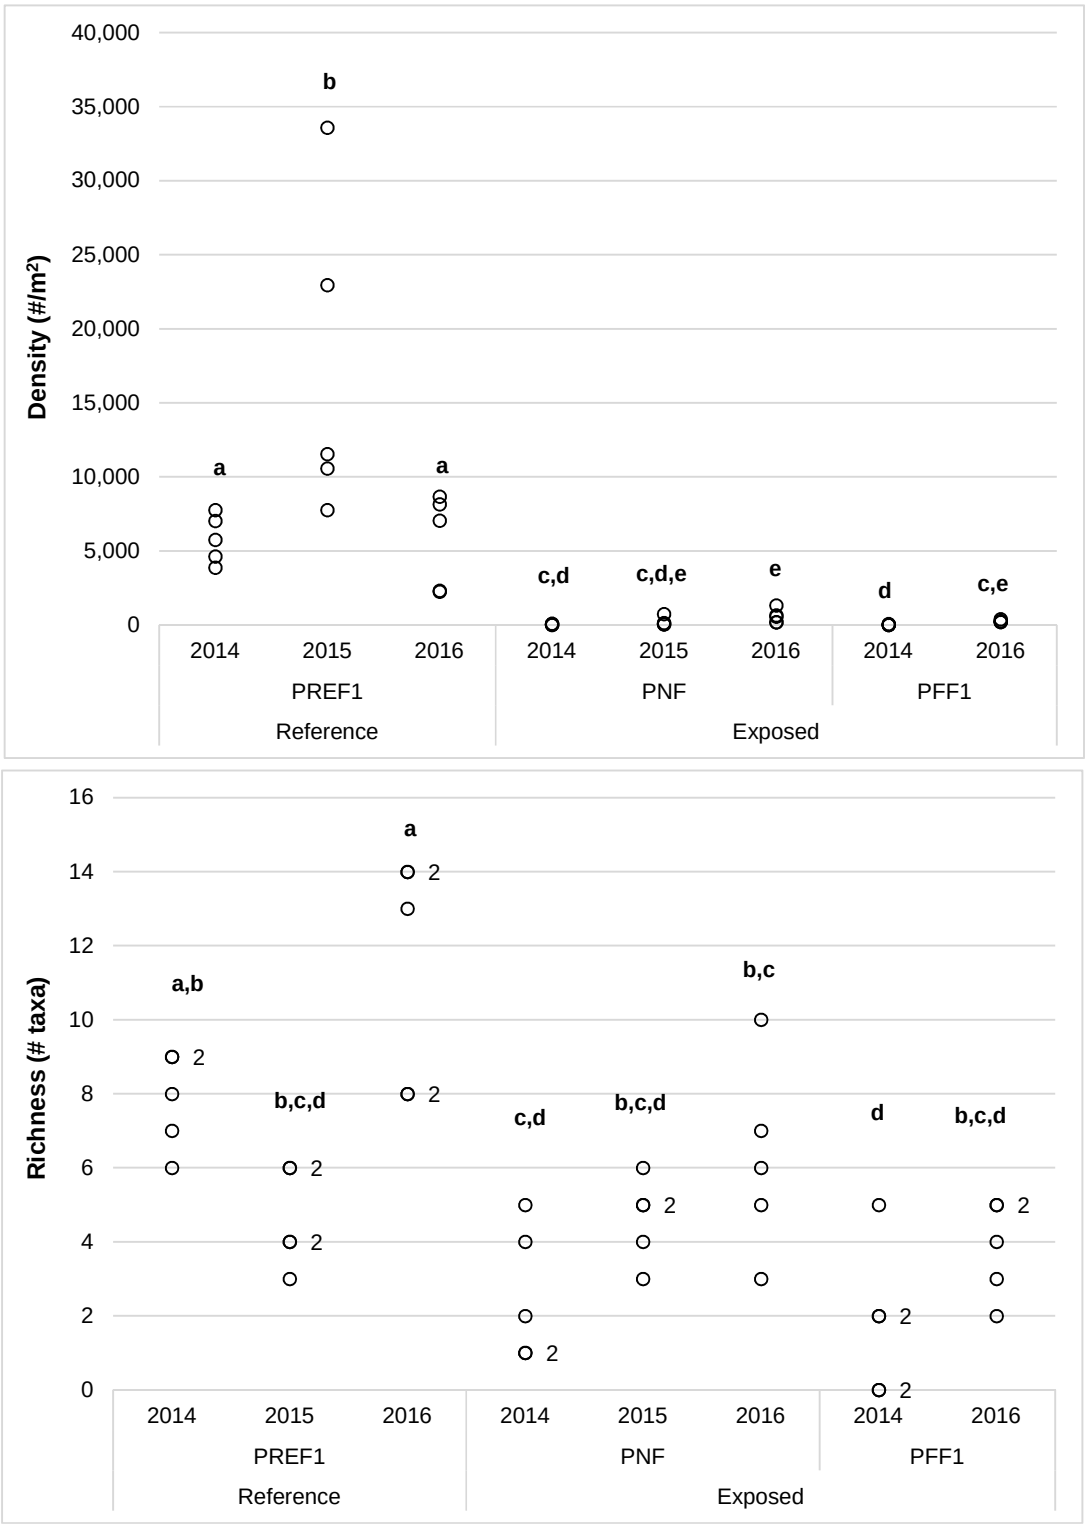

Figure 5: Benthic Invertebrate Community Endpoints in Quesnel Lake Deep Areas, Mount Polley Mine, 2014-2016 [a]

[a] Values shown beside data points indicate number of stations sharing a similar result. Areas not sharing a letter differed significantly ($p < 0.1$).

Note: Sample size = 5.

3 STUDY DESIGN OVERVIEW AND RATIONALE

Benthic invertebrate monitoring under the CEMP is designed to meet the combined needs of: 1) operational monitoring (including the discharge of treated effluent to Quesnel Lake); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to reclamation activity following the TSF embankment breach. An overview of the proposed benthic invertebrate monitoring program is provided in Table 3, and includes benthic invertebrate community, productivity, and tissue quality. Benthic invertebrate monitoring is focused on Polley Lake, Hazeltine Creek, lower Edney Creek, Quesnel Lake, and associated reference areas (Figures 6 and 7).

3.1 Community and Productivity

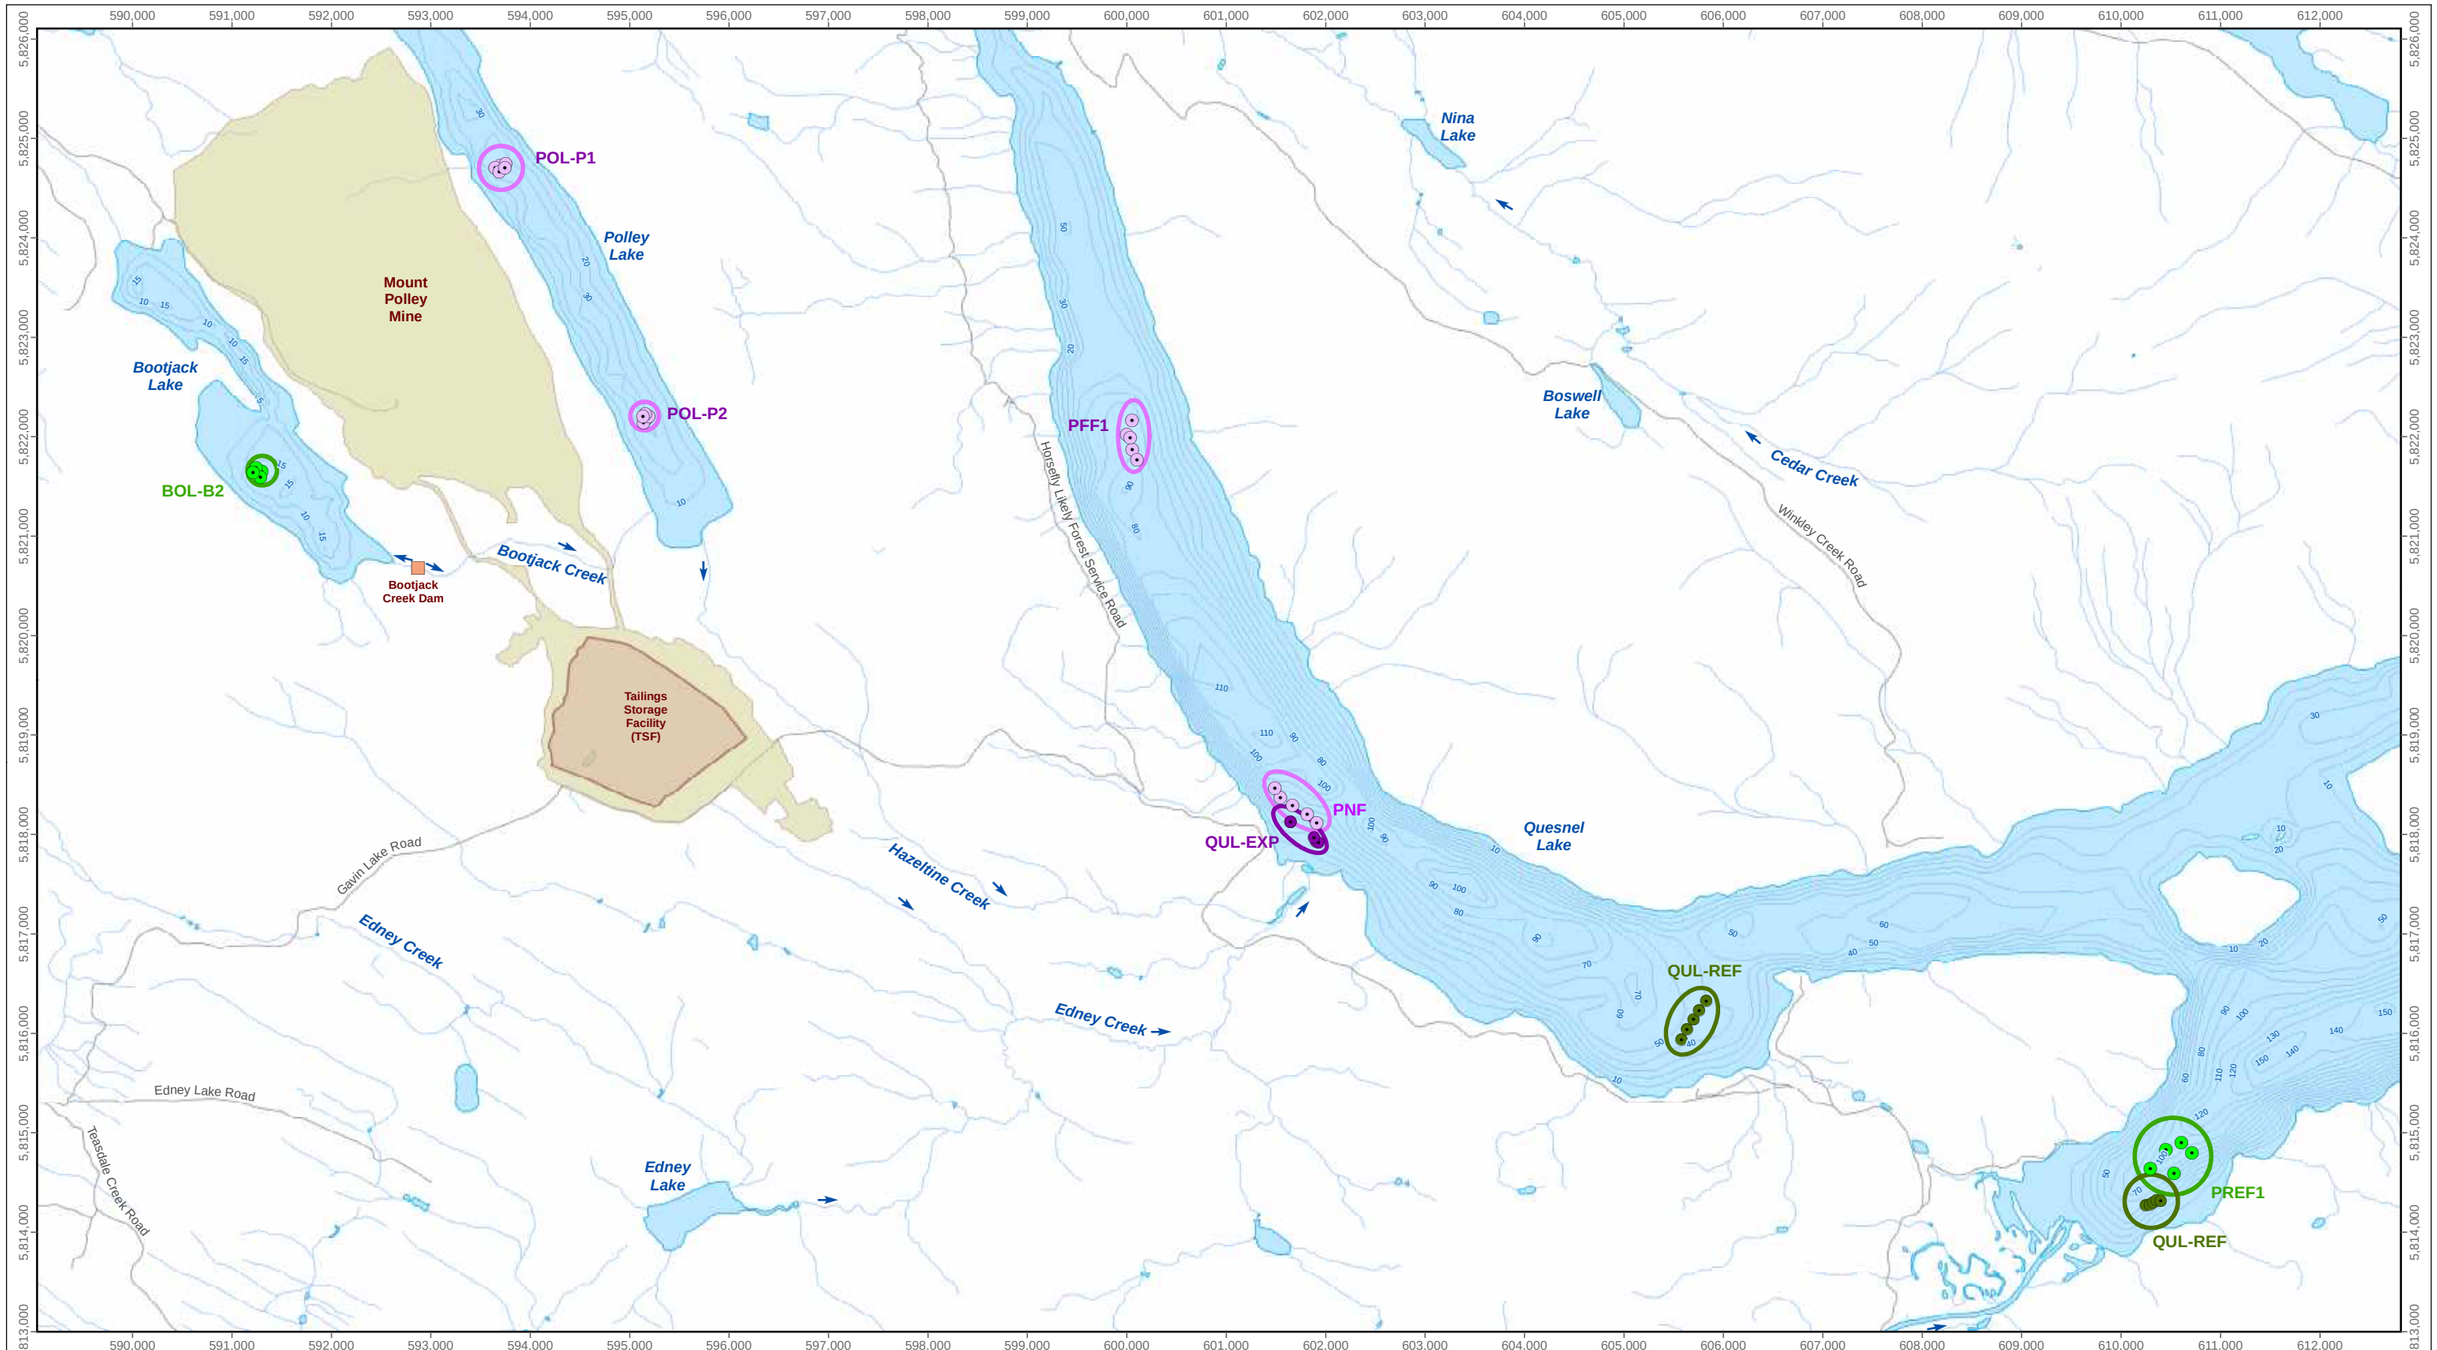
3.1.1 Lakes

Benthic invertebrate community monitoring in lakes is focused on Polley Lake and Quesnel Lake, with reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake for Polley Lake, unaffected areas of Quesnel Lake for impacted areas of Quesnel Lake; Table 3; Figure 6). In Polley Lake, benthic invertebrate community sampling will focus on the two basins (deepest locations in Polley Lake, representing locations of sediment accumulation/fate, and long-term monitoring locations), with the deepest location in Bootjack Lake serving as reference. In Quesnel Lake, benthic invertebrate community sampling for MDMER EEM will focus on the area near the point of effluent discharge (per Minnow 2016e) with two areas serving as reference (one unaffected by the breach and one affected by the breach but outside of the influence of effluent discharge; Minnow 2018c). Sediment investigations following the TSF embankment breach indicated that the majority of breach-derived material was deposited to deep habitat of Quesnel Lake (Minnow 2015a,b, 2016c), therefore benthic invertebrate community sampling in Quesnel Lake will focus on the deep areas that were previously monitored as near-field and far-field areas, with concurrent sampling of suitable reference areas.

Benthic invertebrate community sampling will be completed in August or September using a petite-ponar, consistent with previous data collections (HKP 1996, 1997; Beak 2000; Minnow 2015a, 2016b,e, 2017a), and with technical guidance (e.g., Environment Canada 2012a; BCMOE 2013, 2016). Detailed methodology is provided in Section 4, including: quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting. Sampling will be supported by sediment quality sampling (see CEMP Section 6.12), measurements of *in situ* water quality near the sediment-water interface (temperature, dissolved oxygen, pH, and specific conductance), water depth, GPS coordinates, and supporting photographs at all sampling stations. Data

Table 3: Mount Polley CEMP Benthic Invertebrate Monitoring Program Overview

A) Lakes



Water Body	Sampling Area	Type	Components [a]	Replication [b]	Rationale
Polley Lake	POL - P1 (Northwest Basin)	Exposed	T	5	immediately adjacent to mine and breach-influenced
	POL - P2 (Southeast Basin)	Exposed	T	5	immediately adjacent to mine and breach-influenced
Bootjack Lake	BOL - B2 (Southeast Basin)	Reference	T	5	reference for Polley Lake
Quesnel Lake	QUL - EEMNF	Exposed	T	5	adjacent to effluent discharge and breach-influenced
	QUL - EEMREF1	Reference	T	5	reference for EEMNF - breach-influenced reference
	QUL - EEMREF2	Reference	T	5	reference for EEMNF - non-breach-influenced reference
	QUL - PNF	Exposed	T	5	breach-influenced deep habitat
	QUL - PFF1	Exposed	T	5	breach influenced deep habitat
	QUL - PREF1	Reference	T	5	reference for exposed deep habitat areas of Quesnel Lake

[a] Core benthic invertebrate monitoring components: T = community taxonomy (Lowest-Practicable-Level).
[b] Number of replicate stations within the specified sampling area.

B) Creeks

Water Body	Sampling Area	Type	Monitoring Frequency	Components [a]	Replication [b]			Rationale
					T	P	C	
Hazeltine Creek	HAC-R1 (Upper, Reach 1)	Exposed	Annual	T,P,C	5	5	8	adjacent to mine and breach-influenced
	HAC-U (Upper)	Exposed	Annual	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
	HAC-D (Lower)	Exposed	Bi-annual [c]	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
Frypan Creek	FPC-R3 (Reach 3)	Reference	2018 only	P, C	-	5	8	reference for upper Hazeltine Creek
Edney Creek	EDC-U (Upper)	Reference	Annual	T,P,C	5	5	8	reference for upper Hazeltine Creek
	E1 (Lower)	Exposed	Bi-annual [c]	T,P	5	5	-	adjacent to mine and breach-influenced
	EDC-D (Lower, unimpacted)	Reference	Bi-annual [c]	T,P,C	5	5	8	reference for lower Hazeltine Creek [d]

[a] Core benthic invertebrate monitoring components: T = community taxonomy (Lowest-Practicable-Level), P = productivity (wet and dry benthic biomass), and C = chemistry (see Table 4 for analytes).
[b] Number of replicate stations within the specified sampling area for a given program component.
[c] Bi-annual indicates sampling will occur every other year for all parameters indicated with the exception of tissue chemistry, which will be monitored annually. The next bi-annual sampling event will occur in 2019.
[d] Lower Edney Creek reference area will be located in an unimpacted area upstream of the breach influence (see Figure 7).

interpretation will be based on a combination of: 1) statistical comparison to previous conditions; and 2) statistical comparison to reference conditions. Accordingly, five stations per area are proposed for each sampling area to provide replication for the statistical contrasts.

The frequency of benthic invertebrate community monitoring at the federal EEM sampling areas in Quesnel Lake (to evaluate potential effects of effluent discharge) is initially at a prescribed frequency of every three years, subject to modification based on the findings of at least two EEM phases (Environment Canada 2012a). Additional benthic invertebrate community sampling in Quesnel Lake and Polley Lake (not associated with EEM) will also initially be completed in 2018 and then every three years concurrent with EEM (2018, 2021, etc.). Based on results of benthic invertebrate community monitoring undertaken from 2014 to 2017 which demonstrated some recovery following the TSF embankment breach (see Section 2 for details), and on low sediment deposition rates documented in Polley Lake and Quesnel Lake (see CEMP Section 6.12), it is anticipated that a three-year frequency will be sufficient to track benthic invertebrate recovery. Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) may be made in response to QP recommendations. These may include further reduction in monitoring frequency if continued recovery of benthic community results relative to reference is demonstrated.

3.1.2 Creeks

Benthic invertebrate community monitoring in creeks is focused on rehabilitated areas of Hazeltine Creek and lower Edney Creek, with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and an unaffected area of lower Edney Creek for rehabilitated areas of lower Edney Creek and lower Hazeltine Creek; Table 3; Figure 7). Benthic invertebrate monitoring in Hazeltine Creek will focus on three areas (Figure 7)[3], including one area in Reach 1 (HAC-R1; where rehabilitation was completed in 2016), one area in Reach 2 (HAC-U; where rehabilitation was completed in 2017), and one area in lower Hazeltine Creek (HAC-D; where initial rehabilitation activities have been completed but additional rehabilitation will be conducted). The locations of sampling areas in upper and lower Hazeltine Creek (HAC-U and HAC-D) are generally consistent with those monitored prior to the TSF embankment breach, as is the location of the upper Edney Creek reference area (UER; Figure 7). Monitoring in lower Edney Creek will focus on one rehabilitated area (E1; where rehabilitation was completed in 2015). Suitable reference areas will be sampled concurrently. In Frypan Creek, the reference sampling area was selected to match habitat

[3] Note that previous creek sampling station locations are presented in Figure 7. These locations may change slightly depending on substrate, water depth, and water velocity. Similarly, conceptual station locations are displayed for Frypan Creek and Upper Edney reference areas, and will be established during the field campaign.

conditions in upper Hazeltine Creek as closely as possible, based on results of preliminary fish habitat assessment and benthic invertebrate monitoring (area selection was based primarily on substrate type and size; Minnow 2018d). The location of all benthic invertebrate community sampling stations will align with those proposed for periphyton monitoring (see CEMP Section 6.15).

Benthic invertebrate community sampling will be completed in August or September using a Hess or Surber sampler[4], consistent with previous data collections (HKP 1996, 1997; Beak 2000; Minnow 2009, 2016b, 2017a, 2018a). Detailed methodology is provided in Section 4. All benthic invertebrate community samples collected from creeks will also be evaluated for benthic invertebrate productivity (biomass; through the documentation of benthic invertebrate community sample weight by the laboratory) for the purposes of relating productivity to the assessment of fish habitat. Sampling at each station will be supported by measures of sampling depth, water velocity, in situ water quality measurements (as outlined in Section 3.1.1), GPS coordinates, notes of the presence of aquatic vegetation/bryophytes on sampled substrate and other physical observations, and supporting photographs of the sampling location and samples. Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (i.e., Frypan Creek and upper Edney reference). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; and 2) statistical comparison to reference conditions. Accordingly, five stations per area are proposed to provide replication for the statistical contrasts.

The initial frequency of benthic invertebrate community and productivity monitoring in Reaches 1 and 2 of upper Hazeltine Creek (and associated reference areas) is annual given the recent disturbance to these rehabilitated areas, and recent reopening of upper Hazeltine Creek as fish habitat to Polley Lake fish. The frequency in rehabilitated areas of lower Hazeltine Creek and lower Edney Creek (and associated reference areas) is every second year because these areas have been undisturbed since 2015 and the benthic community monitoring in these areas has demonstrated recovery (Minnow 2016b, 2017a, 2018a; see Section 2.2). Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) may be made in response to QP recommendations. If results indicate stabilizing benthic communities and productivity during this period, then a reduction of monitoring frequency to every second year will be considered for upper Hazeltine Creek areas. The Frypan Creek reference area will only be sampled in 2018 (Table 3) to provide

[4] If sufficient sampling locations with habitat attributes suitable for Hess/Surber sampling cannot be located (particularly in the recently rehabilitated areas of upper Hazeltine Creek), kick and sweep sampling consistent with CABIN guidance (Environment Canada 2012a) may be implemented instead of Hess/Surber sampling.

comparison for benthic community data from upper Hazeltine Creek following the initial reopening of upper Hazeltine Creek as fish habitat (Minnow 2018e).

3.2 Tissue Quality

Benthic invertebrate tissue quality monitoring is focused on upper and lower areas of Hazeltine Creek, with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and lower Edney Creek for lower Hazeltine Creek; Table 3; Figure 7). Benthic invertebrate tissue quality monitoring in Hazeltine Creek is undertaken to monitor the combined influence of uncontrolled surface runoff from the north dump and downstream influence on Hazeltine Creek (which occurred from 2006 to 2009), the conveyance of mine effluent between December 2015 to December 2017, and the TSF embankment breach. Benthic invertebrate tissue quality monitoring will focus on three areas of Hazeltine Creek, including one area in Reach 1 (HAC-R1) and one in Reach 2 (HAC-U) of upper Hazeltine Creek, and one area in lower Hazeltine Creek (HAC-D). As described in Section 3.1.2, the locations of sampling areas in upper and lower Hazeltine Creek are generally consistent with those monitored prior to the TSF embankment breach (Figure 7). It should be noted that sampling areas HAC-U and HAC-D were previously exposed to the discharge of treated mine effluent (December 2015 to December 2017), whereas HAC-R1 is located upstream of the previous discharge point (Figure 7). As of November 2017, treated effluent is no longer discharged into Hazeltine Creek, and upper Hazeltine Creek has been reopened as fish habitat to Polley Lake fish as of spring 2018.

Benthic invertebrate tissue quality sampling will be completed in August or September concurrent with benthic invertebrate community sample collections described in Section 3.1.2, and will be consistent with previous data collections (Minnow 2011, 2013a,b, 2016a, 2017b, 2018b). Tissue samples collected from each station will include one composite-taxa sample that contains a mixture of taxa that is proportional to biomass at the station, and one single-taxon sample[5] (e.g., a sample of only one taxon). Composite-taxa benthic invertebrate tissue samples are reflective of dietary exposure for fish, and can therefore be used in assessment of fish habitat. Alternatively, single-taxon samples are beneficial for limiting variability associated with different benthic invertebrate taxon composition. The collection of both sample types will ensure temporal comparability with previous data collections which have included both composite-taxa and single-taxon tissue samples (e.g., Minnow 2011, 2013a,b, 2016a, 2017b, 2018b). Tissues will be collected for the analytical determination of moisture content, metals, and mercury (Section 4.3.2). Supporting measures at each station will include *in situ* water quality measurements as outlined

[5] Single-taxon sampling will be completed only if adequate sample material from any one taxon can be collected with a reasonable sampling effort.

above (Section 3.1.1), GPS coordinates, physical observations, and supporting photographs. Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (i.e., Frypan Creek and upper Edney reference areas). Data interpretation for all parameters will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) comparison relative to BCWQG (i.e., tissue selenium concentrations; BCMOE 2014). A replication level of eight samples per area will be used to support the statistical contrasts.

The initial frequency of benthic invertebrate tissue quality monitoring at Hazeltine Creek (and associated reference areas) is annual given the recent disturbance of upper creek areas related to rehabilitation activities, and changes to the effluent exposure status. Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) may be made in response to QP recommendations. If results indicate stabilizing or decreasing benthic tissue concentrations during this period, then a reduction of monitoring frequency to every second year will be considered. The Frypan Creek reference area which is included for comparison with upper Hazeltine Creek will be sampled in 2018 only (see Table 3). Benthic invertebrate tissue quality sampling at this reference area will support rainbow trout tissue quality sampling in these areas only in 2018 following the initial reopening of upper Hazeltine Creek as fish habitat (Minnow 2018e).

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be performed by qualified field staff experienced in the implementation of benthic invertebrate community, productivity, and tissue chemistry monitoring programs. All sample collection, quality assurance and quality control, and laboratory analysis methods will be implemented in accordance with technical guidance (BCMOE 2013, 2015, 2016). Specifically, quality assurance and quality control measures will include program review prior implementation, adequate resources for all field teams including field checklists and field data sheets, the availability and maintenance of clean sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination.

Quality control (QC) samples will be collected to support the benthic invertebrate tissue quality monitoring program. To capture within-area variability, eight replicate composite-taxa and up to eight replicate single-taxa tissue quality samples will be collected from each sampling area. Field duplicate samples (i.e. splits samples of the benthic invertebrate tissue collected from one sampling station) will be collected for 10% of samples to assess field precision as part of the Data Quality Review (DQR; Section 4.4). Duplicate water samples will be collected at a frequency of 10% to assess field precision associated with the water samples that support benthic invertebrate community and tissue quality monitoring. In addition to field QA/QC, the laboratory responsible for chemical analyses will be accredited by the Canadian Association for Laboratory Accreditation (CALA) for these analyses. Specific QC sampling and associated reporting for tissue quality results will be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). Laboratory Reporting Limits (LRLs) will also be evaluated in comparison to targets established by the analytical laboratory.

QC samples to assess field precision (field duplicates) will not be collected for benthic community or productivity monitoring endpoints due to the high inherent natural variability of these parameters. However, composite benthic invertebrate community samples will be collected at all sampling locations to ensure that each sample is representative of the station. Taxonomic identification of benthic invertebrate community samples will be completed by a qualified laboratory certified under the Taxonomic Certification Program of the Society for Freshwater Science (SFS; formerly the North American Benthological Society). Quality control for benthic invertebrate taxonomic analyses will be consistent with federal requirements for metal mining EEM (Environment Canada 2012a). Specific QC sampling and associated reporting will be requested from the taxonomic laboratory, including an assessment of sub-sampling error, sorting

efficiency, and identification accuracy (Environment Canada 2012a, 2014). These results will be assessed as part of the DQR (Section 4.4).

All raw field data will be transcribed from field sheets into an electronic spreadsheet. Data will then checked by a separate individual for data entry errors as part of routine Quality Assurance/Quality Control (QA/QC) procedures.

4.2 Sample Collection Methods

4.2.1 Community and Productivity

Benthic invertebrate sampling in lakes for community analysis will be collected using a stainless steel petite ponar grab sampler, consistent with previous monitoring (e.g., Minnow 2015a, 2016b,d, 2017a, 2018a) and in accordance with provincial and federal technical guidance (i.e., BCMOE 2013; Environment Canada 2012a). Briefly, the petite ponar is a 6" x 6" (15.24 cm x 15.24 cm) grab sampler with jaws that can be held open by shear-pressure on a spring-loaded pin. The grab sampler is lowered to the substrate at which point shear-pressure is eliminated and the pin springs out. Upon upward pull at the initiation of retrieval, the jaws of the ponar close to grab surficial sediment. Care must be taken to control the rate at which the petite ponar is lowered to allow appropriate sediment penetration and to minimize sediment disturbance. The petite ponar will be carefully retrieved to surface and each grab will be placed into a plastic tote and observed for completeness and any unusual characteristics. In Quesnel Lake, samples will be retrieved with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). Only high quality, comparable samples will be retained. If the sample is deemed acceptable, the sample will rinsed from the ponar into the tub to ensure the complete removal of all material The sample material will then be placed into a 250 µm mesh sieve bag and sieved free of all material less than 250 µm in diameter. At each station, a composite sample of five acceptable grabs will be collected (0.116 m^2 of bottom area in total) to ensure that each sample is representative of the station. After sieving, the retained material (sample) from the five composited grabs will then be carefully transferred to 1 or 2-L wide mouth plastic jars using a wash bottle while working over a plastic tub to avoid any potential loss of organisms. Any organisms that adhere to the inside of the sieve bag will be retrieved and added to the sample jar. Each jar will receive an internal and external label with the station number, area identifier, project number, date, and the initials of the field personnel. Each sample will be preserved with a 10% buffered formalin solution within six hours of collection to eliminate the potential effects of within-sample predation, which could affect abundance estimates. Sampling will be conducted at five replicate stations in each area (see Table 3).

Supporting information collected at all lake sampling stations will include sediment quality measures (see CEMP Section 6.12), GPS (Geographic Positioning System) coordinates; water depth; *in situ* water quality near the sediment-water interface (temperature, dissolved oxygen, pH, and specific conductance), site and sample photographs, notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). In addition, a full vertical profile of the field meter measurements will collected at one station per area. Supporting water samples will also be collected from each sampling area associated with EEM (see Table 3), including samples for total and dissolved constituents (including metals), the latter prepared by field filtration using a 0.45 µm syringe filter. Water samples will be placed into a dedicated cooler with frozen ice packs, and kept cool prior to transport to the field laboratory.

Sampling of benthic invertebrates in creeks for community and productivity analysis will be consistent with previous monitoring (e.g., Minnow 2009, 2016b, 2017a, 2018a), and with technical guidance (BCMOE 2013). A Hess sampler with a 0.1 m^2 diameter and upstream (incurrent) and downstream (excurrent) openings will be used if water depth allows. The incurrent opening will be covered with a mesh to prevent contamination of the sample with organisms from upstream. The excurrent opening will consist of a conical net equipped with 250 µm mesh attached to a removable collection cup that has mesh on the downstream end to allow water to exit. If creek environments are too shallow to accommodate Hess sampling, a Surber sampler (30.5 x 30.5 cm; 0.093 m^2) equipped with 250 µm mesh will be used. Each Hess/Surber sample will be collected by firmly and carefully placing the sampler on undisturbed substrate to a depth of 5 to 10 cm. All cobble and gravel within the sampler area (to a depth of approximately 10 cm) will be scrubbed and the current will be allowed to carry all dislodged organisms into the 250 µm net. The sampler net and collection cup will be rinsed and the contents will be carefully transferred to internally and externally labelled 1 or 2 L wide mouth plastic jars. Any remaining invertebrates found clinging to the sampling equipment will be removed and placed in the sample jar. At each station, one composite sample of three sub-samples (i.e., approximately 0.3 m^2 of creek surface area if a Hess sampler is used, 0.279 m^2 if a Surber sampler is used) will be collected to ensure that each sample is representative of the station. Each sample will be preserved with a 10% buffered formalin solution as described above. Sampling will be conducted at five replicate stations in each area (see Table 3), and each station will be established at a minimum distance of approximately three bankfull widths from adjacent stations, where habitat allows. A concerted effort will be made to

ensure that water velocity, water depth, and substrate characteristics are comparable among sub-samples and among respective stations to minimize natural influences on community variability[6].

Supporting information collected at each creek sampling station will include those parameters listed above for lakes, with the addition of substrate size measurements wherein 100 randomly selected substrate pebbles per station will be measured along their intermediate axis and the percent embeddedness 10% of the pebbles will be recorded, consistent with the CABIN protocol (Environment Canada 2012b). Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (e.g., in Frypan Creek and upper Edney Creek). Water samples will be collected as described above.

4.2.2 Tissue Quality

Benthic invertebrate tissue samples will be collected using a combination of hand picking and kick-and-sweep, consistent with previous monitoring (e.g., Minnow 2011, 2013a,b, 2016a, 2017b, 2018b) and with technical guidance (e.g., BCMOE 2016). Hand picking entails overturning rocks in the streambed and collecting any of benthic invertebrates observed. The kick-and-sweep method involves a field technician moving upstream and across the stream channel (in a zig-zag pattern) while holding a kick net (a net with a triangular opening and a 400 µm mesh bag) immediately downstream, and disturbing the substrate with his or her feet to dislodge benthic organisms into the net (a method modified from the Canadian Aquatic Biomonitoring Network [CABIN] 3-minute travelling kick-and-sweep; Environment Canada 2012b). The net will then be rinsed with water to move all debris and invertebrates to the collection cup at the bottom of the net. The collection cup will be removed and its contents (i.e., invertebrates and debris) will be placed into a plastic tote. Organisms will then be picked free of debris, and transferred into a labeled scintillation vial, without rinsing, to minimize the amount of water in each sample. One composite-taxa sample (containing a mixture of taxa that is proportional to biomass at the station), and one single-taxon sample (containing one taxon only) will be collected at each station. As possible, the taxa selected for the single-taxon samples will be consistent among sampling areas, and consistent with previous monitoring (Minnow 2017b, 2018b). However, single-taxon sampling will only be completed at each station if adequate sample material can be collected with a reasonable sampling effort[7]. Sampling will be conducted at eight replicate stations in each area

[6] If five stations with closely matching habitat attributes cannot be located (particularly in the recently rehabilitated areas of upper Hazeltine Creek), kick and sweep sampling consistent with CABIN guidance (Environment Canada 2012a) may be implemented instead of Hess/Surber sampling.

[7] A reasonable sampling effort will be considered approximately 1 hour per sample. If sample collection is nearly complete within this time frame, additional sampling effort will be applied to complete the sample collection.

(see Table 3). Samples will stored in a cooler containing ice packs for transport to the mine, where they will be frozen.

4.3 Sample Handling and Laboratory Analysis

4.3.1 Community and Productivity

Preserved benthic invertebrate community samples will be stored at room temperature until shipment to the laboratory for taxonomic identification and enumeration. Samples will be shipped with completed Chain-of-Custody (COC) forms immediately after the completion of the field campaign, however there are no recommended hold times for analysis.

Taxonomic identification of benthic invertebrate community samples will be completed by a qualified laboratory using standard methods that incorporate QA/QC measures (e.g., Environment Canada 2012a; 2014). Upon sample receipt, the laboratory will provide a sample receipt confirmation which will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. All samples will be sieved and processed in the laboratory using the same mesh size as used in during field collections (250 µm), with the exception of those collected for MDMER EEM which will be identified and enumerated based on both the 250 µm and 500 µm fractions (Minnow 2018c). If the estimated number of invertebrates in a sample is greater than 600 individuals and the sample is fine and non-clumping, a subsample will be taken using a Marchant Box (Marchant 1989) as described by Environment Canada (2014). Samples (or sub-samples) will then be sorted using a gridded Petri dish under a low power stereo microscope into family/order while maintaining counts (but totals exclude Porifera, Nemata, Platyhelminthes, Ostracoda, Copepoda, Cladocera, and any terrestrial drop-ins). All samples will be processed to a minimum 300 organism count, and if 300 organisms have not been reached by the 50th cell of the Marchant Box, then the entire sample will be sorted (i.e., all 100 cells). All sorted organisms will be stored in 80% ethanol by family/order in separate labeled vials and debris will be preserved and labeled separately. Identifications of all insects to the lowest practicable level (LPL; typically genus or species) and non-insects to the genus/species level (where possible, but to a minimum of family level) will be conducted by experienced, certified taxonomists using up-to-date taxonomic keys, comparisons to an externally-verified reference collection, and effort lists compiled by CABIN, SAFIT (Southwest Association of Freshwater Invertebrate Taxonomists), and PNAMP (Pacific Northwest Aquatic Monitoring Partnership). Following identification, representative specimens may be preserved and retained for inclusion in a voucher collection for Mount Polley.

Following taxonomic identification, the wet and dry biomass of total organisms in each sample from creek environments (benthic invertebrate productivity) will be determined. For wet biomass,

samples will be poured through a piece of pre-weighed 212 µm Nitex mesh and dried gently between two pieces of absorbent paper. Each sample will then be weighed to the nearest 0.0001 g, and the weight of the mesh will be subtracted from the total weight to determine total sample wet weight. For dry biomass, wet samples will be then placed on a piece of pre-dried and pre-weighed glass fiber filter before being dried at 160^0F (71°C) for six hours. Following a short period of cooling, samples will be weighed as described above, and total sample dry weight will be calculated.

4.3.2 Tissue Quality

Benthic invertebrate tissue quality samples will remain frozen until overnight shipment on ice with completed COCs to ALS Environmental, Burnaby BC; an analytical laboratory accredited by the Canadian Association for Laboratory Accreditation (CALA). Samples will be sent to the laboratory with sufficient time to complete analyses within the recommended sample hold times. Analyses will be completed using methods that are consistent with those specified in the British Columbia Environmental Laboratory Manual (BCMOE 2015). Upon sample receipt, the laboratory will provide a sample receipt confirmation when the samples are received and logged. These receipts will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. Tissue quality samples will be analysed for metals by CRC-ICP-MS (Collision Cell Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/6020A [USEPA 2004]) or HR-ICP-MS (High Resolution Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/ 200.8 [USEPA 1994]), mercury by CVAFS (Cold Vapour Atomic Fluorescence Spectrophotometry; USEPA Method 200.3 [USEPA 1991]/Method 245.7 [USEPA 2001]), and moisture content. The method selected for metals analysis will depend on sample weight, with HR-ICP-MS employed for smaller sample sizes. Tissue quality analytes are provided in Table 4, with the associated target LRLs, detection limit objectives outlined in technical guidance (“consensus detection limits”; BCMOE 2016), and available BCWQG (i.e., selenium; BCMOE 2014). Upon completion of the analyses, the laboratory will provide a data report in Microsoft (MS) Excel™ and as an Adobe Acrobat Portable Document Format (PDF). Reporting will include the results of the laboratory QC sample results.

4.4 Data Quality Review

Upon receipt of all analytical data, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs have been achieved. The DQR will also include an evaluation of differences between duplicate (split) samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the benthic invertebrate monitoring data will ensure timely communication with the laboratory should any issues be identified

Table 4: Target Laboratory Reporting Limits (LRL) and Analytical Methods for Benthic Invertebrate Tissue Quality Analytes

[a] From Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators (BCMOE 2016).

[b] British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture (BCMOE 2018).

[c] Method for total mercury analysis will be according to USEPA (1991, 2001).

For benthic invertebrate tissue quality samples, LRLs will be evaluated relative to targets established for the analytes, to "consensus detection limits" (Table 4), and to relevant British Columbia guidelines (i.e., selenium; BCMOE 2014). Comparisons between duplicate samples will be made by calculating the relative percent difference (RPD) of metal concentrations between paired duplicates. If the RPD is <25% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Results for laboratory blanks, precision, and accuracy will be evaluated relative to Data Quality Objectives (DQO) established by the analytical laboratory that performed the analyses. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping). For benthic invertebrate community samples, reanalysis for quality control endpoints (organism sorting efficiency, subsampling precision and accuracy error, and taxonomic identification error) will be performed on 10% of samples, and results of quality control measures will be evaluated relative to pre-established DQOs. Specifically, evaluation of organism sorting efficiency will involve reprocessing previously sorted material from randomly selected samples, and then determining the number of invertebrates that were not recovered during processing of the original sample, and an efficiency of < 10% missed organisms will be considered acceptable. Evaluation of subsampling error provides a measure of analytical accuracy by comparing the numbers of benthic invertebrates recovered between at least two sub-samples, and of analytical precision by comparing sub-sample derived benthic invertebrate community numbers with the densities determined for whole benthic invertebrate community samples. An error of < 20% will be considered acceptable for subsampling accuracy and precision. Evaluation of taxonomic identification error involves an internal quality control audit of taxonomic identification results whereby blind re-enumeration and re-identification of random samples will be performed by an analyst not involved in the original sample processing, and an error of < 5% for this endpoint will be considered acceptable.

4.5 Data Handling and Interpretation

Upon receipt of data from the analytical laboratories, all laboratory data files will be managed by the Mount Polley Mining Corporation (MPMC) Environment Department. In addition, chemical data provided by the primary analytical laboratories as an Electronic Data Deliverable (EDD) will be imported directly into the MPMC's database following completion of the DQR. Following the data quality review described above (Section 4.4), all benthic invertebrate community, benthic invertebrate tissue chemistry data, and supporting data will be managed in Microsoft (MS) Excel™. For all replicated data (typically based on a sample size of five or eight stations per area), data will be provided to the QP for analysis and summarized by calculating mean, median,

standard deviation, minimum, and maximum for each endpoint. Data analysis will be completed for each monitoring component (community, productivity, and tissue quality).

4.5.1 Community and Productivity

Benthic invertebrate communities will be evaluated using metrics of organism density (organisms per m²; grab samples, and Hess/Surber samples) or abundance[8] (organisms per sample; kick-and-sweep samples), taxonomic richness, Simpson's Index of Diversity, Simpson's Index of Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012a). The Bray-Curtis Index of Dissimilarity will also be used in the evaluation of samples collected for MDMER EEM as per technical guidance (Environment Canada 2012a). These primary indices will be calculated at the LPL of taxonomy for the 250 µm fraction of all samples, with the exception of samples collected for EEM which will be calculated using family-level data for the 500 µm sample fraction (Minnow 2018c). The densities and relative densities of the most abundant taxa will also be calculated (relative densities calculated as the abundance of each respective dominant/indicator taxon relative to the total number of organisms in the sample and expressed as a percentage). Dominant/indicator taxon groups will be defined as those groups representing more than 5% of total organism abundance within each set of areas being compared, or any taxon groups considered to be important indicators of environmental stress. In addition, benthic invertebrate productivity in creeks will also be evaluated using wet and dry total biomass converted to a standard area-based measurement (g/m^2). Summary statistics for all endpoints will be reported by area and year as described above (sample size, mean, median, minimum, maximum, and standard deviation).

Correspondence analysis (CA) or Nonmetric Multidimensional Scaling (NMDS) multivariate ordination methods will be used to further examine benthic invertebrate community structure. These are multivariate ordination methods used to reduce multivariate data into a manageable number of variables and will be applied to assist in the identification of key spatial or temporal differences in benthic invertebrate community (i.e., which stations have distinct benthic communities but also how these benthic communities differ among stations). The results of these multivariate analyses will be incorporated into the comparison of benthic invertebrate indices described below.

Benthic invertebrate community and productivity metrics from exposed areas will be compared to reference results in a control-impact study design, as well as compared temporally to previous monitoring results if data are available. Comparisons will be completed primarily using Analysis

[8] Abundance (as opposed to density) will be calculated only if kick-and-sweep sampling methods are used in creek due to lack of suitable Hess/Surber sampling habitat. See Section 3.1.2 for details.

of Variance (ANOVA) to test for statistically significant differences. For these analyses, the assumptions of normality and homogeneity of variances will be tested on the residuals of the ANOVA model using the Shapiro-Wilk test and Levene's test based on median values, respectively, using a significance level (α) of 0.1. Data will be transformed as necessary to satisfy assumptions of normality and homogeneity of variance. In instances where the residuals of the ANOVA model do not meet the assumptions of normality and homogeneity of variances, a non-parametric Kruskal-Wallis test will be conducted. When the overall results of an ANOVA or Kruskal-Wallis test are significant, differences between specific areas will be evaluated using post-hoc contrasts for ANOVA or Dunn's test for the Kruskal-Wallis test. A Bonferroni correction on the p-values will be used to conserve the overall Type I error rate. Statistical temporal contrasts may also be completed using Two-Way ANOVA (with factors *Area* and *Year*) if data are available for both the exposed and reference areas for all years being evaluated. For the Two-Way ANOVA model, assumptions of normality and homogeneity will be tested on the residuals of the model as described above using the Shapiro-Wilk test and Levene's test based on median values, respectively ($\alpha = 0.05$). Data will be transformed as necessary to satisfy assumptions of normality and homogeneity of variance and if these assumptions are not met, the analysis will be conducted on ranks (equivalent to a non-parametric test). When the interaction between *Area* and *Year* is significant ($\alpha = 0.1$) the following post-hoc contrasts will be conducted, and when the interaction between *Area* and *Year* is not significant, the effect of area and year will be assessed ($\alpha = 0.1$) using the *Area* and *Year* terms in the ANOVA model. Further detailed analyses will be completed as required for data interpretation, and may include graphical comparisons to reference and historical data, and formal spatial statistical contrasts using methods similar to those described above.

If exposed versus reference or temporal differences in benthic invertebrate community and/or productivity results are noted, potential relationships between benthic invertebrate community metrics and physical and chemical conditions of the study areas will be explored using Spearman correlation (often referred to a Spearman Rank-Order correlation). For lake sampling areas, these physical/chemical endpoints may include results of multivariate statistical analyses used to identify key sediment quality parameters (e.g., CA or PCA axis scores; see CEMP Section 6.12). For most areas, correlation analyses will likely only include data from a single year of sampling in order to focus the analysis on differences between rehabilitated and exposed areas relative to reference, rather than on differences among years. Following the derivation of correlation coefficients, a Bonferroni-type correction (i.e., p-value [0.05] divided by the total number of correlations examined for independent variables) will be applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected p-value of 0.05. Any significant correlations found at the

Bonferroni-adjusted p-value or at a p-value of 0.01 will be further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were "leveraged" by outlying points (or groups of points). Although it is recognized that a significant correlation or regression does not indicate causation (e.g., Norton et al. 2015), it is desirable to not only characterize the nature of a response (e.g., differences in benthic invertebrate community), but to also obtain evidence of cause. Correlation / regression analyses are commonly applied tools for identifying potential cause (e.g., Norton et al. 2015). Evidence of causation obtained from correlation or regression analysis will be carefully considered in light of the strength, range, and continuity of the relationships as well as mechanistic knowledge/understanding of potential cause.

4.5.2 Tissue Quality

Data analysis and interpretation of benthic invertebrate tissue quality results will focus on Parameters of Interest (POIs [representing the chemical influence of the TSF embankment breach on sediment quality]: arsenic, copper, iron, and nickel), and on Indicator Parameters (IPs [identified in evaluations of water, soil, or fish tissue quality for Hazeltine Creek]: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium; Golder 2015b, 2016, Minnow 2015a). Benthic invertebrate tissue quality results for these analytes will be compared to available pre-breach data (for selenium only in 2009, 2012 and 2013, and for all analytes in 2010; Minnow 2011, 2013a,b), contrasted between exposed and reference areas, and also compared temporally within exposed areas. In addition, tissue quality results for selenium will be compared to the relevant BCWQG (BCMOE 2014). Detailed analyses and interpretation related to these comparisons will be completed as required, and may include: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations tissue concentrations (control-impact study design using Analysis of Variance [ANOVA]) as described above. Formal statistical temporal and spatial contrasts may also be completed using ANOVA methods similar to those described for benthic invertebrate community data analysis to augment interpretation, where data allows.

Concentrations of the POIs and IPs in benthic invertebrate tissue will also be evaluated relative to concentrations in water. These ratios of concentrations will be calculated as: [tissue sample concentration]/[dissolved water concentration], and are referred to as Bioconcentration Factors (BCFs). BCFs are often used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes other than diet (i.e., Arnot and Gobas 2006), and are applicable to erosional areas where sediment is generally not present. BCFs will be calculated using tissue metal concentrations (dry weight) and mean dissolved metal concentrations in water from each sampling area. Calculated BCFs will then be qualitatively

compared among areas to identify differences in the uptake of metals by benthic invertebrate in areas impacted by effluent discharge and/or the TSF embankment breach.

Additionally, concentrations of POIs and IPs in benthic invertebrates will be evaluated relative to concentrations in periphyton, based on Trophic Transfer Factors (TTFs; the ratio of tissue concentrations in benthic invertebrates relative to concentrations in periphyton (i.e., TTF = [benthic invertebrate sample]/[periphyton sample]). TTFs can be used to generally describe the extent to which the concentration of an analyte increases between lower and higher trophic levels (e.g., Presser and Luoma 2010). TTFs greater than 1 indicate that the analyte is accumulating in benthic invertebrates to a greater extent than would be expected if ingestion of periphyton was the sole source of that analyte to the benthic invertebrates (assuming uptake and excretion of the analyte by the benthic invertebrates are equal). Co-located observations of benthic invertebrate and periphyton tissue chemistry will be used to calculate TTFs for each replicate station. Comparisons of TTFs will then be made between exposed and reference areas as well as with pre-breach results.

An interpretive report based on the benthic invertebrate monitoring data will be prepared for integration into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

1 INTRODUCTION

1.1 Background

Periphyton represents an important component of aquatic food webs in creeks, and consists of a complex matrix of organisms. Periphyton generally includes algae, fungi, bacteria, and protozoa attached to submerged substrate (e.g., rocks, bedrock, woody debris). These organisms are representative of the lowest trophic level in running water and take up nutrients such as nitrogen (e.g., nitrate, nitrite) and phosphorus (e.g., ortho-phosphate), as well as other substances dissolved in water (e.g., major ions, metals) to serve physiological functions, which thereby become available via dietary pathways to consumer organisms at higher trophic levels. Periphyton productivity and community characteristics can be influenced by factors such as physical disturbance (i.e., changes to surface water hydrology) and water quality (relating to toxicity or changes in productivity due to nutrient chemistry), and periphyton tissue quality can be influenced by water and/or sediment quality (although the latter is primarily present in suspended form in erosional streams). Therefore, periphyton monitoring is an important tool for both the assessment of creek productivity (through measures of periphyton productivity and community) and the evaluation of the trophic transfer of substances (through measures of periphyton tissue quality), and these monitoring components have been incorporated into the CEMP.

The influence of the Mount Polley Mine on periphyton productivity, community, and tissue quality can occur by several key mechanisms: 1) general mine influence from dustfall and/or uncontained surface or groundwater flows: 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to December 2017, and directly since January 2018]); 3) the TSF embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Reclamation activities in lower Edney Creek and Hazeltine Creek were initiated in 2014 following the TSF embankment breach, and were completed in lower Edney Creek in August 2015 (Golder 2017b). Construction / rehabilitation in areas of upper Hazeltine Creek (Reaches 1 and 2) were completed between July and September of 2016 and 2017, respectively (Golder 2017a,c), with Reach 2 encompassing an upper Hazeltine Creek monitoring area established prior to the TSF embankment breach (W7; Minnow 2009). In lower Hazeltine Creek, initial channel rehabilitation was completed in 2015, and further rehabilitation has yet to be completed.

Periphyton tissue quality in creeks adjacent to the Mount Polley Mine has been monitored since prior to the TSF embankment breach (2010, 2012, and 2013; Minnow 2011, 2013a, 2013b). Periphyton productivity (chlorophyll-a and Ash-Free-Dry-Mass [AFDM]) has been monitored since 2013 (Minnow 2013c, 2018a,b), and periphyton community characteristics have not been

documented in these waterbodies. Results of previous periphyton productivity and tissue quality monitoring are reviewed in Section 2. These results provide context for a periphyton monitoring program that is guided by a combination of available historical findings, representative locations downstream of Mount Polley Mine operations (taking into consideration recent stream rehabilitation activities), representative reference locations, and considerations for a statistically-based design that will facilitate the detection of potential spatial and/or temporal differences in periphyton endpoints (productivity, community, and tissue quality), in addition to providing data to evaluate productivity endpoints (i.e., chlorophyll-a) against provincial water guidelines for the protection of aquatic life (e.g., BCWQG; BCMOE 2018) and literature-based productivity classification values (e.g., Biggs 1996).

The following sections of the CEMP Periphyton Monitoring Plan provide the objectives of periphyton productivity and tissue quality monitoring, a summary of historical periphyton monitoring results, an overview of the CEMP study design and associated rationale (including sampling locations, replication, frequency, and analytes), and detailed methodology for periphyton productivity and tissue quality monitoring (sampling methods, analytical methods, quality control methods, data interpretation, and reporting).

1.1 Monitoring Objectives

The objective of periphyton monitoring in the Mount Polley receiving environment is to evaluate the influence of Mount Polley Mine activities (related to mine operations, the TSF embankment breach, and/or rehabilitation activities) on Hazeltine Creek (the creek receiving environment directly influenced by Mount Polley Mine activity) and lower Edney Creek (a creek environment directly influenced by the TSF embankment breach), and to serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (benthic invertebrates and fish; Sections 6.13 and 6.16). Periphyton monitoring will include assessment of productivity, community composition, and tissue quality, with comparison to previous and/or reference conditions, to applicable guidelines (i.e., chlorophyll-a; BCMOE 2018), and to literature-based criteria (or classification ranges) for productivity. Periphyton monitoring results also provide supporting information for the assessment of benthic invertebrate tissue quality, benthic invertebrate community condition, and fish habitat productivity, as well as supporting the exposure assessment for the ecological risk assessment (ERA) and human health risk assessment (HHRA).

2 SUMMARY OF HISTORICAL FINDINGS

2.1 Productivity

Periphyton productivity monitoring completed during mine operations but before the TSF embankment breach indicated that productivity was low in a creek adjacent to the Mount Polley Mine (Bootjack Creek; 1.42 mg/m^2 of chlorophyll-a; Minnow 2013c) relative to the BCWQG of 100 mg/m^2 (BCMOE 2018). Following the TSF embankment breach, periphyton productivity in rehabilitated areas of upper and lower Hazeltine Creek and lower Edney Creek were also generally low (1.76 to 40.1 mg/m^2 of chlorophyll-a; Minnow 2018a; Figure 1), as evidenced by results well below the BCWQG and generally below chlorophyll-a levels associated with moderately enriched streams (21 mg/m^2; Biggs 1996) despite full sun exposure in these recently rehabilitated areas. Periphyton chlorophyll-a results from these rehabilitated areas following the TSF embankment breach were generally within the range documented in the associated reference areas (4.6 to 40.1 mg/m^2), as was periphyton biomass (AFDM; Figure 1; Minnow 2018a,b).

2.2 Tissue Quality

Periphyton tissue quality has been monitored since 2010 in the vicinity of the Mount Polley Mine (primarily within Hazeltine Creek), with a focus on selenium monitoring relative to reference (Minnow 2011, 2013a,b, 2018c), although additional analytes were included in analyses completed in 2010 (Minnow 2011). Mean periphyton selenium concentrations in upper and lower Hazeltine Creek have shown limited temporal change over the monitoring period, with the most recent results (2017) being similar to, or lower than, concentrations documented prior to the TSF embankment breach (Figure 2).

The inclusion of additional analytes in periphyton tissue quality monitoring continued in 2017 (Minnow 2018d), with tissue quality characterized in three rehabilitated areas of Hazeltine Creek (2 of which were effluent exposed during sample collection), relative to reference (an unimpacted area of lower Edney Creek). Data interpretation of these additional analytes focused on Parameters of Interest (POIs [representing the chemical influence of the TSF embankment breach on sediment quality]: arsenic, copper, iron, and nickel), and on Indicator Parameters (IPs [identified in evaluations of water, soil, or fish tissue quality for Hazeltine Creek]: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium; Golder 2015, 2016, Minnow 2015). Periphyton tissue quality from all rehabilitated Hazeltine Creek areas (both effluent exposed and not exposed) was characterized by copper concentrations that were significantly higher than reference (Figure 3), while concentrations of a number of additional analytes were higher than reference in at least one Hazeltine Creek area (two POIs: arsenic, iron;

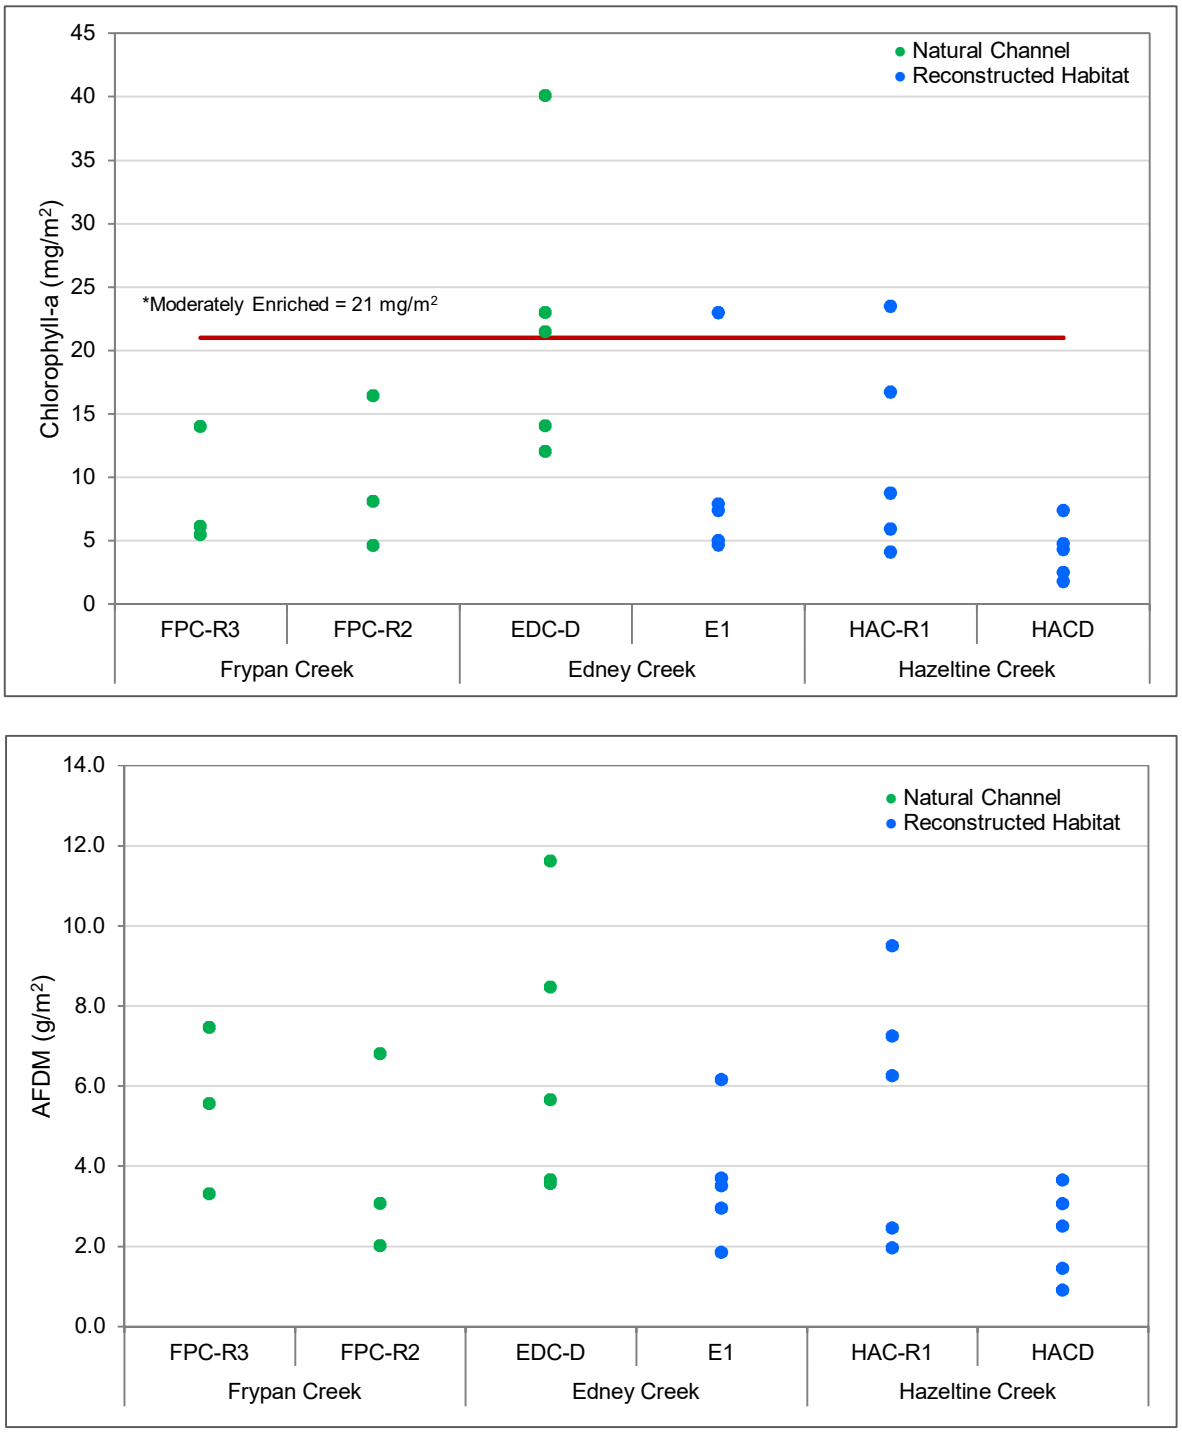

Figure 1: Chlorophyll-a and Ash-Free-Dry-Mass (AFDM) for Frypan, Edney and Hazeltine Creeks, 2017

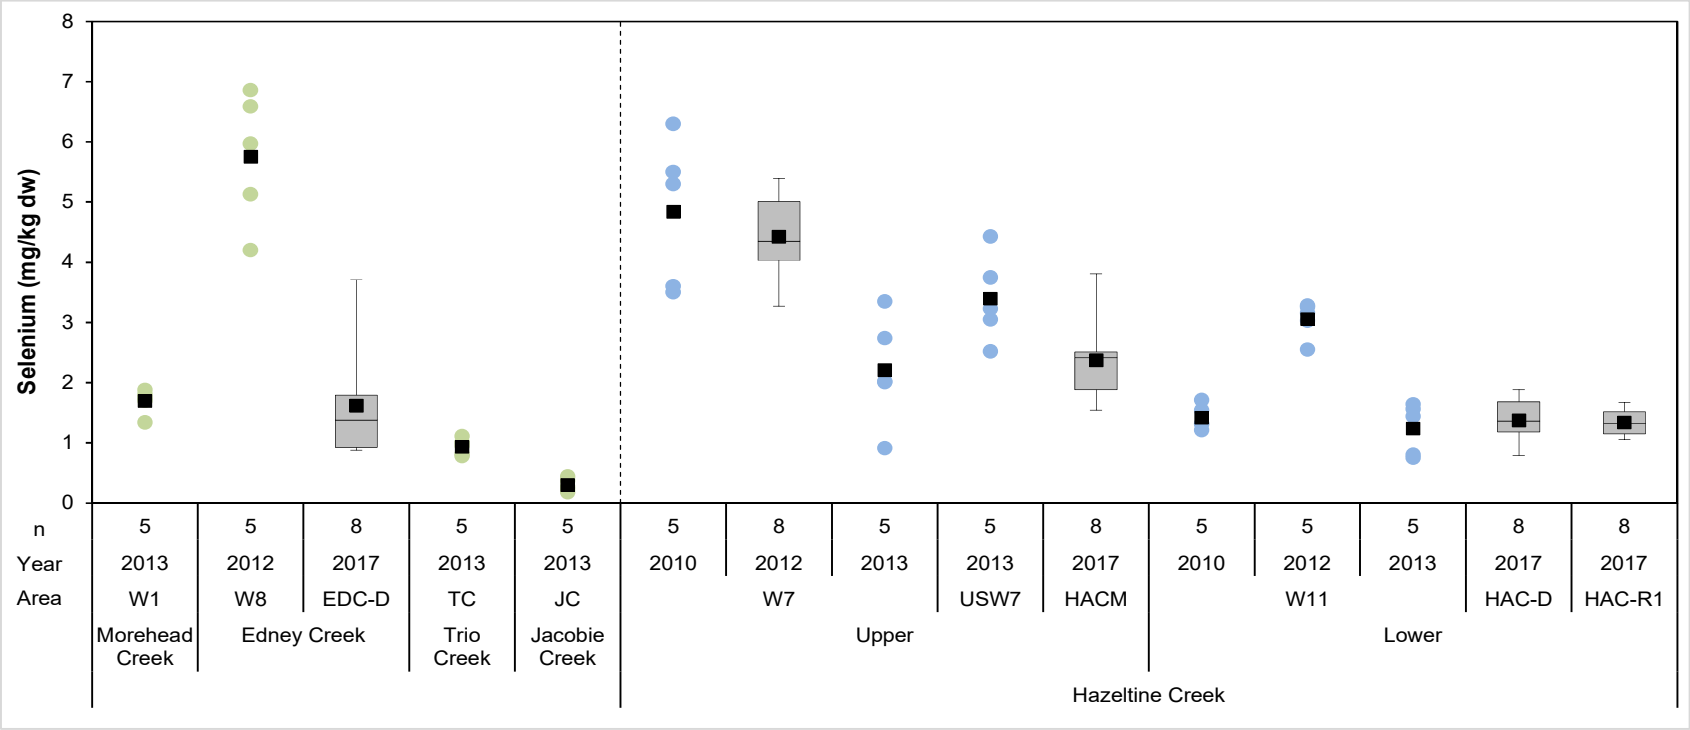
* Value taken from Biggs 1996



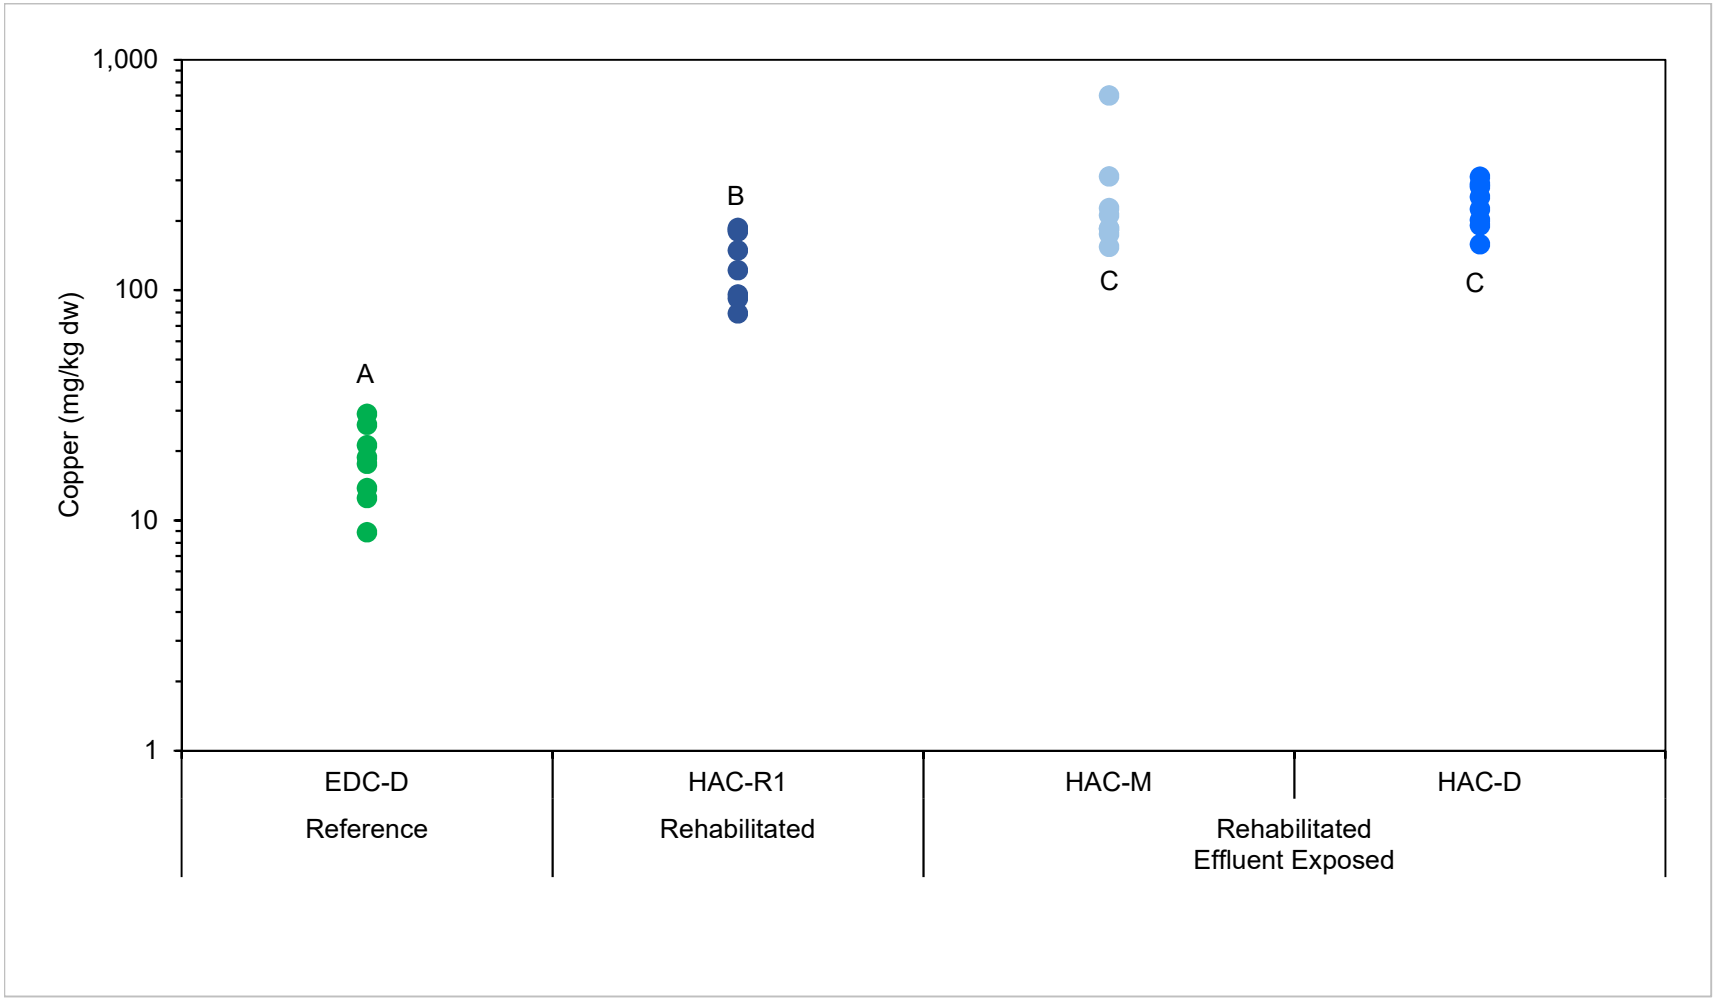


Figure 2: Selenium Concentrations in Periphyton Tissue at Hazeltine Creek with Associated Reference Areas, Mount Polley, 2010 to 2017

Note: Dashed line used to separate reference (left side) and exposed (right side) areas. Black squares represent means and whiskers represent minimum and maximum values. Box plots are presented when there are 8 or more samples.

Note: Groups that share a letter (e.g., AB) are not significantly different from each other.

Figure 3: Periphyton Tissue Copper Concentrations at Rehabilitated and Effluent Exposed (HAC-M, HAC-D), Rehabilitated (HAC-R1), and Reference (EDC-D) Area, Mount Polley Mine, 2017

and six IPs: calcium, cobalt, molybdenum, phosphorus, sodium, and vanadium; Minnow 2018d) These results were consistent with the higher water concentrations of most of these analytes in Hazeltine Creek due to a combination of breach influence and effluent conveyance preceding and during sample collection.

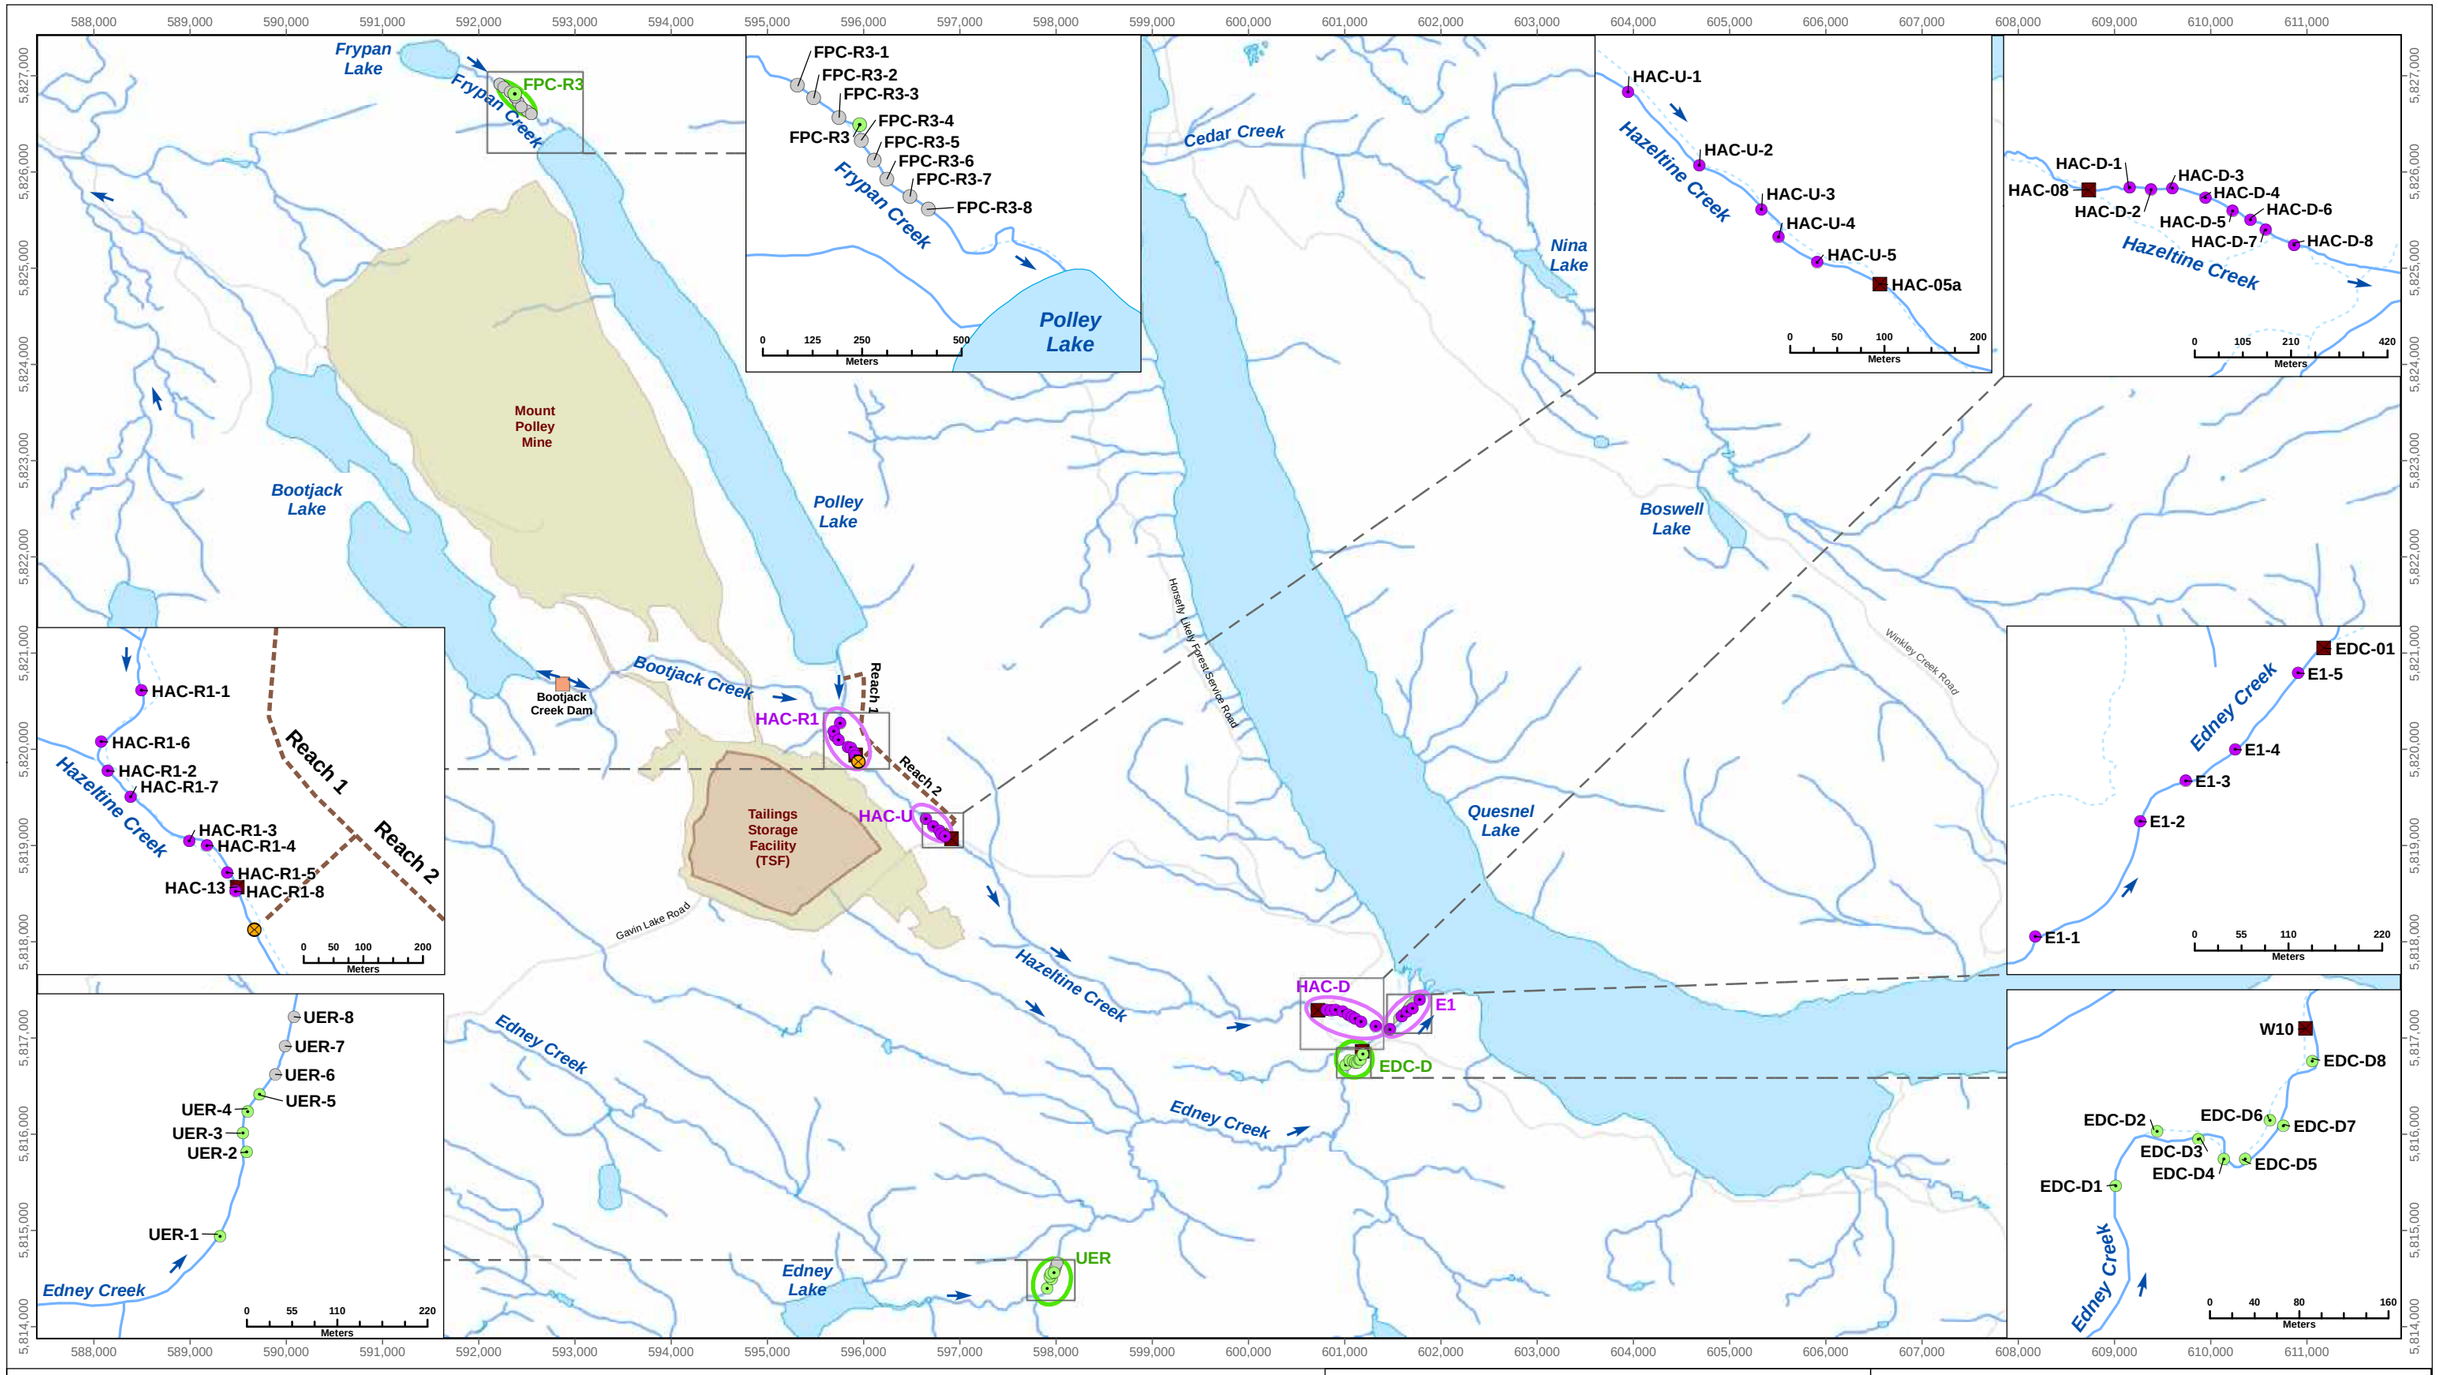
3 STUDY DESIGN OVERVIEW AND RATIONALE

Periphyton monitoring under the CEMP is proposed to meet the combined needs of: 1) operational monitoring (including the previous discharge of treated effluent to Hazeltine Creek); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to reclamation activity following the TSF embankment breach. An overview of the proposed periphyton monitoring program is provided in Table 1 and Figure 4. Periphyton monitoring is focused on Hazeltine Creek and lower Edney Creek with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and an unaffected area of lower Edney Creek for rehabilitated areas of lower Edney Creek and lower Hazeltine Creek; Table 1; Figure 4). As described in Section 1.1, reclamation activities in Hazeltine Creek and lower Edney Creek were initiated in 2014 following the TSF embankment breach, and were completed in lower Edney Creek in August 2015 (Golder 2017b), and in 2016 and 2017 in sections of upper Hazeltine Creek in (Reaches 1 and 2, respectively; Golder 2017a,b). As such, periphyton monitoring in Hazeltine Creek will focus on three areas (Figure 4)[1], including one area in Reach 1 (HAC-R1; where rehabilitation was completed in 2016), one area in Reach 2 (HAC-U; where rehabilitation was completed in 2017), and one area in lower Hazeltine Creek (HAC-D, where initial rehabilitation activities have been completed but additional rehabilitation will be conducted). Monitoring in lower Edney Creek will focus on one rehabilitated area (E1; where rehabilitation was completed in 2015). These sampling areas also align with those proposed for benthic invertebrate community and tissue quality monitoring (see CEMP Section 6.13). It should be noted that sampling areas HAC-U and HAC-D were previously exposed to the discharge of treated mine effluent (December 2015 to December 2017), whereas HAC-R1 is located upstream of the previous discharge point (Figure 4). As of January 2018, treated effluent is no longer discharged into Hazeltine Creek. Concurrent sampling of suitable reference areas will be conducted in lower Edney Creek and Frypan Creek. In Frypan Creek, the reference sampling area was selected to match habitat conditions in upper Hazeltine Creek as closely as possible, based on results of preliminary fish habitat assessment and benthic invertebrate monitoring (area selection was based primarily on substrate type and size; Minnow 2018b).

Periphyton monitoring includes assessment of productivity (chlorophyll-a and AFDM) at all sampling locations. Periphyton community will also be monitored at all locations with the exception of Frypan Creek, which will be sampled in 2018 only for the purposes of comparison of

[1] Note that previous creek sampling station locations are presented in Figure 4. These locations may change slightly depending on substrate, water depth, and water velocity. Similarly, conceptual station locations are displayed for upper Edney Creek and Frypan Creek, and will be established during the field campaign.

Table 1: Mount Polley CEMP Periphyton Monitoring Program Overview



Water Body	Sampling Area	Type	Monitoring Frequency	Components [a]	Replication [b]			Rationale
					T	P	C	
Hazeltine Creek	HAC-R1 (Upper, Reach 1)	Rehabilitated	Annual	T,P,C	5	5	8	adjacent to mine and breach-influenced
	HAC-U (Upper)	Rehabilitated	Annual	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
	HAC-D (Lower)	Rehabilitated	Bi-annual [c]	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
Frypan Creek	FPC-R3 (Reach 3)	Reference	2018 only	P, C	-	5	8	reference for upper Hazeltine Creek
Edney Creek	UER (Upper)	Reference	Annual	T,P,C	5	5	8	reference for upper Hazeltine Creek
	E1 (Lower)	Exposed	Bi-annual [c]	T,P	5	5	-	adjacent to mine and breach-influenced
	EDC-D (Lower, unimpacted)	Reference	Bi-annual [c]	T,P,C	5	5	8	reference for lower Hazeltine Creek [d]

[a] core periphyton monitoring components: T = community taxonomic analysis, P = productivity (chlorophyll-a and Ash-Free-Dry-Mass, see Table 2), C = chemistry (see Table 2 for analytes).

[b] number of replicate stations within the specified sampling area for a given program component.

[c] Bi-annual indicates sampling will occur every other year for all parameters indicated with the exception of tissue chemistry, which will be monitored annually. The next bi-annual sampling event will occur in 2019.

[d] Lower Edney Creek reference area will be located in an unimpacted area upstream of the breach influence (see Figure 4).

Figure 4

Document Path: S:\Projects\177202\177202.0042 - MPMC Fall 2017 Monitoring\Mapping\CEMP\2-Periphyton\17-42 Fig 4 MP PER and BI Creek.mxd

fish habitat productivity (Table 1). Periphyton community monitoring provides a means for evaluating re-establishment of the periphyton community in these recently disturbed areas, and is an additional line of evidence for assessing temporal changes in periphyton productivity. Periphyton tissue quality monitoring, which includes evaluation of concentrations of metals[2] and moisture content, will be included at all sampling locations with the exception of the rehabilitated area of lower Edney Creek (E1; Table 1). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; 3) comparison of productivity results relative to BCWQG and literature-based classification values. Accordingly, five stations per area for the assessment of productivity and community, and eight stations per area for the assessment of tissue quality are proposed to provide replication for the statistical contrasts.

Periphyton monitoring will be supported by measures of sampling depth, water velocity, and *in situ* water quality measurements (temperature, dissolved oxygen, pH, and specific conductance) at each sampling station. Additional information to be collected includes GPS coordinates of each station, notes of the presence of aquatic vegetation/bryophytes on sampled substrate and other physical observations, and supporting photographs of the sampling location and samples. Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (e.g., in Frypan Creek and upper Edney Creek).

Periphyton sampling will be completed in August or September consistent with previous data collections (Minnow 2011, 2013a,b, 2018a,b,c,d). The initial frequency of periphyton community, productivity, and tissue quality monitoring at upper Hazeltine Creek (and associated reference areas) is annual given the recent disturbance to these rehabilitated areas, and changes to the effluent exposure status (Table 1). This frequency will enable tracking of recovery in these recently disturbed habitats. The frequency of periphyton community and productivity monitoring in rehabilitated areas of lower Hazeltine Creek and lower Edney Creek (and associated reference areas) is every second year because these areas have been undisturbed since 2015, however the frequency of tissue quality monitoring in lower Hazeltine Creek (and the associated reference area) is annual. Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) will be made in response to QP recommendations. If results indicate stable periphyton productivity, community, and tissue quality during this period, then a reduction of monitoring frequency to every second year will be considered for upper Hazeltine Creek areas. The Frypan Creek reference area will only be sampled in 2018 (Table 1) to provide comparison for periphyton biomass and

[2] For simplicity, the term metals is used herein to include metalloids.

tissue quality data from upper Hazeltine Creek following the initial reopening of upper Hazeltine Creek as fish habitat (see CEMP Section 6.16).

Periphyton samples will be collected, processed, analyzed, and the associated data interpreted using methodology consistent with previous assessment at Mount Polley (e.g., Minnow 2011, 2013a,b, 2018a,b,c,d), which is also consistent with technical guidance (e.g., BCMOE 2013, 2016). Detailed methodology is provided in Section 4, including: quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality assessment, and data handling and interpretation.

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be led by qualified field staff experienced in the implementation of periphyton monitoring programs, and all sample collection methods, quality assurance and quality control measures, and laboratory analysis methods will be implemented in accordance with technical guidance (BCMOE 2013, 2015, 2016). Specifically, quality assurance and quality control measures will include program review prior implementation, adequate resources for all field teams including field checklists and field data sheets, the availability (and maintenance) of clean sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination.

Quality control (QC) samples will be collected to support the periphyton monitoring program. Replicate samples will be collected from each sampling area in order to capture within-area variability (samples from 5 and 8 separate stations will be collected to represent the sampling area for productivity/community and tissue quality endpoints, respectively). Specific field QC samples will include duplicates (i.e., splits) of periphyton tissue quality samples collected at a frequency of 10% of the total number of samples to assess field precision as part of the Data Quality Review (DQR; Section 4.4). QC samples to assess field precision (field duplicates) will not be collected for periphyton productivity (chlorophyll-a and AFDM) or community monitoring endpoints due to high the inherent natural variability in these parameters. In addition to field QA/QC, the laboratory responsible for the physical or chemical analyses will be accredited by the Canadian Association for Laboratory Accreditation (CALA) for these analyses. Specific QC sampling and associated reporting will for tissue quality and periphyton productivity endpoints be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). QC reporting will also be requested of the laboratory performing taxonomic analysis of the periphyton community samples, including organism enumeration checks for a minimum of 10% of samples. These results will be assessed as part of the DQR (Section 4.4).

All raw field data will be transcribed from field sheets into an electronic spreadsheet. Data will then checked by a separate individual for data entry errors as part of routine Quality Assurance/Quality Control (QA/QC) procedures.

4.2 Sample Collection Methods

4.2.1 Biomass and Chlorophyll-a

Periphyton samples for chlorophyll-a analysis and biomass (AFDM) will be collected by selecting five representative submerged rocks from each monitoring station. Representative rocks from each station will be selected from locations with similar habitat (depth, velocity, and substrate characteristics), while attempting to match depth and velocity among periphyton collection stations and areas as closely as possible. Selected rocks (excluding those that are too small, highly angular, or uncharacteristic in surface texture) will be taken to shore. For chlorophyll-a sample collection, a thin acetate template with a 2x2 cm opening in the middle will then be placed firmly on each rock, and the periphyton within this area will be scraped off using a stainless-steel razor blade or scalpel. Sample material from each of the five rocks will then be transferred from the razor blade or scalpel to a large (47 mm) 0.45 µm pore diameter Whatman mixed cellulose ester (MCE) filter paper until a single composite sample of approximately 200 mg to 1 g wet weight is obtained per station. If material collected from the five rocks sampled is insufficient, additional rocks will be sampled from the same area with similar habitat characteristics until the required sample volume is obtained. The filter paper will then be folded and placed into a labeled opaque centrifuge tube. The total surface area sampled at each station (0.002 m^2: 5 x 4 cm^2, or any deviations from this surface area), will be recorded to allow calculation of chlorophyll-a on a unit area basis for comparison to the British Columbia Water Quality Guideline (BCWQG; 100 mg/m^2; BCMOE 2018). The same five rocks sampled for chlorophyll-a analysis (and additional rocks if they were required) will be used to collect separate scrapings for analysis of AFDM. For AFDM sampling, sampling methods will follow those outlined above for chlorophyll-a, however material on the razor blade or scalpel from scraping of each rock will be rinsed into a small pre-labelled plastic jar with additional water added to cover the tissue (as necessary). Sampling will be conducted at five replicate stations in each area (see Table 1). Immediately after collection, all chlorophyll-a and AFDM samples will be placed in a cooler on ice for transport to the mine, where they will be frozen.

4.2.2 Community

Periphyton community samples will be collected from the same five rocks used for chlorohyll-a and biomass sampling whenever possible (and additional rocks if they were required), or from rocks of a similar size collected from the same general location and habitat (depth and velocity). Sample collection methods will be similar to those outlined for chlorophyll-a and AFDM. Briefly, a thin acetate template with a 2x2 cm opening in the middle will be placed firmly on each rock and all of the periphyton within this area will then be removed using a scalpel and/or brush and a squirt bottle filled with site water (BCMOE 2013, 2016; Stevenson and Bahls 2006). The collected

periphyton will then be transferred into a labelled sample jar, and this process will be repeated for the five rocks, resulting in a single composite sample from each station. The total surface area sampled at each station (0.002 m^2: 5 x 4 cm^2, or any deviations from this surface area if additional rocks are sampled) will be recorded. Immediately after collection, the sample will be preserved with Lugol's iodine solution until the sample is the colour of weak tea (approximately 1 mL of Lugol's per 250 mL of sample; BCMOE 2013), and will be mixed gently by inverting the sampling jar. All samples will be stored at room temperature. Sampling will be conducted at five replicate stations in each area (see Table 1).

4.2.3 Tissue Quality

Periphyton samples collected for tissue quality analysis will be collected by scraping periphyton from the surface of rocks using a scalpel until sufficient sample weight for analysis is attained (more than 500 mg wet weight). A minimum of five rocks will be sampled to ensure the sample is representative of the sampling station. Rocks sampled for productivity and community will be used preferentially, plus additional rocks (as necessary) to obtain the required sample weight. Periphyton scrapings will be transferred directly from the scalpel onto the wall of a labeled scintillation vial, without rinsing, to minimize the amount of water in each sample. Sampling will be conducted at eight replicate stations in each area (see Table 1). Samples will be placed in a cooler on ice for transport to the mine, where they will be frozen.

4.3 Sample Handling and Laboratory Analysis

Periphyton productivity (chlorophyll-a and AFDM) and tissue quality samples will remain frozen until overnight shipment on ice to the analytical laboratory. Samples will be sent to the laboratory with sufficient time to complete analyses within the recommended sample hold times (28 days for chlorophyll-a, 6 months for AFDM, 1 year for tissue quality [metals analysis]). Analyses will be completed at an analytical laboratory accredited by the Canadian Association for Laboratory Accreditation (CALA) using methods that are consistent with those specified in the British Columbia Environmental Laboratory Manual (BCMOE 2015). Upon sample receipt, the laboratory will provide a sample receipt confirmation which will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. Analysis of chlorophyll-a will follow procedures adapted from USEPA Method 445.0 (USEPA 1997). Briefly, chlorophyll-a will be determined by routine acetone extraction followed by fluorescence detection using a non-acidification procedure (a method that is not subject to interferences from chlorophyll-b). Determination of total AFDM will follow procedures adapted from APHA Method 10300 C (APHA 2010). Total AFDM will be calculated as the difference between the dried sample weight and the ash weight, both of which will be determined gravimetrically. Dry weight will be determined by drying the sample at 105 °C, and the ash weight will be subsequently determined

by ashing the dried sample at 500 °C. Tissue quality samples will be analysed for metals by CRC-ICP-MS (Collision Cell Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/6020A [USEPA 2004]) or HR-ICP-MS (High Resolution Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/ 200.8 [USEPA 1994]), mercury by CVAFS (Cold Vapour Atomic Fluorescence Spectrophotometry; USEPA Method 200.3 [USEPA 1991]/Method 245.7 [USEPA 2001]), and moisture content. The method selected for metals analysis will depend on sample weight, with HR-ICP-MS employed for smaller sample sizes. Periphyton productivity and tissue quality parameters are provided in Table 2, with the associated target laboratory reporting limits (LRLs) and detection limit objectives outlined in technical guidance ("consensus detection limits"; BCMOE 2016). Upon completion of the analyses, the laboratory will provide a data report in Microsoft (MS) Excel™ and as an Adobe Acrobat Portable Document Format (PDF). Reporting will include the results of the laboratory QC sample results.

Periphyton community samples will be stored at room temperature until shipment to the taxonomy laboratory for taxonomic identification and enumeration. Samples will be shipped immediately after the completion of the field campaign, however there are no recommended hold times for analysis. Sample analysis will be completed as follows. Briefly, samples will be homogenized, settled in Ütermohl chambers for 24 h, and all cells within randomly selected fields of view will be enumerated until a minimum count of 300 algal units (1 unit = >1 cell for colonial or filamentous taxa) is reached. Identification will be performed using an inverted phase contrast microscope, and algal taxa will be identified to minimum of genus-level according to the most up-to-date taxonomic references. Periphyton density will be determined using the area sampled, proportion subsampled, and the total area of the selected fields of view. Biomass estimates will be generated for each taxon using taxon-specific biovolume formulae (Hillebrand et al. 1999) for cell measurements, and taxon-specific densities.

4.4 Data Quality Review

Upon receipt of all analytical data, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs have been achieved. The DQR will also include an evaluation of differences between duplicate (split) samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the periphyton monitoring data will ensure timely communication with the laboratory should any issues be identified

Specifically, LRLs will be evaluated relative to targets established for the analytes and to "consensus detection limits" (Table 2), and to relevant British Columbia guidelines (i.e., chlorophyll-a for productivity samples; BCMOE 2018). Comparisons between duplicate samples

Table 2: Target Laboratory Reporting Limits (LRL) and Analytical Methods for Periphyton Productivity and Tissue Quality Analytes

A) Tissue Quality Parameters

Parameter	Metals in Tissue by HR-ICPMS Micro (USEPA 1991, 1994)		Metals in Tissue by CMC ICPMS (USEPA 1991, 2004)		Concensus DLs [a]

[a] from Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators (BCMOE 2016).

[b] Method for total mercury analysis will be according to USEPA (1991, 2001).

B) Productivity Parameters

Parameter	Units	Method	LRL
Chlorophyll-a	µg	USEPA 1997	0.02
Ash Free Dry Weight	g	APHA 2010	0.001

will be made by calculating the relative percent difference (RPD) between concentrations between paired duplicates. If the RPD is <25% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Results for laboratory blanks, precision, and accuracy will be evaluated relative to Data Quality Objectives (DQO) established by the analytical laboratory that performed the analyses. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping).

4.5 Data Handling, Interpretation, and Reporting

Upon receipt of data from the analytical laboratories, all laboratory data files will be managed by the Mount Polley Mining Corporation (MPMC) Environment Department. In addition, data provided by the primary analytical laboratories as an Electronic Data Deliverable (EDD) will be imported directly into the MPMC's database following completion of the DQR. Following the DQR, all periphyton data and supporting data will be managed in MS Excel. For all replicated data (typically based on a sample size of five or eight stations per area), data will be provided to the QP and summarized by calculating mean, median, standard deviation, minimum, and maximum for each analyte. Data analysis will be completed for each monitoring component (productivity, community, and tissue quality).

Periphyton productivity (chlorophyll-a and AFDM) results will be converted to a standard area-based measurement (mg/m^2 and g/m^2 for chlorophyll-a and AFDM, respectively), and chlorophyll-a results will be compared to water quality guidelines for the protection of aquatic life (BCWQG = 100 mg/m^2; BCMOE 2018) and to literature-based criteria for moderately enriched streams (21 mg/m^2; Biggs 1996). Periphyton productivity results will also be compared to previous data (where possible), and to reference results. For periphyton community, endpoints including density, taxon richness, diversity indices, and dominant community composition endpoints will be calculated, and compared to reference results. Temporal comparisons of periphyton community results will be made once data are available (2018 represents the first year of periphyton community sample collection). More detailed evaluation of periphyton productivity and community results will include analyses using a control-impact study design. Specifically, Analysis of Variance (ANOVA) will be used to test for differences in periphyton productivity and community endpoints between rehabilitated areas of Hazeltine Creek and lower Edney Creek, and associated reference areas. For these analyses, the assumptions of normality and homogeneity of variances will be tested on the residuals of the ANOVA model using the Shapiro-Wilk test and Levene's test based on median values, respectively, using a significance level (α) of 0.05. Data will be transformed as necessary to satisfy assumptions of normality and

homogeneity of variance as required. In instances where the residuals of the ANOVA model do not meet the assumptions of normality and homogeneity of variances, a non-parametric Kruskal-Wallis test will be conducted. When the overall results of an ANOVA or Kruskal-Wallis test are significant, differences between specific areas will be evaluated using post-hoc contrasts for ANOVA or Dunn's test for the Kruskal-Wallis test. A Bonferroni correction on the p-values will be used to conserve the overall Type I error rate. Further detailed analyses will be completed as required for data interpretation, and may include: graphical comparisons to reference and historical data (if available), graphical plots in relation to guidelines and criteria, and formal statistical temporal and spatial contrasts using methods similar to those described above.

If exposed versus reference or temporal differences in periphyton productivity and community results are noted, relationships between periphyton productivity and community endpoints and supporting water quality will be evaluated using Spearman correlation (often referred to a Spearman Rank-Order correlation). Following the derivation of correlation coefficients, a Bonferroni-type correction (i.e., p-value [0.05] divided by the total number of correlations examined for independent variables) will be applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected p-value of 0.05. Any significant correlations found at the Bonferroni-adjusted p-value or at a p-value of 0.01 will be further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were "leveraged" by outlying points (or groups of points). Although it is recognized that a significant correlation or regression does not indicate causation (e.g., Norton et al. 2015), it is desirable to not only characterize the nature of a response (e.g., changes in periphyton productivity or community), but to also obtain evidence of cause. Correlation / regression analyses are commonly applied tools for identifying potential cause (e.g., Norton et al. 2015). Evidence of causation obtained from correlation or regression analysis will be carefully considered in light of the strength, range, and continuity of the relationships as well as mechanistic knowledge/understanding of potential cause.

Data analysis and interpretation of periphyton tissue quality results will focus on Parameters of Interest (POIs [representing the chemical influence of the TSF embankment breach on sediment quality]: arsenic, copper, iron, and nickel), and on Indicator Parameters (IPs [identified in evaluations of water, soil, or fish tissue quality for Hazeltine Creek]: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium; Golder 2015, 2016, Minnow 2015). Periphyton tissue quality results for these analytes will be compared to available pre-breach data (for selenium only [2010, 2012, and 2013]; Minnow 2011, 2013a, 2013b), contrasted between exposed and reference areas, and also compared temporally within exposed areas. Detailed analyses and interpretation related to these comparisons will be completed as required, and may

include: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations tissue concentrations as described above

Concentrations of the POIs and IPs in periphyton tissue will also be evaluated relative to concentrations in water. These ratios of concentrations will be calculated as: [tissue sample concentration]/[dissolved water concentration], and are referred to as Bioconcentration Factors (BCFs). BCFs are often used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes other than diet (i.e., Arnot and Gobas 2006), and are applicable to erosional areas where sediment is generally not present. BCFs will be calculated using tissue metal concentrations (dry weight) and mean dissolved metal concentrations in water from each sampling area. Calculated BCFs will then be qualitatively compared among areas to identify differences in the uptake of metals by periphyton in areas impacted by effluent discharge and/or the TSF embankment breach. Mean BCFs will also be qualitatively compared between or among years to examine any broad temporal changes in metal accumulation in periphyton tissue at exposed sites. In addition, concentrations of POIs and IPs in periphyton tissue will be used in the evaluation of Trophic Transfer Factors (TTFs) to benthic invertebrates; the ratio of tissue concentrations in benthic invertebrates relative to concentrations in periphyton (i.e., TTF = [benthic invertebrate sample]/[periphyton sample]). TTFs can be used generally to describe the extent to which the concentration of an analyte increases between lower and higher trophic levels (e.g., Presser and Luoma 2010; see CEMP Benthic Invertebrate Section 6.13 for details).

An interpretive report based on the periphyton monitoring data will be prepared for integration into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWQG and other guidelines or classification schemes, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

1 INTRODUCTION

1.1 Background

Fish are important and highly valued aquatic ecosystem components. Fish community composition, fish population characteristics (e.g., survival, growth, and reproduction), and fish tissue quality can be effective monitors of potential biological effects associated with water quality, sediment quality, and/or physical disturbance. Fish tissue quality is also an important measure of potential exposure to metals, metalloids, nutrients[1], and other substances to humans and wildlife that consume fish. Lastly, the use of fish habitat by fish is an important monitor of the physical and chemical quality of aquatic habitat.

The influence of the Mount Polley Mine on fish communities, populations, and/or tissue quality can occur by several key mechanisms: 1) general mine influence on creeks and lakes from physical impingement, dustfall, and/or uncontained surface or groundwater flows; 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to November 2017, and directly since January 2018]); 3) the Tailings Storage Facility (TSF) embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Potential effects associated with effluent discharge are chemical, while those associated with general mine influence, the TSF embankment breach, and subsequent remediation can be both physical and chemical.

Fish in waterbodies adjacent to the Mount Polley Mine have been monitored historically by the provincial government (Burns and Klein 1973; Lirette and Tredger 1991; Bruce and Slaney 1991) and by the Mount Polley Mine starting with baseline investigations in 1989, 1995, and 1996 (Imperial Metals 1990; HKP 1996a,b,c, 1997a). Results of fish monitoring are reviewed in Section 2 and provide context for a CEMP fish monitoring program (community, population, and tissue quality) that is guided by a combination of historical findings, representative locations downstream of Mount Polley Mine operations, representative reference locations, and considerations for a statistically-based design that will facilitate the detection of spatial and temporal differences. Fish tissue quality monitoring data will also be evaluated relative to guidelines for the protection of aquatic life and/or human health (e.g., the British Columbia Water Quality Guideline for selenium [BCMOE 2014] and the Health Canada guideline for mercury [CFIA 2015]). In addition, fish population monitoring is required as part of Environmental Effects Monitoring (EEM) under the Metal and Diamond Mining Effluent Regulations (MDMER) of the

[1] Through the remainder of this section, the term “metals” will be used to include metals, metalloids, and nutrients for ease of communication.

federal *Fisheries Act* (Government of Canada 2018). The focus of the federal EEM fish survey is to determine if there are effects to sentinel fish population characteristics (e.g., survival, growth, and/or reproduction) associated with the discharge of mine effluent (currently to Quesnel Lake). Lastly, fish habitat characterization and fish usage monitoring serves to document and track the effectiveness of fish habitat that has been reconstructed/rehabilitated following the TSF embankment breach.

The following sections of the CEMP Fish Monitoring Plan provide the objectives of fish monitoring, a summary of historical fish community, population, and tissue quality findings, an overview of the CEMP study design and associated rationale (including sampling locations, replication, frequency, and analytes), and detailed methodology for fish monitoring (quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting).

1.2 Monitoring Objective

The objective of fish monitoring is to evaluate the influence of Mount Polley Mine activities on fish communities, populations, and tissue quality in receiving environments (Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions, and to determine potential implications to aquatic ecosystem health and human health (e.g., relative to available fish tissue quality guidelines [BCMOE 2014; CFIA 2015]). Fish monitoring also provides data to support exposure assessment as part of post-breach ecological risk assessment (ERA) and human health risk assessment (HHRA). Lastly, fish monitoring documents fish habitat utilization in creek and lake areas that were physically impacted by the TSF embankment breach (most notably Hazeltine Creek and the lower segment of Edney Creek), thereby documenting the effectiveness of fish habitat rehabilitation efforts. The objective of the MDMER EEM fish monitoring is to evaluate whether there are differences in population endpoints (survival, growth, and reproduction) of sentinel fish species between the area of Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012). As prescribed by the MDMER, there is no requirement to monitor fish tissue quality under the MDMER because the concentration of mercury in Mount Polley Mine effluent is less than 0.1 µg/L (0.0001 mg/L; Government of Canada 2018).

2 SUMMARY OF HISTORICAL FINDINGS

Fish monitoring in the vicinity of the Mount Polley Mine has been undertaken since 1989, with most of the monitoring conducted in Polley Lake, Bootjack Lake, Hazeltine Creek, and Edney Creek (Table 1). Fish in Quesnel Lake have also been intensively monitored since the TSF embankment breach in August 2014 and following the initiation of effluent discharge to Quesnel Lake in December 2015. Fish monitoring in the vicinity of the Mount Polley Mine has spanned four distinct time periods:

1. Baseline monitoring (1989, 1991, 1995, 1996);
2. Pre-breach operational monitoring (1997, 1998, 1999, 2007, 2009, 2010, 2012, 2013, 2014);
3. Post-breach operational monitoring (2014, 2015); and
4. Post-breach and post-discharge operational monitoring (2016, 2017).

For Polley Lake and Hazeltine Creek, the second time period can be sub-divided into periods of: 1) prior to; 2) during; and 3) after, an uncontrolled surface runoff event from the north waste rock dump which reported to Polley Lake via North Dump Creek. This runoff started in 2006, was controlled in 2009 with the construction of the Long Ditch, and was characterized by elevated concentrations of sulphate and selenium. In addition to the construction of the Long Ditch, Mount Polley initiated selenium-specific aquatic environmental monitoring in 2009.

Fish community, population, and/or tissue quality data collected prior to the breach were summarized in an Aquatic Environmental Description Report prepared concurrent with an application for water discharge to Polley Lake in 2014 (Minnow 2014a). General findings of the historical monitoring, as well as fish monitoring data collected from 2014 to present, are provided in the following sections, by sampling area, to support the design of the CEMP Fish Monitoring Plan.

2.1 Polley Lake

2.1.1 Fish Community / Population

Baseline monitoring in Polley Lake and reference lakes (Bootjack, Trio, Morehead, and Frypan lakes) was conducted in 1989, 1995, and 1996 and documented the presence of rainbow trout, longnose sucker, and redside shiner. Peamouth chub and largescale sucker have also been reported in Bootjack Lake (in 2014 and 2016, respectively). The fish species composition of Polley and Bootjack lakes has remained the same through operational monitoring and following the perimeter embankment breach. Catchability of rainbow trout and longnose sucker in Polley

[3] Rainbow trout collected from Frypan Creek and pooled with samples from Polley Lake.

Lake and Bootjack Lake by gill netting has remained reasonably consistent from baseline to the most recent gill netting effort in 2016 (Table 2). More recent hoop netting efforts (adopted as a preferred method as captures are non-lethal) document good catchability of both large-bodied species (Table 2).

After the perimeter embankment breach (August 2014), a barrier was installed at the outlet of Polley Lake preventing Polley Lake fish from accessing Hazeltine Creek. There was a noticeable decline in rainbow trout recruitment post-breach as evident in the smaller relative sizes of the age 1 and 2 cohorts in 2016, and the age 1 to 3 cohorts in 2017 (Figures 1 and 2; Minnow 2017a). The barrier preventing fish from entering Hazeltine Creek from Polley Lake was removed in the early spring of 2018 and recruitment is expected to increase accordingly.

2.1.2 Fish Tissue Quality

Tissue quality of Polley Lake (and Bootjack Lake) fish was evaluated in 1989, 1995, 1996, and 1999[2], providing baseline metal concentrations in muscle and liver tissue of rainbow trout and longnose sucker (Imperial Metals 1990; HKP 1996a, 1997a; Beak 2000). Fish tissue quality monitoring was subsequently undertaken in 2009 in response to the uncontrolled surface runoff event from a north waste rock dump which reported to Polley Lake via North Dump Creek (Minnow 2011). Results of the post-runoff but pre-breach monitoring (2009 to 2012) indicated that selenium concentrations in rainbow trout muscle and ovary tissue[3] were stable, that concentrations in muscle tissue were near the British Columbia water quality guideline (BCWQG; BCMOE 2014), and that concentrations in ovary tissue were below the BCWQG (Figure 3). A decrease in selenium concentrations in rainbow trout muscle and ovary concentrations appeared to occur from 2012 to 2014 (pre-breach; Figure 3). Ovary tissue is the best tissue for evaluating the potential adverse effects of selenium to fish (which are considered the most selenium sensitive organisms; Presser and Luoma 2009; Janz et al. 2010; DeForest et al. 2012; Janz 2012). Concentrations in selenium were also well below the effect threshold of 20 mg/kg dw developed by DeForest et al. (2012). Following the TSF embankment breach, an increase in concentrations of selenium in rainbow trout muscle (to above BCWQG) and ovary (below BCWQG) were observed (Figure 3), but the latter remained below the effect threshold.

Following the TSF embankment breach, fish tissue quality investigations were expanded to focus on a suite of analytes that included selenium and also included metals that: 1) were identified as

[2] Although the 1999 collections occurred after mine startup, the results of the collections were verified against previous data and, based on similar results, were used to augment the baseline database to a sample size of ten fish.

[3] Adult rainbow trout were collected either from Polley Lake or from upper Hazeltine Creek. The latter were adult fish from Polley Lake that had moved into Hazeltine Creek to spawn and are considered indistinct from Polley Lake fish for tissue quality monitoring purposes.

Table 2: Catch-Per-Unit-Effort (CPUE) Data for Rainbow Trout and Longnose Sucker in Polley Lake, 1995 - 2017

Year	Data source	Fishing Method	Effort (h)	Rainbow Trout		Longnose Sucker	
				Catch	CPUE	Catch	CPUE
1995	**HKP (1996a)**	Experimental gill net [a] (0.5" - 4" mesh)	15.72	16	0.0006	37	0.0014
2012	**Minnow (2013a)**	Multiple gill nets [b]	48.42	30	0.0006	68	0.0013

[a] CPUE values calculated using reported fishing effort time (15h 43min), and gillnet dimensions (67.5m x 2.35m) (HKP 1996a).
[b] CPUE values calculated as (caught / [ft^2 * h]).
[c] CPUE values calculated as number of fish per trap-day.
[d] CPUE values calculated as number of fish captured per m^2 (Area = 10 m^2).

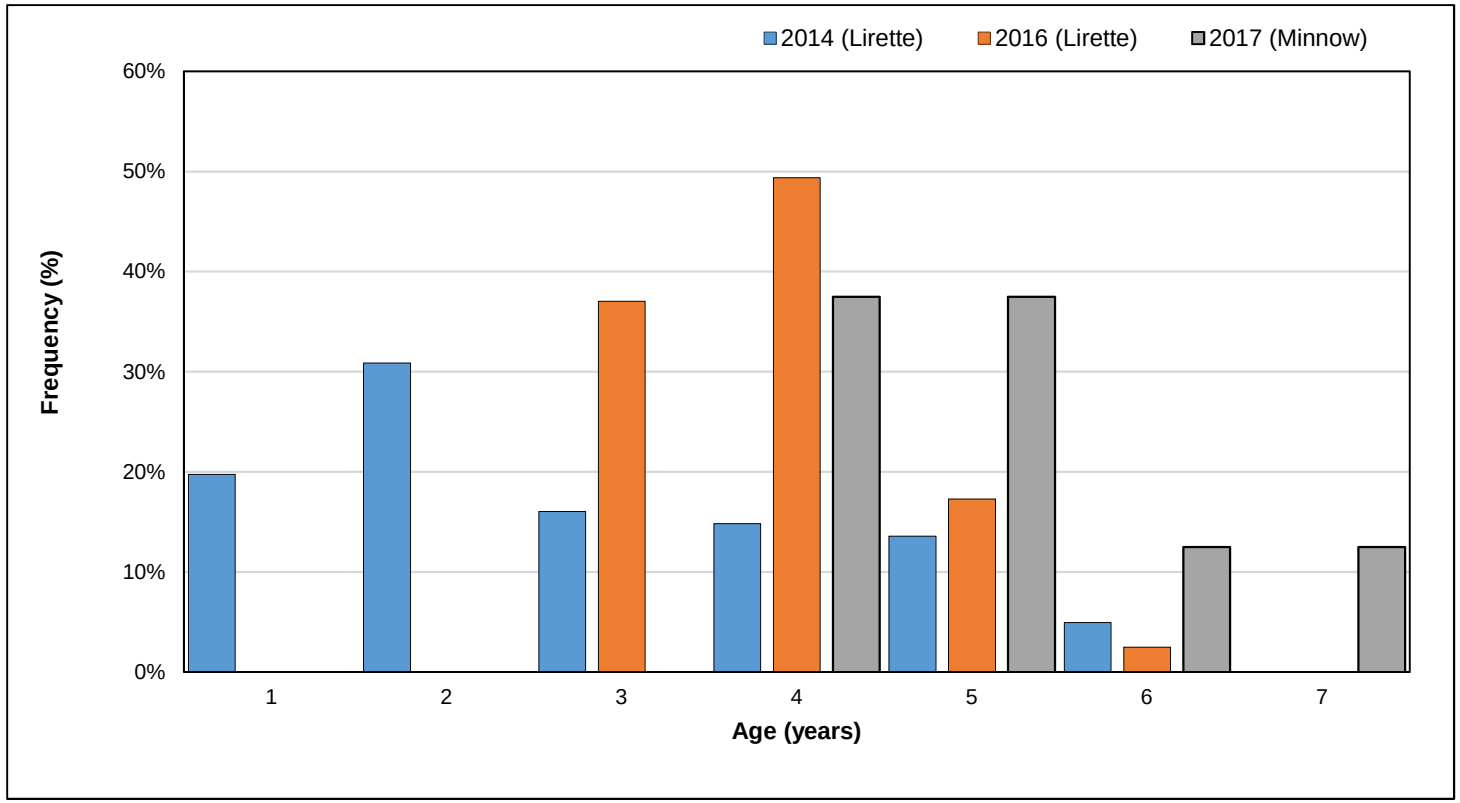

Figure 1: **Rainbow trout age frequency distribution in Polley Lake (data from Lirette 2014 and 2016, and Minnow 2017a)**

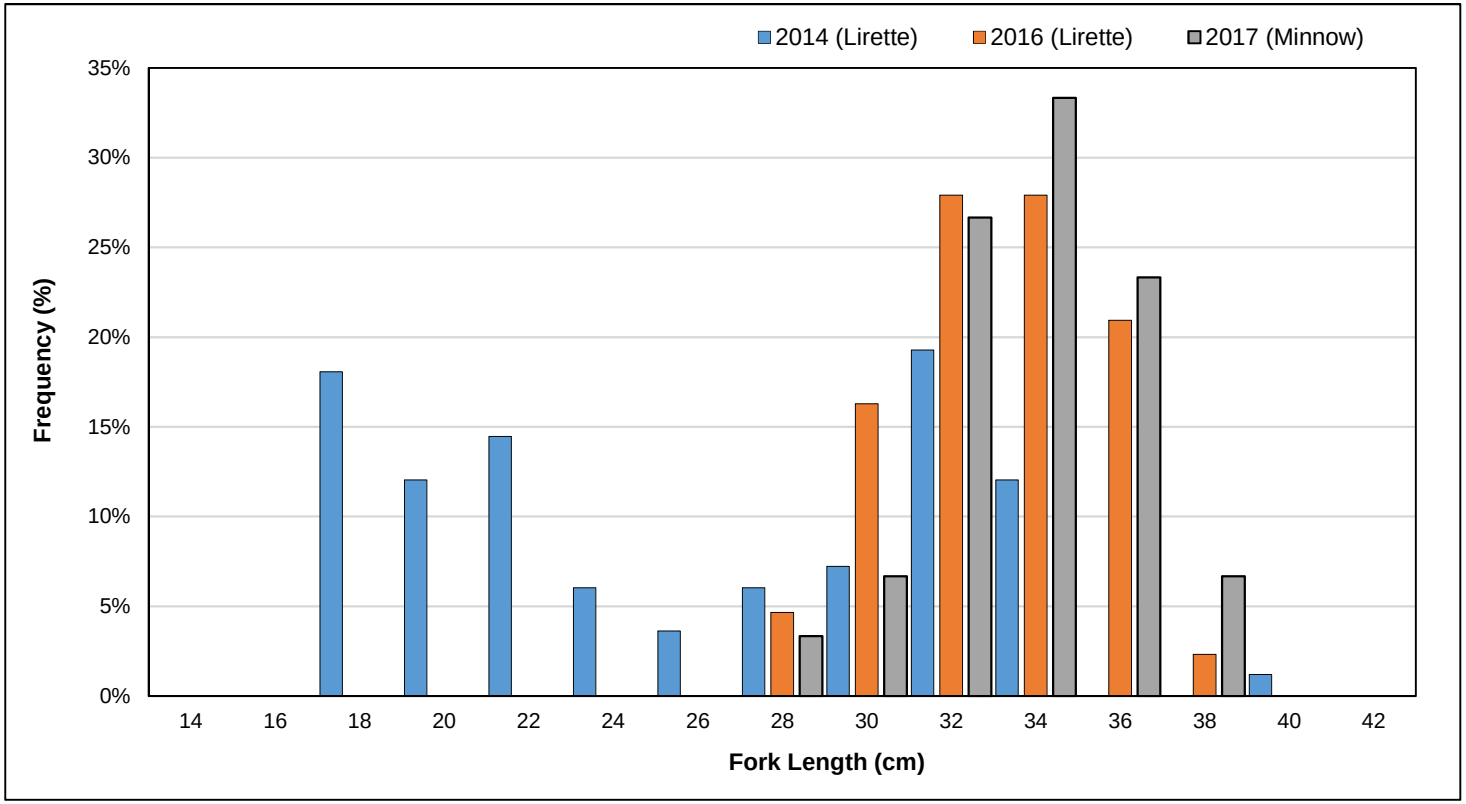

Figure 2: Rainbow trout fork length frequency distribution in Polley Lake (data from Lirette 2014 and 2016, and Minnow 2017a)

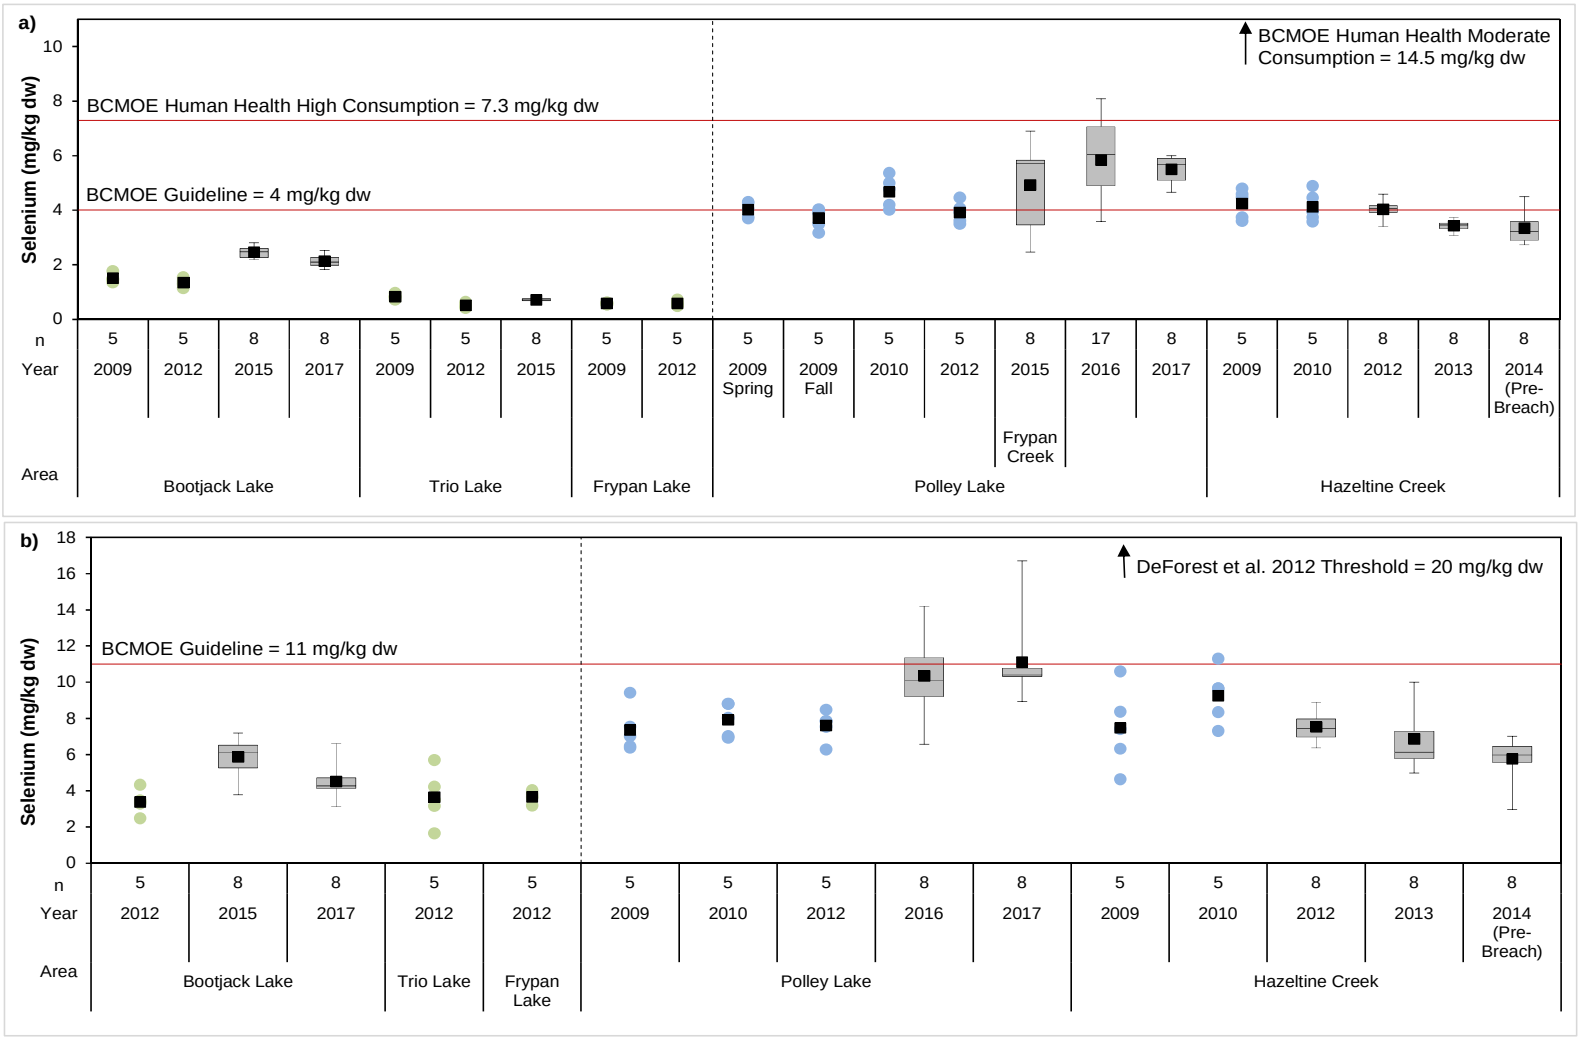

Figure 3: Selenium Concentrations in Rainbow Trout a) Muscle and b) Ovaries from Polley Lake, Hazeltine Creek, and Associated Reference Areas, Mount Polley, 2009 to 2017

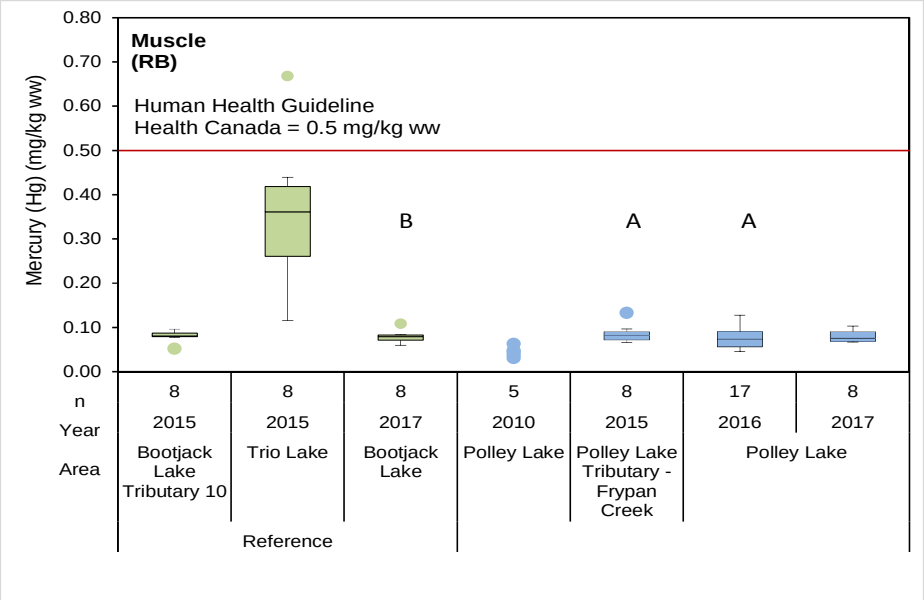
Notes: Dashed line used to separate reference (left side) and exposed (right side) areas. Black squares represent means and whiskers represent minimum and maximum values. Box plots are presented when there are 8 or more samples.



indicative of the influence of the TSF embankment breach on the receiving environment (arsenic, copper, iron [Minnow 2015], molybdenum, phosphorus, selenium [Golder 2015, 2016a]; and/or 2) had tissue quality guidelines (mercury and selenium). Concentrations of mercury and selenium in tissues of rainbow trout and longnose sucker collected in Polley Lake in 2015 to 2017 were lower than guidelines for the protection of human health (Figures 3 and 4), indicating that the fish can be safely consumed at consumption levels typical of the general population (Minnow 2017b, 2018a). Statistical contrasts of concentrations of the expanded suite of analytes in the tissues of Polley Lake fish relative to Bootjack Lake fish showed little agreement in terms of significant differences among species and/or tissues for almost all analytes, nor in the direction of differences when they were observed. This pattern indicates that, if there was any breach-related influence on Polley Lake fish tissue quality, it was minor. In Polley Lake, the only corroborated (reasonably unequivocal) differences were in selenium concentrations in the ovaries of Polley Lake rainbow trout, which were higher than reference and pre-breach in 2016 and 2017, potentially indicative of a breach-related influence (Minnow 2017b, 2018a). The same was not observed in longnose sucker; concentrations in longnose sucker tissues from Polley Lake (2017) were elevated relative to Bootjack Lake (2017), but were significantly lower than selenium concentrations in Polley Lake in 2010. For both species (rainbow trout and longnose sucker), selenium concentrations in ovary tissue were not at levels where adverse effects to fish would be expected (i.e., were not above the effect threshold).

2.2 Hazeltine Creek

2.2.1 Fish Community / Population

The fish community of Upper Hazeltine Creek has been dominated by juvenile rainbow trout during every sampling effort (Table 3). The fish community of Lower Hazeltine Creek (and Lower Edney Creek; both of which flow into Quesnel Lake) included bridgelip sucker, burbot, chinook salmon, coho salmon, kokanee, largescale sucker, longnose dace, longnose sucker, mountain whitefish, northern pikeminnow, peamouth chub, rainbow trout, and redside shiner (Table 3). Most of the fish species documented in Lower Hazeltine Creek or Lower Edney Creek in baseline (1989; Imperial Metals 1990) and in 2007 (Minnow 2009) were also observed in the rehabilitated section of Lower Edney Creek in 2016 and 2017 (Minnow 2018b).

The majority of rainbow trout collected in upper Hazeltine Creek and Edney Creek (79%; SNC-Lavalin 2015) have been young-of-the-year (YOY). In baseline, the density of rearing rainbow trout was 710 fish/100 m^2 and in lower Hazeltine Creek was 325 fish/100 m^2 (Imperial Metals 1990). By comparison, density in Bootjack Creek was 1,500 fish/100 m^2 (Imperial Metals 1990). Sampling in 1991 documented rainbow trout YOY density of 287 to 444 fish/100 m^2 in Hazeltine Creek compared to Bootjack Creek which had a density of 465 fish/100 m^2 (Bruce

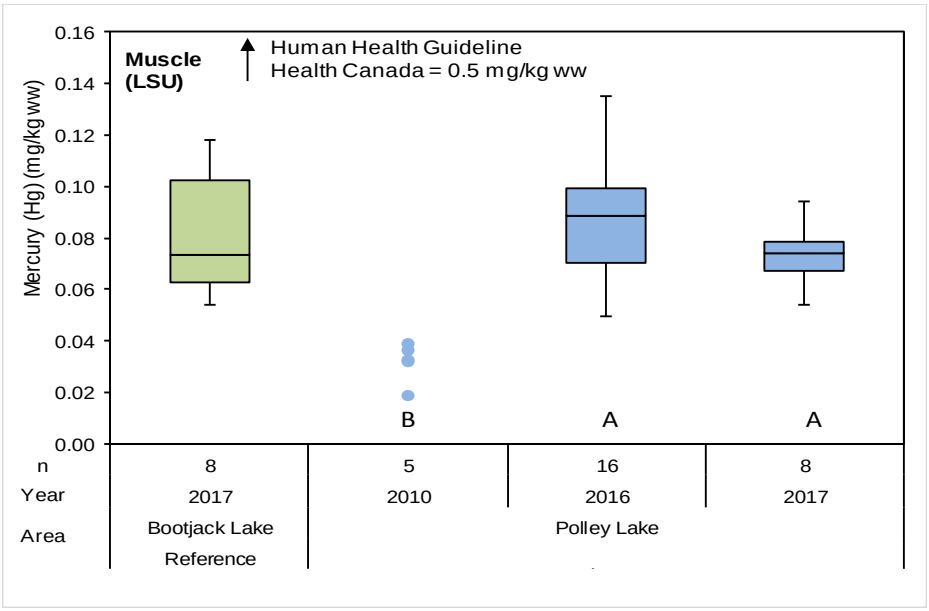


Figure 4: Mercury Concentrations (mg/kg ww) in Muscle Tissue of Fish from Polley Lake (2015 to 2017) Relative to Reference Areas (Bootjack Lake and Trio Lake; 2015 to 2017) and Pre-Breach (Polley Lake; 2010) [a,b,c]

[a] Concentrations in rainbow trout (RB) and longnose sucker (LSU) tissues from Polley Lake (2017) that differed significantly ($p<0.05$) from Bootjack Lake (2017) are denoted by an asterisk (*).

[b] Among-year comparisons were completed for Polley Lake only (2010, 2016 and 2017). The absence of letters (A,B,C) for 2010, 2016, and 2017 indicates no significant difference exists among years. Where significant differences were identified (family-wise $\alpha=0.05$), the years that were not significantly different from each other were assigned a common letter (A,B,C). The year with the greatest mean is assigned "A".

[c] Data summarized as boxplots when sample size was 8 or more; dot plots when sample size was 8 or fewer, or fewer than 8 results were detectable.

[a] Catch numbers are amount of fish retained for tissue analysis, more fish may have been collected.
[b] Upper Edney Creek includes all stations on Upper Edney as well as two tributaries of Edney Creek
[c] Fry could not be identified to species level but suspected to include Coho, Chinook, and Sockeye

and Slaney 1991). In 2007, Upper Hazeltine Creek had a higher density of rainbow trout (400 to 700 fish/100 m^2) compared to the reference area, upper Edney Creek in 2007 (200 to 640 fish/100 m^2; Minnow 2009). Rainbow trout densities in Edney Creek varied considerably over time, with baseline densities of 169 fish/100 m^2 in 1996 and 17 fish/100 m^2 in 1997 (Minnow 2014b).

2.2.2 Fish Tissue Quality

Fish tissue quality evaluations have focussed on lake fish (see above). Adult rainbow trout have been collected from Hazeltine Creek for tissue quality characterization, and the associated data interpretation is integrated with the data for Polley Lake (above) as adult rainbow trout captured in Hazeltine Creek migrate into the creek to spawn.

2.3 Quesnel Lake

2.3.1 Fish Community / Population

The fish community of Quesnel Lake has been well characterized and includes a total of 20 species (Table 4). Prior to the TSF embankment breach, fish monitoring in Quesnel Lake was limited to collections for tissue quality analysis (2009, 2012, and 2014). These collections resulted in the capture of burbot, lake trout, largescale sucker, longnose sucker, mountain whitefish, peamouth chub, and rainbow trout (Table 5). Fish collections, primarily for tissue quality, have been undertaken annually since the TSF embankment breach in 2014, with community composition similar to that documented previously (Table 5). Additional collections for federal Environmental Effects Monitoring (EEM) were undertaken in 2016 (Minnow 2016).

The Mount Polley Phase 1 EEM included a population study of two sentinel species – northern pikeminnow and largescale sucker (with a supporting evaluation of peamouth chub; Minnow 2016). The objective of this monitoring was to determine if exposure to Mount Polley mine effluent (discharged to Quesnel Lake starting in December 2015) has an effect on the survival, growth, or reproduction of sentinel fish populations as compared to reference populations. Some differences in fish population endpoints (i.e., survival and energy use) were observed for northern pikeminnow, largescale sucker, and peamouth chub captured from effluent-exposed versus reference areas (Minnow 2016). However, there was no concordance between the results of comparisons of effluent-exposed populations to the two reference area populations (i.e., the metrics for effluent-exposed populations were often intermediate between the two references) nor among the three species. Overall, it was concluded that fish communities in the effluent-exposed and reference areas were similar and that effluent discharges from the mine were not affecting fish populations or fish health (Minnow 2016).

Table 4: Fish Species Documented in Quesnel Lake

Common Name	Latin Name
Sockeye Salmon	*Oncorhynchus nerka*
Coho Salmon	*Oncorhynchus kisutch*
Chinook Salmon	*Oncorhynchus tshawytscha*
Kokanee	*Oncorhynchus nerka*
Rainbow Trout	*Oncorhynchus mykiss*
Bull Trout	*Salvelinus confluentus*
Lake Trout	*Salvelinus namaycush*
Pygmy Whitefish	*Prosopium coulteri*
Mountain Whitefish	*Prosopium williamsoni*
Lake Whitefish	*Coregonus clupeaformis*
Burbot	*Lota lota*
Largescale Sucker	*Catostomus macrocheilus*
Longnose Sucker	*Catostomus catostomus*
Slimy Sculpin	*Cottus cognatus*
Northern Pikeminnow	*Ptychocheilus oregonensis*
Peamouth Chub	*Mylocheilus caurinus*
Leopard Dace	*Rhinichthys falcatus*
Longnose Dace	*Rhinichthys cataractae*
Redside Shiner	*Richardsonius balteatus*
Lake Chub	*Couesius plumbeus*

[c] Potentially exposed.

2.3.2 Fish Tissue Quality

Tissue quality of Quesnel Lake fish was evaluated following the TSF embankment breach in 2014. This monitoring has included 12 fish species and variously included whole body, muscle tissue, liver tissue, Kidney tissue, and ovary tissue samples (Golder 2016; Minnow 2017b, 2018a). Fish tissue quality investigations were focussed on a suite of analytes that included metals that: 1) were identified as potentially indicative of the influence of the TSF embankment breach on the receiving environment (arsenic, cadmium, copper, iron, mercury, molybdenum, phosphorus, selenium, vanadium, and zinc; and/or or 2) had tissue quality guidelines (mercury and selenium).

Concentrations of mercury and selenium in tissues of fish collected in Quesnel Lake from 2015 to 2017 (burbot, kokanee, lake trout, largescale sucker, northern pikeminnow, peamouth chub, redside shiner) were lower than guidelines for the protection of human health in all cases except for mercury in large burbot and lake trout (Table 6; Minnow 2017b, 2018a). Large burbot and large lake trout (greater than approximately 66 cm in length [fork length and total length, respectively]) had mercury concentrations at levels where consumption limitation should be considered in accordance with provincial and federal guidance (e.g., BCMOE 2014; CFIA 2015). Smaller burbot and lake trout, as well as all other species can be safely consumed at consumption levels typical of the general population. There was no evidence that the Mount Polley Mine had any influence on mercury concentrations in burbot or lake trout. Rather, these species are piscivores (eat other fish) and are expected to have naturally higher concentrations of mercury (which is known to biomagnify). Concentrations of selenium in all fish species and tissues collected in Quesnel Lake were below BCWQGs for the protection of aquatic life.

In Quesnel Lake, uncertainty over fish movement between the exposed and reference areas and the absence of pre-breach datasets (of similar species) made interpretation of fish tissue quality results challenging. In Quesnel Lake, the only corroborated (reasonably unequivocal) differences in tissue metal concentrations of fish collected from exposed versus reference areas were higher concentrations of arsenic, cadmium, mercury, and selenium in tissues or whole bodies of northern pikeminnow and/or peamouth chub collected from exposed areas relative to reference areas. However, results of Environmental Effects Monitoring (EEM) undertaken in 2016 indicated that populations of northern pikeminnow and peamouth chub collected at the exposed area had very slightly (but not biologically meaningful) lower condition than reference fish (3.6% lower; Minnow 2016). Accordingly, the few corroborated differences in tissue metal concentrations were not associated with any adverse effect on the health of peamouth chub or northern pikeminnow. In 2017, no corroborated (reasonably unequivocal) temporal changes were identified for northern pikeminnow (whole bodies) collected from Quesnel Lake (relative to 2016; Minnow 2018a). This

Table 6: Comparison of Muscle and Whole Body Samples Collected in Quesnel Lake to Consumption Guidelines for Protection of Human Health or Guidelines for the Protection of Aquatic Life, MPMC, 2015 to 2017

Sample Collection Timing	Area	Species (Species Code)	Tissue	Sample Size	Mercury (Hg) mg/kg ww		Selenium (Se) mg/kg dw				
					Health Canada Human Health (0.5 mg/kg ww)		BCMOE Human Health (Moderate = 14.5 mg/kg dw) (High = 7.3 mg/kg dw)			BCMOE Guideline (4 mg/kg dw)	
					Mean	Frequency > guideline	Mean	Frequency > moderate	Frequency > high	Mean	Frequency > guideline

	Near Grain Creek (North Arm, Reference)	Largescale Sucker (CSU)	Muscle	8	0.11	0%	1.6	0%	0%	1.6	0%
		Northern Pikeminnow (NSC)	Whole Body	8	-	-	-	-	-	2.1	0%
		Peamouth Chub (PCC)	Muscle	8	0.15	0%	1.6	0%	0%	1.6	0%
Fall 2017	near Hazeltine Creek	Northern Pikeminnow (NSC)	Whole Body	8	-	-	-	-	-	2.3	0%

Note: ww = wet weight; dw = dry weight.

Indicates mean mercury concentration greater than Health Canada's Human Health concentration for muscle tissue in fish (0.5 mg/kg ww; CFIA 2015).

Indicates mean selenium concentration greater than the BCMOE Human Health guideline for moderate fish consumption (14.5 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than the BCMOE guideline for muscle tissue or whole body in fish (4 mg/kg dw; BCMOE 2014).

pattern indicates that, if there was any breach-related influence on Quesnel Lake fish tissue quality, it was minor.

2.4 Quesnel River

2.4.1 Fish Community / Population

Fish were sampled in the Quesnel River in 2014, 2015, and 2017, targeting rainbow trout, primarily by angling (Table 7). Other species were captured, including burbot, mountain whitefish, and peamouth chub (Table 7). Rainbow trout that were collected in the Quesnel River in 2017 were of similar age and size to those collected in 2015 (Minnow 2018a).

2.4.2 Fish Tissue Quality

Tissue quality of rainbow trout collected from the Quesnel River in 2015 and 2017 did not exceeded Health Canada's Human Health guideline for mercury (Minnow 2018a). In 2015, selenium concentrations in rainbow trout were below the BCMOE guideline for human health and for the protection of aquatic life, but in 2017, one sample exceeded these guidelines (Minnow 2018a). As observed in Quesnel Lake, no corroborated (reasonably unequivocal) temporal changes were identified for rainbow trout (muscle, liver, and kidney tissue) collected from the Quesnel River in 2017 (relative to 2015; Minnow 2018a).

Table 7: Summary of Fish Collected in Quesnel River, Mount Polley, 2014 to 2017

Quesnel River	2014	Golder 2016	unknown	-	-	3	12
	2015	Zirnhelt and Dolighan 2015	angling	-	-	-	8
	2017	Minnow 2018a	angling	1	2	-	8

3 STUDY DESIGN OVERVIEW AND RATIONALE

Fish monitoring under the CEMP is designed to meet the combined needs of: 1) operational monitoring (including the discharge of treated effluent to Quesnel Lake); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to remediation following the TSF embankment breach. As previously indicated, fish monitoring includes fish tissue quality monitoring, sentinel fish population monitoring, fish habitat characterization and fish usage monitoring, and fish community monitoring. An overview of the proposed fish monitoring program is provided in Table 8 and Figures 5 and 6.

3.1 Fish Tissue Quality

Fish tissue quality monitoring is focused on Polley Lake and Quesnel Lake, with un-impacted reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake for Polley Lake, unaffected areas of Quesnel Lake for exposed areas of Quesnel Lake; Table 8; Figures 5 and 6). In Polley Lake, fish tissue quality monitoring is undertaken to monitor the combined influence of general mine proximity, uncontrolled surface runoff from the north dump (2006 to 2009), and influence of the TSF embankment breach. In Quesnel Lake and Quesnel River, fish tissue quality monitoring is undertaken to monitor the combined influence of the TSF embankment breach and the discharge of Mount Polley mine effluent (December 2015 to present). In Polley Lake (and reference), fish tissue quality monitoring will focus on rainbow trout and longnose sucker. Because selenium was elevated in the 2006 to 2009 surface runoff, this monitoring will be focussed on the collection of females in the spring so that ripe ovaries can be collected. The full complement of tissues to be collected will include muscle, liver, kidney, and ovary (Table 8). Scientific consensus is that the best tissues for evaluating the potential adverse effects of selenium to fish (which are considered to be the most selenium sensitive organisms) are ripe ovaries or eggs (Presser and Luoma 2009; Janz et al. 2010; DeForest et al. 2012; Janz 2012). Tissues will be collected for the analytical determination of moisture content, metals, and mercury (Section 4.3). Supporting data will include catch per unit effort, length, weight, and age (see below). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) concentrations relative to fish tissue quality guidelines for the protection of aquatic life and human health (BCMOE 2014; CFIA 2015). A sample size of eight fish per species per area will provide replication for the statistical contrasts. Fish tissue quality monitoring in Polley and Bootjack lakes will be undertaken at an annual monitoring frequency from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

Table 8: Mount Polley CEMP Fish Monitoring Plan Overview

A) Fish Tissue Quality Monitoring [1]

Water Body	Type	Fish Species	Tissues [2,3]	Replication	Frequency [4]	Rationale
Polley Lake	Exposed	RB, LSU	M,L,K,O	8	annual	immediately adjacent to mine and breach-influenced
Bootjack Lake	Reference	RB, LSU	M,L,K,O	8	annual	reference for Polley Lake [5]
Quesnel Lake	Exposed	RB, LT, KO, NSC, PCC	M,L,K,O	8	annual	adjacent to effluent discharge and breach-influenced
	Reference	RB, LT, KO, NSC, PCC	M,L,K,O	8	annual	reference for Quesnel Lake exposed
Quesnel River	Far-Field Exposed	RB	M,L,K,O	8	annual	far-field exposed area near Quesnel Lake outlet

[1] All fish tissues will be evaluated for the following analytes: percent moisture, metals by ICP-MS scan, and total mercury (Table 9).

[2] Fish tissues: M = muscle, L = liver, K = kidney, O = ovary (as available/developed; note that females will only be specifically targeted in Polley and Bootjack lakes).

[3] Except for small bodied fish (PCC and juvenile NSC), which will be submitted whole.

[4] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

[5] Bootjack Lake is retained as the reference for Polley Lake due to the fact that it has not been notably affected by the mine, there is a long-term dataset available for it, and its watershed includes similar geology to Polley lake. The latter is not true for other potential reference areas.

B) Fish Population Monitoring

Water Body	Type	Fish Species	Endpoints	Replication	Frequency [3]	Rationale
Polley Lake	Exposed	RB, LSU	L,W,C [1]	100	annual	immediately adjacent to mine and breach-influenced
Quesnel Lake	Exposed	NSC, RSC	Federal EEM [2]	20 / sex	every 3 years [4]	adjacent to effluent discharge and breach-influenced
	Reference	NSC, RSC	Federal EEM [2]	20 / sex		reference for Quesnel Lake exposed

[1] L = length-frequency distribution (indicative of recruitment and survival), W = weight, C = condition (indicative of overall health / energy storage).

[2] Fish population endpoints prescribed for federal EEM will be applied. These differ for lethal and non-lethal designs as described in Section 4.2.

[3] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

[4] Frequency prescribed for federal EEM.

C) Fish Habitat Characterization and Usage Monitoring

Water Body	Type	Fish Species	Measures	Frequency [5]	Rationale
Upper Hazeltine Creek	Impacted [1]	RB, LSU	Fish habitat characterization [3], fish occupancy and meristics [4]	annual	immediately adjacent to mine and breach-impacted
Lower Hazeltine Creek	Impacted [1]	all / any [2]		every 2 years	breach-impacted
Lower Edney Creek	Impacted [1]	all / any [2]		every 2 years	breach impacted

[1] Impacted by the TSF embankment breach.

[2] A total of 20 fish species have been documented in Quesnel Lake (SNC-Lavalin 2015) and would have access to Lower Hazeltine and Lower Edney creeks.

[3] Fish habitat characterization using methodology applied in 2016 and 2017 (Minnow 2018b), as adapted from Johnston and Slaney 1996.

[4] Fish occupancy as determined by observation (including spawning, and general presence) and by fishing with record of catch/effort and meristic measures (length and weight).

[5] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

D) Fish Community Monitoring

** qualitative fish community data will be collected to support all fish tissue, fish population, and fish habitat usage collections

Water Body	Collection Methods [1,2,3]	Endpoint	Frequency [6]	Rationale
Polley Lake	HN, MT, FT, SN, EF, GN	CPUE [5]	annual	to support fish tissue quality and population monitoring
Bootjack Lake	HN	CPUE [5]	annual	to support fish tissue quality and population monitoring
Quesnel Lake	HN, MT, FT, SN, GN	CPUE [5]	annual	to support fish tissue quality and population monitoring
Upper Hazeltine Creek	MT, FT, SN, EF [4]	CPUE [5]	annual	to support fish population and habitat usage monitoring
Lower Hazeltine Creek	MT, FT, SN, EF [4]	CPUE [5]	every 2 years	to support fish habitat usage monitoring
Lower Edney Creek	MT, FT, SN, EF [4]	CPUE [5]	every 2 years	to support fish habitat usage monitoring
Quesnel River	AG	CPUE [5]		to support fish tissue quality monitoring

[1] In order of preference for non-lethal fish collection methods whenever possible (e.g., hoop netting, minnow trapping, electrofishing).

[2] HN = hoop netting, MT = minnow trapping, FT = fry trapping, SN = seining, EF = electrofishing, GN = gill netting, AG = angling.

[3] Prohibited in waters over twenty degrees Celsius.

[4] Subject to electrofishing prohibition during spawning and incubation periods and in waters below five degrees Celsius.

[5] CPUE = catch per unit effort. For HN, MT, and FT, CPUE will be expressed as catch per unit deployment time; for SN, CPUE will be expressed as catch per unit area; for EF, CPUE will be expressed as catch per unit electroshocking time and per unit area; for GN, CPUE will be expressed as catch per unit net surface area-time; and for AG, CPUE will be expressed as catch per unit of angling effort.

[6] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

In Quesnel Lake (exposed and reference), fish tissue quality monitoring will focus on sentinel species. Sentinel species were selected on the basis of their trophic position, their status as sportfish or non-sportfish, their typical home range sizes, and the availability of historical tissue quality data. Rainbow trout (to be collected in the Quesnel River near the lake outlet; see below) and lake trout were selected as the sentinel sportfish species to monitor potential changes in tissue quality over time relative to human consumption of sportfish. In 2018, kokanee will also be monitored for this purpose (as there is a dataset from 2014 to which they can be compared). Northern pikeminnow and peamouth chub were selected as sentinel species with small home ranges to monitor potential changes in fish tissue quality associated with the TSF embankment breach and effluent discharge from the perspective of aquatic ecosystem health. Redside shiner may be used as an alternate sentinel species for this purpose depending upon future capture success. Fish species with small home ranges are better monitors of the potential effects of defined point sources (due to the fact that they are more continuously exposed) than fish with larger home ranges (e.g., Environment Canada 2012). The larger bodied fish will be subject to sampling the full complement of tissues, including muscle, liver, kidney, and ovary (Table 8). Ovary will only be sampled when available (i.e., when fully developed in mature females); additional fish will not be targeted and sacrificed to achieve the target sample size for ovary tissues (i.e., it is expected that ovary sample sizes will be less than eight). The small bodied fish (i.e., small northern pikeminnow, peamouth, and/or redside shiner) will be submitted as headless carcasses (as the heads will be submitted for otolith extraction and age determination). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) concentrations relative to fish tissue quality guidelines for the protection of aquatic life and human health (for selenium and mercury; BCMOE 2014; CFIA 2015). It is noted that comparison to reference conditions has previously proven to be challenging due to uncertainty over exposure given the large home ranges of the sportfish species and the apparent absence of a strong mine influence (Golder 2016; Minnow 2017b, 2018a). Thus, the greatest utility of fish tissue monitoring is as a temporal monitor and for comparison to available guidelines. A sample size of eight fish per species per area will provide replication for the statistical contrasts. Fish tissue quality monitoring in Quesnel Lake will be undertaken at an annual monitoring frequency from 2018 to 2020 (although, as previously noted, kokanee will only be collected in 2018), and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

In the Quesnel River, rainbow trout were selected as a sentinel sportfish species to monitor potential changes in tissue quality over time. Rainbow trout will be collected in the late summer and will be subject to sampling the full complement of tissues, including muscle, liver, kidney, and ovary (Table 8). As noted above, ovary will only be sampled when available (i.e., when fully

developed in mature females); additional fish will not be targeted and sacrificed to achieve the target sample size for ovary tissues (i.e., it is expected that ovary sample sizes will be less than eight). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; and 2) concentrations relative to fish tissue quality guidelines for the protection of aquatic life and human health (BCMOE 2014; CFIA 2015). A sample size of eight fish per species per area will provide replication for the statistical contrasts. Fish tissue quality monitoring in the Quesnel River will be undertaken at an annual monitoring frequency from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

Fish community and population data will be collected to support all fish tissue quality monitoring (as discussed in greater detail below). All collections will be supported by capture records for all species and documentation of effort that will be used to calculate Catch-Per-Unit-Effort (CPUE). All fish selected for tissue quality will be subject to measurement of length, weight (total and fork), and the collection of structures for age determination. Detailed methodology for fish collection, measurement, tissue sample collection, tissue sample processing, sample handling and laboratory analysis, quality control/quality assurance, data quality review, data handling, interpretation, and reporting is provided in Section 4.

3.2 Sentinel Fish Populations

Fish population monitoring is focused on Polley Lake and Quesnel Lake (Table 8; Figures 5 and 6). In Polley Lake, population monitoring is focused on tracking the population structure of rainbow trout. Specifically, with the inaccessibility of Hazeltine Creek (the major spawning and juvenile rearing location for Polley Lake Fish) between August 2014 and spring 2018, recruitment of Polley Lake rainbow trout was substantially diminished for four years (i.e., juvenile fish in Hazeltine were eliminated with the breach in August 2014 and recruitment from Hazeltine was unavailable in 2015, 2016, and 2017). Following the re-opening of Upper Hazeltine Creek in spring 2018, Polley Lake rainbow trout will again have access to the major spawning and rearing habitat and fish population monitoring will document changes in population structure over time (i.e., recovery of age-class balance). Polley Lake fish population monitoring will be conducted by hoop netting in the spring and fall. This non-lethal technique has previously proven effective for the collection of adult rainbow trout, adult longnose sucker, and larger redside shiner. All captured fish will be identified and counted, and all captured rainbow trout will be measured (total length, fork length, and weight) to provide data that can be used to characterize size-frequency distributions indicative of recruitment and survival. In 2018 only, an additional gill netting effort will be completed in the fall using methodology identical to that applied in 2014 and 2016 (Lirette 2015, 2017). This effort will apply experimental gill nets to achieve a high level of comparability to the previous work. The same measurements as noted above will be collected.

As this technique is destructive (lethal), age structures will also be collected and will allow age-frequency distributions to be determined in addition to the size frequency distributions noted above. Summary rainbow trout population metrics (mean age, mean size, size-at-age, and condition [weight-at-length]) as well as community metrics (CPUE, relative species proportions, as discussed in greater detail below) will be calculated and compared between areas (Polley Lake and Bootjack Lake), and over time. A target sample size of 50 (100 preferred) will provide replication for statistical contrasts. Data collected by the two different techniques in 2018 (hoop netting and gill netting) will be compared to determine if the non-destructive technique adequately addresses key questions, in which case future destructive sampling will be considered unnecessary. Fish population monitoring in Polley Lake will be undertaken at an annual monitoring frequency from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

Additional fishing efforts in Polley Lake shoreline areas will be undertaken to monitor the presence and abundance of juvenile rainbow trout. This will serve to monitor the recovery of rainbow trout in Polley Lake and to specifically augment the monitoring of juvenile trout recruitment determined for Upper Hazeltine Creek (as discussed in more detail in Section 3.3 below). Juvenile rainbow trout will be collected from shoreline areas in Polley Lake by minnow trapping, fry trapping, and backpack electrofishing. All captured fish will be identified, recorded, measured (fork length, total length, and weight) and released. Endpoints of CPUE, mean length, mean weight, size-frequency distributions, and condition will be calculated and monitored for comparison over time. Monitoring of juvenile rainbow trout in Polley Lake will be undertaken annually in the fall from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

In Quesnel Lake, populations of sentinel fish species (northern pikeminnow and redside shiner) will be monitored to evaluate potential effects associated with Mount Polley mine effluent discharge in accordance with requirements for EEM under the MDMER of the federal *Fisheries Act* (Environment Canada 2012; Government of Canada 2018). The fish population survey will be undertaken using prescribed methodology (Environment Canada 2012) and as described in detail in the Study Design report for the Phase 2 EEM (Minnow 2018c). Briefly, sentinel fish population monitoring in Quesnel Lake will evaluate population health (survival, growth, reproduction, and condition) of the two sentinel species. The study will be completed as a conventional (lethal) design (Environment Canada 2012) and will target 20 mature males and 20 mature females of each of the two sentinel species at the exposed area (near the Mount Polley effluent discharge) and at a reference area (Table 8; Figure 5). Fish collections will be completed by hoop netting and gill netting, and all fish measurements will be completed as prescribed by Environment Canada (2012) and as described in detail in Section 4.2. Quesnel Lake fish population monitoring will be completed in early spring when the sentinel species are fully

developed prior to spawning (McPhail 2007; Barrett and Munkittrick 2010). Northern pikeminnow typically spawn in the spring at a threshold temperature of 12 °C and redside shiner typically spawn in the spring at a threshold temperature of 10 °C (McPhail 2007). Both species typically spawn in flowing water over clean gravel substrates, but can also spawn in lakes. Sentinel fish species (up to the target sample size) will be subject to sacrifice and collection of the following measures prescribed for EEM: fork length, total length, weight, liver weight, gonad weight, and fecundity (Environment Canada 2012). Sentinel fish population endpoints (survival, growth, and reproduction) will be calculated for each species-area combination and statistically contrasted between effluent-exposed and reference areas as prescribed under EEM (Environment Canada 2012) and described in Section 4. Fish population monitoring in Quesnel Lake will be undertaken at the prescribed frequency of once every three years, with next collection in the spring of 2019. As outlined in EEM technical guidance, future frequency can change is response to findings. Detailed methodology for fish collection, measurement, tissue sample measurement, sample handling and laboratory analysis, quality control/quality assurance, data quality review, data handling, interpretation, and reporting is provided in Section 4.

3.3 Fish Habitat Characterization and Usage

Fish habitat characterization and usage monitoring is focused on Hazeltine Creek and lower Edney Creek, both of which were physically impacted by the TSF embankment breach (Table 8; Figure 6). Fish habitat characterization will monitor key characteristics of rehabilitated Hazeltine and Edney creek habitat in order to document recovery. Fish habitat usage monitoring will document the use of these rehabilitated creek habitats by all fish species and life stages, including the specific documentation of spawning and rearing in spring, summer, and fall months (May to October). Fish habitat characterization methods will be similar to those previously applied (Minnow 2018b) which are adapted from Johnston and Slaney (1996) and described in detail in Section 4.2. Fish habitat will be characterized in spring, summer, and fall in relation to the needs of fish that could potentially use the habitat (i.e., Polley Lake fish in the case of Upper Hazeltine Creek and Quesnel Lake fish in the case of Lower Hazeltine creek and Lower Edney Creek), and will include documentation of in-stream barriers and cover, spawning and overwintering habitat, riparian features, channel hydrology, bank condition, and water quality parameters. Fish habitat usage will be determined by a combination of visual observation and fish collection with measurement. Fish habitat usage monitoring will commence in the spring (May) once fish have begun to aggregate for spawning, and will be conducted again in the summer (August), and in the fall (September / October, including when fish are spawning). Fish collections will be completed using hoop netting, minnow trapping, fry trapping, seining, and backpack electrofishing (the latter only when appropriate based on non-spawning/egg incubation periods and when juvenile salmonids are not present). All captured fish will be identified and enumerated, and

fishing efforts will be documented for CPUE or density calculations (see following section). Up to 100 individuals from each collected species will be temporarily retained for length and weight measurements, which will be used to calculate summary statistics of length, weight, condition, and size-frequency distributions that will be monitored over time to document recovery. Fish habitat characterization and fish usage monitoring in lower Hazeltine Creek and lower Edney Creek will be undertaken at frequency of every two years starting in 2019[4], and the frequency will re-evaluated prior to 2021 based on QP recommendations. Detailed methodology for fish collection, fish measurement, quality control/quality assurance, data quality review, data handling, interpretation, and reporting is provided in Section 4.

For Upper Hazeltine Creek, fish collection will also include closed-station electrofishing that will provide the best possible estimate of the density of rearing rainbow trout (using removal calculators as outlined in Section 4). Fish capture data will be utilized to document the production of rainbow trout and any temporal changes therein including comparison to historical estimates (e.g., Minnow 2009). Fish meristic data will be used to calculate summary statistics of length, weight, condition, and size-frequency distributions that will also be compared to historical results (e.g., Minnow 2009). Fish habitat characterization and fish usage monitoring in upper Hazeltine Creek will be undertaken at an annual frequency from 2018 to 2020, and the frequency will re-evaluated prior to 2021 based on QP recommendations. Detailed methodology is provided in Section 4.

3.4 Fish Community

Fish community monitoring is a supporting measure to be determined in association with all fish collections (i.e., fish tissue quality monitoring, fish population monitoring, and fish habitat usage monitoring). Fish community monitoring effort will only be as required to collect the fish needed for these other purposes. Thus, the locations, timing, and frequency of fish community monitoring will be as outlined above (Sections 3.1 to 3.3, inclusive). In association with each fishing effort, all captured fish will be identified and counted. Details of each fishing effort (GPS coordinates, gear type and dimensions, and actual fishing time) will be recorded to provide the most quantitative record of fish community results possible. Specifically, the effort details will be collected to support the expression of CPUE on the basis of time (catch per time), area (catch per area), or the combination of gear-dimension and time (e.g., catch per 100 m net-hour). Interpretation of CPUE data will be based on a combination of: 1) comparison to previous conditions; 2) comparison to reference conditions; and 3) comparison of species proportions temporally and spatially (e.g., has the relative abundance rainbow trout versus longnose sucker

[4] Note that fish habitat characterization and usage monitoring in lower Hazeltine Creek will only be initiated after lower Hazeltine Creek is opened up as fish habitat (i.e., ponds and/or fish fences are removed).

changed over time and/or relative to the reference lake). Detailed methodology for fish collection, quality control/quality assurance, data quality review, data handling, data interpretation, and reporting is provided in Section 4.

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be performed by qualified field staff experienced in the implementation of fish and fish habitat monitoring programs. Quality Assurance/Quality Control (QA/QC) measures will be consistent with requirements outlined in the BC Field Sampling Manual (BCMOE 2013) and the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016). Specific QA/QC measures will include program review prior implementation, adequate resources for all field teams including field checklists and field data sheets, the availability and maintenance of appropriate sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination (i.e., for tissue quality samples).

To capture within-area variability and support the tissue quality component of the fish monitoring program, eight replicate tissue chemistry samples will be collected from each sampling area. Fish tissue samples will include muscle, liver, kidney, and ovary tissues (or whole body analysis for smaller fish). Field duplicates (i.e., split samples collected from the same fish tissue) will be collected at a frequency of 10% of the total number of tissue samples to assess field precision, and will be evenly distributed among species and tissue types, to the extent possible. A Data Quality Objective (DQO) of <25% RPD will be applied to the duplicate (i.e., split) QC samples.

All chemical analyses will be completed by a laboratory that is accredited by the Canadian Association for Laboratory Accreditation (CALA), and will be required to include specific QC samples and report associated results. Specific QC samples will include laboratory blanks, laboratory replicates, and laboratory accuracy samples (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). The QC sample results will be assessed as part of the Data Quality Review (DQR; Section 4.4). Laboratory reporting Limits (LRLs) will also be evaluated in comparison to targets established by the analytical laboratory.

Raw field data recorded on field sheets will be transcribed into an electronic spreadsheet and data collected using digital data collection devices will be exported from a geodatabase to electronic spreadsheets. Electronic spreadsheets will be checked by a separate individual for entry errors as part of routine QA/QC procedures.

4.2 Sample Collection Methods

4.2.1 Fish Collection

All fish monitoring will be undertaken under fish collection permits from the British Columbia Ministry of Forests, Lands and Natural Resource Operations (FNLNRO) and all fish monitoring in

waters frequented by salmon (e.g., Quesnel Lake and Quesnel River) will also be undertaken under fish collection permits from Fisheries and Oceans Canada (DFO). All conditions associated with the fish collection permits will be strictly adhered to (including the general prohibition of fishing in waters with temperatures >20°C).

Fish collections will be completed in accordance with applicable technical guidance outlined in the BC Field Sampling Manual (BCMOE 2013), the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016), and/or the Technical Guidance Document for EEM (Environment Canada 2012). A variety of fish collection techniques will be applied to collecting the fish required for the monitoring of fish tissue quality, fish populations, and habitat usage. To the extent possible, preference will be for non-destructive fish collection methods (e.g., hoop nets, minnow traps, fry traps, backpack electrofishing) in order to minimize the potential impact of fish monitoring on fish populations and/or communities. The following fish collection techniques will be used to support the CEMP fish monitoring plan:

- hoop netting;
- gill netting;
- minnow trapping;
- fry trapping;
- seining; and
- backpack electrofishing.

Hoop netting will be applied to the collection of large-bodied fish in lakes as the preferred collection method due to the fact that it is a non-lethal method. Hoop nets ranging in size from 0.6 m diameter, 2 cm stretched mesh to 0.75 m diameter, 3.8 cm stretched mesh with four to eight hoops and leads of approximately 30.5 m in length will be set as appropriate to target the fish required for tissue quality monitoring and fish population monitoring, and will be checked at a minimum frequency of every other day (although daily checks will be most common). The location of each net set will be recorded using a handheld GPS accompanied by notes on the set configuration (depth, lead to shore, trap to shore, etc.) and the time of deployment. Upon collection, the time of collection will be recorded and fish will be identified and counted as they are removed from the trap. Target species will be identified, counted, and then retained or measured (depending on the objective of the monitoring component). Non-target species will be identified, counted, and released at the location of capture. Individuals of the target fish species will be measured as outlined in Sections 4.2.2 and 4.2.3, per requirements of the particular monitoring component of the CEMP Fish Monitoring Plan.

Gill nets will be used as required to support hoop netting for fish tissue collection in lakes, as required, with application minimized and short deployment duration. Gill netting will also be applied in Polley Lake in late summer 2018 as a repeat of previous efforts (Lirette 2015, 2017). As required, gill nets will be set in lakes to collect large-bodied fish, consistent with historical sampling (e.g., Minnow 2018a) and recommendations from the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016). Net size and deployment configuration will be as required to most effectively capture target fish. For example, lake trout will be targeted in Quesnel Lake using a Profundal Index Netting methodology similar to the Summer Profundal Index Netting (SPIN) method (e.g., Jessup and Millar 2011). Fall 2018 gill netting in Polley Lake will employ experimental gill nets (two multi-panel gill nets of mesh size 38, 64, 38, and 89 mm), which will be set overnight. The nets will be set perpendicular to shore, with the smallest mesh orientated closest to shore. Set locations and configurations will be similar to those used in 2014 and 2016 (Lirette 2015, 2017). The location of each gill net set will be recorded using a handheld GPS accompanied by notes on the set configuration and the time of deployment. Check and retrieval times will be recorded and fish will be identified and counted as they are removed from the net. For experimental nets, fish counts will be recorded for each gill net panel. Non-target species will be identified, counted, and released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Minnow traps (galvanized mesh – 42 cm length, 0.6 cm mesh, 2.5 cm diameter opening) will be set in lakes and creeks to capture small-bodied fish and juveniles. Juvenile rainbow trout (1+ or 2+ rainbow trout) will be targeted in Polley Lake. Minnow traps will be baited and will be tied off on shore or set on the substrate and marked with a float. Minnow traps set in creeks will be set so that the openings will be oriented upstream and downstream. Minnow traps will be checked at a minimum frequency of every other day (although daily checks will be most common). The location of each trap will be recorded using a handheld GPS accompanied by notes on the set configuration and the time of deployment. The retrieval time will be recorded and fish will be identified and counted as they are removed from the trap. Non-target species will be enumerated by species and released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Fry traps will be set in selected lakes and creeks (Polley Lake, Hazeltine Creek, Edney Creek, and Frypan Creek) to augment minnow trap catches. Traps will be placed in habitat deemed suitable for juveniles (e.g., in slow flowing water near undercut banks, behind woody debris) and oriented with the closed end angled upstream. Traps will be weighed down on the streambed using small stones and will be checked daily. The location of each trap will be recorded using a

handheld GPS accompanied by notes on the set configuration and the time of deployment. Fry traps will be checked at a minimum frequency of every other day (although daily checks will be most common). The retrieval time will be recorded and fish will be identified and counted as they are removed from the trap. Non-target species will be enumerated by species and released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Seining may also be completed in lakes and creeks to augment catches by other techniques. A 15 m long seine with a 0.3 mm mesh size will be used. The seine net will be pulled through shallow habitats by wading through the sampling area; in deeper areas, a boat may be used to pull one end of the seine (BCMOE 2013). Care will be taken to ensure that the lead line remains in contact with the substrate and the float-line remains at the surface to prevent fish from escaping. The contents of the seine will be brought to shore, and depending catch numbers, may be emptied into a water-filled tote and the seine will be inspected to confirm that all fish are removed. The location of each effort will be recorded using a handheld GPS accompanied by notes regarding habitat features and the area and maximum depth sampled. The date and time will be recorded and fish will be enumerated by species. Non-target species will be released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Open-station and/or closed-station backpack electrofishing will be completed in Polley Lake (along the shoreline) and in creeks. All electrofishing will be completed by an experienced and certified electrofishing team, consisting of a backpack electrofisher operator and one or more netters using electrofisher settings appropriate for the target species (i.e., frequencies and pulse width) and starting with lowest possible power output (voltage and duty cycle). Open stations will be fished by single electrofishing pass in an upstream direction. During open-station electrofishing, the operator will create a series of smooth, zig-zagging sweeps with the anode. Fish will follow the anode; therefore, the operator will move the anode towards the netter, who will net the stunned fish. Closed stations will be created using 3/8” mesh stop nets and care will be taken to ensure that the enclosed habitat is suitable for the potential presence of target fish. The dimensions (length and wetted and bankfull widths) and water depth (average of three measures) of each open and closed station will be measured at equally-spaced transects using a measuring tape and meter stick, respectively. During each closed station electrofishing effort, the electrofisher operator and netter will employ a multiple pass removal method at each station whereby one upstream pass (or “sweep”) of the enclosed reach is repeated three or more times to yield a fish removal pattern (i.e., diminishing catches) that can be used to determine fish density

using removal method equations. Fish captured during each open electrofishing pass or closed station sweep will be placed in separate buckets of aerated water. The location of each effort will be recorded using a handheld GPS accompanied by the start and end times and active electrofishing seconds. The total sampling area will be documented, along with a habitat descriptions that include observations of stream morphology and substrate characteristics, riparian vegetation and relative stream shading, as well as any potential confounding influences or other observations deemed relevant to interpretation of the fish survey data. The fish in each bucket will be enumerated by species. Non-target species will then be released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Fish will be captured from the Quesnel River by angling (targeting rainbow trout for fish tissue quality monitoring). Angling will be conducted using barbless, single hook lures, and/or flies. The general location of each effort will be recorded using a handheld GPS accompanied by notes on the hooks/lures/flies used, effort duration, and habitat. Captured fish will be identified and counted. Non-target species will be released at the location of capture and target species will be retained or measured. Retained rainbow trout will be measured as outlined in Sections 4.2.2 and 4.2.3, per requirements of the particular monitoring.

All fishing effort data will be recorded on field sheets or digital data collection devices. *In situ* water quality measurements (i.e., temperature, pH, dissolved oxygen, conductivity, and specific conductance) will also be recorded to support fishing efforts.

4.2.2 Fish meristic data

Meristic measurements on fish that will not be retained for lethal sampling will be recorded prior to releasing the fish at their point of capture. Fish retained for lethal sampling will be anesthetized using a clove oil solution or will be euthanized with a decisive blow to the head and spinal severance. Fish will be subjected to measurement of fork length, total length, and body weight (BCMOE 2013). Fork and total length of large-bodied fish will be measured to the nearest millimeter using a measuring board and fork and total length of small-bodied fish will be measured to the nearest 0.1 mm using digital calipers. Fresh body weight will be measured using an analytical balance or a set of Pesola™ spring scales (depending on fish weight). The Pesola™ scales are demarcated at intervals of 1 to 2% of the total scale range, providing an accuracy of plus or minus (±) 0.3% of the fish mass. The Pesola™ spring scale for individual weight measurement will be selected so that the fish weight is near the top of the scale's range to ensure that measurements achieve a resolution near 1%. Northern pikeminnow and redside shiner that will be lethally sampled as part of MDMER/EEM will also undergo an external health assessment

(Environment Canada 2012). Following external health assessment, each fish will be cut open and sex will be recorded. Gonads and liver will be removed for weighing and sampling as required. Tissues will be weighed to the nearest milligram using a portable analytical balance (capable of measurement to 0.001 g). For EEM, whole ovaries from sexually mature females will be placed in individually labelled sample vials and preserved with a 10% buffered formalin solution for determination of fecundity.

Age structures will be retained for all fish collected for fish tissue quality monitoring using available guidance for the best age structure for each species (e.g., Environment Canada 2012). Otoliths will be removed and used as the primary aging structure for all fish species except for sucker. Pectoral fin rays will be removed and used as the primary aging structure for sucker. Scales will also be collected for use as backup structures for age determination. Aging structures will be wrapped in waxed paper, and placed in labelled coin envelopes, which will then be frozen prior to submission to a qualified fish aging laboratory.

4.2.3 Fish Tissue Quality

For large-bodied fish targeted for tissue quality monitoring, tissue quality samples will be collected after meristic measures are collected and will include muscle, liver, kidney, and ovary (the latter as available). For small-bodied fish targeted for tissue quality monitoring (i.e., juvenile northern pikeminnow and peamouth chub), whole body samples will be analyzed for tissue chemistry. Tissue samples (muscle, liver, kidney, and/or ovary) will be removed, weighed to the nearest 0.001 g (±1% precision) using an analytical balance, placed in labelled Whirl-Pak™ bags, and frozen until analysis. All tissue samples will be collected using clean implements (cutting boards, filet knives, and tweezers; BCMOE 2016). Livers and kidneys will be collected whole, whereas approximately 10 to 50 g of boneless, skinless muscle will be collected, and a similar sized ovary sub-sample will be collected when available (or will be collected whole if smaller than this). Duplicate QC samples (i.e., split samples collected from the same fish tissue) will be collected for 10% of tissue samples to assess field precision, and will be evenly distributed among species and collected tissue types, to the extent possible. A DQO of <25% RPD will be applied to the duplicate (i.e., split) QC samples.

4.2.4 Fish Habitat Characterization and Usage

Habitat characterization methods will include those applied in 2016 and 2017 (Minnow 2018b; adapted from Johnston and Slaney 1996). Data will be recorded on field data sheets or using digital data collection devices. The following characteristics will be documented:

- stream dimensions (i.e., wetted and bankfull width, length, and depth) within each habitat unit;

- channel gradient;
- substrate type;
- in-stream barriers and cover;
- the presence/absence of spawning and overwintering habitat;
- riparian features (e.g., vegetation types and canopy cover);
- channel hydrology;
- bank condition; and
- *in situ* water quality.

Habitat characterization methods will be a composite of two standard methods: 1) Reconnaissance Fish Habitat Inventory (RIC 2001); and 2) Level 1 Field Fish Habitat Assessment ("Habitat Unit Assessment"; Johnston and Slaney 1996). Habitat characterization using methods adapted from RIC (2001) will be completed at replicate stations (three per area) and will include include measures of channel dimensions, water velocity, and in situ water quality at each station. Channel dimensions (bankfull width, wetted width, and a minimum of 5 incremental wetted depth measures), will be measured using a tape measure and metre stick. Water velocity will be measured using a portable velocity meter. At each velocity transect, water velocity, wetted depth, and bankfull-wetted depth will be measured at a minimum of five incremental distances (points) along one wetted channel cross-sectional width. Water velocity measurements will be obtained at 60 percent of depth as an estimate of the mean vertical velocity at each measurement point. In situ water quality measures will include temperature, specific conductance, dissolved oxygen, and pH using a calibrated handheld portable field meter. Additional habitat characteristics to be assessed at each station will include description of channel bed features (substrate type, relative proportion of each substrate type, etc.), channel and bank gradient, substrate size, bank stability, riparian vegetation (vegetation types, overhead shading), and in-stream cover (as the relative proportion that each contributed to total creek surface area at each station). Substrate size will be assessed (100 randomly selected rocks per station) for the purpose of monitoring temporal changes in substrate size distribution. Photographs of representative habitat will be taken at each station in each season to further support the habitat descriptions. During each seasonal survey, any unique or significant physical or biological features (e.g., tributaries, groundwater seeps, partial or seasonal fish barriers to fish migration) will be documented, including a brief description of the feature, together with its GPS coordinates. In addition, the GPS coordinates of pools present in the rehabilitated and reference reaches, and physical dimensions of the pools (length, width, and maximum depth) will be recorded.

Habitat assessment using Level 1 Field Fish Habitat Assessment methods ("Habitat Unit Assessment"; Johnston and Slaney 1996) will also be undertaken. At least seven consecutive habitat units (i.e., pool, glide, or riffle) will be identified towards the center of each reach and the dimensions of each habitat unit will be recorded. Specifically, the length, mean width (wetted and bankfull; mean of at least 3 measures), and mean depth (wetted and bankfull; mean of at least 5 measures) will be determined for each habitat unit using a tape measure and meter stick. For pools, the maximum and residual (maximum minus crest depth) wetted depth will also be measured, as well as pool type. A minimum residual depth of 0.2 m is required for classification of a habitat unit as a pool (Johnston and Slaney 1996). Additional habitat characteristics assessed at each habitat unit will include included channel gradient, substrate type, riparian vegetation (vegetation types, growth stage, and canopy cover), in-stream cover, access to off-channel habitat, the number of pieces of large woody debris (LWD) present, and indicators of disturbance.

Fish habitat usage monitoring will document the use of these rehabilitated creek habitats by all fish species and life stages, including the specific documentation of spawning and rearing in spring, summer, and fall months (May to October). Fish habitat usage will be determined by a combination of visual observation and fish collection using techniques described above (hoop netting, minnow trapping, fry trapping, seining, and backpack electrofishing; the latter only when appropriate based on non-spawning/egg incubation periods and when juvenile salmonids are not present). All captured fish will be identified and enumerated, and fishing efforts will be documented for CPUE or density calculations (as described above). Any observations of specific behaviours (e.g., spawning) will be noted.

4.3 Sample Handling and Laboratory analysis

To the extent possible, sample handling and laboratory analyses will be completed in accordance with technical guidance outlined in the BC Field Sampling Manual (BCMOE 2013), the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016), the Technical Guidance Document for EEM (Environment Canada 2012), and the BC Environmental Laboratory Manual (BCMOE 2015).

At the termination of each field program or at intervals of no more than seven days, fish tissue samples will be shipped in coolers with ice packs and chain-of-custody forms (COCs) to the analytical laboratory. Shipment transit time will be less than one day. Chemical analyses will be completed by a CALA-accredited analytical laboratory and will include moisture content and total metal concentrations (Table 9). Concentrations of mercury and other metals will be analyzed using Cold Vapour Atomic Fluorescence Spectrophotometry (CVAFS; USEPA [United States Environmental Protection Agency] Method 200.3/245.7) and Collision Cell Inductively Coupled

Table 9: Analytes and Laboratory Reporting Limits for Mount Polley CEMP Fish Tissue Quality Monitoring

Analyte	Target LRLs	Units	Consensus DLs [1]	Units	Consensus DLs [1] as dw [2]	Units	Tissue Quality Guidelines

[3] Health Canada guideline for mercury (CFIA 2015).

[4] British Columbia Water Quality Guideline for aquatic life for selenium in fish ovary tissue (BCMOE 2014). Additional guidelines for the protection of aquatic life of 4 mg/dw in fish muscle or whole fish and for the protection of human health at moderate consumption levels (14.5 mg/kg dw for the general population) will also be applied.

Plasma-Mass Spectrometry (CRC-ICP-MS; USEPA Method 200.3/6020A) or High Resolution Inductively Coupled Plasma-Mass Spectrometry (HR-ICP-MS; USEPA Method 200.3/200.8), respectively (USEPA 1991, 1994, 2001, 2004). All samples will be submitted to the laboratory with a chain-of-custody (COC) record, a list of expected Laboratory Reporting Limits (LRLs), and laboratory QA/QC requirements.

Aging structures will be shipped to a qualified fish ageing laboratory, along with a chain-of-custody form (COC), for determination of fish ages. At the fish aging laboratory, samples will be thawed, otoliths extracted from heads if required, and the otoliths and fin rays will be sectioned, mounted on a glass slide using a mounting medium, and then read under a compound microscope using transmitted light. For each structure, age and edge condition will be recorded along with a confidence rating for the age determination. Scales collected as backup structures will only be used as required. Similarly, preserved egg samples will be shipped to a qualified laboratory, along with a chain-of-custody form (COC), for determination of fecundity. Methods for determining fish age and fecundity will be fully consistent with the technical guidance (Environment Canada 2012).

4.4 Data Quality Review

Upon receipt of fish tissue quality data from the analytical laboratory, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs are achieved. The DQR will also include an evaluation of differences between duplicate (i.e., split) samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the tissue quality data will ensure timely communication with the laboratory should any issues be identified.

Comparisons between duplicate samples will be made by calculating the RPD for concentrations measured in paired samples. If the RPD is <25% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping).

4.5 Data Handling, Interpretation, and Reporting

Catch-per-unit-effort (CPUE) and summary statistics for meristic measurements taken in the field will be calculated. CPUE will be calculated for each fish species by fishing method and sampling area. For hoop netting, minnow trapping, and fry trapping efforts, CPUE will be expressed as number of fish per day. For seining, CPUE will be calculated as the number of fish per square metre. CPUE will be calculated as the number of fish per 100 electrofishing seconds for open-

station electrofishing efforts. For closed station electrofishing, density will be determined using removal calculators (i.e., number of fish per unit area determined using Moran-Zippin estimators; Ricker 1971). CPUE for gill netting and angling will be calculated as the number of fish captured per square metre-hour and the number of fish per angler day, respectively.

Although community and population data is collected during every phase or component of the fish monitoring program, the sample size will be defined by the study objectives and may be insufficient to address corollary questions. For example, the sample size required for tissue quality analyses (n = 8) is not large enough to support formal contrasts of population endpoints. To this end, evaluation of fish community data will rely on qualitative comparisons, and conclusions regarding fish populations will be supported by non-lethal measurements and sampling under the MDMER/EEM (with larger sample size), as described in Section 4.2.2 and below. Analysis methods for the MDMER/EEM fish population data will be consistent with EEM technical guidance (Environment Canada 2012). Summary statistics, including mean, median, minimum, maximum, standard deviation, standard error, and sample size, will be calculated for fish age, fork length, total length, body weight, condition, liver weight, gonad weight, and fecundity; calculations will be completed according to species and area. In a lethal design EEM fish survey, detailed statistical analyses will focus on indicators of survival, energy use, and energy storage and will be completed based on guidance from Environment Canada (2012). These indicators include fish age, size-at-age, gonad size relative to body weight, condition, liver size relative to body weight, and fecundity, and egg size relative to body weight (Table 10). In a non-lethal design, histograms will be used to examine length-frequency distributions by species and area, and indicators include fish size and condition. All data sets will be assessed for normality and equality of variance in order to determine the suitability of parametric statistical procedures. An effect on the fish population will be evaluated for each of these measures and is defined as a statistically significant difference between the effluent-exposed area and the reference area (Environment Canada 2012). For each endpoint, statistically significant differences between effluent-exposed and reference areas (by species and sex) will be assessed using ANOVA, Analysis of Covariance (ANCOVA), or non-parametric equivalents, as appropriate, following technical guidance (Environment Canada 2012).

For the fish tissue data sets, statistical comparisons of age, length, weight, and concentrations of metals in fish tissues (n = 8) will be completed among years and locations. Following completion of the DQR, fish tissue quality data will be provided to the QP and summarized according to species, tissue type, and area. The LRL for each analyte and the number of samples below the LRL will be determined. Censored data will be managed using methods described in Helsel (2012), and those used in the R package NADA: Non-detects and Data Analysis for Environmental Data (Lee 2017). Any value below a LRL (i.e., a <LRL result) that exceeds the

Table 10: Survival, Energy Storage, and Energy Use Endpoints for Mount Polley EEM Fish Population Evaluation

Response		Measurement Endpoints [a]	Statistical Procedure
Effects on Fish [a]	Survival	Age	ANOVA[c]
	Energy Use	Size-at-age (body weight against age)	ANCOVA[c,d]
		Relative gonad size (gonad weight against body weight)	ANCOVA[c,d]
	Energy Storage	Condition (body weight against length)	ANCOVA[c,d]
		Relative liver size (liver weight against body weight)	ANCOVA[c,d]
Supporting Response Variables [b]	Energy Use	Relative fecundity (# of eggs/female against body weight)	ANCOVA[c,d]
		Relative egg size (mean egg weight against body weight)	ANCOVA[c,d]

Notes: ANOVA = Analysis of Variance; ANCOVA = Analysis of Covariance; # = number.

[a] Endpoints to be used for determining "effects" as designated by statistically significant differences between effluent-exposed and reference areas.

[b] These analyses are for informational purposes and significant differences between exposure and reference areas are not necessarily used to designate an effect (Environment Canada 2012).

[c] Or appropriate non-parametric equivalent, as required.

[d] For the ANCOVA analyses, the first term in parentheses is the endpoint (dependent variable Y) that is analyzed for an effluent effect. The second term in parentheses is the covariate, X (age, weight, or length).

maximum detected value for that parameter at the given station will be removed. The removal of the poor LRLs does not influence the estimation of the mean or standard deviation, but does influence the overall sample size. The sample size, mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile will be calculated for each analyte. Means will be calculated using the Kaplan-Meier (K-M) method. The standard deviation and the median for each analyte will also be calculated using the K-M method. When a standard deviation cannot be estimated (i.e., when an analyte has a high proportion of censored values), it will be reported as "not calculated".

Statistical comparisons of age, length, weight, and concentrations of metals in fish tissues will be completed among years and locations. Statistical comparisons among groups will completed using an analysis of variance (ANOVA) if assumptions of normality and homogeneity of variances are met. These assumptions will tested using the Shapiro Wilk's test and Levene's test (α=0.05), respectively. Data will be transformed, as required, to meet these assumptions. If the assumptions cannot be met, the Kruskal-Wallis test will be used. Response variables with censored observations will be compared among groups using the Wilcoxon score test. Specific contrasts will be conducted after an overall significant difference among groups. Bonferroni adjustments to the p-values will be made to maintain the family-wise Type I error rate at α=0.05. A magnitude of difference (MOD) will be calculated for each contrast. For metals for which information is available on accumulation in specific organs (e.g., copper accumulation in fish liver; Grosell 2012), interpretation will focus on the results associated with that organ.

Statistical comparisons of concentrations of mercury in fish tissue will be compared using analysis of covariance (ANCOVA) with fork length as a covariate (as mercury is known to bioaccumulate in fish tissue; e.g., Kidd and Batchelar 2012). The response variable and covariate will be $\log_{10}$-transformed, as required, for analysis. The significance of the interaction term of the ANOVA model will be assessed to compare regression slopes between groups. If the interaction term is not significant (α=0.05) it will be removed and the parallel slope ANCOVA model will be fit. If the fork length is not a significant predictor of mercury concentration in the parallel slope ANCOVA model, it will be removed from the model and comparisons of mercury concentrations between groups will be conducted using a t-test. If the fork length is a significant predictor of mercury concentration in the parallel slope ANCOVA model, comparisons of mercury concentrations between groups will be assessed using the group term of the model. Adjusted means will be reported for the average (geometric mean) fork length from the parallel slope ANCOVA model. A MOD will be calculated for each contrast.

Fish tissue quality data will also be evaluated in comparison to tissue quality guidelines for human health and/or for aquatic ecosystem health (available for mercury and selenium). Tissue quality

guidelines will include the Canadian Food Inspection Agency/Health Canada mercury guideline for the protection of human health (0.5 milligrams per kilogram wet weight [mg/kg ww]; CFIA 2015) and the BC selenium guidelines (BCMOE 2014). Selenium guidelines for BC include guidelines for the protection of human health, which are based on fish consumption levels (7.3 milligrams per kilogram dry weight [mg/kg dw] for subsistence consumers, 14.5 mg/kg dw for the general population, and 75 mg/kg dw for the recommended two servings of fish per week). Selenium guidelines for BC also include guidelines for the protection of aquatic life, which are 4 mg/kg dw in muscle tissue and whole body samples, and 11 mg/kg dw in egg/ovary tissues. Selenium concentrations in fish ovaries will also be compared to the threshold for reproductive effects in eggs and ovaries (20 mg/kg dw; DeForest et al. 2012).

Results of the fish habitat characterizations for Upper Hazeltine, Lower Hazeltine, and Lower Edney creeks will be summarized, along with fish usage results, according to season (spring, summer, and fall) and year. Fish habitat characterization measures will be summarized by season, reach, and area (rehabilitated and reference), with summary statistics (mean and standard deviation) calculated for all numerical parameters. These summarized variables will then be compared to general habitat preferences for relevant fish species. Additionally, recorded habitat measures will also be compared to "optimal" ranges of habitat parameters indicated in Habitat Suitability Index (HSI) models (i.e., suitability index value = 1) or in the literature (where available) for those fish species identified in rehabilitation design criteria and objectives. Specifically, mean results for habitat measures collected in each season at each reach will be compared to the tabulated optimal "habitat suitability criteria" ranges and identified as either meeting or not meeting these criteria. The proportions of habitat measures meeting the habitat suitability criteria in the rehabilitated and reference areas, respectively, will also be compared.

Habitat unit assessment measures will be summarized by habitat unit type within each reach, with mean values calculated for all numerical parameters. Measures will be used to calculate endpoints such as bankfull width to depth ratio, channel complexity, % pool, pool frequency, and LWD pieces per bankfull channel width. These endpoints and other observational measures (presence of off-channel habitat) will then be evaluated relative to diagnostics of salmonid habitat condition modified from Johnston and Slaney (1996), rated as poor, fair, or good. Lastly, quantitative (closed station) data will be used to determine fish density (number of fish per unit area determined using Moran-Zippin estimations; Ricker 1971). The presence and abundance of juvenile rainbow trout in these creeks will be compared to densities previously observed in Edney and Bootjack creeks (Minnow 2014a).

An interpretive report based on the fish monitoring data will be prepared to be integrated into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared

annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWQGs, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

STUDY DESIGN CONCEPT: TERRESTRIAL COMPONENT FOR THE MOUNT POLLEY MINE COMPREHENSIVE ENVIRONMENTAL MONITORING PLAN – MOUNT POLLEY MINE

1.0 INTRODUCTION

1.1 Purpose of the Study Design Concept

Mount Polley Mining Corporation (MPMC) is preparing a Comprehensive Environmental Monitoring Plan (CEMP) to integrate the environmental monitoring components from a variety of regulatory processes applicable to the Mount Polley Mine into a single document. An Ecological Risk Assessment (the ERA; Golder 2017) was prepared that integrated the available chemical and biological information to provide an overall conclusion about the magnitude and extent of ecological risks associated with the deposit of tailings. The ERA was accepted by the Ministry of Environment & Climate Change Strategy (ENV) on 31 January 2018, contingent on the implementation of additional monitoring in relation to specific areas of uncertainty identified in the ERA. There were several points of uncertainty in the terrestrial ERA with respect to plants, soil invertebrates and wildlife and these are outlined in Table 53 of the ERA. The purpose of this memorandum is to outline the monitoring concept proposed to MPMC to address those terrestrial ERA uncertainties in the CEMP. Contingent on acceptance by ENV, a detailed study design document and specific work instructions will be prepared by Golder as the basis for executing of the CEMP process.

1.2 Scope and Approach of the Risk Assessment

The ERA evaluated the site conditions as they existed in the first few years after the failure of the glacial lacustrine layer beneath the Perimeter Embankment of the Tailings Storage Facility. The terrestrial ERA included the “floodplain” area where the forest and native soils were removed by the debris flow, and the “halo” area where the forest floor was relatively undisturbed but buried to varying depths by scoured material and tailings. Tailings can limit the successful re-establishment of ecological communities because of a variety of chemical and/or physical limitations in the soil (Hossner and Hons 1992). The ERA used a “triad” style approach to evaluate the relative influence of physical issues versus chemical issues for a given receptor group using three different types of information:

- What is the magnitude of the exposure associated with tailings?
- What is the magnitude of effects associated with tailings under controlled experimental conditions?
- What is the magnitude of effects associated with tailings under field conditions?

Golder and the G logo are trademarks of Golder Associates Corporation **golder.com**

Copper was identified as the primary contaminant of concern. The ERA also found that the bioavailability of copper in tailings at the site was low. A low bioavailability does not mean that bioaccumulation was zero as copper has bioaccumulated in different parts of the ecosystem at concentrations that are greater than reference areas. However, the overall conclusion, based on a weight-of-evidence integration of the available information collected over several years, was that risks associated with copper were low, and that the effects associated with nutrient deficiencies and soil structural limitations were likely to be a larger influence on the long-term management goal of reintroducing a biologically diverse, functional and self-sustaining ecosystem. As with any complex risk assessment, there was uncertainty associated with the risk conclusions which were described in the risk assessment.

1.3 Summary of Main Areas of Uncertainty

The study design concept focuses on reducing the main sources of uncertainty described in Table 53 of the ERA. In brief, the main sources of uncertainty in the terrestrial ERA were:

1) Field-based monitoring of the diversity or abundance of plants, soil invertebrates or other parts of the soil ecosystem is valuable in an ecological risk assessment but was not practical in the current application because of the expected variability related to natural successional changes.

2) The ability to quantify the relative influence of copper versus the physical limitations of the soil is important from a theoretical perspective. This would typically be evaluated using controlled experiments. However, further experiment-based studies are not warranted unless there is evidence (from field monitoring) that natural succession is not progressing. It is reasonable to continue refining the site-specific understanding of copper bioaccumulation in plants and soil invertebrates in lieu of further experimental studies while the long-term field monitoring is executed.

3) Risks to wildlife are assessed with a single technique (a food chain model). Conservative assumptions were used in the model. Hazard quotients were less than 1 for eleven of the 15 receptor species evaluated in the model. Further refinement of the wildlife food chain model was requested with respect to the four receptor species that had a hazard quotient greater than 1.

Each of these main sources of uncertainty are addressed in further detail in Section 3.

2.0 BASIS OF DESIGN

Golder understands that MPMC is structuring the CEMP to be a stand-alone document that does not require reviewers to have a detailed understanding of the ERA. A summary of the available data and how those data were evaluated in the ERA (Golder 2017) is provided in this section as context for the specific recommendations in Section 4.

2.1 Plants

Information relevant to plants that was evaluated in the ERA included:

- Concentrations of metals in tailings were lower than numerical standards for the protection of soil invertebrates and plants, except for copper (and marginally, vanadium).
  - For copper, the numerical standard is 150 mg/kg. The 95% upper confidence limit of the mean (UCLM) concentration in untreated tailings was 737 mg/kg. Treatment (scarification, intermixing or transplanting soils) resulted in 95% UCLMs ranging from 197 to 538 mg/kg.
  - For vanadium, the numerical standard is 200 mg/kg. The 95% UCLM vanadium concentration in untreated tailings and the three treatment types were less than the numerical standard. Vanadium was retained as a contaminant of potential concern because the 90th percentile concentration in untreated tailings was marginally greater than the standard (213 mg/kg versus 200 mg/kg).
- A 42-d lodgepole pine (*Pinus contorta*) and bluebunch wheatgrass (*Pseudorogneria spicata*) germination and growth toxicity test was conducted on two representative samples of tailings (Section 3.3.3 of the ERA). Seedling emergence or survival was not impacted, but greater than 20% reductions in growth were observed for both species compared to the performance of a negative control consisting of clean silica sand of a similar grain size. All plants demonstrated some degree of growth over the 42-day exposure, despite copper concentrations ranging from approximately 800 to 1100 mg/kg.
- Multiple lines of evidence in the ERA demonstrated that copper had low bioavailability. The lines of evidence included geochemical modeling and three different chemical surrogate measurements in tailings samples (water soluble fraction; humidity cell and leach tests; physiological-based extraction tests – see Section 3.2.2 of the ERA). The toxicity testing (see above) also included a side-by-side trial where an equivalent concentration of copper was added to clean silica sand (in the form of copper sulphate). The bioavailability of copper from tailings was much lower than copper added to the tailings.
- There were physical effects of tailings on plant growth. The toxicity testing (see above) found that tailings tended to form hard crusts and germination was highest in the surface cracks. The measured bulk densities of tailings, till and lacustrine deposits at the site were greater than values from the literature that correspond to reductions in plant growth. Nutrient levels in the tailings were also limited and in a range that could limit plant growth (see Section 3.2.3.2 of the ERA).
- Plants appeared to bioaccumulate copper, but bioaccumulation factors were less than 1 and the bioaccumulation was concentration-dependent. There were no obvious differences in copper bioaccumulation during the 42-d toxicity testing (see above) between tailings and copper added to soils. There was no consistent pattern where copper concentrations in field-collected plant samples were greater in the impacted areas than in background and/or baseline samples (see Section 3.3.2.2 of the ERA). Copper concentrations were within the range of concentration considered to be adequate for plant growth (see Section 3.3.2.4 of the ERA) despite being collected over a wide range of soil concentrations. Overall, these lines of evidence demonstrate that many plants can control the uptake of copper.

2.2 Soil Invertebrates

The ERA involved fewer lines of evidence for soil invertebrates because: a) the findings of low copper bioavailability from plants would be expected to be consistent for soil invertebrates, and b) the physical alterations to the soil and habitat would be expected to have a more significant effect on soil invertebrates. Further discussion about the overall ecological succession expected at the site is provided below in Section 3.1. Additional information specific to soil invertebrates that was considered in the ERA included:

- There were relatively few soil invertebrates collected in 2015 and 2016. Composite samples were collected for beetles/ants (n = 15), spiders (n = 4), and worms/slugs (n = 8). Between two and four tissue samples of each soil invertebrate type were collected from background areas and the data used in a control chart (i.e., the average ± 2 standard deviations [SD]). There was a high degree of variability between individual samples in a given tissue composite type, but the average concentration of copper in beetle/ant composite samples was higher than the average (+ 2SD) upper limit of the control chart.
- The limited number of worm/slug samples had an average copper concentration that was within the range of copper tissue concentrations from laboratory studies that had the potential for reduced survival, growth or reproduction of soil invertebrates. There was not sufficient data to determine the relationship between soil concentrations and the tissue concentration of specific types of soil invertebrates, and many of the papers that evaluated the critical body residue of copper in soil invertebrates acknowledge that there are many factors that can limit site-specific bioavailability. The available data were thus not definitive that a risk to soil invertebrates is present but did provide a qualitative indicator that monitoring was appropriate.

2.3 Wildlife

Risks to wildlife were evaluated using a food chain model. In brief:

- A total of 15 surrogate species were selected from different feeding guilds (e.g., herbivores, carnivores; Table 1). Species-specific variables such as body weight, ingestion rates, and dietary preferences were adopted from federal risk assessment guidance or other reputable sources.
- Realistic worst-case exposure concentrations were determined for soil, water and the various dietary items, typically based on the 95% upper confidence limit of the mean. Site-specific bioaccumulation models were developed and used to predict tissue concentrations from soil concentrations. Bioaccumulation factors for small mammal tissue concentrations (needed to evaluate risk to carnivores) were taken from the literature.
- Relative bioavailability was used to calculate the dose for the wildlife receptors. Relative bioavailability of copper in water was assumed to be 100%. Relative bioavailability of copper in soil was based on site-specific physiologically-based extraction test (PBET) data. Relative bioavailability of copper in dietary items was assumed to be 40% based on information from the literature.
- The total amount of copper ingested per day was compared to conservative toxicity reference values. The food chain model was run separately for different areas and different soil rehabilitation approaches (i.e., transplanted, scarified or intermixed). A risk estimate for each surrogate species was calculated for the entire study area using area weighting. Risks were also calculated for background areas for context.

- Hazard quotients (HQ) were less than 1 for all receptors exposed to vanadium, and most receptors exposed to copper. HQs were greater than 1 for robin, common nighthawk, olive-sided flycatcher and masked shrew. The aggregate HQs (i.e., the area-weighted HQ for the site as a whole) for those four receptors ranged from 1.7 to 2.8. The maximum observed HQ for an individual subarea was 5.1 for masked shrew in the Polley Flats area.
- A hazard quotient greater than 1 does not mean that there are risks to wildlife. The food chain model used many conservative assumptions which were identified in the terrestrial ERA. HQs were also greater than 1 for olive-sided flycatcher and masked shrew exposed to background copper concentrations.

Table 1: Wildlife receptors evaluated with the food chain model

Receptor Group	Feeding Guild	Surrogate Species
Birds	Herbivore	Dark-eyed junco
	Insectivore	Robin; olive-sided flycatcher; common nighthawk
	Omnivore	Raven
	Carnivore	Northern pygmy owl
	Piscivore	Osprey, great blue heron
Mammals	Herbivore	Meadow vole; mule deer

3.0 FURTHER CONSIDERATION OF UNCERTAINTY

3.1 Uncertainty Related to Ecological Succession

A “triad” style approach (exposure, experimental effects, field effects) is common in weight-of-evidence because the three different types of information are complementary. A well-designed field study provides a meaningful evaluation of risks because it provides direct information about what is being protected under realistic conditions. However, field studies are not always able to determine the cause of effects (if any are observed) and can be confounded by many different variables. Many of those variables (e.g., weather) are unrelated to the management question being evaluated.

A “triad” approach was used in the terrestrial ERA but it was not possible to assess every terrestrial receptor with a field study. In areas of the site that were subjected to extensive scouring, there was a near-complete loss of natural soils and their related ecological communities (i.e., soil microbes, fungi, invertebrates and plants). Quantitative assessment to establish the magnitude of that physical impact was unnecessary. Field measurement of the structure of the plant or soil invertebrate community was not possible because recolonization and ecological succession had only just started. Nevertheless, field studies are expected to be an important aspect of long-term monitoring because they will help to determine if the soil ecosystem is recovering as expected over time.

3.1.1 Summary of Expected Ecological Succession

An example of ecological succession in a hypothetical plant community is provided in Figure 1. Succession progresses through several distinct phases:

- Early succession is dominated by opportunistic species that have high growth or reproductive output, or some specialized ability to occupy a niche that other species cannot. An example would be an invasive, weedy species with a high output of wind-carried seeds. Species that can grow in nutrient-poor soil because they can convert nitrogen to a useable form (“nitrogen fixation”) would also have an advantage. Mites are an example of a primary colonizer from the soil invertebrate community because they have a high dispersal capacity, can tolerate low nutrient levels, and reproduce quickly (Hagvar et al. 2009).
- Middle succession involves increasing competition for resources (i.e., the limited nutrients that are introduced by the decay of leaf litter from the early stages). An example of the middle stages of succession would be the proliferation of alder which have a similar capacity for nitrogen fixation as grasses, but also the ability to outcompete grasses for moisture and light through root and shoot growth. Examples of invertebrates at this stage include ground-dwelling beetles or ants.
- Late succession continues competition in an increasingly diverse number of niches. At a late succession stage, the humic layer has regenerated through the decay and processing of organic material, and there is an ongoing cycle of nutrients in soils from the activity of microbes, fungi and soil invertebrates. Earthworms and other invertebrates that process organic material would be common. The overall ecological function (e.g., production of biomass, respiration, diversity) in the ecosystem has reached its maximum capacity, and the ecosystem has settled into a dynamic equilibrium.

Golder has identified several examples of natural ecological succession from the literature in Table 2, including recolonization of a landscape after a landslide or retreat of a glacier, or reclamation from non-metal mining such as quarrying.

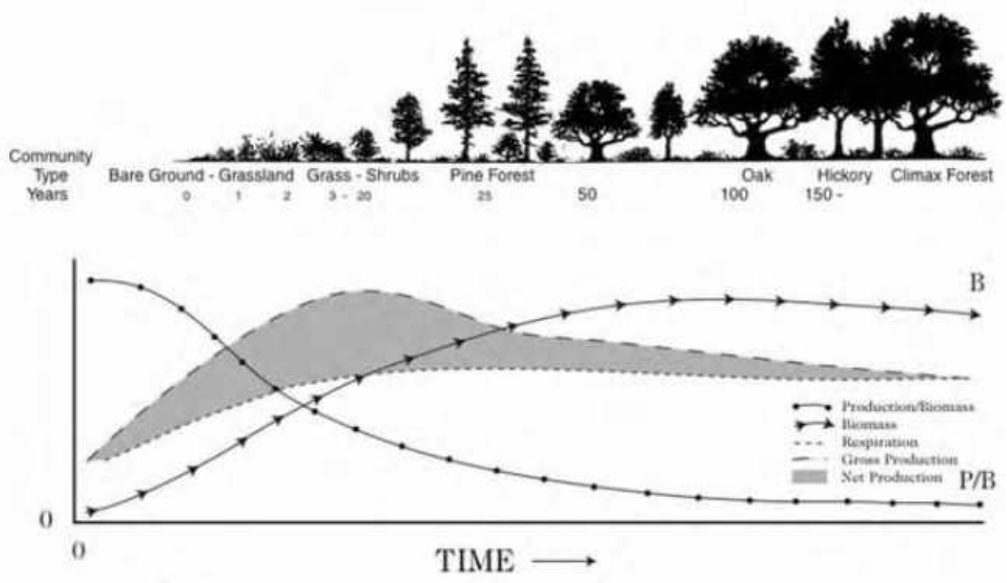

Figure 1: General schematic of vegetative succession over time (from Schneider 2008)

Table 2: Examples of Ecological Succession

Authors	Site Context	Observations
Russell and La Roi (1986)	34-hectare spoil heap of overburden generated from coal mining activities in Rocky Mountain foothills, Alberta.	Vegetative cover limited by coarseness of material and low nutrient levels. Total plant cover is less than 10% despite relatively long length of time since formation of the spoil heap (34 years). Perennial grass and forbs are the dominant species.
Frouz et al. (2008)	Chronosequence of 27 sites on four different coal mine spoil heaps (100+ km^2) in Europe. Total length of time since disturbance was 40 years.	Plant and soil invertebrate communities were assessed. Statistical analysis found that succession was driven by the formation of the humic layer. Sites tended to switch from “no humus” to “humus forming” at roughly 15 years, and from “humus forming” to “humus present” at roughly 25 years.
Miles and Swanson (1986)	Chronosequence of 25 landslides in Oregon. Total length of time since disturbance was 30 years.	Total vegetation cover ranged from 51% (in the primary scar) to 78% (in the primary deposition area). Cover consisted of trees (approximately 50% of the total), shrubs (25% of total) and herbs (25% of total), suggesting that succession had progressed to a mature state.

Authors	Site Context	Observations
Smith et al (1986)	Chronosequence of 49 landslides in Haida Gwaii. Total length of time since disturbance was 150 years. Logged and non-logged areas included for comparison.	Humic layer reformed relatively quickly but had decreased nutrient levels until Year 30. There was a relatively thick cover of red alder (an early colonizing tree species) within 20 years, but the total vegetative cover in the slide areas did not reach the undisturbed areas for 50 years. (For context, a logged area returned to a total cover like the undisturbed area within 20 years).
Gobbi et al. (2006).	Chronosequence of soil invertebrates colonizing a receding terminal glacier moraine. Total length of time was 150 years.	Species richness increased from 2 to 26 genera. Spiders and beetles were the primary colonizers, while ants and centipedes are only present in the older sites. The pattern of succession was consistent with the available information about the habitat preference and life history strategies of each species.

Note: A chronosequence is an ecological study that investigates a set of similar sites that share similar attributes and a similar disturbance but have different ages in order to understand the time-dependent aspects of succession.

3.1.2 Influence of Natural Succession on the Design of the CEMP

Although MPMC has conducted a variety of actions over the last two years to facilitate natural ecological succession, the plant and soil invertebrate community in the area impacted by tailing deposition is likely still in the early, opportunistic stages of recolonization. Further information about the following activities conducted to date can be found in the Conceptual Remediation Plan (Golder 2018):

- Soil manipulation (e.g., scarification to create a “rough and loose” soil material with better physical structure)
- Blending and placement of native topsoils to improve moisture retention and nutrient levels, and to reintroduce native microbes, fungi, seeds and soil invertebrates
- Mounding and placement of coarse woody debris to create preferential microsites where plant recolonization can be accelerated
- Placement of wood chip mulch to increase organic carbon and nutrient levels as the mulch decays
- Riparian planting of native shrubs and conifers
- Seeding of upland areas with a mix of native grasses

The net effect of the original impact and the subsequent rehabilitation effort is that a high degree of variability between areas is still expected because the treated and untreated areas are still in the first few years of succession. The total length of time to reach a mature, dynamic equilibrium is unknown, but likely on the order of 20 to 30 years based on the examples from Table 2. The rehabilitation activities described above would be expected to accelerate and enhance that process. A field study to measure the difference between "control" and "impact" that could separate the relative influence of copper versus physical limitations would be challenging in this early phase. Specifically:

- Comparison to reference is not expected to be practical in the near-term (i.e., one can reasonably conclude that there will be substantive changes between the impacted areas and areas that have not covered with tailings). No suitable reference areas (i.e., an area that has been logged and all vegetation and humic material removed) are currently known.
- Comparison between individual years may not add significant value because differences in weather (e.g., rainfall, snowpack, temperature) would also introduce significant year-to-year variability.

Instead, monitoring of the plant and soil invertebrate community should focus on establishing a long-term trend analysis rather than to support a multitude of pair-wise comparisons that would have limited value for making site management decisions. This would involve:

- **Selecting representative, permanent monitoring plots.** The number of plots will depend on the number of different habitat units to be monitored. These units could be based on copper concentrations, remedial areas, the types of rehabilitation already applied, or other attributes that will influence succession (e.g., slope, moisture content, distance from undisturbed edge).
- **Monitoring each plot in a consistent manner to support analysis of trends over time.** No consensus exists at this time about which specific metrics are needed to monitor progress towards a biologically diverse, functional and self-sustaining ecosystem. Input from other subject matter experts (e.g., mine reclamation specialists) is likely required given that the timelines for monitoring will extend into the mine closure process.
- **Sufficient sampling effort to make informed management decisions.** A defensible trend analysis needs to consider statistical power. Statistical power is influenced by the minimum measurable change and the variability amongst replicates of a given habitat unit. Even if a formal power analysis is not needed, the study design needs a common understanding about how the trend analysis would be used to make future decisions. For example, trend analysis may benefit more from measuring 5 metrics at 50 plots for three years followed by a 5-year hiatus than measuring 10 metrics at 20 plots every year. The 750 measurements in the first option may be more meaningful than the 1,600 measurements in the second option because option 1 provides more spatial coverage and measures inter-year variability.

3.2 Uncertainty about the Relative Influence of Copper on Soil Invertebrates and Plants

The ERA concluded that risks from copper were low, and therefore, further focused investigations to determine the relative influence of copper on soil invertebrates and plants versus physical variables (such as through toxicity testing or greenhouse experiments) were not warranted until there was information from the field monitoring that succession was not progressing towards the long-term management goal of reintroducing a biologically diverse, functional and self-sustaining ecosystem (Table 53 of the ERA). A trend analysis will not provide a definitive check on progress towards this management goal for several years. In the meantime, continued refinement of the site-specific relationships between copper concentrations in soil and copper concentrations in various soil invertebrate and plant tissues is recommended because:

- The presence of sufficient plants or invertebrates for sampling across the range of copper concentrations in soil provides important qualitative evidence (pending confirmation from the trend analysis) that copper is not exerting a significant effect on the survival of soil invertebrates or plants. If areas with the upper range of copper concentrations in soil lack soil invertebrates, or show visual evidence of copper toxicity to plants, it would be a trigger for the more focused investigation (or, could lead directly to supplemental remediation as part of the overall adaptive management strategy).
- Refining the soil-to-tissue relationships provides direct evidence about copper bioavailability and bioaccumulation. This helps to clarify potential differences in copper bioaccumulation between different species or taxonomic groups, and the site-specific relationships can be compared to similar relationships from the scientific literature or other copper-contaminated sites to provide further support to the ERA conclusion that copper bioavailability is relatively low.
- The site-specific bioaccumulation relationships are also used as part of the wildlife food chain model. Some of the existing relationships are based on limited data sets, which have added uncertainty to the results of the food chain model. A more robust relationship between soil and tissue concentrations increases the overall sophistication and future application of the food chain model as part of the CEMP.

3.2.1 Uncertainty in Risk Estimates for Wildlife Species

The food chain model used appropriately conservative assumptions and model parameters consistent with common practices for a screening-level risk assessment.

In terms of risk management decisions, some qualified professionals default to a prescriptive interpretation that any HQ than 1 represents a potential risk that requires further assessment or remediation. Realistically, marginal HQs (e.g., less than 2 or 3) are unlikely to present an unacceptable risk but there is no consensus on a specific threshold between acceptable or unacceptable risk beyond the prescriptive guidance about HQ = 1. The existing HQs are not considered to represent an unacceptable risk but are sufficiently higher than 1 to warrant further refinement of the model to reduce uncertainty. The uncertainty in the HQs generated from the food chain model is the product of the uncertainty in each of the variables used. Not all variables need to be refined. The variables that would benefit most from refinement are:

- Improving the quality of data with respect to tissue concentrations in invertebrates. This can be accomplished by expanding on the bioaccumulation sampling as described in Section 3.2. The food chain model has also conservatively assumed that flying insects have the same tissue concentrations as soil-dwelling insects, which is a data gap that should be addressed by further sampling.

- Refining the toxicity reference values (i.e., the denominator in the HQ). The current toxicity reference value was taken from the ECO-SSL guidance (USEPA 2018) and is based on a conservative “no-observed adverse effect level” from the available literature. This toxicity reference value may be substantially lower than a true “acceptable” concentration that corresponds to low (i.e., not statistically significant) effects on growth or reproduction. A common area for refinement in a wildlife risk assessment is to update the toxicity reference value to reflect an effects-based threshold in lieu of a highly conservative screening threshold.
- Reviewers of the ERA identified the use of relative bioavailability as an uncertainty in the food chain model but did not reach a consensus about whether this issue was significant in terms of the final risk conclusion. There are unresolved differences in professional opinion on this topic which would ideally be addressed as part of the food chain model refinement. Golder notes that ENV has previously accepted the approach used in the current ERA at other sites and believes that further dialogue on this point prior to initiating additional investigation is warranted.

Refinement (or resolution) on these three topics is expected to reduce the overall uncertainty in the food chain model. Golder understands that the refined model would be run for the same subareas and HQs presented for both individual subareas and for the aggregate of the entire study area. Golder also understand that ENV desires that bats (*Myotis* sp.) be added as an additional receptor.

4.0 CONCEPTUAL STUDY DESIGN

4.1 General Approach

A proposed approach to address the remaining areas of uncertainty in the terrestrial ERA is provided in Figure 2. In brief, the following activities are proposed for the remainder of 2018 and the first quarter of 2019:

- Conduct a reconnaissance-level assessment and conduct limited pilot-scale investigation for candidate metrics for inclusion in the long-term trend analysis monitoring of ecological succession.
- Engage stakeholders and subject matter experts in a workshop to review the findings from the reconnaissance-level assessment and to obtain consensus about how a “biologically diverse, functional and self-sustaining ecosystem” will be measured.
- Conduct a one-time supplemental sampling program to refine the current information regarding copper bioaccumulation and relative bioavailability. Refine the toxicity reference values and use all three outputs from the one-time supplemental sampling program to update the food chain model.
- Develop the preliminary design for the trend monitoring in terms of specific metrics, sampling effort, frequency and interpretative approaches and submit for regulatory approval.

At the completion of these four activities, the CEMP will be updated to incorporate the specific design for long-term monitoring of the ecological succession expected to occur over time. The long-term monitoring will need triggers for when ecological succession will be deemed to be insufficient (even if such triggers are narrative). Additional rehabilitation or additional investigation regarding the cause of the insufficient progress would occur if those triggers are exceeded.

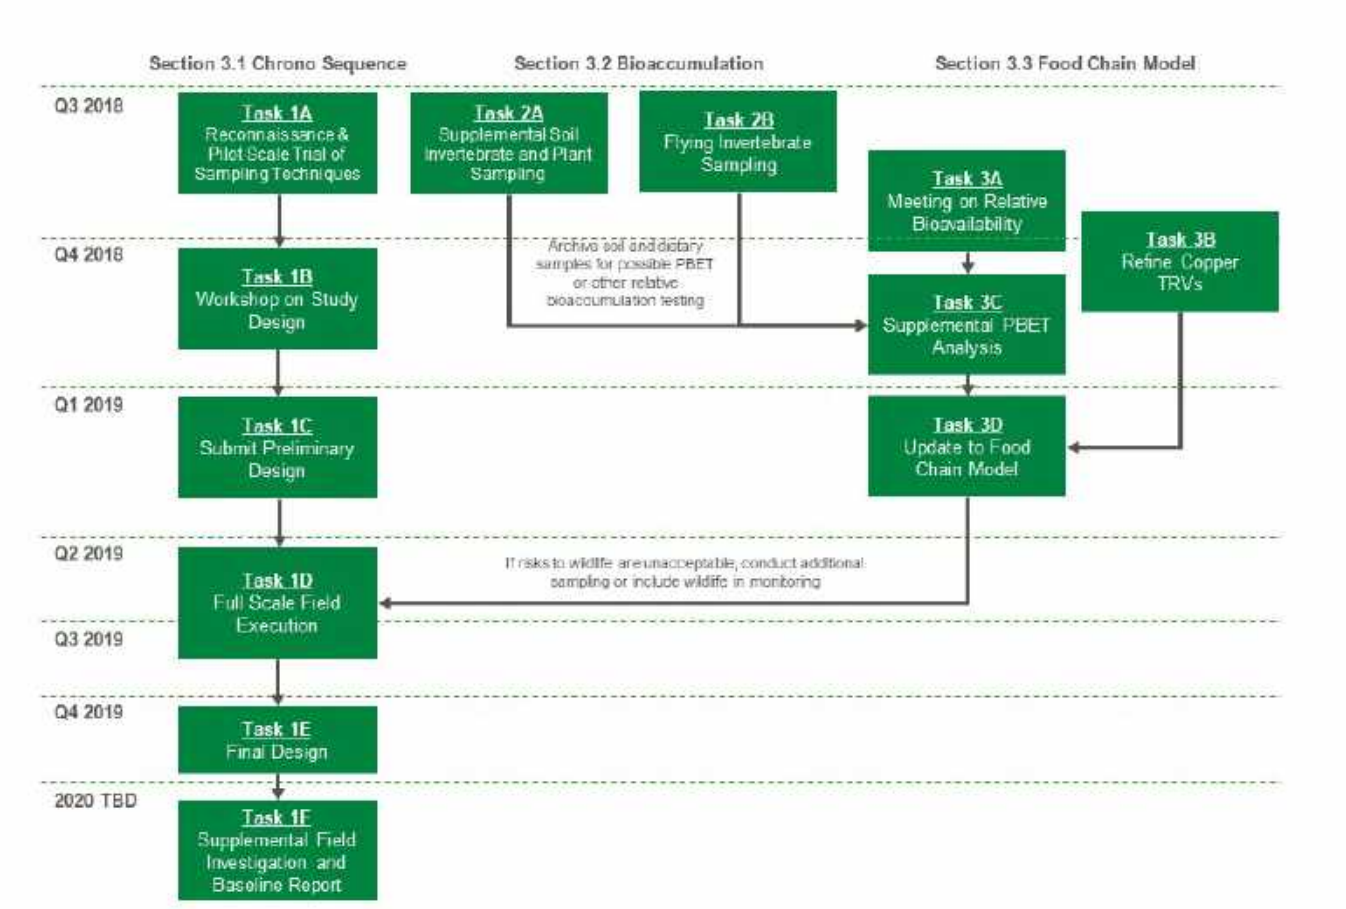

Figure 2: Proposed Approach for the Terrestrial CEMP Component

4.2 Additional Information

4.2.1 Task 1A – Reconnaissance and Pilot-Scale Sampling

There is value in conducting a reconnaissance-level sampling program in the summer of 2018 to provide at least a narrative description (supported by field measurement) of the current state of ecological succession. The reconnaissance-level sampling will focus on:

- Determining the diversity and percent cover of plants in three plots in each of the seven major terrestrial units (Halo; Untreated – Polley Flats; Untreated – Upper Hazeltine; Untreated – Lower Hazeltine; Transplanted; Intermixed; Scarified) for a total of 21 plots.
- Making detailed observations about plant succession in selected locations where additional rehabilitation was conducted (e.g., placement of large woody debris, mounding, placement of mulch).
- Conduct an overall site inspection to identify if there are areas that were subject to additional rehabilitation where no ecological succession appears to be occurring.

- Conducting a standardized bird survey at five locations (for spatial coverage) to document which species are using the available habitat. (Birds are selected for the survey because of the potential that listed species would use the habitat). Habitat monitoring for other wildlife species is not included in the scope of this reconnaissance-level sampling.

Data from the reconnaissance sampling will help to inform the design of the long-term trend analysis. Golder will also use the opportunity to conduct a pilot-scale trial of sampling techniques that could be used to measure other aspects of ecological succession. For example, the future trend analysis (see tasks below) may involve a metric related to soil invertebrate diversity, density or function. The literature describes a wide array of possible sampling techniques (e.g., a soil core to measure the diversity and abundance of mites; a bait-trap to measure the biomass of ants; a pit-fall trap to measure the diversity of ground-dwelling beetles). Golder is using malaise traps, pit-fall traps and Berlese funnels as part of the tissue sampling, any one of which could add value to the design of the long-term monitoring.

4.2.2 Task 1B – Workshop on Design of Trend Analysis

Golder expects that reviewers and stakeholders would comment extensively on the design of the trend analysis, and a variety of technical opinions are expected. There is a wide diversity of possible technical approaches, compounded by an absence of risk assessment guidance on how ecological succession should be monitored.

Golder expects that it will be necessary to draw on regulatory guidance from other relevant Ministries (e.g., Mines, Forestry) where landscape level changes in plant communities are more commonly assessed. For example, BCMOFR/BCMOE (2010) provides guidance on how to assess terrestrial ecosystems, but guidance on measuring successional state is limited to a semi-quantitative assessment that tracks the proportion of early colonizers (‘seral’ species) to later colonizers (‘climax’ species). No specific thresholds for the different states are described and therefore, the site could conceivably remain in a “pioneer” state for 60 or more years. This type of narrative assessment, although described in regulatory guidance, would not add value for site management decisions. Conversely, there are examples of how plant succession is being monitored for mine closure purposes in a quantitative manner (e.g., Highland Valley Copper focuses on plant diversity and functional contribution as a surrogate for the broader ecological succession; Smyth et al. 2016) but no specific thresholds are described beyond “continued progress”.

Golder proposes a one-day workshop where a focused overview of the findings from the reconnaissance-level sampling and tissue sampling can be presented, followed by discussion of relevant examples of risk-based mine closure and monitoring elsewhere in British Columbia. Potential examples where publicly-available information is likely available include the Britannia Mine, the Sullivan Mine, and Highland Valley Copper. It is important to establish at least a preliminary consensus with the regulators about the intended application of this part of the CEMP before effort is expended on the design and costing of specific methods. This workshop is intended to be similar to the Problem Formulation Workshop that helped to build consensus on how the ERA was ultimately executed.

4.2.3 Task 1C – Preliminary Design of Trend Analysis

Golder will develop a preliminary design for the long-term trend analysis based on the reconnaissance sampling, further consideration of relevant examples at other BC mine sites, and input from the reviewers.

4.2.4 Task 1D – Full Scale Field Execution

Golder proposes that the preliminary sampling design would be implemented in the spring and summer of 2019. The scope of this program is currently unknown, pending the outcome of the preliminary design.

4.2.5 Task 1E – Refinement to Design

Conceptually, Golder envisions that the preliminary design might specify a larger number of potential metrics which would be reduced to a final subset based on the data collected in 2019. The intent of the refinement step is to provide a formal check that the preliminary design has been fully optimized in terms of effectiveness and efficiency. A key aspect of optimization is that it is not necessary to continually monitor all aspects of the ecosystem as a conservative, precautionary approach. Instead, the goal is that the CEMP component provides a science-based framework for adaptive management. Adaptive management focuses on monitoring a smaller number of metrics (but monitoring them well) so that there is a clear baseline with pre-defined triggers for when one-time supplemental investigations might become necessary.

4.2.6 Task 1F – Baseline Report

Conceptually, the terrestrial monitoring component will focus on monitoring succession at pre-defined intervals rather than annually. The ERA and its supporting appendices contain information about conditions up to approximately D+3 (disturbance + 3 years). The reconnaissance sampling is effectively an interim snapshot about D+4, and the full field execution would provide the formal baseline that reflects conditions at D+6 (and possibly D+7, if year-to-year variability is included in the study design). Subsequent cycles of the terrestrial monitoring program would then document the ongoing ecological succession at defined intervals post-baseline (e.g., baseline + 2 years, B+5, B+10, B+20).

4.2.7 Task 2A – Soil Invertebrate and Plant Sampling

This task is a standalone activity intended to reduce the uncertainty in the existing site-specific bioaccumulation models (Figure 3) for soil invertebrates and plants. Both models could be improved by obtaining additional co-located soil and tissue samples so that the relationships are not based on composite samples (e.g., separate ‘surface insects’ into ‘ants’, ‘spiders’ and ‘beetles’; separate ‘grass’ into the main species that have been seeded on the site). Conceptually, Golder would target different specific taxa or species emphasizing areas that have not yet been sampled (i.e., the three reclamation treatments). These areas tended to have copper concentrations in the middle of the range bounded by the background and untreated areas. All data (i.e., data from Golder 2017 and data collected in August 2018) will be used to refine the existing bioaccumulation relationships (see Figure 3, below). Note that the total number of tissue samples submitted for analysis will be dependent on the trap effectiveness. A decision on whether the supplemental data are sufficient will be made in light of the uncertainty in the regression equation.

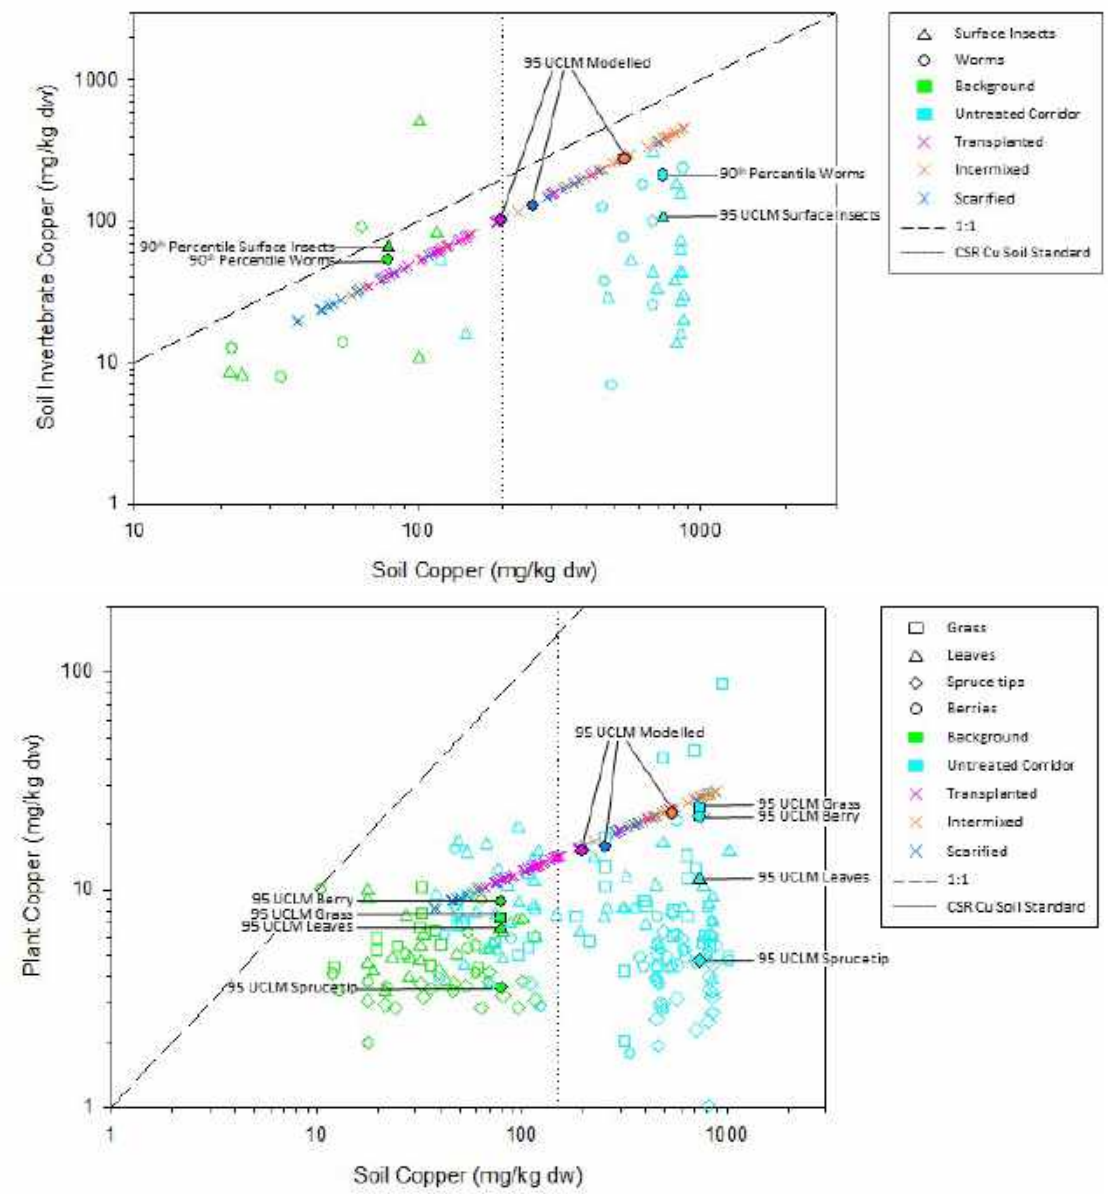

Figure 3: Existing bioaccumulation models for soil invertebrates and plants (from Golder 2017, Appendix F)

4.2.8 Task 2B – Flying Insect Sampling

This task is a standalone activity to address a data gap in the food chain model. Golder will collect flying insects (e.g., moths, flies, flying ants, grasshoppers) using malaise traps with lights. These taxonomic groups reflect the likely dietary items for insectivorous birds and bats. Hand collection with butterfly nets will also be employed. Ideally, sufficient biomass will be collected from a single location to allow for submission of taxa-specific composites (not a composite of all flying insects). Tissue concentrations are not expected to be directly related to local soil concentrations because flying insects are mobile, and therefore, the goal would be to focus on sampling from five broad zones (e.g., Polley Flats, Upper Hazeltine, Lower Hazeltine, Halo, and Background. The goal is to obtain at least seven tissue samples per taxonomic group per area (to allow for the calculation of a 95% upper confidence limit of the mean). The total number of tissue samples submitted for analysis will be dependent on the trap effectiveness.

4.2.9 Task 3A – Meeting on Relative Bioavailability

There was conflicting feedback from technical reviewers about how the food chain model incorporated the relative bioavailability of copper in water, food and dietary items once ingested by different ecological receptors. Golder assumed that copper in water would have a 100% bioavailability relative to the form of copper added to the food used in the original mammalian or avian toxicity test. Site-specific PBET data was used as a surrogate for the relative bioavailability of soil, and information from the literature was used to provide a conservative estimate of the relative bioavailability of copper once incorporated into biological tissues. Similar approaches have been approved by ENV at other sites, including the risk-based management of elevated copper in soils at the Britannia Mine. Relative bioavailability for soil and dietary items has also been evaluated in the risk assessment literature with specific consideration of the potential for differences in gastrointestinal bioavailability between mammals and birds (e.g., Sample et al., 2014; Kaufman et al., 2007).

Golder recommends holding a focused meeting on this specific technical topic with the subject matter experts and ENV. Eliminating relative bioavailability from the food chain model would be demonstrably over-conservative and inconsistent with the scientific principles that influence how an ingested dose is ultimately absorbed by birds and mammals. If the consensus from that meeting is that further quantitative assessment is needed to support the existing approach, it would be completed this fall in Task 3C. Golder proposes to collect archive tissue and soil samples in the summer sampling program (Task 2A) as a precaution (subject to the availability of sufficient tissue mass).

4.2.10 Task 3B – Refinement of Copper TRV

Golder will update the existing toxicity reference values for copper to use a multi-study concentration profile in lieu of the existing point-estimate based TRVs adopted from ECO-SSL. A similar approach has been proposed in the amphibian monitoring component of the CEMP. The development and application of ECx-based toxicity reference values in wildlife food chain model is well-established in the scientific literature (e.g., Allard et al. 2010) and has been adopted by provincial and federal risk assessment guidance manuals (e.g., Environment Canada 2010) as an accepted practice to refine screening-level ERAs.

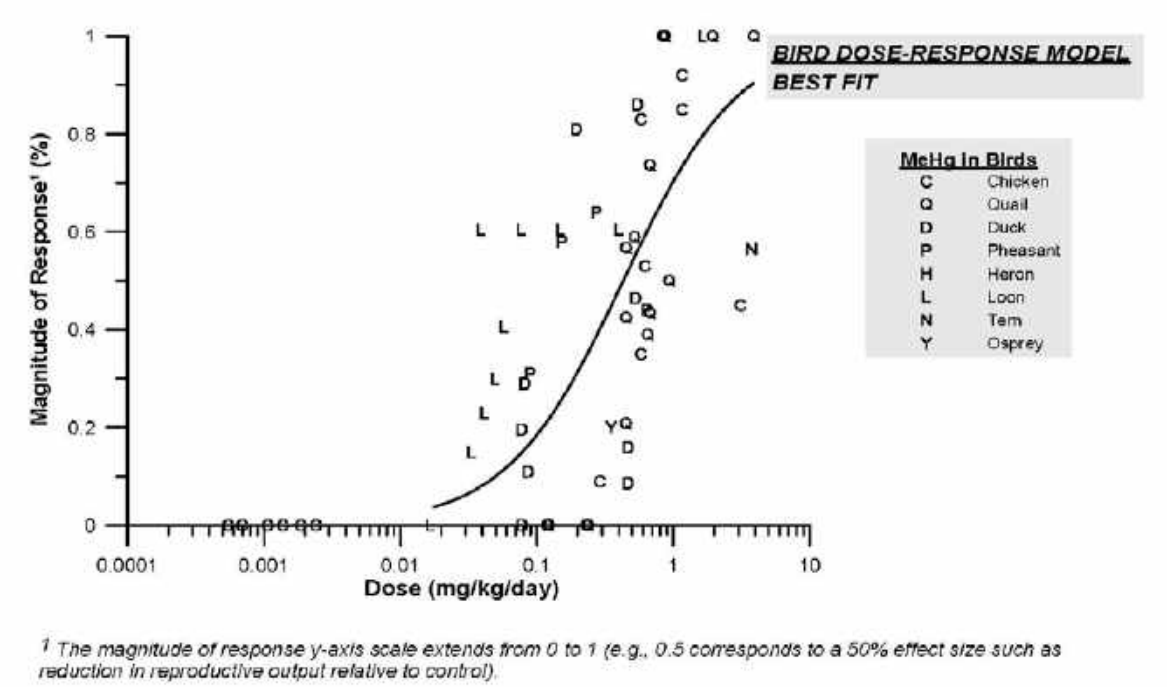

Figure 4: Example of a multi-study concentration response profile (from Environment Canada 2010, courtesy of Azimuth Consulting Group)

4.2.11 Task 3C – Supplemental Bioavailability Analysis

Golder believes that there is sufficient technical support and past precedents for the current use of relative bioavailability in the wildlife food chain model. However, if necessary based on Task 3A, Golder would conduct additional analysis on archived soil, plant and invertebrate tissue samples to provide further information about how bioavailability can be incorporated into the food chain model. Conceptually, relative bioavailability is about establishing a common modifying factor to interpret the total copper concentrations that are established by the chemical analytical laboratory. A focused assessment that involves the same bioavailability analysis on water, soil, food and representative “spiked-food” samples made to duplicate the original approach used in the key toxicology studies from the literature would create a common basis for relative bioavailability in the food chain model.

4.2.12 Task 3D – Update to Food Chain Model

This task is a standalone activity to update the food chain model with the information obtained in Tasks 2A, 2B, 3B, and 3C. Depending on the quantity of information from 2A and 2B, it may be possible to add additional refinement in terms of dietary preferences to more closely reflect how different receptors would be expected to use the site. A bat will also be added as an additional surrogate receptor per ENV’s request. The deliverable for this task would be an update to the existing food chain model report (Appendix F of the ERA).

5.0 SUMMARY

This memorandum describes a proposed approach for the terrestrial component of the CEMP. Not all tiers are recommended for immediate implementation, and there are significant technical and regulatory issues that would need to be resolved as part of the design and execution. Golder recommends that the current CEMP focus on executing the proposed tasks up to the end of Q1 2019. This includes progressing the proposed chrono sequence approach for the long-term CEMP up to the point of submitting a preliminary design for formal ENV approval. The proposed tasks also include activities to reduce the uncertainty in risk estimates to soil invertebrates and wildlife that addresses the content of Table 53 of the ERA.

6.0 CLOSURE

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this technical memorandum.

Please do not hesitate to contact the undersigned if there are questions regarding this memorandum.

Amphibian and Reptile Monitoring

Golder Associates Ltd.

TECHNICAL MEMORANDUM

DATE 9 August 2018 **Reference No.** 1894924-018-TM-Rev1-23182

TO Stephen Monninger
Mount Polley Mining Corporation

CC Colleen Hughes

FROM Blair McDonald and Barbara Wernick **EMAIL Blair_McDonald@golder.com; Barbara_Wernick@golder.com**

STUDY DESIGN CONCEPT: AMPHIBIAN COMPONENT FOR THE MOUNT POLLEY MINE COMPREHENSIVE ENVIRONMENTAL MONITORING PLAN

Introduction

Golder Associates Ltd. (Golder) understands that Mount Polley Mine is preparing a Comprehensive Environmental Monitoring Plan (CEMP) to integrate the monitoring components from a variety of regulatory processes applicable to the mine into a single document. One element of the regulatory process involved the submission of an Ecological Risk Assessment (the ERA; Golder 2017) which integrated the available chemical and biological information to provide an overall conclusion about the magnitude and extent of ecological risks associated with the deposit of tailings. The ERA was accepted by Ministry of Environment & Climate Change Strategy (ENV) on 31 January 2018, contingent on the implementation of additional monitoring in relation to specific areas of uncertainty identified in the ERA. One of the identified areas of uncertainty at the conclusion of the ecological risk assessment (Table 53 of the ERA) was that amphibians were not formally assessed. The ERA identified amphibians and reptiles as a relevant receptor group (Section 2.3.3.4 of Golder 2017) with western toad and common gartersnake identified as possible receptors. Western toad was selected as the receptor of potential concern for the broader amphibian and reptile community because it is also a listed species.

This purpose of this memorandum is to outline the monitoring concept proposed to address the uncertainty associated with the amphibian component for the Mount Polley CEMP. If this concept meets ENV expectations, a detailed study design document and specific work instructions will be prepared by Golder as the basis for executing this component as part of the Mount Polley-led CEMP process.

Golder and the G logo are trademarks of Golder Associates Corporation

Basis of Design

The basis of design consists of a summary of the available data and how those data were evaluated in the ERA, provided for the convenience of the reviewers. Copper and vanadium were retained as the contaminants of potential concern in the terrestrial ERA, and copper was retained as the contaminant of potential concern in the aquatic risk assessment. Although no amphibian-specific toxicity reference values were available, these contaminants of potential concern were selected by comparing the maximum observed concentrations conservative, regulatory-approved standards and guidelines. The maximum observed vanadium concentration was only marginally greater than the generic soil standard, and therefore, copper is expected to be the primary contaminant of potential concern for amphibians. Other data relevant to amphibians were described in Section 3.4 of Golder (2017) and consisted of:

- Substantial numbers of tadpoles were observed in 2015 in pooled water that formed throughout the Hazeltine Creek corridor. These tadpoles were confirmed to be western toad (*Anaxyrus boreas*) which is listed on Schedule 1 of the federal *Species at Risk Act*. More than 75,000 individual western toads (approximately 66,000 tadpoles, 9,000 juveniles, 300 sub-adults and 50 non-breeding adults) were subsequently salvaged from 40 different standing water depressions over a two-month period in 2016 prior to the start of rehabilitation. Long-toed salamanders (*Ambystoma macrodactyllium*) and Columbia spotted frogs (*Rana luteiventris*) were also salvaged (at lower numbers). Golder (2017) concluded that the salvage provided qualitative information that amphibians were able to successfully survive, grow and reproduce despite direct contact with tailings and surface water.
- Tissue samples were collected from three amphibians (species not identified) were collected by ENV in August 2016. Golder was not able to confirm the methods used for sampling, processing or analysis and did not review the certificate of analysis with respect to quality assurance/quality control measures. Tissue concentrations in two samples collected from impacted areas ranged from 56.4 to 871 mg/kg Cu dry weight. A tissue sample collected from Gavin Lake (considered by ENV to be a background area) was 12.4 mg/kg Cu dry weight. Data were compared to literature that indicated that copper tissue concentrations corresponding to a lowest-observed effect concentration (LOEC) or no-observed effect concentration (NOEC) ranged from 60 to 325 mg/kg dw (Attachment F, Appendix J of Golder 2017). The average concentration of the two impacted samples was also considered in the uncertainty analysis for the wildlife food chain model (i.e., would the risk conclusion be different if piscivorous birds and mammals had a diet consisting entirely of amphibians). Beyond these qualitative observations, data were not formally evaluated because methods and quality assurance/quality control practices could not be verified.
- Multiple lines of evidence in the ERA demonstrated that copper had low bioavailability. The lines of evidence included geochemical modeling and three different chemical surrogate measurements in tailings samples (water soluble fraction; humidity cell and leach tests; physiological-based extraction tests – see Section 3.2.2 of Golder 2017). Speciation modelling of copper in water showed most of the dissolved copper in Quesnel Lake water would be bound to carbonates which have lower bioavailability than copper ions (see Section 4.2.1.3 of Golder 2017). Golder concluded that the bioavailability of copper would be unlikely to be high for amphibians if there were multiple lines of evidence showing that copper bioavailability to other receptors was low.

Further Consideration of Uncertainty

The purpose of this section is to expand on the specific uncertainties identified in the ERA to be evaluated by focussed monitoring as outlined in this conceptual design document. Golder (2017; Table 53) provided an overview of the uncertainties to assist with future risk management decisions, but a one or two sentence summary does not necessarily convey sufficient detail to show how the design of the amphibian monitoring is linked to the findings of the ERA.

For amphibians, uncertainty is because of the absence of quantitative risk assessment for amphibians. Notwithstanding the value of the inferences and qualitative observations described above, there was only a limited amount of direct measurement of exposure or effects relevant to amphibians at the time the ERA was undertaken. From a practical perspective, rehabilitation of the riparian areas, and restoration of Hazeltine Creek was ongoing throughout the risk assessment process and therefore the habitat suitability for amphibians was considered low. Moreover, completion of the ERA for other major groups of receptors (e.g., mammals, plants) was needed to determine if further remediation activities, which would further disrupt habitat suitability, was needed to address the residual concentrations of copper in the deposited material. Therefore, Golder (2017) determined that it would be inappropriate to arrive at a risk conclusion at that time without further evaluation.

The ERA found that risks for the major groups of receptors were generally low to moderate (reflecting the low bioavailability of copper in tailings) and therefore, extensive additional intrusive works are less likely. Thus, it is appropriate to now consider a monitoring plan that will contribute to confirming that the risk conclusions for other major groups of receptors are also applicable to amphibians.

Conceptual Approach

The amphibian component is essentially a continuation from the problem formulation already completed (Golder 2017) (which identified amphibians as a relevant receptor). In brief, the proposed approach is to continue the risk assessment process by proceeding through the following tiers to the point needed to support an informed risk management decision. The tiering is described in Figure 1, and consists of the following main tasks:

1) Conduct a hazard evaluation – Screen existing soil, sediment and surface water chemistry data for different habitat units against a conservative amphibian-specific screening value. Eliminate habitat units from consideration if copper concentrations are sufficiently low (i.e., the 90th percentile and 95% upper confidence limit of the mean) that risks are not expected.

2) Conduct an exposure assessment – For those areas that are not screened out in Step 1, compare the distribution of soil (or sediment, or water) concentrations for that area to a multi-study concentration response profile for copper. Areas where the average concentrations (e.g., 95% UCLM) are less than the toxicity reference value (TRV) (e.g., geometric mean of chronic, relevant no-observed effect levels) will be excluded from evaluation. Areas that cannot be excluded will be prioritized according to their potential risks (e.g., based on the degree of overlap between the distribution of concentration data and the response profile).

3) Conduct a laboratory-based effects assessment – The exposure assessment above assumes that copper in tailings is equally bioavailable as the original toxicity test. This is unlikely to be true because the ERA had multiple lines of evidence that showed bioavailability of tailings were low. If Step 2 demonstrates the potential for unacceptable risks, then laboratory-based toxicity testing will be used to establish a site-specific copper TRV and the representative soil, sediment and surface water data will be re-screened. Laboratory testing will likely need to include the physical nature tailings as a variable.

4) Refine the application of the toxicity reference values – The evaluation in Steps 2 and 3 assume that all soils, sediment and surface water are representative of a potential amphibian exposure. There may be portions of the terrestrial zone that are unlikely to be suitable amphibian habitat because of their distance from water, substrates or other factors. Refinement of the screening process from Step 3 to focus on the potential areas of habitat may be considered.

5) Conduct a field-based effects assessment – A field-based effects assessment is not contemplated unless concentrations in relevant amphibian habitats exceed both the literature-based and site-specific TRVs. Field-based measurements focus on comparison of population-level or organism-level endpoints between impacted and reference amphibian habitats. A mesocosm study could also be considered (e.g., transplant amphibian larvae between enclosures established in reference and impacted habitats and measure survival and growth at end of chronic exposure)

6) Integrate toxicity and habitat data in a population model – If a copper concentration response relationship has been established, it could be used in a population model to determine the relative influence of copper and physical stressors in the context of natural stressors (e.g., low precipitation) and habitat quality. This assumes that there is adequate information about the population dynamics of the western toad.

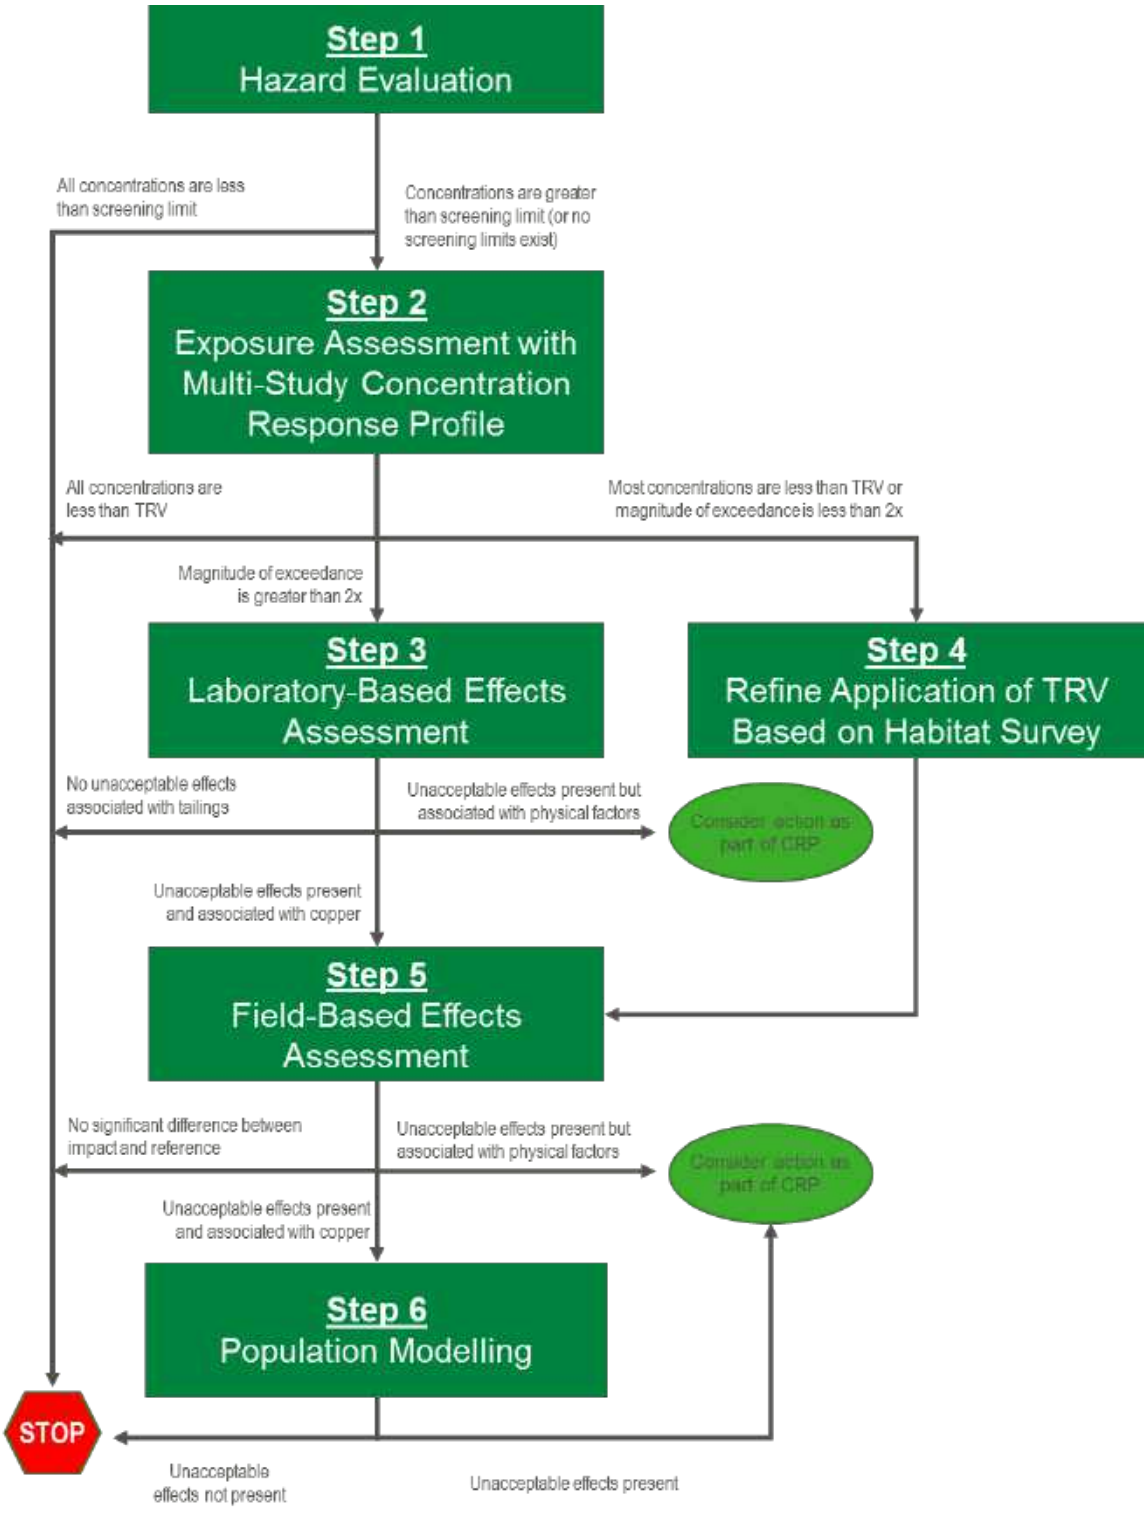

Figure 1: Proposed Tiering for Amphibian CEMP Component

Additional Information

This section expands on each tier in terms of potential sampling activities, levels of effort, and decision criteria. Further expansion of the rationale in the detailed study design is expected based on ENV feedback regarding the approach. The following guidance documents were reviewed as part of the development of this conceptual approach:

- FSCAP. 2016. Module 6: Ecological Risk Assessment for Amphibians on Federal Contaminated Sites. Draft (Not Approved as Guidance).
- Navfac (US Navy, Naval Facilities Engineering Command). 2004. Development of a standardized approach for assessing potential risks to amphibians exposed to sediment and hydric soils. TR-2245-ENV.

These documents provide amphibian-specific risk assessment information that was considered in the context of provincial guidance on conducted detailed ecological risk assessments at contaminated sites.

Step 1: Hazard Evaluation

FSCAP (2016) comment that there are relatively few summaries of amphibian toxicity data that provide generic screening limits. Golder will conduct a brief literature search to seek out amphibian-specific screening limits and review the available environmental quality guidelines to determine the degree to which they are protective of amphibians. The screening limits (if available) will be used to provide an initial evaluation of the soil, sediment and surface water data that is representative of the current-day exposure scenario for amphibians. The purpose of this initial hazard evaluation is to determine if portions of the site can be excluded from the amphibian assessment. An area will be excluded if: a) there is sufficient data to characterize the defined unit; and b) if the 90th percentile and 95% upper confidence limit of the mean concentrations in the unit are less than screening limit. If multiple screening limits are identified, an area will be excluded only if it has concentrations that are less than all limits. If no defensible screening limits are identified, we will proceed directly to Step 2.

Step 2: Multi-study Concentration Response Profile

FSCAP (2016) describe a process for integrating all available literature toxicity data into an overall concentration response profile for each media This “response profile” is then used to derive point-estimate screening limit (i.e., a single “safe” concentration) or effects-based TRVs (e.g., the range of values that correspond to a ECx effect). An example for zinc from FSCAP (2016) is provided in Figure 1.

Golder will develop multi-study concentration response profiles for copper in water and sediment/hydric soils consistent with FSCAP (2016). The overall process involves a literature review (with quality assurance procedures to eliminate unreliable data) consistent with ECO-SSL procedures. The general approach to integrating the literature data into a concentration-effect relationship is like that described by Allard et al. (2010) for wildlife TRVs. The ECO-SSL process is endorsed as a preferred approach in BC risk assessment by Technical Guidance 6 (guidance under the Contaminated Sites Regulation) and wildlife TRVs that consider the entirety of the available literature (instead of a single point estimate) are increasingly common in contaminated sites risk assessments.

Not all data have the same value in the derivation process:

1) Data that fail to meet basic test acceptability criteria (e.g., negative control are not present) will be rejected.

2) More weight will be given to North American species. Many toxicity studies use the African clawed toad (*Xenopus*) as a surrogate, but this species is not native to North America. Removing species that cannot be present at the site is consistent with provincial guidance about establishing site-specific water quality objectives (BCMOE 2013) and is also discussed by FSCAP (2016).

3) More weight will be given to studies that involved measured (instead of nominal) concentrations and/or involved field-collected samples instead of laboratory-spiked samples.

The specific derivation of a screening limit or a TRV is ultimately dependent on the quality and quantity of toxicity data available. It is likely that there will be a wide range of effects associated with a given concentration (e.g., Figure 2, which is for lead), and therefore, a specific derivation rule cannot be proposed at this time. FSCAP (2016) recommends that the data set should be explored to determine if there are significant differences in toxicity profiles for different species, exposure duration, endpoints and life stage. A specific decision about what constitutes an acceptable effect was not proposed by FSCAP (2016), but realistically, screening limits or toxicity reference values that are meant to be protective of western toads would need to reflect a low risk (e.g., EC10 or EC20). Moderate-to-high risk limits (e.g., an EC50-based TRV) may also be derived to help provide further context. Golder will need to consider the totality of the available data and provide a rationale for the TRV proposed. The available soil data will be compared to the TRVs using the same approach as described in Step 1.

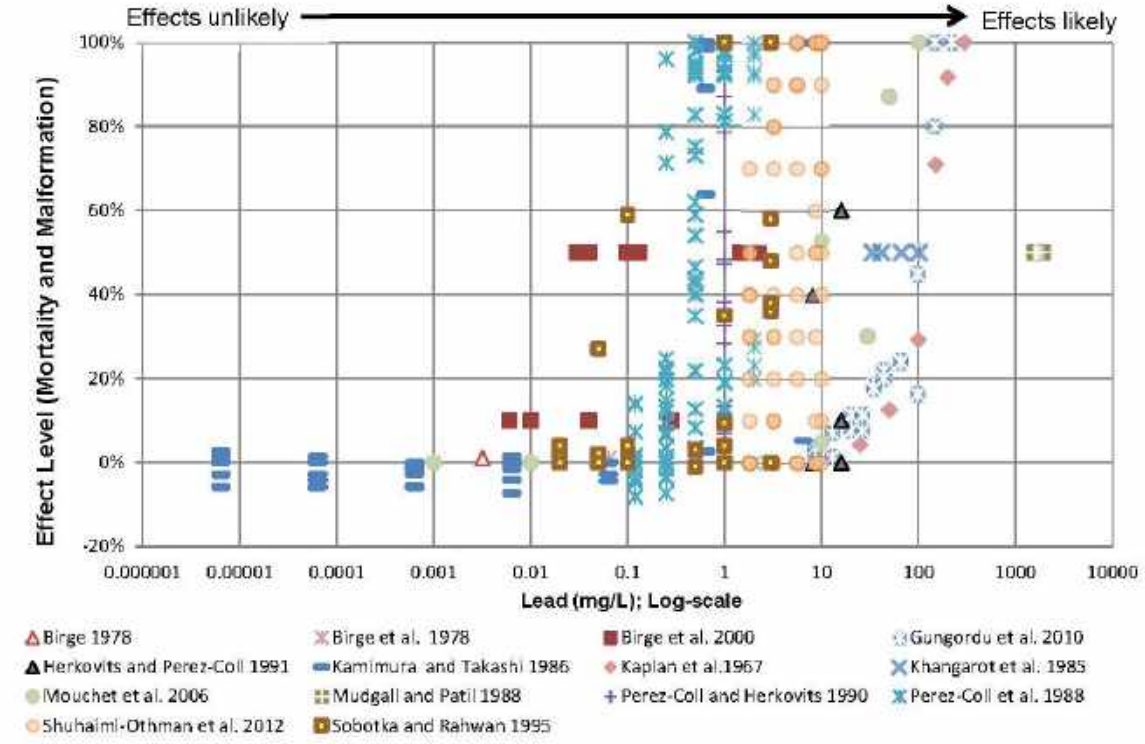

Figure 2: Example of a concentration-response profile (from FSCAP 2016)

Detailed reviewer comments were provided by ENV on May 29, 2018 and a teleconference was held on 9 July 2018 to discuss the conceptual approach and the reviewer comments. Golder understood from the teleconference that a topic of concern relates to how the results from the comparison of soil, sediment and surface water data to the amphibian-specific TRVs would account for amphibian habitat requirements.

Golder notes that there have been many soil samples collected from the site which were considered in the terrestrial risk assessment, and that additional soil sampling is being conducted in August 2018 as part of the supplemental terrestrial monitoring described under separate cover. Nevertheless, it would be a potential gap in the assessment if there were no data available regarding concentrations of copper in soil in areas that are important rearing or feeding habitat for amphibian species. Golder intends to present the data screening from Steps 1 and 2 in a manner that provides context for how the available data helps to inform hazards to amphibians. Specifically, a qualified biologist will provide a summary of habitat requirements for each of the individual amphibian species found in the area and will determine the extent of “high-quality” and “low-quality” habitat using existing information. This desktop-level review will help to place the hazard evaluation from Steps 1 and 2 in context. Further refinement of the hazard assessment based on a detailed habitat survey (Step 4) or a field-based assessment of effects (Step 5) will be considered based on the outcome of Steps 2 and 3.

Step 3: Site-specific Concentration-Response Relationship

A site-specific concentration response could be developed using amphibian toxicity testing in a manner similar to the approaches used for benthic organisms and plants in the ERA. Conceptually, the testing would include:

- Between 5 and 10 field-collected samples with varying copper concentrations that capture the range at which copper would be expected to exert a negative effect (based on Step 2).
- Additional negative controls to evaluate the physical nature of the tailings (e.g., low organic carbon; grain size and shape).
- Inclusion of spiked-copper samples (e.g., silica sand and natural soils spiked with a range of copper concentrations) to evaluate the difference in bioavailability between tailings and the typical literature values.

A detailed design for a laboratory-based toxicity test has not yet been developed, and there would need to be clarification from ENV about how the amphibian toxicity data would be used to make site management decisions before a suitable detailed design could be prepared. Amphibian toxicity testing is not a common approach and there are multiple laboratory-, organism- or sample-related factors that could lead to an unacceptable level of uncertainty in the results. For example:

- Nearly all available standardized protocols (ASTM, USEPA) use *Xenopus* which is not native to North America and it is not clear that this species is appropriate for the current application. Environment and Climate Change Canada (ECCC) is in the process of developing a standardized protocol with a relevant, Canadian species, but Golder understands that there are methodological challenges and organism supply issues yet to be resolved. The status of the draft method is unknown.

- Most standardized protocols are designed for spiked-water applications which would not necessarily provide value to the current application. One exception is NavFac (2004) which describes a method for exposing North American frog and toad tadpoles to field-collected sediment samples for a 10 to 14-day exposure. An ASTM test method is also available for sediment (but it uses *Xenopus*).
- It may be necessary to field-collect test organisms which would not be possible without applicable provincial scientific collection permits and/or federal permits under the Species at Risk Act.

Step 3 could provide value for site management decisions, but there are technical and regulatory issues to be resolved. Further development of a detailed study design for amphibian toxicity testing is not recommended until Step 2 has been completed, and only if there is consensus about how risk management decisions would factor in the possibility of high uncertainty associated with the use of a non-standard toxicity testing method. Ideally, an approved ECCC test method would be available at the time this step would be undertaken.

Step 4: Refinement of the TRV Application

A specific design for this step has not yet been developed. As a default, all soil, surface water and near-shore sediment data will be evaluated in Steps 2 and 3. The general concept for Step 4 is to refine how those TRVs are applied to different areas of the site based on whether the area provides (or will in the future) meaningful habitat for amphibians. The nearshore of the various waterbodies and their immediate riparian zones are likely amphibian habitat and would be included. Conversely, although western toads forage over relatively large areas and can use a range of different habitats (ECCC 2016), portions of the study area that are not suitable habitat for amphibians would then be excluded from the exposure estimates. Step 4 would involve a survey of the impacted area by biologists with specialized amphibian expertise. Areas of the site would be classified according to their suitability as amphibian breeding, hibernation, and foraging habitat (both at present, and in the future). This information would be used to refine how the TRVs are applied (e.g., exclude areas with minimal value to amphibians, and focus on understanding the risks in areas that are key to sustaining the amphibian population).

Step 5: Field-based Effects Assessment

From a risk assessment perspective, field programs provide valuable information because they provide a direct measurement of effects under field conditions. However, in the current application, direct measurement of effects does not necessarily help to differentiate the effects of the residual concentrations of metals associated with tailings from the physical effect of the tailings themselves. The physical alteration of habitat in the impacted areas was substantial, and as a result, a control-impact study design needs to account for the fact that risk management decisions will be different depending on whether the main stressor is physical or chemical.

FSCAP (2016) comments that amphibian risk assessment can incorporate field-based assessments and lists a number of standard methods for conducting field surveys for amphibians. Field assessment would involve a control-impact comparison (similar to the approach used for the benthic taxonomy studies in Quesnel and Polley Lake) and each type of area would preferably involve multiple locations to minimize the effect of natural variability of the risk management outcome. A variety of endpoints could be measured in a control-impact study design (e.g., number of egg masses per unit area; frequency of lesions or malformations per adult; abundance of amphibian larvae per unit catch effort).

Further development of a detailed study design for an amphibian field assessment is not recommended until Step 2 has been completed, and only if there is consensus about how risk management decisions would factor in the possibility of high uncertainty in its outcome. A key question is to determine the number of amphibian breeding sites within the impacted area, and to conduct a baseline survey to confirm that there is an adequate number of potential control sites available in the area. This baseline survey could be conducted as part of Step 4.

Step 6: Population Model

An additional line of evidence in an amphibian risk assessment is to combine the available toxicity and habitat data into a population model. A population model, in this context, simulates the stability of a given local population under a range of future conditions. The model is used to determine if reductions in survival, growth or reproduction from the physical or chemical stressors associated with tailings will impact the population as a whole. An example of a contaminant-habitat population model is provided for context.

Willson et al. (2012) used a population model (at a site unrelated to Mount Polley) to evaluate the impact of mercury on individual toads on the overall viability of population of American toads (*Bufo americanus*). The model simulated the population dynamics of toads to establish a baseline discrete-time model (e.g., how many toads will survive to each successive life-stage based on habitat quality; how big are the toads at reproductive age as a function of food availability; how many eggs will be produced as a function of adult toad size). The effect of mercury on the population was then added to the model as a reduction in the survival, growth and reproduction baseline as a function of mercury concentration. The net effect was a model that simulated how different concentrations of mercury would contribute to the stability of the toad population over time, and to determine which type (and how much) habitat enhancement was needed to off-set the influence of mercury.

In the current application, a model similar to Willson et al. (2012) would provide value by integrating the information from Steps 3, 4 and 5. However, a model like this would only be appropriate if there was evidence that copper was exerting an unacceptable effect which could not be readily remediated. Golder recognizes that habitat compensation to address residual contamination is a policy question that would need to be resolved, particularly for a listed species where the intent is to protect the individuals of the population, not just the population itself. There are also technical limitations to this type of model in terms of the quality and quantity of data available for parameterization. Golder assumes that there would be sufficient species-specific information for western toads because the species is listed and would be a priority for researchers (at least relative to other Canadian amphibians). It may also be reasonable to assume the population variables for western toads are similar to American toads.

Further development of a detailed study design for an amphibian population model is not recommended until Step 2 has been completed, and only if there is compelling evidence that there is a chemical-related impact that would be likely to cause an unacceptable outcome to amphibian populations. In the absence of a chemical-related impact, a model would not necessarily add any value (i.e., a decision to conduct habitat improvement to mitigate a physical stressor does not need to be based on a model).

Summary

This memorandum describes a proposed tiered approach for the amphibian component of the CEMP. Not all tiers are recommended for implementation, and there are significant technical and regulatory issues that would need to be resolved as part of the design and execution of Steps 3 onwards. However, Steps 1 and 2 provide a framework that is similar to a screening-level risk assessment for amphibians, and the process for accomplishing those steps has already been described by draft regulatory guidance (i.e., there is a basis for developing a clear process for those steps).

Golder recommends that Steps 1 and 2 should be completed as part of the current CEMP. No further action would be necessary if risks to amphibians can be shown to be low based on comparison of the relevant soil, surface water and chemistry data to toxicity reference values derived from the available literature. A preliminary review indicates that there will be sufficient data in the literature of suitable quality to support Step 2. If risks are found to be unacceptable at the conclusion of Step 2, further investigation following the tiered approach described in this memorandum may be necessary.

Closure

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this memorandum.

Please do not hesitate to contact the undersigned if there are questions regarding this memorandum.

STUDY DESIGN FOR DEVELOPING REFERENCE CONDITIONS FOR POLLEY LAKE – MOUNT POLLEY MINE

Dear Mr. Parsons,

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with this study design for characterizing reference conditions for Polley Lake. This study design was prepared in response to a condition set by the Ministry of Environment and Climate Change Strategy (ENV) for approval of the Comprehensive Environmental Monitoring Plan (CEMP), specifically:

> *An updated study design must be provided, which includes the monitoring location, frequency, and methods for assessing reference conditions for Polley Lake, and which includes a description of the process for characterizing the relative differences between Bootjack Lake, Polley Lake, and the newly identified reference location.*[1]

1.0 OBJECTIVES

Polley Lake is adjacent to the Mount Polley Mine, and environmental monitoring is undertaken to assess the potential for mining activities to affect biological communities in the lake. At the present time, the reference lake for Polley Lake is Bootjack Lake, on the opposite side of the mine site from Polley Lake. Because there is potential for mine-contact water to enter Bootjack Lake in the future, ENV requested that MPMC identify one or more alternate lakes to function as references and to begin data collection early on to provide temporal and spatial continuity to the program. The purpose of this letter is to provide a decision framework and methods for selecting candidate alternate reference lakes for Polley Lake.

[1] 9 November 2018 letter from D. Hill, ENV, to D. Reimer, MPMC, "Approval of the August 15, 2018 Comprehensive Environmental Management Plan (CEMP) – Mount Polley Mine Permit PE-11678".

2.0 IDENTIFICATION OF CANDIDATE LAKES

The decision framework for identifying potential candidate reference lakes is illustrated in Figure 1. The primary variables expected to have an influence on hydrodynamics and biological communities in a given lake, and which can be characterized at a desktop level, are: biogeoclimatic zone, size, depth, surrounding land use, and underlying geology. Ideally, reference areas will have as similar characteristics to the exposed area as is reasonably practicable. Once a subset of lakes is identified, collection of sediment and water samples will be needed to select the final candidate reference lake(s).

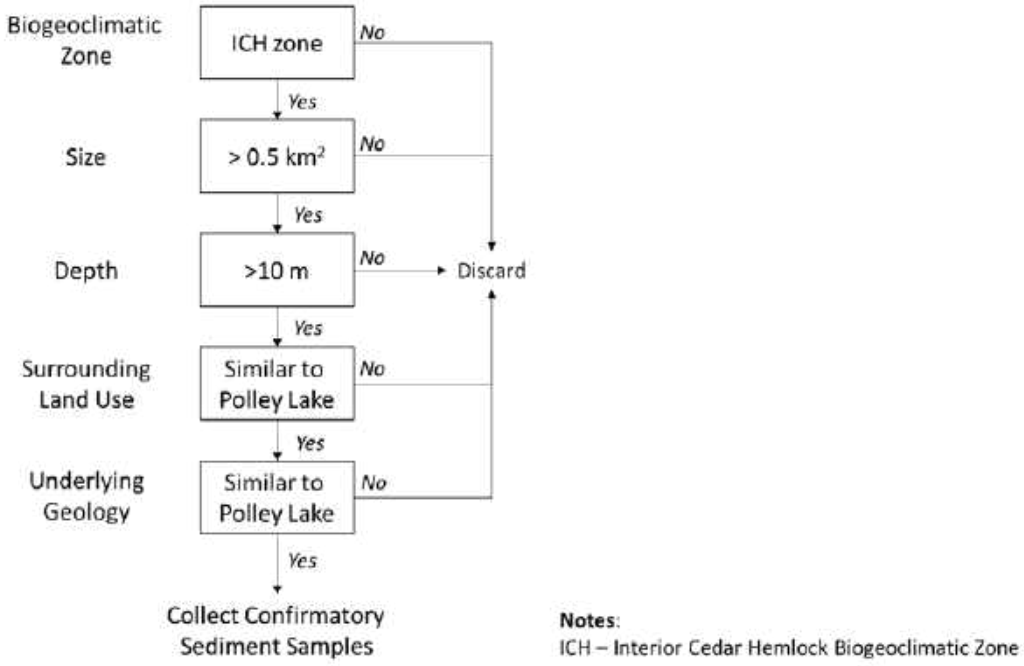

Figure 1: Decision Framework for Selection of Candidate Reference Lakes

Following this approach, Table 1 provides a summary of an initial subset of candidate reference lakes. Jacobie Lake was sampled in 2018 and the results confirm that the underlying geology is likely too dissimilar to Polley Lake to provide a suitable reference. It is also expected that Spanish Lake is unsuitable because it is in a wet subzone (wk2) of the Interior Cedar Hemlock (ICH) zone, has notably different underlying geology (arsenic and selenium is enriched in rocks on the opposite shore of Quesnel Lake), and is subject to mineral exploration and planned mine development (and therefore potential future mine-related activities).

Morehead and Gavin Lakes are both in the moist cool subzone (mk3) of the ICH zone, and Morehead coincides with at least one geological unit (LT_{Nvl}) that is similar to Polley Lake. Geological mapping will be further reviewed to evaluate similarity in the composition of the underlying geology vis-à-vis similarity to be a source of primary metals/metalloids of concern (e.g., copper, selenium, arsenic). However, Morehead Lake receives drainage from Bootjack Lake.

Table 1: Characteristics of Polley Lake and Candidate Reference Lakes

Lake	Elevation (m) [(a)]	Area (km^2) [(a)]	Depth: max (mean) (m) [(a)]	Underlying Geology [(b)]	Biogeoclimatic Zone [(c)]	Activities
Polley Lake	920	3.9	35 (18)	LT_{Nvl}, LT_{MPic}, LT_{Nav}	■ ICHmk3	■ Adjacent to Mount Polley Mine ■ Recreation (camping, fishing)
Bootjack Lake	983	2.6	15	LT_{Nvl}, LT_{Npt}	■ ICHmk3	■ Adjacent to Mount Polley Mine ■ Recreation (camping, fishing)
Jacobie Lake	1,122	0.86	20 (7)	LT_{Npv}, LT_{Nvb}	■ ICHmk3	■ Recreation (camping, fishing)
Morehead Lake	916	2	17	$LT_{Nvl,}$ Qal	■ ICHmk3	■ Recreation (camping, fishing)
Gavin Lake	963	0.94	24	MJ_{Qm}, LT_{Ns}	■ ICHmk3	■ Recreation (camping, fishing)
Spanish Lake	919	4.6	72.5 (29.6)	MLT_{Ns}	■ ICHwk2	■ Mineral exploration ■ Recreation (camping, fishing)

Notes:

(a) Activities, elevation and area identified from various angler and recreational use information websites.

(b) BC Forest Service Biogeoclimatic Ecosystem Classification System (ftp://ftp.for.gov.bc.ca/HRE/external/!publish/becmaps/PaperMaps/field/DHO_HorseflySubunit_Cariboo-ChilcotinResourceDistrict_CaribooRegion__field.pdf).

(c) BC EMPR Geoscience Map 2007-1 Regional Geology of the Mount Polley Area, central British Columbia (http://cmscontent.nrs.gov.bc.ca/geoscience/PublicationCatalogue/GeoscienceMap/BCGS_GM2007-01.pdf).

ICH: Interior Cedar Hemlock.

LT_{MPic}: Hydrothermal altered intrusive carapace holocrystalline monzonitic intrusions and volcaniclastic wall rock.

LT_{Nav}: Pink-white analcime pyroxene+/-olivine basalt breccia, flows and tuffs.

LT_{Npt}: Plagioclase phyric, pyroxene lapilli tuff, breccia and minor flows.

LT_{Npv}: Green and maroon pyroxene porphyry breccias, pyroxene-olivine basalt flows, and crystal-rich sediments.

LTNs: Grey siltstone, normal graded sandstone and cherty shale with pyroxene and plagioclase-rich crystal sandstones.

LTNvb: Massive, coarse polymictic volcanic breccias, graded sandstones, siltstone and rare limestone breccia horizons.

LTNvl: Red-brown, massive, polymictic breccia, feldspar, and hornblende crystal tuff.

MLTNs: Graphitic and quartzose phyllite, shale, siltstone and sandstone.

MJQm: Hornblende-biotite quartz monzonite.

mk3: moist cool zone.

wk2: wet cool zone.

3.0 VERIFICATION OF SUITABLE REFERENCE LAKE

Prior to the 2021 benthic invertebrate sampling program for Polley Lake, five sediment samples will be collected from lakes with similar geology to Polley Lake and analyzed for metals and grainsize distribution. Water samples will be collected from two locations and two depths (surface and depth) and analyzed for metals, hardness, total and dissolved organic carbon, and nutrients. At each of the two sampling locations, field measurements of pH, temperature, dissolved oxygen and conductivity will be recorded at 1 m intervals. Sampling methods (including quality assurance/quality control procedures) as outlined in the CEMP will be followed.

The resulting physico-chemical data will be compared to data from Polley Lake and Bootjack Lake. The comparisons may be made visually using graphs; through screening against sediment quality guidelines; and/or using statistical tests such as principle components analysis (PCA) or non-metric multidimensional scaling NMDS). The specific tests will be determined at the time of analysis, as factors such as variance and distribution (normal/non-normal) of the data and proportion of detectable versus non-detectable concentrations will need to be taken into account.

Sampling of the benthic invertebrate community of the selected lake will be conducted in 2021, along with sampling in Polley Lake.

4.0 CLOSURE

We trust that this letter provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at 604-296-4200.

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

Yours very truly,

Golder Associates Ltd.

STUDY LIMITATIONS

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by Golder for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents Golder's professional judgement based on the knowledge and information available at the time of completion. Golder is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document

pertain to the specific project, site conditions, design objective, development and purpose described to Golder by MPMC, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by Golder are considered its professional work product and shall remain the copyright property of Golder. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

Appendix C

Combined Monitoring Schedule 2019

Mount Polley Mining Corporation

Monitoring Schedule

Task	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
	31	1	2	3	4	5	6
					No staff on weekend		
Lakes							
Surface Water		Discharge: E19, HAD-3 Surface water sampling: W1, WA (W1 dup), W4a, W5, W8, W8z, W20, W21, Gavin's Ditch, WL (W12 dup), East 12204 (East MTD dup), West MTD, LD, SERD, E1a, ED (E4 dup), **2 ppl; 8**	Surface water sampling: E13, E14, E15, E17, E18, E19a, E20, E21, E22, E23, STD, TB + FB ; JCP, Boundary Seep 2, MDC, SERD Seep 13 **2 ppl; 8 hours**	SERD Seep Survey **2 ppl; 5 hours**			
Reclamation		Seeding/Monitoring as necessary					
Groundwater				GW15-1A/B & GW15-2A/B SWLs			
Hydrology							
Weather		Snowpack/Manual Rain Gauge		Manual Rain Gauge			
Inspections		Mill Potable Water Meter **2 per; 5 hours (winter)**	HAC Fish Spawning Survey **1 per; 6 hours** **2 ppl; 4 hours**	EDC Fish Spawning Survey; Waste Inspection			
Soil/Sediment		ABA (if dumping NAG waste)					
	7	8	9	10	11	12	13
Lakes	P1 (S+P)[1] + PA-B + P2 (S+P)[1] B1 IS+P) + B2 (S+P) + BB-S **2 ppl; 8 hours**						
Surface Water		**DO all locations:** HAC-01c, HAC-13 + HAC-08, HAC-05a, HAC-10 + HAC-J + HAC-10-FB, POF-1, POF-5, CSD Bridge photos Discharge:E19, HAD-3 + HAD-C BAC-01 (Ladies Dry) **2 ppl; 8**	PAG Seep Survey **2 ppl; 5 hours**	East RDS Seep Survey **2 ppl; 5 hours**			
Dustfalls				Dustfalls **2 ppl; 7 hours in winter** **1 per: 4 hours in summer**			
Reclamation	Seeding/Monitoring as necessary						
Groundwater	GW15-1A/B & GW15-2A/B SWLs						
Hydrology	W1b, W5, W12, SERD, H6 **if safe and not frozen**						
Weather	Manual Rain Gauge	snowpack if melting event forecast		Manual Rain Gauge			
Inspections	Waste inspection	Spring/Fall Ditch Inspections	HAC Fish Spawning Survey	EDC Fish Spawning Survey			
Soil/Sediment	ABA (if dumping NAG waste)						
	14	15	16	17	18	19	20
Lakes	QUL-ZOO-8 (S+C)[3] + QUL-ZOO-8-FB QUL-ZOO-7 (S+C)[3] QUL-ZOO-1 (S+C)[3]	QUL-58 (S+C)[1] + T.Hg + Ra-226 QUL-57 (C) + QUL-59 (C) QUL-2a (S+C)[1] + T.Hg + Ra-226	QUL-18 (S+C)[1] + QUL-R-50m QUL-120a (S+C[f] * + QUL-ATa-190m				
Surface Water		Discharge: E19, HAD-3 + T.Hg + Ra-226+ toxicity[4, g, h] (100L) BAC-02 (Pit shop sink)		NEZ Seep Survey + DO at all locations: NEZ Samples + 2119 NEZ Seep LD (US NEZ Seep LD dup)+ Martel Sump + NEZ Seep -TB			
Reclamation	Seeding/Monitoring as necessary						
Groundwater	GW15-1A/B & GW15-2A/B SWLs						
Hydrology	H1, H2, H3, H4 **if safe and not frozen**						
Weather	Manual Rain Gauge	snowpack if melting event forecast		Manual Rain Gauge			
Inspections	Waste inspection	Trailer Inventory	HAC Fish Inspection (if ice free)/Fish Spawning	EDC Fish Spawning Survey			
Soil/Sediment	ABA (if dumping NAG waste)						
	21	22	23	24	25	26	27
Lakes							
Surface Water		Discharge:E19, HAD-3 BAC-03 (3rd floor mill lunchroom)					
Reclamation	Seeding/Monitoring as necessary						
Groundwater	Quarterly GW: GW 15-1a & 1b GW 15-2a & 2b GW 12-2a + GWL-Ba & GW 12-2b GW96-7 95-R5 **2 ppl; 8 hours**	Quarterly GW: GW95R-1 + Ecoli + GWIER-A GW05-01 + Ecoli GW04-1 + Ecoli GW-Low Flow + GW-Grundfos GW16-6a & 6b **2 ppl; 8 hours**	Bi-annual GW: GW00-1a & 1b GW00-2a GW00-3a & 3b GW96-3a GW96-4a & 4b **2 ppl; 8 hours**	Bi-annual GW: GW96-2a & 2b GW16-4a & 4b GW16-3a & 3b GW16-5a & 5b GW16-2a & 2b **2 ppl; 8**			
Hydrology	W4a, JCP, NW Ditch, H5 (Junction Zone Ditch), STD, MTD, NEZ Seep 1, SERD Seep 13 **if safe and not frozen**						
Weather	Manual Rain Gauge	snowpack if melting event forecast	Check HOBO Link online	Manual Rain Gauge			
Inspections	Waste inspection	HAC Fish Spawning Survey	Pipeline Inspection	EDC Fish Spawning Survey			
Soil/Sediment	ABA (if dumping NAG waste)						
	28	29	30	31			
Lakes							
Surface Water		Discharge:E19, HAD-3 BAC-04 (Assay Lab Eyewash)					
Reclamation	Seeding/Monitoring as necessary						
Groundwater	GW15-1A/B & GW15-2A/B SWLs Bi-annual GW: GW11-1a & 1b GW11-2a & 2b GW12-1a & 1b GW12-3a & 3b GW12-4a & 4b **2 ppl; 8 hours**	Bi-annual GW: GW12-5a & 5b GW16-7 & 8 GW16-1a & 1b **2 ppl; 8 hours**	HAC Creek GW	HAC Creek GW			
Hydrology							
Weather	Manual Rain Gauge	snowpack if melting event forecast		Manual Rain Gauge			
Inspections	Waste inspection	Spring/Fall Ditch Inspections	HAC Fish Spawning Survey	EDC Fish Spawning Survey			
Soil/Sediment	ABA (if dumping NAG waste)						

C = cast + secchi
P = profile + secchi
S = sample

Special Sampling:
1) Chlorophyll a, phytoplankton, [zooplankton - POL only] (Jun/Aug)
3) Zooplankton, chlorophyll *a* , phytoplankton, surface sample

QA/QC Sampling:
Field Blank - 2x monthly minimum
Trip Blank - 2x monthly minimum
Equipment Blank KEM2 - monthly; GW - quarterly
Duplicates - 2x monthly minimum

Quarterly Wells (SWL): Complete Q1

~~GW96-1a~~	GW96-2a
GW96-4a	GW16-2a,3a,4a,5a
GW00-1a	GW96-3a
GW00-2a	GW00-3a

Flows:
Purple:Bucket Black: Tracker

Ongoing/When Time:
Crew Training
Battery recycling
Trailer Clean Up/Safety -test PFDs
Wash trucks (in and out)

Seep Sampling:

SERD	WHR
PAG	TSF
BOUNDARY	NBD
EAST RDS	NEZ

Reclamation Activities:
Grass Seeding

QUL Sample Depths (m):

QUL-18	0, 20, 50, 100
QUL-2a	0, 20, 40, 60
QUL-58	If detect plume: Middle of plume (MP) + 5m above (AP) + 5m below (BP) (all sites) If can't detect plume: S, 1m above thermo , 1m below thermo [or MID if no thermo], bottom * write sample depths in field book **4x per year: T.Hg taken at QUL-58 (depth at which plume expected), QUL-2a (close to same depth as QUL-58), & HAD-3 *** write field parameters for each sample taken and indicate if discharging in field book
QUL-55	0, 15, 30
QUL- 42:	0, 10, 20
QUL-120a:	0, 40, 80, 120, 140 well-mixed: 0, 80, 190

BJ + POL Sample Depths (m):
S, 1m above thermo , 1m below thermo [or MID if no thermo], bottom
* write sample depths in field book
** monthly profiles between spring and fall overturns

Toxicity:
a) 96h LC50 RBT, 48h LC50 *D. magna*
b) 7 day ELS RBT
c) 7d C. dubia S&R
d) 7d RBT S&G
e) 30d ELS RBT
f) 30d ELS top-up (100L)
g) 72h algal (MMER)
h) 7 day duckweed (MMER)

Chorophyll *a* :
250ml polyethylene bottle wrapped in aluminum foil

Phytoplanton:
polyethylene bottle, preserved with Lugol solution

Zooplankton taxonomy (1 haul):
Quesnel Lake --> 150µm mesh net to 30m depth (1 tow), preserved with buffered sucrose
Polley Lake --> 50µm mesh net to 28m depth (1 tow), preserved with 85% ethanol

Zooplankton metals:
minimum amount of water, kept frozen, multiple hauls (depending on biomass)
QUL --> 50 µm mesh net minimum amount of water, kept frozen, multiple hauls (depending on biomass)
POL --> 50 µm mesh net minimum amount of water, kept frozen, multiple hauls (depending on biomass)

Special Analyses:
T.Hg - 40ml glass vial with 1x HCl
Ra-226 - 1L plastic with 6x HNO3

Appendix D

Site Matrix

Mount Polley Mining Corporation

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
W1 Morehead Creek	E 587262 N 5826275	1990	Meandering creek with lots of willows and grass, no distinct trail. Large marsh to the North.	Drive to km 4.5 on Bootjack Road to a small opening in the trees, and walk down the bank on the south side for 50 m. Trail and site marked with orange flagging tape.	Radio communication must be used on the Bootjack Road (Channel RR-25). Ensure that vehicle is parked to the side of the road out of the way of traffic. Watch for wildlife. Watch for rotten logs while approaching site. Follow working in/near water procedures.	Downstream of mine impacted area. Provides opportunity to monitor potential changes in POI's in Bootjack Lake.
W1b Morehead Creek	E 588920 N 5825173	2003	Meandering creek that flows under a bridge.	Drive to approx. km 7 on Bootjack Road and turn south onto side road for approx. 90 m until you reach a bridge. Walk down an embankment on the upstream side of the bridge to the creek.	Radio communication must be used on Bootjack Rd (Channel RR-25). Watch for wildlife. Watch your footing when walking down embankment. Follow working in/near water procedures.	Monitoring flow out of Bootjack Lake.
W4a North Dump Creek	E 593152 N 5824689	2014	Small stream that flows under the Wight Pit road through a culvert.	Drive towards the Wight Pit, before entering pit there will be one last runaway lane on the left hand side, park vehicle on right side of the road. The sample site is located over the berm and down an embankment; there is a large log on the hillside to indicate the sample location.	Watch for wildlife. Watch your step while descending the embankment to monitoring location; there are loose rocks. Follow working in/near water procedures.	Downstream of mine impacted areas. Provides opportunity to monitor for non-contained seeps or run-off collection ditches.
W5 Bootjack Creek	E 594481 N 5820782	1990	Small stream runs through culvert	Drive down the TSF haul road towards Polley lake weir, turn left at the central collection sump. Turn left onto deactivated logging road across from SERD outlet pipe. At top of hill, turn right and at the valley in the road park truck. Trail down to the creek is on the upstream side of creek. Site trail is indicated by fallen tree across path.	Contact Pit Shifter prior to entering haul roads. Drive with caution on haul roads and give heavy equipment the right-of-way. Use 2-way radio communication (Channel 5 – Pit Ops 1). Watch for wildlife. Slippery slopes with quite a few willows and one fallen tree. Old logging road can be very rough and muddy, recommend 4X4 or walk in during snowy conditions. Follow working in/near water procedures.	Downstream of mine impacted areas. Provides an opportunity to monitor for seepage from the SERD.
W8 Edney Creek Tributary	E 597005 N 5817606	1995	Small stream with easy access from the road.	Turn S at the old ABR onto a narrow road. Drive for roughly 2 km, until you come to a small stream flowing under road through a culvert. Monitoring site is located on the downstream side of the road.	This road can be very muddy, recommend 4X4 or walk in during snowy conditions. Look for old orange ribbon. Watch for wildlife. Follow working in/near water procedures.	Downstream of mine impacted area. Provides opportunity to monitor for potential seepage from TSF.
W8z Edney Creek Tributary (control)	E 593290 N 5817920	1997	Small creek flows under road through a culvert. Many trees down over stream and many willows.	Drive to Gavin Lake Rd and turn right. Drive a few kms to about km 15 board, just before a junction with a deactivated logging road. The monitoring location is on the right hand side of the road (upstream side of the road) just before the second landing.	Look for pink ribbon. Park to the side of the road. Short steep incline to access the monitoring site. Watch your step; there is not much room near the creek. Watch for wildlife. Follow working in/near water procedures.	Upstream of mine. Allows for monitoring of seasonal variability of surface water.
W10 Edney Creek	E 601183 N 5816862	1995	Lower Edney Creek underneath a bridge.	Turn left onto Gavin Lake Rd. Continue on and turn right on Ditch Rd towards Horsefly. Travel to the second bridge crossing. On the right hand side of the road past the bridge (upstream side of the creek), there is a path down to the creek.	Watch for public traffic on the road and ensure vehicle is parked out of the way. Flows may be high during freshet. Ice can build up on edges of creek in winter conditions. Watch for wildlife. Follow working in/near water procedures.	Outside of mine impacted area. Allows the opportunity to monitor for changes in newly constructed creek downstream and to monitor for seasonal variability.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
W12 6K Creek (Tributary to Morehead Creek)	E 588360 N 5825961	1990	Small stream that enters a marsh at the end of an old overgrown road. Small fish present in the stream.	Drive to km 5.5 on Bootjack Rd., to the chain-up pullout. Walk down old road on the NE side of Bootjack for roughly 150 m.	Radio communication must be used on the Bootjack Rd (Channel RR-25). Ensure that vehicle is parked to the side of the road out of the way of traffic. Watch for wildlife. Follow working in/near water procedures.	Upstream of mine. Allows for monitoring of seasonal variability of surface water.
W20 Un-named Tributary to Bootjack Lake	E 592161 N 5821586	2013	Small creek on the NE side of Bootjack Lake, lots of grass, willow, alder and fallen trees. Creek flows roughly parallel to the West Ditch.	Walk in or boat access only. Drive midway on the West Ditch Rd. between the Booster Station and Mine Drainage Creek Sump. Park and walk W to the creek. Follow creek to the lakeshore. Monitoring location is in the creek channel approx. 15 m from the lakeshore. Look for orange ribbon at monitoring location.	If accessing by boat, follow safe boating SOP. If walking, watch for wildlife. Watch for Devil's Club. Walk with caution, as there are lots of blowdown. Ensure vehicles are parked out of the way. Follow working in/near water procedures.	Downstream of mine impacted area. Provides the opportunity to monitor for any seepage from the west ditch.
E1a Tailings Storage Facility	E 594495 N5819187	1997	TSF Supernatant	Drive along the TAR to the TSF. Enter the TSF near corner 5 and follow road to the barge.	Use radio communication when travelling on haul roads and contact Pit Shifter prior to entering haul roads and TSF area (switch from Channel 5 to Channel 1 (Tailings) when entering TSF area). Give right-of-way to heavy equipment. Follow working in/near water procedures. Watch for slippery surfaces in freezing conditions.	Monitoring supernatant WQ in the TSF.
E11 Springer Pit	E 591701 N 5823327	2011	At bottom of the Springer Pit.	Travel down into the bottom of the Springer pit ramp and the monitoring location is near the pipes coming out of the springer pit.	Contact the Pit Shifter prior to entering and leaving the Springer Pit. Use caution when walking under highwalls.	When not storing water from other sources on site: source terms. When storing water from other sources on site: monitoring for potential discharge.
E19	E 595760 N 5819760	2015	Water Treatment Plant Influent	Travel down the TSF haul road towards corner 2 of the TSF. Approx. half way to corner 2 there is a road on the left that goes to the WTP. Monitoring site is located inside facility at the influent pipe at the main entrance to plant.	Use caution when driving on haul roads; contact the Pit Shifter prior to traveling to and from WTP. Watch for haul trucks on haul roads. Give the right-of-way to heavy equipment and used 2-way radio communication.	Provides ability to monitor efficacy of treatment.
HAD-3	E 595772 N 5823583	2015	Water Treatment Plant Effluent	Travel down the TSF haul road towards corner 2 of the TSF. Approx. half way to corner 2 there is a road on the left that goes to the WTP. Monitoring site is located inside facility at the effluent pipe located by the door that leads to the WTP office.	Use caution when driving on haul roads; contact the Pit Shifter prior to traveling to and from WTP. Watch for haul trucks on haul roads. Give the right-of-way to heavy equipment and used 2-way radio communication.	Compliance point for discharge to environment.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
H1 Hazeltine Creek	E 597030 N 5818978	2015	Mid Hazeltine Creek hydrology station approximately 100 m downstream of Gavin Lake Bridge.	Travel to Gavin Lake Rd and turn left. Cross the Gavin lake bridge and park off to the side. Walk approx. 100 m downstream of the bridge to hydrological monitoring station and is marked with staff gage and metal pipes.	Used caution when driving on TSF haul road. Contact the Pit Shifter prior to traveling on haul roads. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch your footing on loose rocks. Watch for wildlife. Use caution in high flow times. Follow working in/near water procedures. May need hip waders.	To monitor hydrology of mid Hazeltine Creek.
H2 Hazeltine Creek	E 601024 N 5817253	2015	Lower Hazeltine Creek hydrology station.	Travel to the Gavin Lake Rd and turn left. Continue on road until you reach the Ditch Rd, and turn right towards Horsefly. Before the Ditch Road bridge, turn left through the gate. The station is approx. 200m from the gate. Hydrology station is marked with staff gage and metal pipes.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Watch for wildlife. Use caution in high flow times. Follow working in/near water procedures. May need hip waders.	To monitor hydrology of lower Hazeltine Creek.
H3 Edney Creek	E 601538 N 5817123	2015	Edney Creek Hydrology station.	Travel to the Gavin lake Rd and turn left. Continue on road until you reach the Ditch Rd, and turn right towards Horsefly. Drive past the Ditch Road bridge and turn left through the gate. Drive approx. 300 m and the hydrology station is marked with staff gage and metal pipes on the right hand side of the road.	Park vehicle to the side of road. Watch footing when walking to hydrology station – some loose rocks. Use caution in high flow times – do not complete task if flow is too strong. Follow working in/near water procedures. Watch for wildlife. May need hip waders.	To monitor hydrology of Edney Creek.
H4 Hazeltine Creek	E 595892 N 5819997	2015	Upper Hazeltine Creek hydrology station at Polley lake weir..	Drive down the TSF haul road to Polley lake weir. Hydrology station is marked by staff gauge approx. 50 m downstream, of the weir.	Use caution when driving on haul roads, radio contact the Pit Shifter prior to entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times. Follow working in/near water procedures. Watch footing on loose rocks down to the creek. May need hip waders.	To monitor hydrology in upper Hazeltine Creek and out of Polley Lake.
HAC-05a Hazeltine Creek	E 596916 N 5819074	2015	Upper Hazeltine Creek just upstream of Gavin Lake bridge.	Travel as described above to H1. Monitoring location is the upstream side of Gavin Lake bridge.	Used caution when driving on TSF haul road. Radio contact the Pit Shifter prior to entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch your footing on loose rocks. Watch for wildlife. Use caution in high flow times and winter conditions. Follow working in/near water procedures.	Monitor WQ downstream of the effluent discharge - when discharging. To monitor WQ post creek reconstruction - when not discharging.
HAC-08 Hazeltine Creek	E 600723 N5817290	2015	Lower Hazeltine Creek just upstream of Ditch road bridge.	Travel as described above to H2, but instead of turning left before the bridge, drive to the bridge and park to the side. Monitoring location is just upstream of the Ditch road Bridge.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Use caution in high flow times. Use caution in freezing conditions as ice can build up – may need swing sampler in these conditions. Follow working in/near water procedures.	This site was established to monitor WQ below the canyon. As Hazeltine Creek remediation continues there are opportunities to monitor the effect of remediation on the creek.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
HAC-10 Hazeltine Creek	E 595793 N 5820738	2015	Upper Hazeltine Creek monitoring site just downstream of Polley Lake weir.	Travel as described above to H4. Sample location is just downstream of Polley lake weir, from a large rock on the west side bank.	Use caution when driving on haul roads, radio contact the Pit Shifter before entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times and winter conditions. Follow working in/near water procedures.	Monitor the surface WQ of Polley Lake as the water flows out of the lake and into Hazeltine Creek. The data from this site provides quick feedback on important parameters for fish habitat in the creek (pH, DO, and temperature).
HAC-12 Hazeltine Creek upper settling pond	E 601577 N 5817292	2015	Lower Hazeltine Creek monitoring site at diffuser pipes in upper settling pond.	Travel as described above to H2, but drive approx. 500 m past it towards Quesnel Lake. Site is marked with two curved pipes sticking out of the ground.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Use caution in high flow times and icy conditions as ice can build up on edges. Follow working in/near water procedures.	This site currently monitors the quality of the mixture of effluent discharge and Hazeltine Creek water prior to the outflow to Quesnel Lake – when discharging. Site will be removed from the sampling program once discharge pipeline is complete.
HAC-01c Hazeltine Creek outflow	E 601661 N 5817598	2015	Hazeltine Creek outflow to Quesnel Lake.	Travel as described to HAC-12, and then drive towards Quesnel Lake. Monitoring Site is located at the outflow of Hazeltine Creek into Quesnel Lake.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Use caution in high flow times and icy conditions as ice can build up on edges. Follow working in/near water procedures.	Monitor WQ at the mouth Hazeltine creek at Quesnel lake once the discharge pipeline is complete. It will replace HAC-12 as the outflow site when it is removed from the sampling program.
HAC-14 Hazeltine Creek	E 598742 N 5817299	2017	Mid Hazeltine Creek monitoring site above the canyon.	Drive as described to H1, but continue down Gavin Lake road to approx. km 5.5 and turn right on the creek access road. Continue on road for approx. 2 km and turn right at the second road on the right hand side. Monitoring site is located at the bottom of the ramp marked by a red and white stripped flagging tape.	Use caution when driving on haul roads, radio contact the Pit Shifter before entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times and winter conditions as ice can build up on edges of creek. May need snowshoes in winter. Follow working in/near water procedures.	Monitor WQ of Hazeltine creek above the canyon.
POF-5 Polley Flats	E 595682 N 5820174	2017	Drainage from Polley Flats into Hazeltine Creek	Drive as described to HAC-10. Just before the weir, turn right and follow road to the end. Site is on the left hand side towards Hazeltine Creek and is marked with an orange stake at the outflow to Hazeltine Creek.	Use caution when driving on haul roads, radio contact the Pit Shifter before entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times and winter conditions. Follow working in/near water procedures.	Monitor WQ of the drainage from the Polley Flats.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
EDC-01 Edney Creek	E 601811 N 5817445	2015	Lower Edney Creek Sample site approx. 20 m upstream of the flood channel.	Follow travel instructions as described above to H3. Follow Edney Creek downstream towards Quesnel Lake and the monitoring location is approx. 20 m upstream from the flood channel.	Park vehicle to the side of road. Watch footing over loose rocks to the creek. Use caution in high flow times and freezing conditions as ice can build up on edges of creek. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ of Edney Creek post reclamation of the lower section and its input to Quesnel Lake.
B1 Bootjack Lake	E 590049 N 5823528	2001/2007	Bootjack lake north WQ monitoring site	Drive on the Bootjack Forest service road to the Bootjack lake campsite at km 8 on the access road.	Follow Safe Boating SOP. Contact Pit Shifter and Front Gate person when leaving mine site. Call kms on Channel RR-25 on the Bootjack FSR. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ for potential mine influence in Bootjack Lake.
B2 Bootjack Lake	E 591263 N 5821647	2001/2007	Bootjack Lake south WQ monitoring site	Drive on the Bootjack Forest service road to the Bootjack lake campsite at km 8 on the access road.	Follow Safe Boating SOP. Contact Pit Shifter and Front Gate person when leaving mine site. Call kms on Channel RR-25 on the Bootjack FSR. Watch for wildlife. Follow working in/near water procedures.	Monitor water WQ for potential mine influence in Bootjack Lake
P1 Polley Lake	E 593708 N 5824693	2001/2007	Polley Lake north WQ monitoring site	Drive down the TSF haul road to Central collection sump near corner 1. Turn left as if going to the central collection sump but then drive approx. 500 m and then turn right onto Polley lake boat launch.	Follow Safe Boating SOP. Contact the Pit Shifter prior to traveling on Haul roads. Use caution on Haul roads, give the right-of-way to heavy equipment and use 2-way radio communication. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ water quality for potential mine influence in Polley Lake
P2 Polley Lake	E 595348 N 5821863	2001/2007	Polley Lake south WQ monitoring site	Drive down the TSF haul road to Central collection sump near corner 1. Turn left as if going to the central collection sump but then drive approx. 500 m and then turn right onto Polley lake boat launch.	Follow Safe Boating SOP. Contact the Pit Shifter prior to traveling on Haul roads. Use caution on Haul roads, give the right-of-way to heavy equipment and use 2-way radio communication. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ for potential mine influence in Polley Lake
QUR-11 Quesnel River	E 596625 N 5830438	2016	Quesnel River WQ monitoring site at Likely Bridge	Drive on the Likely Highway towards the town of Likely, approx. 30 km from the Bootjack Forest service road. Park in the pullout just before the bridge. Collect water from the bridge using the Kemmerer sampler. Monitoring site is indicated by darker brown coloured post in the middle of the bridge.	Wear reflective PPE, watch for traffic. Use caution in the winter as bridge can get slippery.	This site was established to mirror the Federal Provincial Monitoring site for the outlet of Quesnel Lake that is funded by MPMC. Monitor WQ in Quesnel River.
QUL-2a Quesnel Lake	E 607988 N 5817214	2014	Quesnel Lake post-breach and effluent discharge monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ upstream of diffuser ports in Quesnel Lake.
QUL-120a Quesnel Lake	E 618271 N 5818030	2014	Quesnel Lake background WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor Quesnel Lake WQ at background site.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
QUL-18 Quesnel Lake	E 600795 N 5819749	2014	Quesnel Lake post-breach and effluent discharge monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ downstream of diffuser ports in Quesnel Lake
QUL-58 Quesnel Lake	E 601791 N 5818025	2015	Quesnel Lake effluent discharge monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor the initial dilution zone of the effluent plume in Quesnel Lake. Default WQ monitoring site when not discharging.
QUL-ZOO-1 Quesnel Lake	E 601058 N 5819925	2015	Quesnel Lake zooplankton and WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ and zooplankton community and tissue in the West Basin of Quesnel Lake.
QUL-ZOO-7 Quesnel Lake	E 612469 N 5816656	2015	Quesnel Lake zooplankton and WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ and zooplankton community and tissue near Horsefly River in Quesnel Lake.
QUL-ZOO-8 Quesnel Lake	E 630691 N 5821991	2014	Quesnel Lake zooplankton and WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ and zooplankton community and tissue background in Quesnel Lake.
Weather Station #1	E 592792 N 5823182	2012	HOBO weather monitoring station.	Drive along the Wight Pit Haul road and turn left onto the road to the Leach Pad. Park beside the leach pad and walk up the grassy hill between the sulphur pile and the research tree plots. Weather station is located at the top of the hill.	Call the Pit Shifter prior to traveling on Haul roads. Give right-of-way to heavy equipment. Watch for wildlife. Use caution near sulphur pile and watch footing walking up hill. Snowshoes may be required in winter.	Monitor wind speed/gust/direction, rain, solar radiation, and min/mean/max temperature continuously for water balance monitoring on site.
Weather Station #2	E 591092 N 5819976	2012	HOBO weather monitoring station.	Drive along light duty road towards the Orica site. Drive up the Orica site road (approx. 30 m) and park slightly off the road as to not block access. The Weather Station is located on top of a small hill on the right hand side of the road.	Call the Pit Shifter prior to traveling on Haul roads. Give right-of-way to heavy equipment. Watch for wildlife. Watch footing walking up hill.	Monitor wind speed/gust/direction, rain, solar radiation, and min/mean/max temperature continuously for water balance monitoring on site.
Snow Course Site: Weather Stn #1	E 592792 N 5823182	1997	Snow course monitoring site.	Follow instructions as described above for Weather Station #1.	Call the Pit Shifter prior to traveling on Haul roads. Give right-of-way to heavy equipment. Use caution when driving in winter conditions. Watch for wildlife. Use caution near sulphur pile and watch footing walking up hill. Snowshoes may be required.	Monitor snowpack-water equivalent for water balance monitoring on site.
Snow Course Site: JCP	E 593632 N 5823895	2012	Snow course monitoring site.	Drive along Wight Pit haul road towards the Wight Pit. Turn right at the third road on the right hand side. Drive up to stream crossing. May need to walk in snowy conditions approx. 100 m to clearing on the left hand side. Snowpack course site is in that clearing.	Call Pit Shifter prior to traveling on haul roads and give right-of-way to heavy equipment. Used Caution when driving in winter conditions. Watch for wildlife. Snowshoes may be required.	Monitor snowpack-water equivalent for water balance monitoring on site.
Snow Course Site: TSF	E 594092	1997	Snow course monitoring site.	Drive as described above to Weather Station #2, but instead of turning at the Orica site, drive past it	Call Pit Shifter prior to traveling on haul roads and give right-of-way to heavy equipment. Used	Monitor snowpack-water equivalent for water balance monitoring on site.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
	N 5819976			approx. 100 m. Pull over to side of road when a small clearing in the trees is reached on the right hand side. A ditch indicates the site.	Caution when driving in winter conditions. Watch for wildlife. Snowshoes may be required.	
Snow Course Site: PAG	E 590835 N 5823537	2015	Snow course monitoring site.	Drive along haul road towards the PAG dump. Take the small ramp on the left hand side towards the 9k sump. Drive to the NW sump. Site is located up ramp beside the sump.	Call Pit Shifter prior to traveling on haul roads and give right-of-way to heavy equipment. Used Caution when driving in winter conditions. Watch for wildlife. Snowshoes may be required.	Monitor snowpack-water equivalent for water balance monitoring on site.

Declaration of Competency Forms

Ministry of
Environment and
Climate Change Strategy

Declaration of Competency

The Ministry of Environment and Climate Change Strategy relies on the work, advice, recommendations and in some cases decision making of qualified professionals[1], under government's professional reliance regime. With this comes an assumption that professionals who undertake work in relation to ministry legislation, regulations and codes of practice have the knowledge, experience and objectivity necessary to fulfill this role.

This declaration of competency is collected for the purposes of increasing government transparency and ensuring professional ethics and accountability. It will be disclosed to the public.

1. Name of Qualified Professional BARBARA WERNICK

   Title SENIOR ENVIRONMENTAL SCIENTIST

2. Are you a registered member of a professional association in B.C.? ☑ Yes ☐ No

   Name of Association: COLLEGE OF APPLIED BIOLOGY (# 1171)

3. Brief description of professional services:

   DEVELOPMENT OF APPROACH TO SELECTION OF REFERENCE LAKES, SUMMARIES OF AMPHIBIAN & TERRESTRIAL STUDY COMPONENTS

Declaration

I declare that I am a qualified professional with the required knowledge, skills and experience to provide expert information, advice and/or recommendations in relation to the specific work described above.

Tracking Number: 375053
Authorization Number: 11678

REGISTERED MAIL

MOUNT POLLEY MINING CORPORATION
SUITE 200
580 HORNBY ST
VANCOUVER, BC
V6C 3B6

Dear Permittee:

Enclosed is Amended Permit 11678 issued under the provisions of the *Environmental Management Act*. Your attention is respectfully directed to the terms and conditions outlined in the permit. An annual fee will be determined according to the Permit Fees Regulation.

This permit does not authorize entry upon, crossing over, or use for any purpose of private or Crown lands or works, unless and except as authorized by the owner of such lands or works. The responsibility for obtaining such authority rests with the permittee. This permit is issued pursuant to the provisions of the *Environmental Management Act* to ensure compliance with Section 120(3) of that statute, which makes it an offence to discharge waste, from a prescribed industry or activity, without proper authorization. It is also the responsibility of the permittee to ensure that all activities conducted under this authorization are carried out with regard to the rights of third parties and comply with other applicable legislation that may be in force.

In the event that a reportable spill occurs, or there is an imminent risk of one occurring, the responsible person must ensure that it is reported in accordance with the Spill Reporting Regulation. Additional information on spill reporting requirements is available at gov.bc.ca/reportaspill

This decision may be appealed to the Environmental Appeal Board in accordance with Part 8 of the *Environmental Management Act*. An appeal must be delivered within 30 days from the date that notice of this decision is given. For further information, please contact the Environmental Appeal Board at (250) 387-3464.

Administration of this permit will be carried out by staff from the Environmental Protection Division's Regional Operations Branch. Plans, data and reports pertinent to the permit are to be submitted by email or electronic transfer to the Director, designated Officer, or as further instructed.

Ministry of Environment and Climate Change Strategy

STRATEGY**

PERMIT

11678

Under the Provisions of the Environmental Management Act

MOUNT POLLEY MINING CORPORATION

**SUITE 200
580 HORNBY ST
VANCOUVER, BC
V6C 3B6**

is authorized to discharge effluent to land and surface water from a copper-gold mine and mill complex located near Likely, British Columbia, subject to the requirements listed below.

Contravention of any of these requirements is a violation of the *Environmental Management Act* and may lead to prosecution.

This Authorization supersedes and replaces all previous versions of Permit 11678 issued under Section 14 of the Environmental Management Act.

1. AUTHORIZED DISCHARGES

1.1 Discharges to Tailings Storage Facility

This section applies to the discharge of effluent from a Copper-Gold Mine and Ore Concentrator to the tailings storage facility. The site reference number for this discharge is E225309.

1.1.1 The monthly average rate of discharge of tailings slurry is 55,500 cubic metres per day.

1.1.2 The authorized discharge period is continuous.

1.1.3 The characteristics of the discharge must be typical of concentrator tailings from the milling of ore or metal contaminated soil, mill site runoff, rock disposal site runoff, open pit water, and septic tank effluent from a copper-gold mine and mill complex.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

1.1.4 The authorized Works are the following; a septic tank, tailings discharge line, open pits, tailings storage facility, water treatment and discharge system, seepage collection and recycle system, surface water collection works, tailings supernatant recycle systems; sediment pond(s) and related appurtenances approximately located as shown on the attached Site Plan A.

1.1.5 The location of the facilities from which the discharge originates is within Mineral Leases No. 345731, No. 410495, No. 524068, No. 573346, No. 933970, and No. 933989 as well as Mineral Claims No. CB16 204475, No. PM5 206540, No. POL2 411010, No. 514039, and No. 514044, Cariboo Mining Division, Cariboo Land District.

1.1.6 The location of the point of discharge (tailings storage facility) is on Mineral Claim No. 514039, Cariboo Mining Division, Cariboo Land District.

1.2 Mine Site Runoff and Seepage

This section applies to the discharge of treated effluent from the site runoff and seepage water collection and management systems to Quesnel Lake as sampled at the Treatment Plant Outlet (HAD-03). The site reference for this discharge is E304230.

1.2.1 The authorized annual average rate of discharge is 29,000 m^3/day.

1.2.2 The maximum rate of discharge is 52,000 m^3/day.

1.2.3 The discharge period is authorized until December 31, 2022.

1.2.4 The characteristics of the discharge at the treatment plant outlet must be equivalent to or less than the values specified below in column 2 of Table 1 below.

1.2.5 The Annual Discharge Plan required under section 2.6 must show how the concentrations of the parameters meet the objectives for the "Edge of Quesnel Lake Initial Dilution Zone (IDZ)" in Quesnel Lake as specified below in Table 1 below.

Date issued: May 30, 1997
Date amended: February 1, 2020

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

Table 1

Parameter	**Treatment Plant Outlet** (1)	**Edge of Quesnel Lake IDZ** (1)(2)(3)
Rainbow Trout 96hrLC50	50 % Mortality in 100% effluent	-
Daphnia Magna 48hrLC50	50 % Mortality in 100% effluent	-
pH	< 9.5 and >6.0 pH units	-
Total Suspended Solids	30 mg/L, and 15 mg/L Monthly Average	-
Total Sulfate	1,100 mg/L	218 mg/L
Total Ammonia (as N)	1.3 mg/L	0.18 mg/l as N
Total Nitrate (as N)	34.0 mg/L	3.0 mg/l as N
Total Nitrite (as N)	0.78 mg/L	0.02 mg/L as N
Total Phosphorus	90.0 µg/L	10.0 µg/L
Fluoride	17.0 mg/L	1.0 mg/L
Total Arsenic	28 µg/L	5.0 µg/L
Total Chromium	4 µg/L	1 µg/L
Total Copper	33 µg/L	2.2 µg/L (30-day rolling average)
Total Iron	1.0 mg/L	1.0 mg/L
Dissolved Iron	0.35 mg/L	0.35 mg/L
Total Manganese	3.4 mg/L	0.84 mg/L
Total Molybdenum	0.36 mg/L	0.05 mg/L
Total Silver	0.24 µg/L	0.05 µg/L
Total Selenium	75 µg/L	2 µg/L
Total Zinc	59 µg/L	7.5 µg/L
Dissolved Aluminum	0.75 mg/L	0.05 mg/L

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

Dissolved Cadmium	0.34 µg/L	0.13 µg/L

(1) All values are maximum values from grab samples unless otherwise specified.

(2) Only applies while discharging directly to Quesnel Lake.

(3) The "Edge of Quesnel Lake IDZ" is a point located 100m from the Quesnel Lake outfall, represented by site QUL-58 mid and/or near bottom samples, or alternative location approved by the Director.

1.2.6 The Permittee must implement the response steps set out in the approved trigger response plan under section 2.6 (5) without delay if either:

(a) The effluent monitoring at the outlet of the treatment plant indicates that trigger levels set out in the approved trigger response plan are reached for any parameter set out in Table 1 above; or,

(b) An objective set for the Edge of Quesnel Lake IDZ in Table 1 above is exceeded, or is predicted to be exceeded, as determined in accordance with procedures in the approved trigger response plan.

Where the Permittee must cease discharging, the discharge may resume only in accordance with the approved trigger response plan. The requirement to implement the trigger response plan does not authorize an exceedance of the maximum values specified in section 1.2.4 for the characteristics of the discharge at the outlet of the treatment plant.

1.2.7 The discharge is authorized from the Authorized Works, which are the settling pond(s), tailings storage facility, mine contact water collection system, the Veolia Actiflo treatment system, flow control valve(s), continuous flow meter, pipeline and outfall system and associated appurtenances as generally shown in the attached Site Plans.

1.2.8 The location of the facilities from which the discharge originates is the same as in section 1.1.5 above.

1.2.9 The location of the discharge is the Quesnel Lake outfall at a point within Mineral Claim No. 501479 when discharging to Quesnel Lake.

1.3. Springer Pit Discharge to Ground

This section applies to the discharge of seepage water from Springer Pit to Ground. The site reference for this discharge is E307887.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

1.3.1. The Permittee must maintain Springer Pit water levels at less than 1025 meters above sea level (masl) to limit seepage towards Bootjack Lake.

1.3.2. The characteristics of the discharge are typical site runoff and seepage water.

1.3.3. The authorized works are Springer Pit, and its associated water management works and related appurtenances.

1.3.4. The location of the facilities from which the discharge originates and the point of discharge are as shown in the attached Site Plan A.

2. GENERAL REQUIREMENTS

2.1. Maintenance of Works and Emergency Procedures

2.1.1. The authorized works must be inspected regularly and maintained in good working order. In the event of an emergency or condition beyond the control of the Permittee which prevents effective operation of the authorized works or leads to an unauthorized discharge, the Permittee must take appropriate remedial action and notify the Director immediately. The Director may require the Permittee to reduce or suspend operations to protect the environment until the authorized works have been restored, and/or corrective steps taken to prevent unauthorized discharges.

2.1.2. All ponds, ditching, and other runoff or seepage collection and diversion works must be inspected at least twice per year, once in the spring after freshet and once in the fall before freeze-up. Records of these inspections must be maintained and made available for inspection by an Officer immediately upon request.

2.1.3. The authorized works must be complete and in operation while discharging.

2.2. Bypasses

Any bypass of the authorized works is prohibited unless prior approval of the Director is obtained and confirmed in writing.

2.3. Process Modifications

The Director must be notified prior to implementing changes to any process that may adversely affect the quality and/or quantity of the authorized discharges. Despite notification under this section, permitted levels must not be exceeded.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

2.4. Surface Runoff and Mine Drainage Control

2.4.1. Unless required for operational purposes, surface runoff from undisturbed areas and groundwater pumped from up gradient of pits or other undisturbed areas, must be diverted so that it does not flow to the tailings impoundment, or to the mine and mill areas.

2.4.2. Seepage and runoff from the open pits, rock disposal sites, and from down gradient of the tailings storage facility must be collected and conveyed to treatment works, the tailings storage facility, mill or open pits.

2.4.3. Inactive open pits may be used for storage of mine water, tailings storage facility supernatant or mill site runoff, provided records of volumes transferred to any pit are maintained and reported quarterly.

2.4.4. Recycling of on-site water and evaporation enhancing techniques must be practiced.

2.4.5. Surface water control works must be provided for all areas disturbed by roads, open pits, rock disposal/storage sites, the mill site and ore storage sites. The surface water control works must convey all flows up to a 1 in 10 year 24-hour storm event and must withstand all flows up to a 1 in 200 year 24-hour storm event, without significant damage.

2.4.6. The tailings storage facility must provide adequate storage, beach width and freeboard as required by Mines Act Permit M-200. All other effluent storage ponds, seepage ponds, and surface runoff ponds must provide at least 0.5 meters of freeboard.

2.4.7 Freeboard is defined as the difference in elevation between the contained liquid level and the top of the berm structure at its lowest point. The lowest point does not include a spillway where a discharge is authorized or where the supernatant over flows to a downstream collection pond that is part of the authorized works.

2.4.8. The Permittee must maintain and implement an Erosion and Sediment Control Plan developed by a qualified professional that will prevent sedimentation of watercourses during construction and operation of any mine structures or facilities. The Director may specify and require implementation of additional measures to prevent sedimentation of watercourses caused by construction or operational activity at the site.

2.5. Environmental Emergency Response Plan

2.5.1. The Permittee must maintain and implement an up to date Environmental Emergency Response Plan by January 31st of each year. The Environmental Emergency Response Plan must include all of the following:

(a) adequate procedures for responding to all probable environmental emergencies, including spills,

(b) permit exceedances associated with the Mount Polley Mine operations and mine site area,

(c) procedures for the suspension of the effluent discharge to Quesnel Lake.

(d) A notification protocol for immediate advising the Soda Creek Indian Band, the Williams Lake Indian Band, the Cariboo Regional District, and the community of Likely of significant emergency events, and permit exceedances at the mine site.

2.5.2. The Permittee must ensure mine personnel are trained on the contents of the Emergency Response Plan and is reviewed annually.

2.6. Annual Discharge Plan

2.6.1. The Permittee must maintain and implement an Annual Discharge Plan approved by the Director for the discharge authorised in section 1.2 above. The plan must include the following:

(a) An outline of the expected volume, timing, and duration of effluent released to Quesnel Lake;

(b) Consideration and account of hydrology and snowpack information, mine water balance information, Polley Lake discharge control, and background water quality information;

(c) Demonstrate how the objectives, set out in column 3 of Table 1 above, will be met at the Edge of Quesnel Lake IDZ in Quesnel Lake;

(d) A maximum turbidity target(s), as measured at the outlet of the treatment plant, which requires immediate reporting to the Director should the turbidity target(s) be exceeded for longer than one hour in duration;

(e) A trigger response plan for treatment system shutdown(s), and/or for suspension or reduction of discharge, and for the resumption of the discharge, if the effluent discharge limits at the outlet of the

treatment plant cannot be met, or if an objective for the Edge of Quesnel Lake IDZ in Quesnel Lake cannot be met;

(f) Identification of the sources of mine water and the percent of each source in the total effluent discharge for each day;

(g) Demonstrate how the discharge will be managed to minimize suspended solids deposition into Quesnel Lake; and,

(h) Identification of equipment, including calibration and maintenance schedules related to continuous measurements of flow, turbidity, specific conductance and temperature.

2.6.2 The Annual Discharge Plan must be reviewed at least once each year, and any necessary updates to the plan must be submitted to the Director for approval at least 30 days prior to adoption.

2.7. Nitrogen Management Plan

The Permittee must maintain and implement a Nitrogen Management Plan developed by a Qualified Professional. The plan must describe measures that prevent the loss of nitrogen species into the environment arising from the use of explosives and handling of waste rock. Any update to the plan must be provided to the Director within 30 days of implementation.

2.8. Water Treatment and Discharge Program

The Permittee must undertake a program to develop passive and semi-passive water treatment options necessary for distributed discharges across the mine site without the use of the Quesnel Lake outfall and to reduce the contaminant levels during and after mine operation. The water treatment and discharge program must include all mine site water treatment works and source control optimization activities which includes the following:

2.8.1. Best Achievable Technology (BAT) Assessment

(a) The Permittee must undertake a BAT assessment when developing treatment technologies for consideration in the water treatment and discharge program.

(b) The Permittee must undertake a BAT assessment when developing bench and pilot scale testing of potential alternative treatment technologies to inform the 2022 Water Management Plan required by Section 2.10.

(c) The Permittee must submit to the Director for approval by January 31st of each year a study plan that details bench and pilot scale testing and other BAT assessment planned for the year. The BAT assessments must be implemented without delay.

2.8.2. Water Treatment Plant Optimization

The Permittee must operate the Veolia Actiflo Water Treatment Plant (WTP) to remove contaminants present in the mine site contact water to meet the discharge requirements of Section 1.2.4.

(a) "Numeric Performance Metric" (NPM) means a measurable value that quantifies the outcome or result of water treatment and the ability of the treatment to remove specified chemical constituent. It forms the basis for a numeric comparison of untreated water, to water that has been treated by the treatment system.

(b) The Permittee must optimize and operate the treatment plant in a manner to target achievement of any prescribed NPM. The stated NPM target value represents operation that achieves average effluent quality that is at or below any specified NPM. Assessment of the attainment of NPM values must be included in the optimization update progress report. If the effluent quality does not achieve an NPM value specified by the Director, the Permittee must identify the reason and propose and implement without delay response actions to achieve the target value including treatment plant optimization and/or source control and/or water management improvements.

The following NPM is established:

Total copper 12 ug/L

(c) Based on the progress reports and any other relevant information available, the Director may amend or specify additional NPM that are suitable for evaluating the effectiveness of removal of parameters of potential concern by the WTP.

2.8.3. Source Control Optimization

The Permittee must undertake ongoing maintenance and surveillance of on-site water management systems and activities undertaken to increase source control of any potential contaminants of concern.

(a) The Permittee must undertake source control optimization yearly.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

(b) The Permittee must undertake an analysis of the treatment plant effluent to determine selenium species present and at a minimum determine the typical proportion of total selenium that is selenate, selenite, and organoselenium. Based on these results the Director may require additional analysis for selenium speciation of mine source waters.

2.8.4. Review of Discharge Alternatives

The Permittee must review discharge alternatives for direct discharge of treated mine water on and around the mine site including consideration of physical (geomorphological and hydrological), chemical, and biological characteristics of potential receiving environments. The Permittee must ensure the proposed discharge locations have the capacity to receive the additional discharges of treated water and meet applicable environmental benchmarks.

2.9. Water Management Progress Reporting

The Permittee must report on all aspects of Section 2.8 every 6 months, beginning June 30, 2020 and continuing until such time as the Director deems the reporting no longer required. The reporting is to include, but is not limited to, the results of all BAT assessments, bench and pilot testing of treatment systems, optimization studies, discussion of proposed discharge locations that have the capacity to receive the treated water and changes from the previous progress reports and any other studies related to the Water Treatment and Discharge Program outlined in section 2.8. The reporting out must include documentation that the testing and piloting programs are relevant for all the different types of mine influenced water on site and for the 2022 Water Management Plan needs.

2.10. The 2022 Water Management Plan

The Permittee must submit a revised water management plan (the "2022 Water Management Plan") and an implementation schedule to the Director for approval prior to December 1st, 2020, outlining the water management and treatment options informed by the requirements in Section 2.8 and the most recent Reclamation and Closure Plan for the site. The 2022 Water Management Plan must address water discharge plans from December 31, 2022 onward.

The 2022 Water Management Plan must meet all of the following requirements:

(a) Provide for the full treatment and/or management of 1 in 10 wet year flows, including the associated freshet flows for all mine influenced water sources on site that do not meet Water Quality Guidelines, once the works are fully complete, without requiring the use of the Quesnel Lake outfall.

(b) Include all the essential information necessary for review and support of the final design, assessing its expected performance and the impacts of the discharge(s) on the receiving environment.

(c) A review of discharge alternatives including assessment of physical (geomorphological and hydrological), chemical and biological assessment of potential receiving environments for direct discharge of treated water on and around the mine site. The Permittee must ensure the proposed discharge locations have the capacity to receive the additional discharges of treated water.

(d) Detailed bench scale, and pilot scale results for all the proposed works. Performance assurances from vendors for active treatment systems may also be considered in lieu of pilot scale tests.

(e) Discussion and documentation of the ability and/or design criteria necessary, for the works to treat all contaminants known to be above all relevant BC Water Quality Criteria at the edge of the IDZ to levels below appropriate water quality guidelines where possible.

(f) Discussion of how all the bench and pilot system findings, and/or other performance assurances have been incorporated into the final design of the individual components and/or the system as a whole to assure discharge standards and/or B.C. Water Quality Criteria at the edge of any IDZ is met.

(g) A siting map and implementation plan for commissioning of all works necessary for full scale operations. Siting must also allow for potential future mining operations or ongoing mining operations to take place.

(h) An updated and refined water balance and water quality model acceptable to the Director, with appropriate sensitivity analyses for both onsite and receiving waters, which predicts the impacts to the receiving environment. The water quality model must use updated site monitoring data to demonstrate how well the model is calibrated to observed site conditions.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

(i) The plan must be prepared by a Qualified Professional.

(j) The Permittee must implement the approved 2022 Water Management Plan according to the approved implementation schedule.

(k) Any updates to the 2022 Water Management Plan or the implementation schedule must be approved by the Director prior to their implementation.

2.11. Communication Plan

The Permittee must maintain and implement the Communication Plan dated March 20, 2016. The Communication Plan must demonstrate the sharing of environmental data with the Soda Creek Indian Band, the Williams Lake Indian Band, the Cariboo Regional District, and the Community of Likely. Any changes to the communication plan must be discussed with the Public Liaison Committee and submitted to the Director prior to adoption.

2.12. Public Liaison Committee

2.12.1. The Permittee must maintain a Public Liaison Committee (PLC), in accordance with the approved Terms of Reference dated November 21, 2018. The Permittee must submit any Terms of Reference updates to the Director for approval 30 days prior to adopting them.

2.12.2. The Committee must meet at least quarterly to share and receive information about mine activities and the results of monitoring programs with interested members of the public, the Soda Creek Indian Band, the Williams Lake Indian Band, and regulating agencies.

2.13. Posting of Security

The Permittee must maintain a Reclamation Security as required by *Mines Act* Permit M-200.

2.14. Metal Contaminated Soil Milling

Tailings from the processing of metal contaminated soils in the mill from off mine site sources may be discharged to the tailings storage facility subject to all the following:

(a) The soils must be contaminated only with metals.
(b) The Permittee must notify the Director 14 days prior to receiving these materials at the mine site and provide results of chemical analysis of the material at the time of notification.
(c) Records of the volumes processed must be maintained and reported as part

of the annual reporting requirements.

2.15. Qualified Professionals

All documents submitted to the Director must be signed by the author and where specifically required by this permit, authored and signed by a Qualified Professional.

A “Qualified Professional" means an applied scientist or technologist specializing in an applied science or technology applicable to the duty or function, including, if applicable and without limiting this, agrology, biology, chemistry, engineering, geology or hydrogeology and who:

(a) is registered with the appropriate professional organization, is acting under that organization's code of ethics and is subject to disciplinary action by that organization; and,

(b) through suitable education, experience, accreditation and/or knowledge, may be reasonably relied on to provide advice within their area of expertise.

3. MONITORING REQUIREMENTS

3.1. Springer-Cariboo Pit Hydrogeology Work Plan and Assessment

3.1.1. The Permittee must submit a summary, when requested by and to the satisfaction of the Director, all hydrogeological work that has been completed downgradient of the Springer Pit and Cariboo Pit relevant to the Springer Pit filling and drawdown. The summary must describe all monitoring, modelling, and drilling investigations, and must provide recommendations by a Qualified Professional for additional hydrogeological investigations required to manage water in the pits during any future refilling and for mine closure. Recommendations must consider ongoing collection of water quality and geology data as the mine advances, review of the groundwater monitoring network, and hydrogeological model refinements, as appropriate.

3.1.2. Based on the review of the summary, the Director may require additional hydrogeological investigation and assessment of the hydrogeology along the seepage path from the Springer-Cariboo Pit to Bootjack Lake. Any additional monitoring recommended in the summary of hydrogeological work or required by the Director must be incorporated into updates of the Comprehensive Environmental Monitoring Plan.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

3.1.3. The recommendations of the summary of hydrogeological work required above, and all ongoing hydrogeological data collected must be re-assessed as part of the annual reporting requirements under section 4.2 of this permit. This includes an annual update to the characterization of the groundwater system in the area between the pit and the lake, refinements and updates to the seepage model near the pit and reporting on the groundwater monitoring network near the pit.

3.1.4. In addition, updated results and interpretations of the Springer-Cariboo Pit Hydrogeology Assessment, including an updated calibration and verification of the seepage model near the pit, must be prepared by a Qualified Professional and must be submitted to the Director prior to any planned refilling of Springer Pit above 1025 masl.

3.2. Comprehensive Environmental Monitoring Plan

3.2.1. The Permittee must continue to develop, submit and implement an ongoing Comprehensive Environmental Monitoring Plan (CEMP) to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas.

3.2.2. An updated CEMP must be submitted to the Director for approval by March 31, 2020 and every three years thereafter.

3.2.3. The Permittee must undertake monitoring in accordance with the approved CEMP immediately following its approval.

3.2.4 The CEMP must meet all the following requirements:

(a) Consolidate and integrate all of the monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.

(b) At a minimum address a three year time span.

(c) At a minimum include all sampling sites, frequency of sampling, variables to be analysed, method detection limits, sampling methods, sample analysis methods, and data analysis methods.

(d) The updated CEMP must be approved by the Director.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

3.2.5. The Permittee must provide all data and information collected under the CEMP to the Director, in electronic format, on a quarterly basis.

3.2.6. The Permittee must submit a three-year detailed monitoring program interpretive report to the Director by March 31, 2022, and every three years thereafter.

3.2.7. During the period of treated effluent discharge authorized by section 1.2 above, the Director may require expedited sampling, testing and reporting of treated effluent discharged during the spring freshet (March through July annually).

3.2.8. The Director may require revisions to the CEMP based on review of monitoring data and/or any other relevant information.

3.3. Effluent Toxicity Testing

Acute and chronic toxicity testing of discharges to Quesnel Lake authorized under section 1.2 of this permit must be conducted as follows:

Acute Bioassay	**Frequency**	**Source for Sample Collection**
96-hr LC50 Rainbow Trout	Monthly	HAD-03 - Effluent discharged to Quesnel Lake (E304230)
48-hr LC50 Daphnia magna	Monthly	HAD-03 - Effluent discharged to Quesnel Lake (E304230)
Chronic Bioassay	**Frequency**	**Source for Sample Collection**
7-day Ceriodaphnia dubia survival and reproduction, and 7-day ELS toxicity test with a salmonid fish and or other tests specified by the Director	Quarterly or as required by the approved CEMP	as specified in the approved CEMP when discharging direct to Quesnel Lake

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

3.4. Water Flow Measurement

3.4.1. The Permittee must provide and maintain suitable flow measuring devices and record staff gauge measurements, during open water, at surface water stations at W1B (Morehead Creek), W4A (North Dump Creek), W5 (Bootjack Creek) W12 (6K Creek), H1 (continuous, Upper Hazeltine Creek), H3 (Edney Creek), H4 (Polley Lake outlet) and H2 (continuous, Lower Hazeltine Creek), located approximately as shown on the attached Site Plan B, or at alternative monitoring stations satisfactory to the Director.

3.4.2. Springer Pit water level elevation shall be monitored and recorded on a monthly basis.

3.4.3. Staff gauge readings must be taken at the same time as stream flow measurements and/or water quality sampling are collected at the same or associated sites.

3.4.4. A stage discharge curve must be developed for all staff gauges.

3.4.5. All staff gauges and flow measuring devices must be checked and calibrated once per year, after June 15th but prior to August 31st of each calendar year.

3.5. Outfall and Pipeline Commissioning and Inspection

3.5.1. The Permittee must develop and implement a monthly visual inspection program for the pipeline from the Actiflo treatment plant to the outfall in Quesnel Lake. The monthly visual inspection program must include all of the following:

(a) The pipeline corridor must be visually inspected every month.

(b) Records of the monthly visual inspections must be made available for inspection by an Officer immediately upon request.

3.5.2. The Permittee must conduct a comprehensive annual inspection of the pipe line corridor by October 1st of each year.

3.5.3. The Permittee must conduct an underwater inspection of the diffusers every 5 years to ensure they remain in good working order.

3.5.4. An annual inspection report with recommended remedial actions must be prepared by a Qualified Professional and submitted to the Director within 60 days of completion of the comprehensive inspection.

3.5.5. The pipeline and outfall must have all the following signage:

(a) A sign must be maintained along the alignment of the outfall facing Quesnel Lake above the high water mark.

(b) Signs must identify the nature of works.

(c) Signs must be posted along the effluent pipeline right-of-way at points of public access to identify the right-of-way.

(d) All signs must include emergency contact information.

3.6. Climate Monitoring

The Permittee must maintain meteorological stations and measure continuous daily precipitation; daily maximum, minimum and mean temperature; and daily evaporation calculation or suitable alternative as approved by the Director. Climate Monitoring sites are as shown in Site Plan C.

3.7. Sampling and Analytical Procedures

3.7.1. The Permittee must carry out sampling in accordance with the procedures described in the "British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples, 2013 Edition (Permittee)" or most recent edition, or by alternative procedures as authorized by the Director.

3.7.2. The Permittee must carry out analyses in accordance with procedures described in the "British Columbia Laboratory Manual (2015 Permittee Edition)", or the most recent edition or by alternative procedures as authorized by the Director.

Copies of the above manuals are available on the Ministry web page at https://www2.gov.bc.ca/gov/content/environment/research-monitoring-reporting/monitoring/laboratory-standards-quality-assurance/bc-field-sampling-manual.

3.7.3. Bioassays must be conducted using the following methods:

(a) the "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Rainbow Trout", Report EPS 1/RM/13 December 2000;

(b) the "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Daphnia magna", Reference Method EPS 1/RM/14 December 2000;

(c) the "Biological Test Method: Toxicity Tests Using Early Life Stages of Salmonid Fish (Rainbow Trout)", Report EPS 1/RM28, July 1998 - Embryo/Alevin;

(d) the "Biological Test Method: Test of Reproduction and Survival Using the Cladoceran Ceriodaphnia dubia", Report EPS l/RM/21, February 2007; or,

(e) by suitable alternative procedures as authorized by the Director.

3.8. Quality Assurance

3.8.1. The Permittee must maintain and implement a "Quality Assurance Manual" consistent with "British Columbia Field Sampling Manual for Continuous Monitoring plus the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples 2013 Edition (Permittee)", or most recent edition. The Permittee must ensure that all data submitted as a requirement of this permit is produced in accordance with the Quality Assurance Manual, that data is handled and reviewed in accordance with protocols established in the Manual and is accompanied by quality assurance data required by the Manual. The Permittee must provide the Director with any updates to this Manual within 30 days of adoption.

3.8.2. Analysis of samples for parameters designated under the Environmental Data Quality Assurance Regulation must be at a laboratory registered for the designated parameter under the Regulation. In addition, the Permittee must participate in quality assurance audits as required by the Regulation.

4. REPORTING

4.1. Routine Reporting

4.1.1. In each month that discharge occurs as authorized by section 1.2 above, the Permittee must submit a monthly report, suitably tabulated and formatted, to the Director summarizing:

(a) the volume of treated effluent discharged,

(b) a summary of continuous Turbidity readings of the treated effluent discharged, and

(c) the most recently available water quality results for the effluent discharged, including toxicity.

4.1.2. Each monthly report must be submitted within seven days of the end of previous month via email to EnvAuthorizationsReporting@gov.bc.ca. Each monthly report must also contain and present all data submitted in the previous 2 monthly reports in a manner that would identify potential trends.

4.1.3. Each monthly report must also be provided to the Williams Lake Indian Band and Xatsull First Nation and be made available to the Public Liaison Committee within 7 calendar days of the submission to the Ministry.

4.1.4. The Permittee must cause each data submission required by this Authorization to include a statement outlining the number of exceedances of permitted discharges that occurred during the reporting period, the dates of each such exceedance, an explanation as to the cause of the exceedances, and a description of the measures taken by the Permittee to rectify the cause of each such exceedance. If no exceedances occurred over the reporting period, the required statement may instead indicate that no exceedance of permitted discharges occurred during the reporting period.

4.1.5. The Permittee must submit all data required to be submitted under this section by email to the Ministry's Routine Environmental Reporting Submission Mailbox (RERSM) at envauthorizationsreporting@gov.bc.ca or as otherwise instructed by the Director. For guidelines on how to properly name the files and email subject lines or for more information visit the Ministry website: https://www2.gov.bc.ca/gov/content/environment/waste-management/waste-discharge-authorization/data-and-report-submissions/routine-environmental-reporting-submission-mailbox.

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

4.1.6. The Director may require modification to the monitoring program based on the evaluation of the monthly and annual reports and on any other information that pertains to the operations and or discharges.

4.1.7. The Permittee must upload monitoring data associated with this permit to the Ministry's Environmental Monitoring System (EMS) database, within 45 days of the end of the three month period in which the data is collected.

4.2. Annual Report

4.2.1. The Permittee must also submit by March 31st of each year, a comprehensive annual report of all monitoring via email to the above email address, in a format suitable for public release. The annual report must include:

(a) all monitoring sample results required under the permit,

(b) an evaluation of quality assurance, including collection, sampling, and data handling protocols,

(c) an evaluation of the treatment plant operation and control,

(d) an evaluation of the impacts of the mining operation on the receiving environment from the previous year,

(e) a summary of any non-compliance with the permit and other incidents that may have led to impacts to the receiving environment,

(f) updates of the water balance, and a calibration assessment of the water balance and water quality models,

(g) assessment of the outfall dispersion and dispersion modelling for the Quesnel Lake discharge,

(h) an update to any modeling relating to the Springer Pit groundwater seepage and its impacts on Bootjack Lake as described in section 3.1,

(i) a progress update with respect to the 2022 Water Management Plan,

(j) a review and update of the assessment of acid rock drainage (ARD) potential and water quality impacts from mine waste management,

(k) a comparison of monitoring data with water quality guidelines, predictions and targets,

(l) an update on the progress of reclamation and any updates to the reclamation plan that impact on site water quality,

(m) an evaluation of the effectiveness of the Surface Runoff and Mine Drainage Control programs,

(n) a summary of the Public Liaison Committee meetings, including any issues and concerns presented,

(o) an evaluation of the Outfall and Pipeline Inspection program; and,

(p) trend analysis (graphs) of water monitoring data at each site for the past 5 years.

4.2.2. Monitoring data and the analysis of that data, as it will be presented in the annual report, must be reviewed by a third party Qualified Professional.

4.2.3. A groundwater monitoring program review, including but not limited to sampling, well locations, site water balance, interpretation of data trends and possible environmental impacts, and suitable recommendations, must be completed for the entire mine site at least every three years, with the next review required by March 31, 2022.

4.2.4. A copy of the annual report must be provided to the Williams Lake Indian Band and Xatsull First Nation within 30 days of the report being submitted to the Director.

4.3. Non-compliance Reporting

4.3.1. The Permittee must immediately notify the Director or designate of any noncompliance with the requirements of this Permit and take appropriate remedial action. Written confirmation of all non-compliance events, including available test results is required within 24 hours of the original notification unless otherwise directed by the Director.

4.3.2. Both the initial notice and the confirmation must also be emailed to EnvironmentalCompliance@gov.bc.ca.

4.3.3. Within 30 days of any non-compliant event, the Permittee must submit a follow-up report to the Director and the above mailbox that includes, but is not necessarily limited to the following:

(a) all relevant test results related to the non-compliance instance(s),

(b) an explanation of the most probable cause(s) of the noncompliance(s); and,

(c) remedial actions taken and planned to prevent similar noncompliance(s).

Date issued: May 30, 1997
Date amended: February 1, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*
Mining Operations

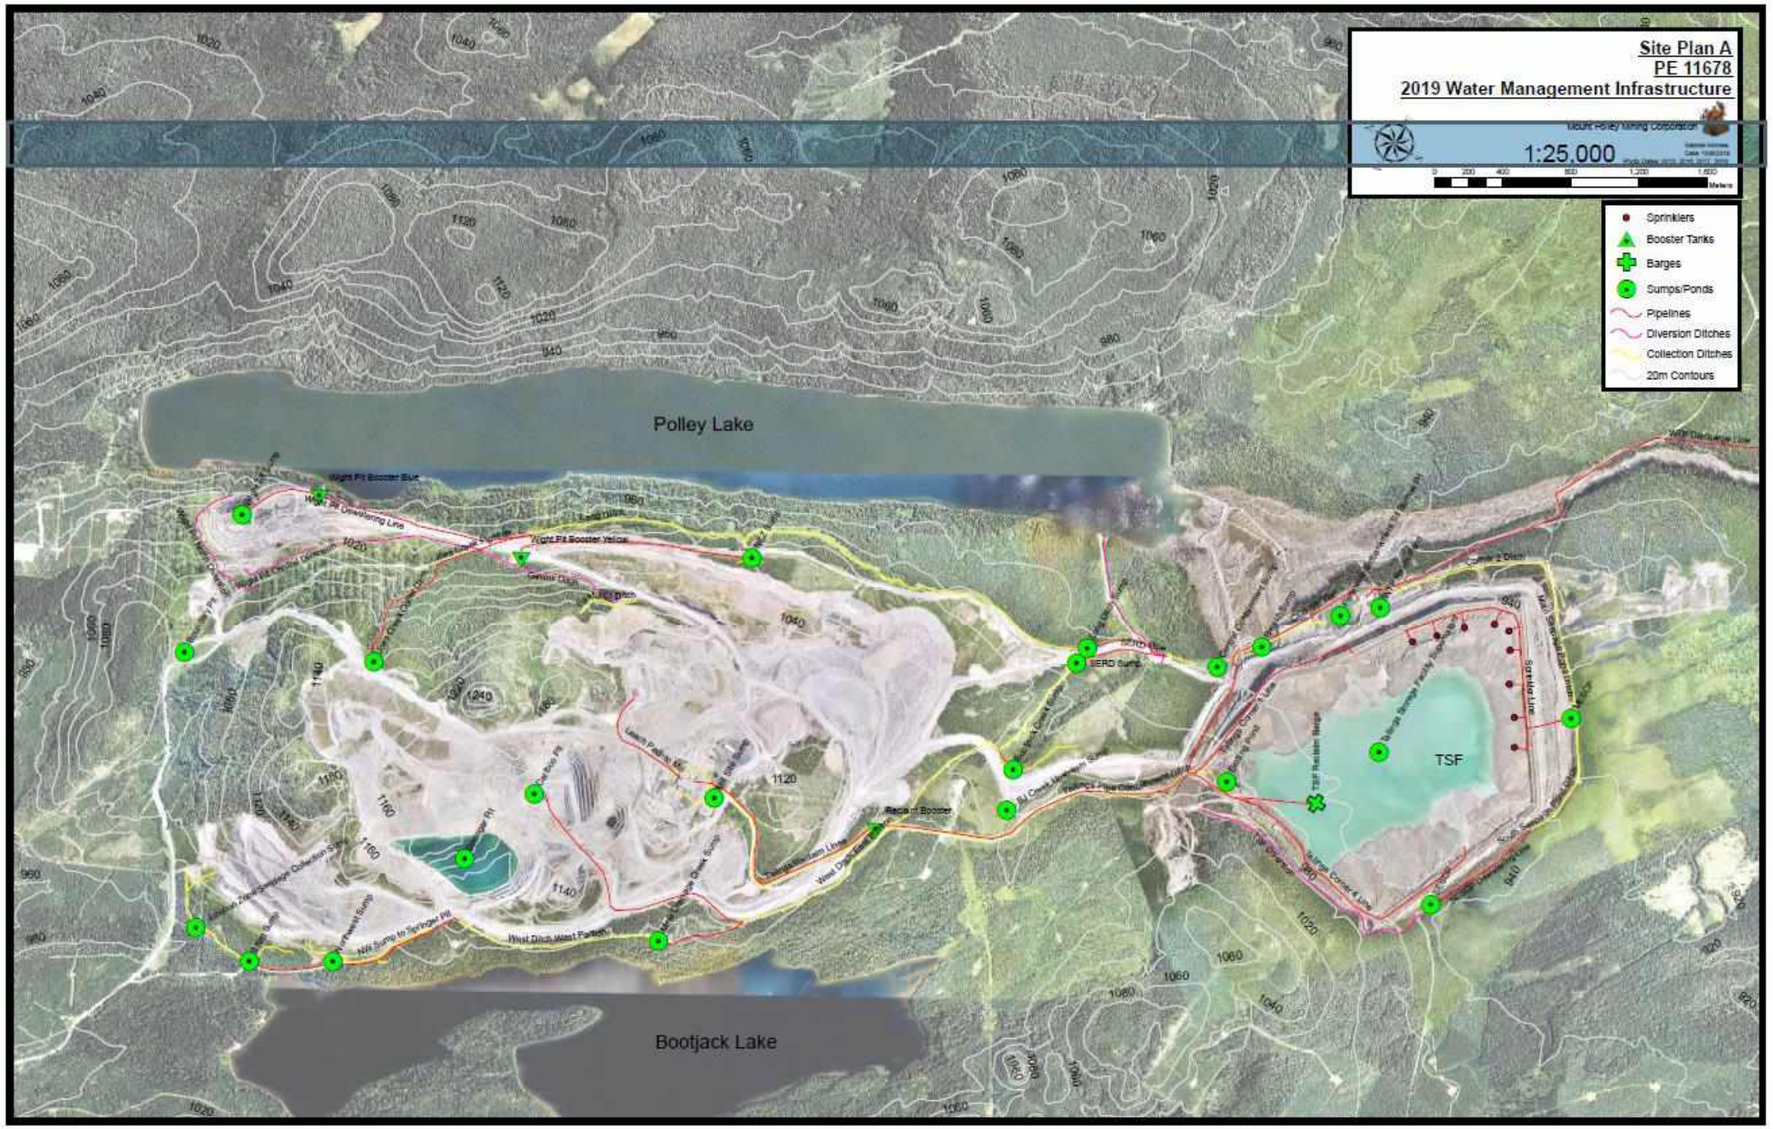
4.4 **Reporting of Toxicity Failure**

4.4.1. The Permittee must immediately notify the Director of any toxicity failure according to the Non-Compliance Reporting requirements in Section 4.3. For the purpose of this section, a sample is considered to have failed the specific toxicity test if:

(a) 96-hr LC50 Rainbow Trout: Using 100% effluent concentration, more than 50% of the fish die within a 96 hour test period,

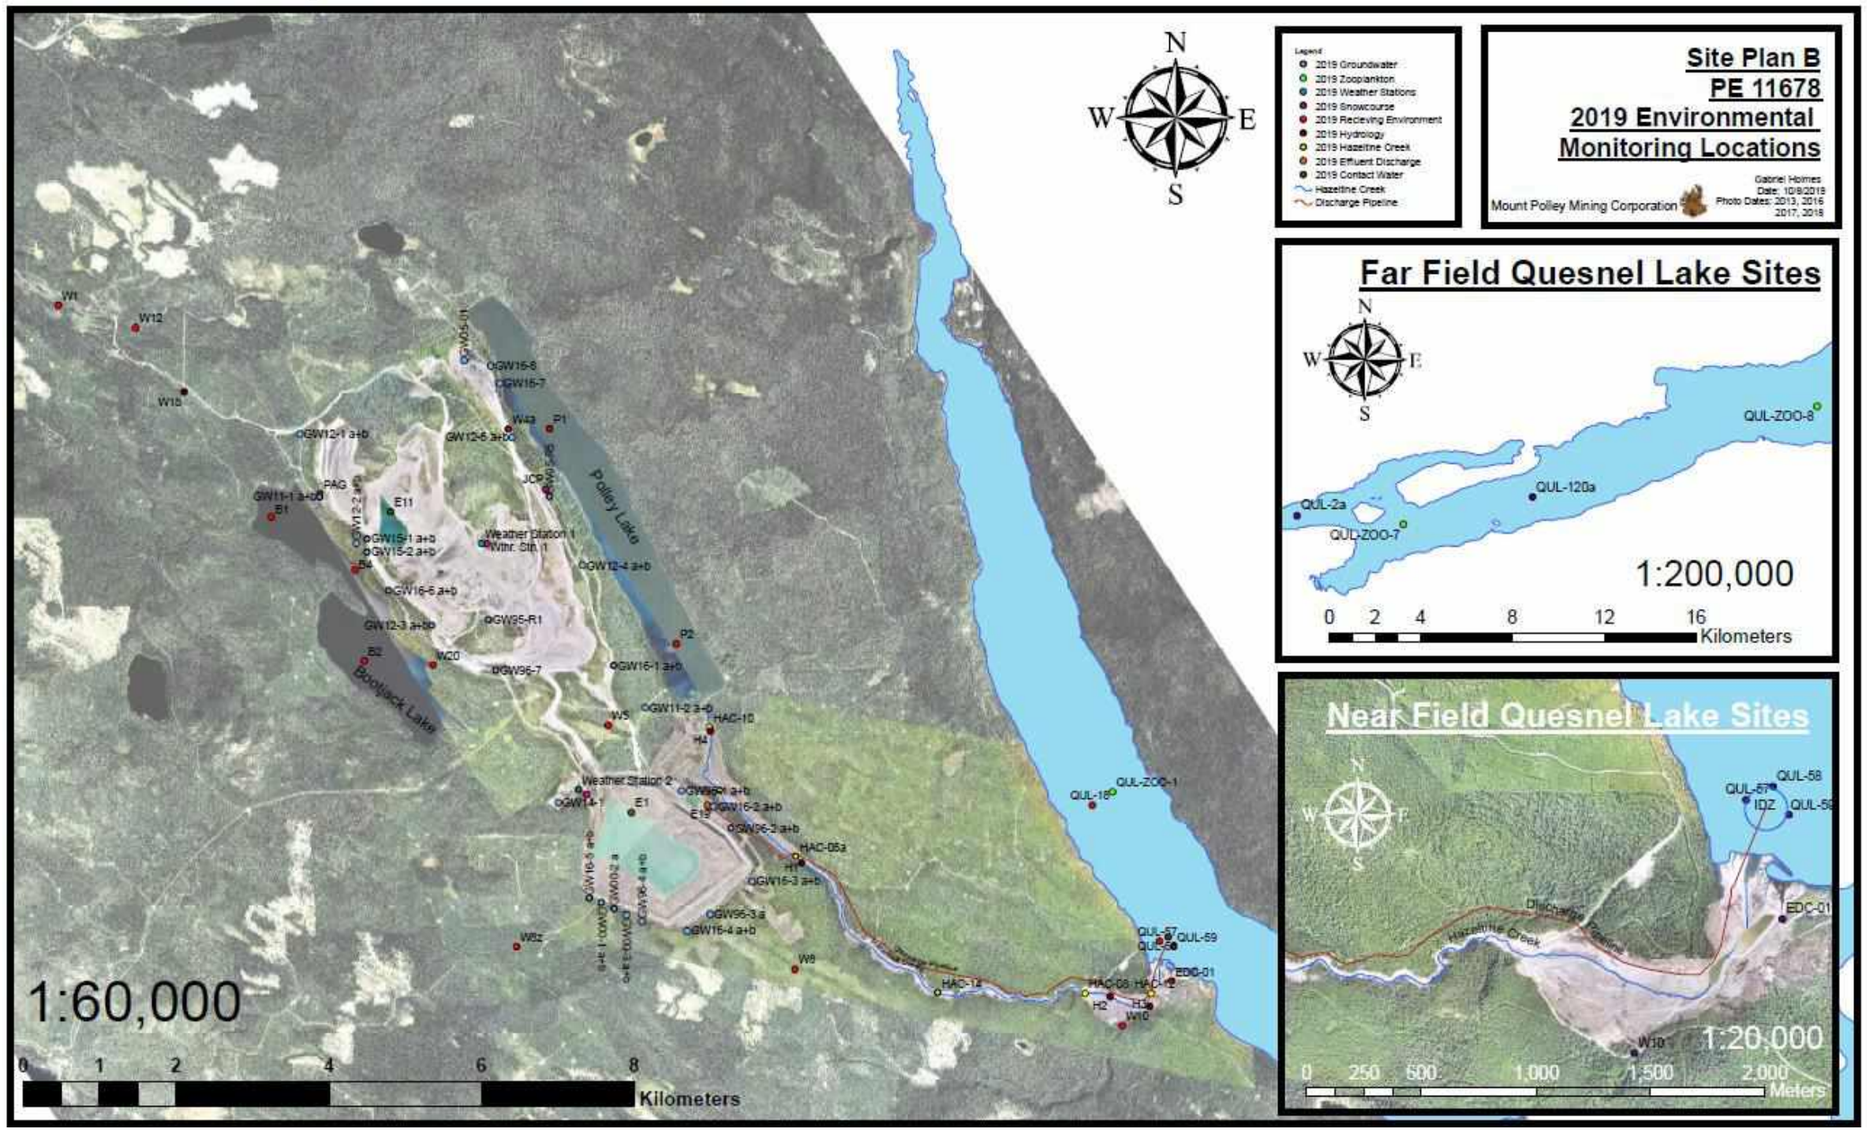
(b) 48-hr LC50 Daphnia magna: Using 100% effluent concentration, more than 50% of the organisms die within a 48 hour test period,

(c) 7-day Ceriodaphnia dubia reproduction: The water is determined to cause greater than 25% inhibition of survival and reproduction; or,



(d) 7-day ELS toxicity test with a salmonid fish: The water is determined to cause greater than 25% non-viable embryos.

4.4.2. The Permittee must investigate each toxicity failure to determine the cause(s). Reasonable efforts must be made to obtain preliminary and in progress results from the analytical laboratory during the toxicity testing. The Permittee must make immediate arrangements to retest in the event of potential and confirmed failures. The Director may require additional toxicity testing based on the evaluation of results from toxicity testing and the causes of failure.



4.5. **Other Documents**

All documents to be submitted to the Director must be sent as a separate document and named according to the name listed in this permit.

Decision No. EAB-EMA-20-A003(a)

ENVIRONMENTAL APPEAL BOARD
IN THE MATTER OF THE *ENVIRONMENTAL MANAGEMENT ACT*
S.B.C. 2003, C. 53

BETWEEN:

MOUNT POLLEY MINING CORPORATION

APPELLANT

AND:

FEBRUARY 1, 2020 DECISION OF THE DIRECTOR, *ENVIRONMENTAL MANAGEMENT ACT* TO AMEND PERMIT 11678

RESPONDENT

CONSENT ORDER

ON THE APPLICATION of the parties, without a hearing and by consent:

THE BOARD ORDERS under section 16 of the *Administrative Tribunals Act*, S.B.C. 2004, c. 45 that:

1. Pursuant to section 103(c) of the *Environmental Management Act*, S.B.C. 2003, c. 53 (the "**Act**"), Mount Polley Mining Corporation ("**MPMC**")'s Permit 11678 ("**Permit**") is amended as follows:

a. The opening paragraph of Clause 2.8. is amended to read as follows:

2.8. Water Treatment and Discharge Program

The Permittee must undertake a program to investigate and develop passive and semi-passive water treatment options for distributed discharges across the mine site in accordance with the Long Term Water Management Plan dated October 17, 2016. The water treatment and discharge program must include all mine site water treatment works and source control optimization activities which includes the following:

b. Clause 2.8.1(a) is amended to read as follows:

2.8.1. Best Achievable Technology (BAT) Assessment

(a) The Permittee must undertake a BAT assessment of any treatment technologies identified in the water treatment and discharge program that the Permittee submits to the Director for consideration as part of an updated water management plan required by section 2.10.

c. Clause 2.8.1(b) is deleted in its entirety.

d. Clause 2.8.1(c) is renumbered "(b)" and amended to read as follows:

(b) The Permittee must submit to the Director for approval by January 31st of each year a study plan that details bench and pilot scale testing that will be undertaken.

e. The opening paragraph of Clause 2.8.2 is amended to read as follows:

2.8.2. Water Treatment Plant Optimization

The Permittee must operate and optimize the performance of the Veolia Actiflo Water Treatment Plant (WTP) to remove contaminants present in the mine site contact water to meet the discharge requirements of Section 1.2.4.

f. Clause 2.8.2(c) is deleted in its entirety.

g. Clause 2.9. is amended to read as follows:

2.9. Water Management Progress Reporting

The Permittee must report to the Director on all aspects of Section 2.8 every 6 months, beginning June 30, 2020 and continuing until such time as the Director deems the reporting no longer required. The reporting is to include, but is not limited to, the results of all BAT assessments, bench and pilot testing of treatment systems, optimization studies, discussion of proposed discharge locations that have the capacity to receive the treated water and changes from the previous progress reports and any other studies related to the Water Treatment and Discharge Program outlined in section 2.8. The reporting must include documentation that the testing and piloting programs are relevant for all the different types of mine influenced water on site and for the approved Water Management Plan needs.

h. Clause 2.10. is amended to read as follows:

2.10. Water Management Planning

The Permittee must submit a revised water management plan including an implementation schedule to the Director for approval prior to December 1st, 2020, outlining the water management and treatment options informed by the requirements in Section 2.8, the Long Term Water Management Plan dated October 17, 2016, and the most recent Reclamation and Closure Plan for the site. The revised Water Management Plan must address the development and implementation of water discharge plans from December 31, 2022 onward.

The revised Water Management Plan must meet the following requirements:

(a) Provide for development and implementation of treatment and management meeting BAT requirements of up to 1 in 10 wet year flows, including the associated freshet

flows, for all mine influenced water sources on site that do not meet Water Quality Guidelines once the works are fully complete.

(b) Include plans for restoring water courses, including the flow patterns, to sustain themselves without maintenance and achieve the original pre-mining productivity to the extent possible.

(c) Include all the essential information necessary for review and support of the final design, assessing its expected performance and the impacts of the discharge(s) on the receiving environment of any works that the Permittee submits to the Director for consideration.

(d) Review discharge alternatives including assessment of physical (geomorphological and hydrological), chemical and biological assessment of potential receiving environments for direct discharge of treated water on and around the mine site as required in Section 2.8.4. of this Authorization.

(e) Provide detailed bench scale, and pilot scale results for any works that the Permittee submits to the Director for consideration. Performance assurances from vendors for active treatment systems may also be considered in lieu of pilot scale tests.

(f) Discuss and document the ability and/or design criteria necessary, for any works submitted to the Director for consideration to treat all contaminants known to be above all relevant BC Water Quality Criteria at the edge of the IDZ to levels below appropriate water quality guidelines where possible.

(g) In any proposal submitted to the Director for consideration, discuss how all the bench and pilot system findings, and/or other performance assurances have been incorporated into the final design of the individual components and/or the system as a whole to assure discharge standards and/or B.C. Water Quality Criteria at the edge of any IDZ is met.

(h) Include a siting map and implementation plan for commissioning of all works necessary for full scale operations of works proposed. Siting must also allow for potential future mining operations or ongoing mining operations to take place.

(i) Include a process for updating and refining the water balance and water quality model acceptable to the Director, with appropriate sensitivity analyses for both onsite and receiving waters, which predicts the impacts to the receiving environment. The water quality model must use updated site monitoring data to demonstrate how well the model is calibrated to observed site conditions and must be updated from time to time to account for planned future mining operations and for ongoing mining operations.

(j) Include a process for ongoing review and updating of the revised Water Management Plan and the implementation schedule after it is approved.

(k) The revised Water Management Plan must be prepared by a Qualified Professional. The Permittee must implement the approved revised Water Management Plan according to the approved implementation schedule. Any updates to the revised Water Management Plan or the implementation schedule must be approved by the Director prior to their implementation.

i. Clause 4.2., sub-clause 4.2.1. (i) is amended to read as follows:

4.2. <u>Annual Report</u>

4.2.1. The Permittee must also submit by March 31st of each year, a comprehensive annual report of all monitoring via email to the above email address, in a format suitable for public release. The annual report must include:

(i) a progress update with respect to the Water Management Plan,

2. This order may be signed by the parties in counterpart.

THE FOLLOWING PARTIES APPROVE THE FORM OF THIS ORDER AND CONSENT TO EACH OF THE ORDERS NOTED ABOVE ON THIS 18th DAY OF SEPTEMBER 2020:

Dear Permittee:

Enclosed is Amended Permit 11678 issued under the provisions of the *Environmental Management Act*. Your attention is respectfully directed to the terms and conditions outlined in the permit. An annual fee will be determined according to the Permit Fees Regulation.

This permit does not authorize entry upon, crossing over, or use for any purpose of private or Crown lands or works, unless and except as authorized by the owner of such lands or works. The responsibility for obtaining such authority rests with the permittee. This permit is issued pursuant to the provisions of the *Environmental Management Act* to ensure compliance with Section 120(3) of that statute, which makes it an offence to discharge waste, from a prescribed industry or activity, without proper authorization. It is also the responsibility of the permittee to ensure that all activities conducted under this authorization are carried out with regard to the rights of third parties and comply with other applicable legislation that may be in force.

In the event that a reportable spill occurs, or there is an imminent risk of one occurring, the responsible person must ensure that it is reported in accordance with the Spill Reporting Regulation. Additional information on spill reporting requirements is available at gov.bc.ca/reportaspill

This decision may be appealed to the Environmental Appeal Board in accordance with Part 8 of the *Environmental Management Act*. An appeal must be delivered within 30 days from the date that notice of this decision is given. For further information, please contact the Environmental Appeal Board at (250) 387-3464.

Administration of this permit will be carried out by staff from the Environmental Protection Division's Regional Operations Branch. Plans, data and reports pertinent to the permit are to be submitted by email or electronic transfer to the Director, designated Officer, or as further instructed.

Ministry of Environment and Climate Change Strategy
Environmental Protection Division
Suite 400 – 640 Borland Street
Williams Lake BC V2G 4T1
Mining Operations
Telephone: (250) 398-4530
Facsimile: (250) 398-4214

For more information about how the Ministry will assesses compliance with your permit please refer to gov.bc.ca/environmentalcompliance.

For more information about how to make changes to your permit and to access waste discharge amendment forms and guidance, please refer to gov.bc.ca/wastedischarge-authorizations.

Yours truly,

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

**MINISTRY OF ENVIRONMENT
AND CLIMATE CHANGE
STRATEGY**

PERMIT

11678

Under the Provisions of the Environmental Management Act

MOUNT POLLEY MINING CORPORATION

**SUITE 200
580 HORNBY ST
VANCOUVER, BC
V6C 3B6**

is authorized to discharge effluent to land and surface water from a copper-gold mine and mill complex located near Likely, British Columbia, subject to the requirements listed below.

Contravention of any of these requirements is a violation of the *Environmental Management Act* and may lead to prosecution.

This Authorization supersedes and replaces all previous versions of Permit 11678 issued under Section 14 of the Environmental Management Act.

1. AUTHORIZED DISCHARGES

1.1 Discharges to Tailings Storage Facility

This section applies to the discharge of effluent from a Copper-Gold Mine and Ore Concentrator to the tailings storage facility. The site reference number for this discharge is E225309.

1.1.1 The monthly average rate of discharge of tailings slurry is 55,500 cubic metres per day.

1.1.2 The authorized discharge period is continuous.

1.1.3 The characteristics of the discharge must be typical of concentrator tailings from the milling of ore or metal contaminated soil, mill site runoff, rock disposal site runoff, open pit water, and septic tank effluent from a copper-gold mine and mill complex.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

1.1.4 The authorized Works are the following; a septic tank, tailings discharge line, open pits, tailings storage facility, water treatment and discharge system, seepage collection and recycle system, surface water collection works, tailings supernatant recycle systems; sediment pond(s) and related appurtenances approximately located as shown on the attached Site Plan A.

1.1.5 The location of the facilities from which the discharge originates is within Mineral Leases No. 345731, No. 410495, No. 524068, No. 573346, No. 933970, and No. 933989 as well as Mineral Claims No. CB16 204475, No. PM5 206540, No. POL2 411010, No. 514039, and No. 514044, Cariboo Mining Division, Cariboo Land District.

1.1.6 The location of the point of discharge (tailings storage facility) is on Mineral Claim No. 514039, Cariboo Mining Division, Cariboo Land District.

1.2 Mine Site Runoff and Seepage

This section applies to the discharge of treated effluent from the site runoff and seepage water collection and management systems to Quesnel Lake as sampled at the Treatment Plant Outlet (HAD-03). The site reference for this discharge is E304230.

1.2.1 The authorized annual average rate of discharge is 29,000 m^3/day.

1.2.2 The maximum rate of discharge is 52,000 m^3/day.

1.2.3 The discharge period is authorized until December 31, 2022.

1.2.4 The characteristics of the discharge at the treatment plant outlet must be equivalent to or less than the values specified below in column 2 of Table 1 below.

1.2.5 The Annual Discharge Plan required under section 2.6 must show how the concentrations of the parameters meet the objectives for the "Edge of Quesnel Lake Initial Dilution Zone (IDZ)" in Quesnel Lake as specified below in Table 1 below.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

Table 1

Parameter	**Treatment Plant Outlet** (1)	**Edge of Quesnel Lake IDZ** (1)(2)(3)
Rainbow Trout 96hrLC50	50 % Mortality in 100% effluent	-
Daphnia Magna 48hrLC50	50 % Mortality in 100% effluent	-
pH	< 9.5 and >6.0 pH units	-
Total Suspended Solids	30 mg/L, and 15 mg/L Monthly Average	-
Total Sulfate	1,100 mg/L	218 mg/L
Total Ammonia (as N)	1.3 mg/L	0.18 mg/l as N
Total Nitrate (as N)	34.0 mg/L	3.0 mg/l as N
Total Nitrite (as N)	0.78 mg/L	0.02 mg/L as N
Total Phosphorus	90.0 µg/L	10.0 µg/L
Fluoride	17.0 mg/L	1.0 mg/L
Total Arsenic	28 µg/L	5.0 µg/L
Total Chromium	4 µg/L	1 µg/L
Total Copper	33 µg/L	2.2 µg/L (30-day rolling average)
Total Iron	1.0 mg/L	1.0 mg/L
Dissolved Iron	0.35 mg/L	0.35 mg/L
Total Manganese	3.4 mg/L	0.84 mg/L
Total Molybdenum	0.36 mg/L	0.05 mg/L
Total Silver	0.24 µg/L	0.05 µg/L
Total Selenium	75 µg/L	2 µg/L
Total Zinc	59 µg/L	7.5 µg/L
Dissolved Aluminum	0.75 mg/L	0.05 mg/L

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

Dissolved Cadmium	0.34 µg/L	0.13 µg/L

(1) All values are maximum values from grab samples unless otherwise specified.

(2) Only applies while discharging directly to Quesnel Lake.

(3) The "Edge of Quesnel Lake IDZ" is a point located 100m from the Quesnel Lake outfall, represented by site QUL-58 mid and/or near bottom samples, or alternative location approved by the Director.

1.2.6 The Permittee must implement the response steps set out in the approved trigger response plan under section 2.6 (5) without delay if either:

(a) The effluent monitoring at the outlet of the treatment plant indicates that trigger levels set out in the approved trigger response plan are reached for any parameter set out in Table 1 above; or,

(b) An objective set for the Edge of Quesnel Lake IDZ in Table 1 above is exceeded, or is predicted to be exceeded, as determined in accordance with procedures in the approved trigger response plan.

Where the Permittee must cease discharging, the discharge may resume only in accordance with the approved trigger response plan. The requirement to implement the trigger response plan does not authorize an exceedance of the maximum values specified in section 1.2.4 for the characteristics of the discharge at the outlet of the treatment plant.

1.2.7 The discharge is authorized from the Authorized Works, which are the settling pond(s), tailings storage facility, mine contact water collection system, the Veolia Actiflo treatment system, flow control valve(s), continuous flow meter, pipeline and outfall system and associated appurtenances as generally shown in the attached Site Plans.

1.2.8 The location of the facilities from which the discharge originates is the same as in section 1.1.5 above.

1.2.9 The location of the discharge is the Quesnel Lake outfall at a point within Mineral Claim No. 501479 when discharging to Quesnel Lake.

1.3. Springer Pit Discharge to Ground

This section applies to the discharge of seepage water from Springer Pit to Ground. The site reference for this discharge is E307887.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

1.3.1. The Permittee must maintain Springer Pit water levels at less than 1025 meters above sea level (masl) to limit seepage towards Bootjack Lake.

1.3.2. The characteristics of the discharge are typical site runoff and seepage water.

1.3.3. The authorized works are Springer Pit, and its associated water management works and related appurtenances.

1.3.4. The location of the facilities from which the discharge originates and the point of discharge are as shown in the attached Site Plan A.

2. GENERAL REQUIREMENTS

2.1. Maintenance of Works and Emergency Procedures

2.1.1. The authorized works must be inspected regularly and maintained in good working order. In the event of an emergency or condition beyond the control of the Permittee which prevents effective operation of the authorized works or leads to an unauthorized discharge, the Permittee must take appropriate remedial action and notify the Director immediately. The Director may require the Permittee to reduce or suspend operations to protect the environment until the authorized works have been restored, and/or corrective steps taken to prevent unauthorized discharges.

2.1.2. All ponds, ditching, and other runoff or seepage collection and diversion works must be inspected at least twice per year, once in the spring after freshet and once in the fall before freeze-up. Records of these inspections must be maintained and made available for inspection by an Officer immediately upon request.

2.1.3. The authorized works must be complete and in operation while discharging.

2.2. Bypasses

Any bypass of the authorized works is prohibited unless prior approval of the Director is obtained and confirmed in writing.

2.3. Process Modifications

The Director must be notified prior to implementing changes to any process that may adversely affect the quality and/or quantity of the authorized discharges. Despite notification under this section, permitted levels must not be exceeded.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

2.4. Surface Runoff and Mine Drainage Control

2.4.1. Unless required for operational purposes, surface runoff from undisturbed areas and groundwater pumped from up gradient of pits or other undisturbed areas, must be diverted so that it does not flow to the tailings impoundment, or to the mine and mill areas.

2.4.2. Seepage and runoff from the open pits, rock disposal sites, and from down gradient of the tailings storage facility must be collected and conveyed to treatment works, the tailings storage facility, mill or open pits.

2.4.3. Inactive open pits may be used for storage of mine water, tailings storage facility supernatant or mill site runoff, provided records of volumes transferred to any pit are maintained and reported quarterly.

2.4.4. Recycling of on-site water and evaporation enhancing techniques must be practiced.

2.4.5. Surface water control works must be provided for all areas disturbed by roads, open pits, rock disposal/storage sites, the mill site and ore storage sites. The surface water control works must convey all flows up to a 1 in 10 year 24-hour storm event and must withstand all flows up to a 1 in 200 year 24-hour storm event, without significant damage.

2.4.6. The tailings storage facility must provide adequate storage, beach width and freeboard as required by Mines Act Permit M-200. All other effluent storage ponds, seepage ponds, and surface runoff ponds must provide at least 0.5 meters of freeboard.

2.4.7 Freeboard is defined as the difference in elevation between the contained liquid level and the top of the berm structure at its lowest point. The lowest point does not include a spillway where a discharge is authorized or where the supernatant over flows to a downstream collection pond that is part of the authorized works.

2.4.8. The Permittee must maintain and implement an Erosion and Sediment Control Plan developed by a qualified professional that will prevent sedimentation of watercourses during construction and operation of any mine structures or facilities. The Director may specify and require implementation of additional measures to prevent sedimentation of watercourses caused by construction or operational activity at the site.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

2.5. Environmental Emergency Response Plan

2.5.1. The Permittee must maintain and implement an up to date Environmental Emergency Response Plan by January 31st of each year. The Environmental Emergency Response Plan must include all of the following:

(a) adequate procedures for responding to all probable environmental emergencies, including spills,

(b) permit exceedances associated with the Mount Polley Mine operations and mine site area,

(c) procedures for the suspension of the effluent discharge to Quesnel Lake.

(d) A notification protocol for immediate advising the Xatsull First Nation, the Williams Lake First Nation, the Cariboo Regional District, and the community of Likely of significant emergency events, and permit exceedances at the mine site.

2.5.2. The Permittee must ensure mine personnel are trained on the contents of the Emergency Response Plan and is reviewed annually.

2.6. Annual Discharge Plan

2.6.1. The Permittee must maintain and implement an Annual Discharge Plan approved by the Director for the discharge authorised in section 1.2 above. The plan must include the following:

(a) An outline of the expected volume, timing, and duration of effluent released to Quesnel Lake;

(b) Consideration and account of hydrology and snowpack information, mine water balance information, Polley Lake discharge control, and background water quality information;

(c) Demonstrate how the objectives, set out in column 3 of Table 1 above, will be met at the Edge of Quesnel Lake IDZ in Quesnel Lake;

(d) A maximum turbidity target(s), as measured at the outlet of the treatment plant, which requires immediate reporting to the Director should the turbidity target(s) be exceeded for longer than one hour in duration;

(e) A trigger response plan for treatment system shutdown(s), and/or for suspension or reduction of discharge, and for the resumption of the discharge, if the effluent discharge limits at the outlet of the

treatment plant cannot be met, or if an objective for the Edge of Quesnel Lake IDZ in Quesnel Lake cannot be met;

(f) Identification of the sources of mine water and the percent of each source in the total effluent discharge for each day;

(g) Demonstrate how the discharge will be managed to minimize suspended solids deposition into Quesnel Lake; and,

(h) Identification of equipment, including calibration and maintenance schedules related to continuous measurements of flow, turbidity, specific conductance and temperature.

2.6.2 The Annual Discharge Plan must be reviewed at least once each year, and any necessary updates to the plan must be submitted to the Director for approval at least 30 days prior to adoption.

2.7. Nitrogen Management Plan

The Permittee must maintain and implement a Nitrogen Management Plan developed by a Qualified Professional. The plan must describe measures that prevent the loss of nitrogen species into the environment arising from the use of explosives and handling of waste rock. Any update to the plan must be provided to the Director within 30 days of implementation.

2.8. Water Treatment and Discharge Program

The Permittee must undertake a program to investigate and develop passive and semi-passive water treatment options for distributed discharges across the mine site in accordance with the Long Term Water Management Plan dated October 17, 2016. The water treatment and discharge program must include all mine site water treatment works and source control optimization activities which includes the following:

2.8.1. Best Achievable Technology (BAT) Assessment

(a) The Permittee must undertake a BAT assessment of any treatment technologies identified in the water treatment and discharge program that the Permittee submits to the Director for consideration as part of an updated water management plan required by Section 2.10.

(b) The Permittee must submit to the Director for approval by January 31st of each year a study plan that details bench and pilot scale testing that will be undertaken.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

2.8.2. Water Treatment Plant Optimization

The Permittee must operate and optimize the performance of the Veolia Actiflo Water Treatment Plant (WTP) to remove contaminants present in the mine site contact water to meet the discharge requirements of Section 1.2.4.

(a) "Numeric Performance Metric" (NPM) means a measurable value that quantifies the outcome or result of water treatment and the ability of the treatment to remove specified chemical constituent. It forms the basis for a numeric comparison of untreated water, to water that has been treated by the treatment system.

(b) The Permittee must optimize and operate the treatment plant in a manner to target achievement of any prescribed NPM. The stated NPM target value represents operation that achieves average effluent quality that is at or below any specified NPM. Assessment of the attainment of NPM values must be included in the optimization update progress report. If the effluent quality does not achieve an NPM value specified by the Director, the Permittee must identify the reason and propose and implement without delay response actions to achieve the target value including treatment plant optimization and/or source control and/or water management improvements.

The following NPM is established:

Total copper 12 ug/L

2.8.3. Source Control Optimization

The Permittee must undertake ongoing maintenance and surveillance of on-site water management systems and activities undertaken to increase source control of any potential contaminants of concern.

(a) The Permittee must undertake source control optimization yearly.

(b) The Permittee must undertake an analysis of the treatment plant effluent to determine selenium species present and at a minimum determine the typical proportion of total selenium that is selenate, selenite, and organoselenium. Based on these results the Director may require additional analysis for selenium speciation of mine source waters.

2.8.4. Review of Discharge Alternatives

The Permittee must review discharge alternatives for direct discharge of treated mine water on and around the mine site including consideration of

physical (geomorphological and hydrological), chemical, and biological characteristics of potential receiving environments. The Permittee must ensure the proposed discharge locations have the capacity to receive the additional discharges of treated water and meet applicable environmental benchmarks.

2.9. Water Management Progress Reporting

The Permittee must report to the Director on all aspects of Section 2.8 every 6 months, beginning June 30, 2020 and continuing until such time as the Director deems the reporting no longer required. The reporting is to include, but is not limited to, the results of all BAT assessments, bench and pilot testing of treatment systems, optimization studies, discussion of proposed discharge locations that have the capacity to receive the treated water and changes from the previous progress reports and any other studies related to the Water Treatment and Discharge Program outlined in Section 2.8. The reporting out must include documentation that the testing and piloting programs are relevant for all the different types of mine influenced water on site and for the approved Water Management Plan needs.

2.10. Water Management Planning

The Permittee must submit a revised water management plan including an implementation schedule to the Director for approval prior to December 1st, 2020, outlining the water management and treatment options informed by the requirements in Section 2.8, the Long Term Water Management Plan dated October 17, 2016 and the most recent Reclamation and Closure Plan for the site. The revised Water Management Plan must address the development and implementation of water discharge plans from December 31, 2022 onward.

The revised Water Management Plan must meet the following requirements:

(a) Provide for development and implementation of treatment and management meeting BAT requirements of up to 1 in 10 wet year flows, including the associated freshet flows for all mine influenced water sources on site that do not meet Water Quality Guidelines, once the works are fully complete.

(b) Include plans for restoring water courses, including the flow patterns, to sustain themselves without maintenance and achieve the original pre-mining productivity to the extent possible.

(c) Include all the essential information necessary for review and support of the final design, assessing its expected performance and the impacts of the

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

discharge(s) on the receiving environment of any works that the Permittee submits to the Director for consideration.

(d) Review discharge alternatives including assessment of physical (geomorphological and hydrological), chemical and biological assessment of potential receiving environments for direct discharge of treated water on and around the mine site as required in Section 2.8.4 of this Authorization.

(e) Provide detailed bench scale, and pilot scale results for any works that the Permittee submits to the Director for consideration. Performance assurances from vendors for active treatment systems may also be considered in lieu of pilot scale tests.

(f) Discuss and document the ability and/or design criteria necessary, for any works submitted to the Director for consideration to treat all contaminants known to be above all relevant BC Water Quality Criteria at the edge of the IDZ to levels below appropriate water quality guidelines where possible.

(g) In any proposal submitted to the Director for consideration, discuss how all the bench and pilot system findings, and/or other performance assurances have been incorporated into the final design of the individual components and/or the system as a whole to assure discharge standards and/or B.C. Water Quality Criteria at the edge of any IDZ is met.

(h) Include a siting map and implementation plan for commissioning of all works necessary for full scale operations of works proposed. Siting must also allow for potential future mining operations or ongoing mining operations to take place.

(i) Include a process for updating and refining the water balance and water quality model acceptable to the Director, with appropriate sensitivity analyses for both onsite and receiving waters, which predicts the impacts to the receiving environment. The water quality model must use updated site monitoring data to demonstrate how well the model is calibrated to observed site conditions and must be updated from time to time to account for planned future mining operations and for ongoing mining operations.

(j) Include a process for ongoing review and updating of the revised Water Management Plan and the implementation schedule after it is approved.

(k) The revised Water Management Plan must be prepared by a Qualified Professional. The Permittee must implement the approved revised Water Management Plan according to the approved implementation schedule. Any updates to the revised Water Management Plan or the implementation schedule must be approved by the Director prior to their implementation.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

2.11. Communication Plan

The Permittee must maintain and implement the Communication Plan dated March 20, 2016. The Communication Plan must demonstrate the sharing of environmental data with the Xatsull First Nation, the Williams Lake First Nation, the Cariboo Regional District, and the community of Likely. Any changes to the communication plan must be discussed with the Public Liaison Committee and submitted to the Director prior to adoption.

2.12. Public Liaison Committee

2.12.1. The Permittee must maintain a Public Liaison Committee (PLC), in accordance with the approved Terms of Reference dated November 21, 2018. The Permittee must submit any Terms of Reference updates to the Director for approval 30 days prior to adopting them.

2.12.2. The Committee must meet at least quarterly to share and receive information about mine activities and the results of monitoring programs with interested members of the public, the Xatsull First Nation, the Williams Lake First Nation, and regulating agencies.

2.13. Posting of Security

The Permittee must maintain a Reclamation Security as required by *Mines Act* Permit M-200.

2.14. Metal Contaminated Soil Milling

Tailings from the processing of metal contaminated soils in the mill from off mine site sources may be discharged to the tailings storage facility subject to all the following:

(a) The soils must be contaminated only with metals.
(b) The Permittee must notify the Director 14 days prior to receiving these materials at the mine site and provide results of chemical analysis of the material at the time of notification.
(c) Records of the volumes processed must be maintained and reported as part of the annual reporting requirements.

2.15. Qualified Professionals

All documents submitted to the Director must be signed by the author and where specifically required by this permit, authored and signed by a Qualified Professional.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

A “Qualified Professional" means an applied scientist or technologist specializing in an applied science or technology applicable to the duty or function, including, if applicable and without limiting this, agrology, biology, chemistry, engineering, geology or hydrogeology and who:

(a) is registered with the appropriate professional organization, is acting under that organization's code of ethics and is subject to disciplinary action by that organization; and,

(b) through suitable education, experience, accreditation and/or knowledge, may be reasonably relied on to provide advice within their area of expertise.

3. MONITORING REQUIREMENTS

3.1. Springer-Cariboo Pit Hydrogeology Work Plan and Assessment

3.1.1. The Permittee must submit a summary, when requested by and to the satisfaction of the Director, all hydrogeological work that has been completed downgradient of the Springer Pit and Cariboo Pit relevant to the Springer Pit filling and drawdown. The summary must describe all monitoring, modelling, and drilling investigations, and must provide recommendations by a Qualified Professional for additional hydrogeological investigations required to manage water in the pits during any future refilling and for mine closure. Recommendations must consider ongoing collection of water quality and geology data as the mine advances, review of the groundwater monitoring network, and hydrogeological model refinements, as appropriate.

3.1.2. Based on the review of the summary, the Director may require additional hydrogeological investigation and assessment of the hydrogeology along the seepage path from the Springer-Cariboo Pit to Bootjack Lake. Any additional monitoring recommended in the summary of hydrogeological work or required by the Director must be incorporated into updates of the Comprehensive Environmental Monitoring Plan.

3.1.3. The recommendations of the summary of hydrogeological work required above, and all ongoing hydrogeological data collected must be re-assessed as part of the annual reporting requirements under section 4.2 of this permit. This includes an annual update to the characterization of the groundwater system in the area between the pit and the lake, refinements and updates to the seepage model near the pit and reporting on the groundwater monitoring network near the pit.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

3.1.4. In addition, updated results and interpretations of the Springer-Cariboo Pit Hydrogeology Assessment, including an updated calibration and verification of the seepage model near the pit, must be prepared by a Qualified Professional and must be submitted to the Director prior to any planned refilling of Springer Pit above 1025 masl.

3.2. Comprehensive Environmental Monitoring Plan

3.2.1. The Permittee must continue to develop, submit and implement an ongoing Comprehensive Environmental Monitoring Plan (CEMP) to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas.

3.2.2. An updated CEMP must be submitted to the Director for approval by March 31, 2020 and every three years thereafter.

3.2.3. The Permittee must undertake monitoring in accordance with the approved CEMP immediately following its approval.

3.2.4 The CEMP must meet all the following requirements:

(a) Consolidate and integrate all of the monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.

(b) At a minimum address a three year time span.

(c) At a minimum include all sampling sites, frequency of sampling, variables to be analysed, method detection limits, sampling methods, sample analysis methods, and data analysis methods.

(d) The updated CEMP must be approved by the Director.

3.2.5. The Permittee must provide all data and information collected under the CEMP to the Director, in electronic format, on a quarterly basis.

3.2.6. The Permittee must submit a three-year detailed monitoring program interpretive report to the Director by March 31, 2022, and every three years thereafter.

3.2.7. During the period of treated effluent discharge authorized by section 1.2

above, the Director may require expedited sampling, testing and reporting of treated effluent discharged during the spring freshet (March through July annually).

3.2.8. The Director may require revisions to the CEMP based on review of monitoring data and/or any other relevant information.

3.3. Effluent Toxicity Testing

Acute and chronic toxicity testing of discharges to Quesnel Lake authorized under section 1.2 of this permit must be conducted as follows:

Acute Bioassay	**Frequency**	**Source for Sample Collection**
96-hr LC50 Rainbow Trout	Monthly	HAD-03 - Effluent discharged to Quesnel Lake (E304230)
48-hr LC50 Daphnia magna	Monthly	HAD-03 - Effluent discharged to Quesnel Lake (E304230)
Chronic Bioassay	**Frequency**	**Source for Sample Collection**
7-day Ceriodaphnia dubia survival and reproduction, and 7-day ELS toxicity test with a salmonid fish and or other tests specified by the Director	Quarterly or as required by the approved CEMP	as specified in the approved CEMP when discharging direct to Quesnel Lake

3.4. Water Flow Measurement

3.4.1. The Permittee must provide and maintain suitable flow measuring devices and record staff gauge measurements, during open water, at surface water stations at W1B (Morehead Creek), W4A (North Dump Creek), W5 (Bootjack Creek) W12 (6K Creek), H1 (continuous, Upper Hazeltine Creek), H3 (Edney Creek), H4 (Polley Lake outlet) and H2 (continuous, Lower Hazeltine Creek), located approximately as shown on the attached Site Plan B, or at alternative monitoring stations satisfactory to the Director.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

3.4.2. Springer Pit water level elevation shall be monitored and recorded on a monthly basis.

3.4.3. Staff gauge readings must be taken at the same time as stream flow measurements and/or water quality sampling are collected at the same or associated sites.

3.4.4. A stage discharge curve must be developed for all staff gauges.

3.4.5. All staff gauges and flow measuring devices must be checked and calibrated once per year, after June 15th but prior to August 31st of each calendar year.

3.5. Outfall and Pipeline Commissioning and Inspection

3.5.1. The Permittee must develop and implement a monthly visual inspection program for the pipeline from the Actiflo treatment plant to the outfall in Quesnel Lake. The monthly visual inspection program must include all of the following:

(a) The pipeline corridor must be visually inspected every month.

(b) Records of the monthly visual inspections must be made available for inspection by an Officer immediately upon request.

3.5.2. The Permittee must conduct a comprehensive annual inspection of the pipe line corridor by October 1st of each year.

3.5.3. The Permittee must conduct an underwater inspection of the diffusers every 5 years to ensure they remain in good working order.

3.5.4. An annual inspection report with recommended remedial actions must be prepared by a Qualified Professional and submitted to the Director within 60 days of completion of the comprehensive inspection.

3.5.5. The pipeline and outfall must have all the following signage:

(a) A sign must be maintained along the alignment of the outfall facing Quesnel Lake above the high water mark.

(b) Signs must identify the nature of works.

(c) Signs must be posted along the effluent pipeline right-of-way at points of public access to identify the right-of-way.

(d) All signs must include emergency contact information.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

3.6. Climate Monitoring

The Permittee must maintain meteorological stations and measure continuous daily precipitation; daily maximum, minimum and mean temperature; and daily evaporation calculation or suitable alternative as approved by the Director. Climate Monitoring sites are as shown in Site Plan C.

3.7. Sampling and Analytical Procedures

3.7.1. The Permittee must carry out sampling in accordance with the procedures described in the "British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples, 2013 Edition (Permittee)" or most recent edition, or by alternative procedures as authorized by the Director.

3.7.2. The Permittee must carry out analyses in accordance with procedures described in the "British Columbia Laboratory Manual (2015 Permittee Edition)", or the most recent edition or by alternative procedures as authorized by the Director.

Copies of the above manuals are available on the Ministry web page at https://www2.gov.bc.ca/gov/content/environment/research-monitoring-reporting/monitoring/laboratory-standards-quality-assurance/bc-field-sampling-manual.

3.7.3. Bioassays must be conducted using the following methods:

(a) the "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Rainbow Trout", Report EPS 1/RM/13 December 2000;

(b) the "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Daphnia magna", Reference Method EPS 1/RM/14 December 2000;

(c) the "Biological Test Method: Toxicity Tests Using Early Life Stages of Salmonid Fish (Rainbow Trout)", Report EPS 1/RM28, July 1998 - Embryo/Alevin;

(d) the "Biological Test Method: Test of Reproduction and Survival Using the Cladoceran Ceriodaphnia dubia", Report EPS l/RM/21, February 2007; or,

(e) by suitable alternative procedures as authorized by the Director.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

3.8. Quality Assurance

3.8.1. The Permittee must maintain and implement a "Quality Assurance Manual" consistent with "British Columbia Field Sampling Manual for Continuous Monitoring plus the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples 2013 Edition (Permittee)", or most recent edition. The Permittee must ensure that all data submitted as a requirement of this permit is produced in accordance with the Quality Assurance Manual, that data is handled and reviewed in accordance with protocols established in the Manual and is accompanied by quality assurance data required by the Manual. The Permittee must provide the Director with any updates to this Manual within 30 days of adoption.

3.8.2. Analysis of samples for parameters designated under the Environmental Data Quality Assurance Regulation must be at a laboratory registered for the designated parameter under the Regulation. In addition, the Permittee must participate in quality assurance audits as required by the Regulation.

4. REPORTING

4.1. Routine Reporting

4.1.1. In each month that discharge occurs as authorized by section 1.2 above, the Permittee must submit a monthly report, suitably tabulated and formatted, to the Director summarizing:

(a) the volume of treated effluent discharged,

(b) a summary of continuous Turbidity readings of the treated effluent discharged, and

(c) the most recently available water quality results for the effluent discharged, including toxicity.

4.1.2. Each monthly report must be submitted within seven days of the end of previous month via email to EnvAuthorizationsReporting@gov.bc.ca. Each monthly report must also contain and present all data submitted in the previous 2 monthly reports in a manner that would identify potential trends.

4.1.3. Each monthly report must also be provided to the Williams Lake First Nation and Xatsull First Nation and be made available to the Public

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

Liaison Committee within 7 calendar days of the submission to the Ministry.

4.1.4. The Permittee must cause each data submission required by this Authorization to include a statement outlining the number of exceedances of permitted discharges that occurred during the reporting period, the dates of each such exceedance, an explanation as to the cause of the exceedances, and a description of the measures taken by the Permittee to rectify the cause of each such exceedance. If no exceedances occurred over the reporting period, the required statement may instead indicate that no exceedance of permitted discharges occurred during the reporting period.

4.1.5. The Permittee must submit all data required to be submitted under this section by email to the Ministry's Routine Environmental Reporting Submission Mailbox (RERSM) at envauthorizationsreporting@gov.bc.ca or as otherwise instructed by the Director. For guidelines on how to properly name the files and email subject lines or for more information visit the Ministry website: https://www2.gov.bc.ca/gov/content/environment/waste-management/waste-discharge-authorization/data-and-report-submissions/routine-environmental-reporting-submission-mailbox.

4.1.6. The Director may require modification to the monitoring program based on the evaluation of the monthly and annual reports and on any other information that pertains to the operations and or discharges.

4.1.7. The Permittee must upload monitoring data associated with this permit to the Ministry's Environmental Monitoring System (EMS) database, within 45 days of the end of the three month period in which the data is collected.

4.2. Annual Report

4.2.1. The Permittee must also submit by March 31st of each year, a comprehensive annual report of all monitoring via email to the above email address, in a format suitable for public release. The annual report must include:

(a) all monitoring sample results required under the permit,

(b) an evaluation of quality assurance, including collection, sampling, and data handling protocols,

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

(c) an evaluation of the treatment plant operation and control,

(d) an evaluation of the impacts of the mining operation on the receiving environment from the previous year,

(e) a summary of any non-compliance with the permit and other incidents that may have led to impacts to the receiving environment,

(f) updates of the water balance, and a calibration assessment of the water balance and water quality models,

(g) assessment of the outfall dispersion and dispersion modelling for the Quesnel Lake discharge,

(h) an update to any modeling relating to the Springer Pit groundwater seepage and its impacts on Bootjack Lake as described in section 3.1,

(i) a progress update with respect to the Water Management Plan,

(j) a review and update of the assessment of acid rock drainage (ARD) potential and water quality impacts from mine waste management,

(k) a comparison of monitoring data with water quality guidelines, predictions and targets,

(l) an update on the progress of reclamation and any updates to the reclamation plan that impact on site water quality,

(m) an evaluation of the effectiveness of the Surface Runoff and Mine Drainage Control programs,

(n) a summary of the Public Liaison Committee meetings, including any issues and concerns presented,

(o) an evaluation of the Outfall and Pipeline Inspection program; and,

(p) trend analysis (graphs) of water monitoring data at each site for the past 5 years.

4.2.2. Monitoring data and the analysis of that data, as it will be presented in the annual report, must be reviewed by a third party Qualified Professional.

4.2.3. A groundwater monitoring program review, including but not limited to sampling, well locations, site water balance, interpretation of data trends and possible environmental impacts, and suitable recommendations, must be completed for the entire mine site at least every three years, with the next review required by March 31, 2022.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

4.2.4. A copy of the annual report must be provided to the Williams Lake First Nation and Xatsull First Nation within 30 days of the report being submitted to the Director.

4.3. Non-compliance Reporting

4.3.1. The Permittee must immediately notify the Director or designate of any noncompliance with the requirements of this Permit and take appropriate remedial action. Written confirmation of all non-compliance events, including available test results is required within 24 hours of the original notification unless otherwise directed by the Director.

4.3.2. Both the initial notice and the confirmation must also be emailed to EnvironmentalCompliance@gov.bc.ca.

4.3.3. Within 30 days of any non-compliant event, the Permittee must submit a follow-up report to the Director and the above mailbox that includes, but is not necessarily limited to the following:

(a) all relevant test results related to the non-compliance instance(s),

(b) an explanation of the most probable cause(s) of the noncompliance(s); and,

(c) remedial actions taken and planned to prevent similar noncompliance(s).

4.4 Reporting of Toxicity Failure

4.4.1. The Permittee must immediately notify the Director of any toxicity failure according to the Non-Compliance Reporting requirements in Section 4.3. For the purpose of this section, a sample is considered to have failed the specific toxicity test if:

(a) 96-hr LC50 Rainbow Trout: Using 100% effluent concentration, more than 50% of the fish die within a 96 hour test period,

(b) 48-hr LC50 Daphnia magna: Using 100% effluent concentration, more than 50% of the organisms die within a 48 hour test period,

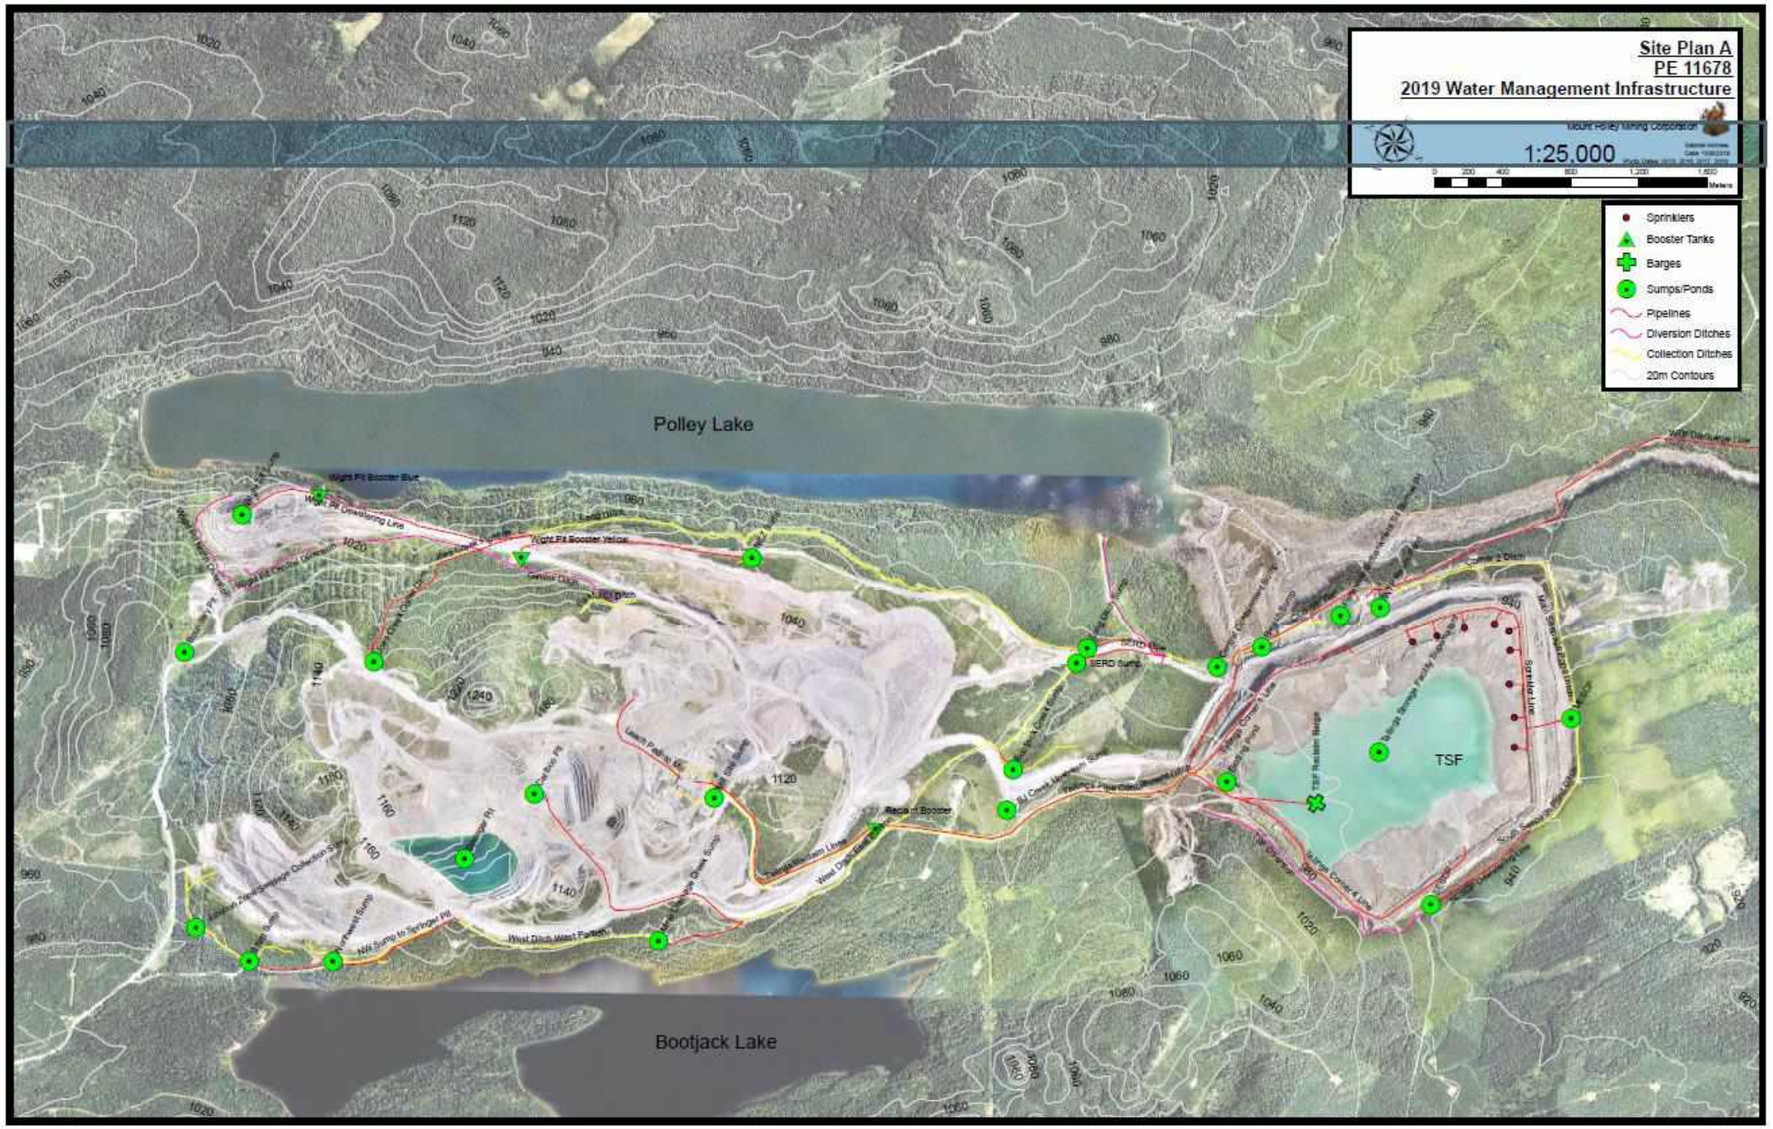
(c) 7-day Ceriodaphnia dubia reproduction: The water is determined to cause greater than 25% inhibition of survival and reproduction; or,

(d) 7-day ELS toxicity test with a salmonid fish: The water is determined to cause greater than 25% non-viable embryos.

Date issued: May 30, 1997
Date amended: December 31, 2020
(most recent)

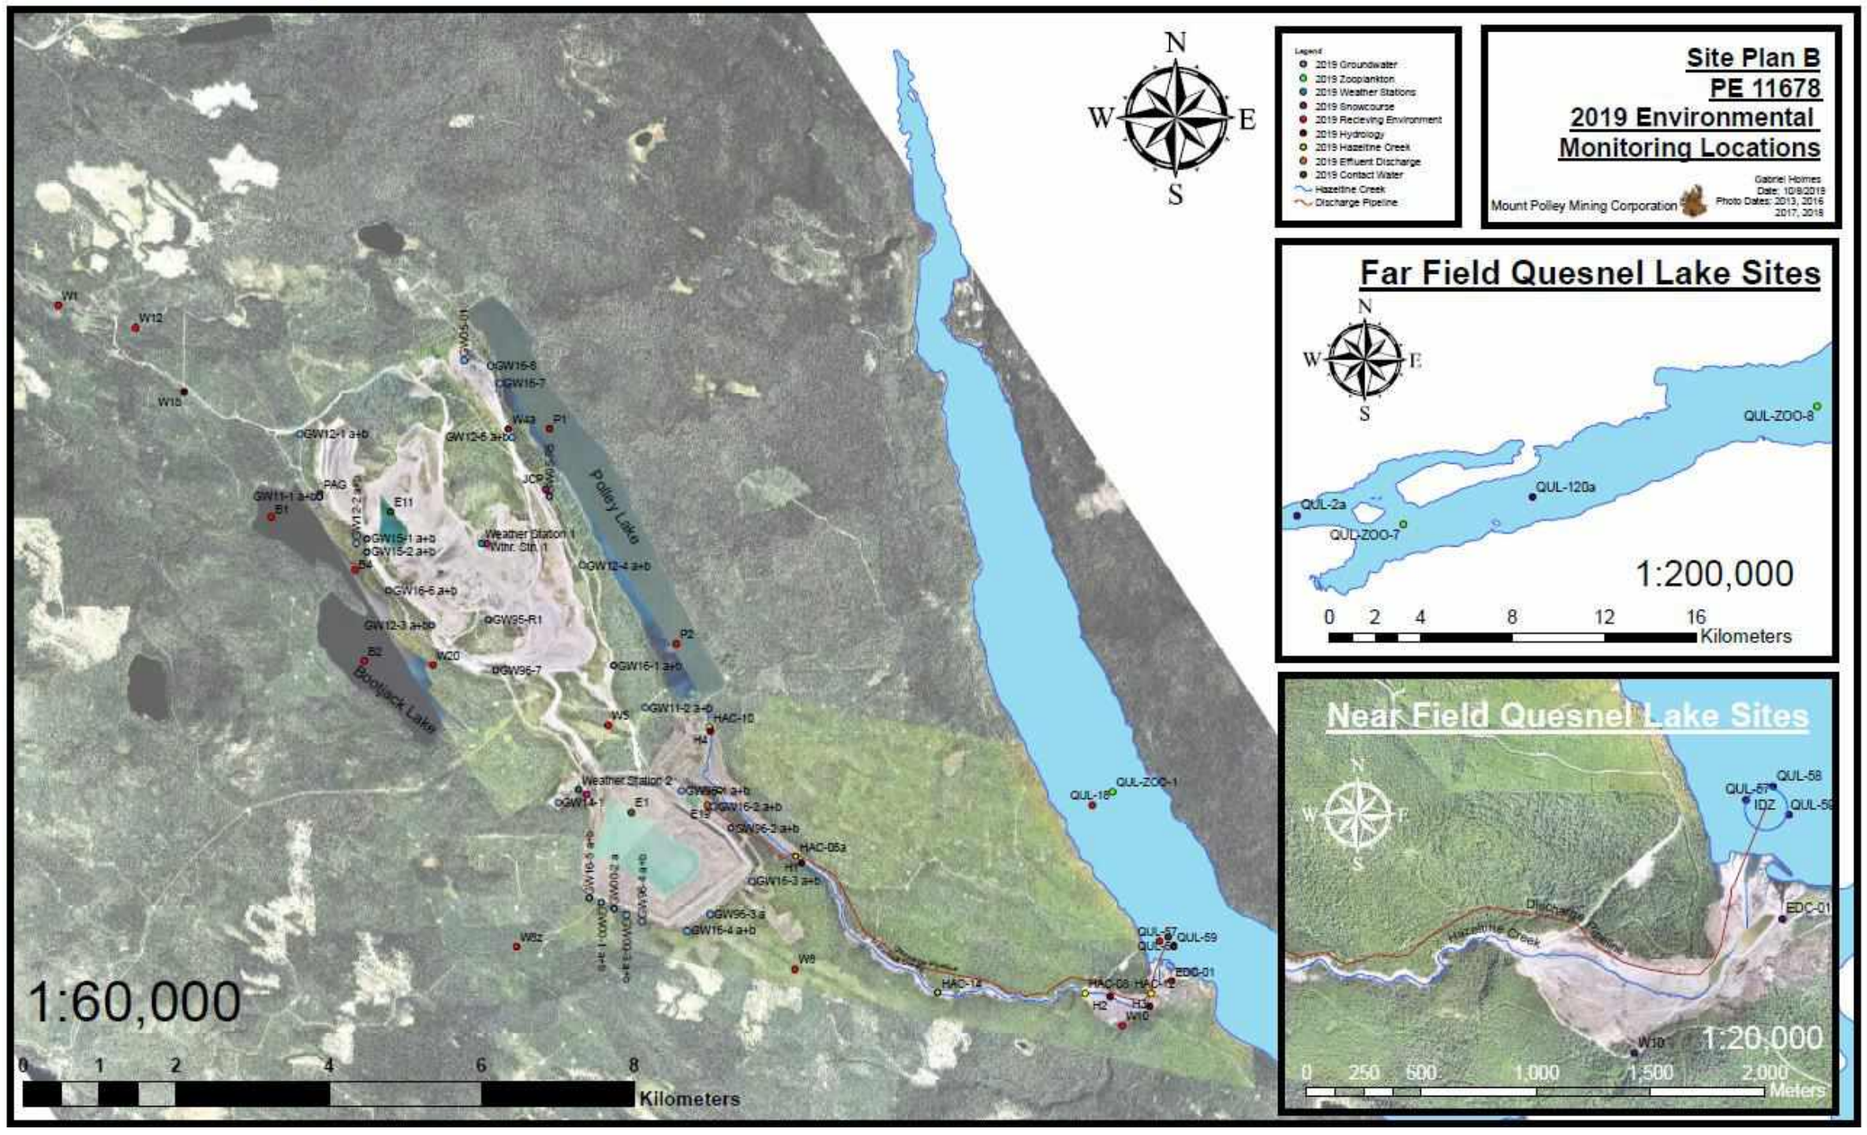
Douglas J. Hill, P.Eng.
for Director, *Environmental Management Act*

4.4.2. The Permittee must investigate each toxicity failure to determine the cause(s). Reasonable efforts must be made to obtain preliminary and in progress results from the analytical laboratory during the toxicity testing. The Permittee must make immediate arrangements to retest in the event of potential and confirmed failures. The Director may require additional toxicity testing based on the evaluation of results from toxicity testing and the causes of failure.



4.5. **Other Documents**

All documents to be submitted to the Director must be sent as a separate document and named according to the name listed in this permit.



Date issued: May 30, 1997

Dear Permittee:

Enclosed is Amended Permit 11678 issued under the provisions of the *Environmental Management Act*. Your attention is respectfully directed to the terms and conditions outlined in the permit. An annual fee will be determined according to the Permit Fees Regulation.

This permit does not authorize entry upon, crossing over, or use for any purpose of private or Crown lands or works, unless and except as authorized by the owner of such lands or works. The responsibility for obtaining such authority rests with the permittee. This permit is issued pursuant to the provisions of the *Environmental Management Act* to ensure compliance with section 120(3) of that statute, which makes it an offence to discharge waste, from a prescribed industry or activity, without proper authorization. It is also the responsibility of the permittee to ensure that all activities conducted under this authorization are carried out with regard to the rights of third parties and comply with other applicable legislation that may be in force.

When a spill or the risk of a spill occurs, the responsible person (spiller) must report it immediately by calling 1-800-663-3456 in accordance with the Spill Reporting Regulation. More information is available at:
https://www2.gov.bc.ca/gov/content?id=1EAB9109A9E9407EA646050A9D431C41

This decision may be appealed to the Environmental Appeal Board in accordance with Part 8 of the *Environmental Management Act*. An appeal must be delivered within 30 days from the date that notice of this decision is given. For further information, please contact the Environmental Appeal Board at (250) 387-3464 or by email at info@bceab.ca.

Administration of this permit will be carried out by staff from the Environmental Protection Division's Regional Operations Branch. Plans, data and reports pertinent to the permit are to be submitted by email or electronic transfer to the director, designated officer, or as further instructed.

Ministry of Environment and Climate Change Strategy
Environmental Protection Division
Suite 400 – 640 Borland Street
Williams Lake BC V2G 4T1
Mining Operations
Telephone: (250) 398-4530
Facsimile: (250) 398-4214

Please be reminded that the director may, for the protection of the environment in accordance with section 16 of the *Environmental Management Act*, require the permittee to do one or more of the following at any time:

- repair, alter, remove, improve or add to existing works, or construct new works, and submit plans and specifications for works specified in this authorization.
- conduct monitoring, and may specify procedures for monitoring and analysis, and procedures or requirements respecting the handling, treatment, transportation, discharge or storage of waste.
- provide security in the amount and form, and subject to the conditions, specified by the director.
- conduct studies and report information in accordance with the specifications of the director.
- recycle certain wastes and recover certain reusable resources, including energy potential from wastes, in accordance with the specifications of the director.
- submit copies of reports and notifications to specified Indigenous Groups, within specified timelines, in accordance with the specifications of the director.

For more information about how the Ministry will assess compliance with your permit please refer to gov.bc.ca/environmentalcompliance.

For more information about how to make changes to your permit and to access waste discharge amendment forms and guidance, please refer to gov.bc.ca/wastedischarge-authorizations.

Yours truly,

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

**MINISTRY OF ENVIRONMENT
AND CLIMATE CHANGE
STRATEGY**

PERMIT

11678

Under the Provisions of the Environmental Management Act

MOUNT POLLEY MINING CORPORATION

**SUITE 200
580 HORNBY ST
VANCOUVER, BC
V6C 3B6**

is authorized to discharge effluent to land and surface water from a copper-gold mine and mill complex located near Likely, British Columbia, subject to the requirements listed below.

Contravention of any of these requirements is a violation of the *Environmental Management Act* and may lead to prosecution.

This Authorization supersedes and replaces all previous versions of Permit 11678 issued under section 14 of the *Environmental Management Act*.

1. AUTHORIZED DISCHARGES

1.1 Discharges to Tailings Storage Facility

This section applies to the discharge of effluent from a Copper-Gold Mine and Ore Concentrator to the tailings storage facility. The site reference number for this discharge is E225309.

1.1.1 The monthly average rate of discharge of tailings slurry is 55,500 m^3/day.

1.1.2 The authorized discharge period is continuous.

1.1.3 The characteristics of the discharge must be typical of concentrator tailings from the milling of ore or metal contaminated soil, mill site

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

runoff, rock disposal site runoff, open pit water, and septic tank effluent from a copper-gold mine and mill complex.

1.1.4 The authorized Works are the following; a septic tank, tailings discharge line, open pits, tailings storage facility, water treatment and discharge system, seepage collection and recycle system, surface water collection works, tailings supernatant recycle systems; sediment pond(s) and related appurtenances approximately located as shown on the attached Site Plan A.

1.1.5 The location of the facilities from which the discharge originates is within Mineral Leases No. 345731, No. 410495, No. 524068, No. 573346, No. 933970, and No. 933989 as well as Mineral Claims No. CB16 204475, No. PM5 206540, No. POL2 411010, No. 514039, and No. 514044, Cariboo Mining Division, Cariboo Land District.

1.1.6 The location of the point of discharge (tailings storage facility) is on Mineral Claim No. 514039, Cariboo Mining Division, Cariboo Land District.

1.2 Mine Site Runoff and Seepage

This section applies to the discharge of treated effluent from the site runoff and seepage water collection and management systems to Quesnel Lake as sampled at the Treatment Plant Outlet (HAD-03). The site reference for this discharge is E304230.

1.2.1 The authorized annual average rate of discharge is 29,000 m^3/day.

1.2.2 The maximum rate of discharge is 52,000 m^3/day.

1.2.3 The discharge period is authorized until June 30, 2025.

1.2.4 The characteristics of the discharge at the treatment plant outlet must be equivalent to or less than the values specified in column 2 of Table 1 below.

1.2.5 The Annual Discharge Plan required under section 2.8 must show how the concentrations of the parameters meet the objectives for the "Edge of Quesnel Lake Initial Dilution Zone (IDZ)" in Quesnel Lake as specified in column 3 below in Table 1.

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

Table 1

Parameter	**Treatment Plant Outlet** (1)	**Edge of Quesnel Lake IDZ** (1)(2)(3)
Rainbow Trout 96hrLC50	50 % Mortality in 100% effluent	-
Daphnia Magna 48hrLC50	50 % Mortality in 100% effluent	-
pH	< 9.5 and >6.0 pH units	-
Total Suspended Solids	30 mg/L, and 15 mg/L Monthly Average	-
Total Sulfate	1,100 mg/L	218 mg/L
Total Ammonia (as N)	1.3 mg/L	0.18 mg/l as N
Total Nitrate (as N)	34.0 mg/L	3.0 mg/l as N
Total Nitrite (as N)	0.78 mg/L	0.02 mg/L as N
Total Phosphorus	90.0 µg/L	10.0 µg/L
Fluoride	17.0 mg/L	1.0 mg/L
Total Arsenic	28 µg/L	5.0 µg/L
Total Chromium	4 µg/L	1 µg/L
Total Copper	33 µg/L	2.2 µg/L (30-day rolling average)
Total Iron	1.0 mg/L	1.0 mg/L
Dissolved Iron	0.35 mg/L	0.35 mg/L
Total Manganese	3.4 mg/L	0.84 mg/L
Total Molybdenum	0.36 mg/L	0.05 mg/L
Total Silver	0.24 µg/L	0.05 µg/L
Total Selenium	75 µg/L	2 µg/L

Dissolved Aluminum	0.75 mg/L	0.05 mg/L
Dissolved Cadmium	0.34 µg/L	0.13 µg/L

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

(1) All values are maximum values from grab samples unless otherwise specified.

(2) Only applies while discharging directly to Quesnel Lake.

(3) The "Edge of Quesnel Lake IDZ" is a point located 100 m from the Quesnel Lake outfall, represented by site QUL-58 mid and/or near bottom samples, or alternative location approved by the director.

1.2.6 The permittee must implement the response steps set out in the approved trigger response plan under section 2.8 (e) without delay if either:

(a) The effluent monitoring at the outlet of the treatment plant indicates that trigger levels set out in the approved trigger response plan are reached for any parameter set out in Table 1 above; or,

(b) An objective set for the Edge of Quesnel Lake IDZ in Table 1 above is exceeded, or is predicted to be exceeded, as determined in accordance with procedures in the approved trigger response plan.

Where the permittee must cease discharging, the discharge may resume only in accordance with the approved trigger response plan. The requirement to implement the trigger response plan does not authorize an exceedance of the maximum values specified in section 1.2.4 for the characteristics of the discharge at the outlet of the treatment plant.

1.2.7 The discharge is authorized from the Authorized Works, which are the settling pond(s), tailings storage facility, mine contact water collection system, the Veolia Actiflo treatment system, flow control valve(s), continuous flow meter, pipeline and outfall system and associated appurtenances as generally shown in the attached Site Plans.

1.2.8 The location of the facilities from which the discharge originates is the same as in section 1.1.5 above.

1.2.9 The location of the discharge is the Quesnel Lake outfall at a point within Mineral Claim No. 501479 when discharging to Quesnel Lake.

1.3 **Springer Pit Discharge to Ground**

This section applies to the discharge of seepage water from Springer Pit to Ground. The site reference for this discharge is E307887.

1.3.1 The permittee must maintain Springer Pit water levels at less than 1025 meters above sea level (masl) to limit seepage towards Bootjack Lake.

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

1.3.2 The characteristics of the discharge must be typical of site runoff and seepage water.

1.3.3 The authorized works are Springer Pit, and its associated water management works and related appurtenances.

1.3.4 The location of the facilities from which the discharge originates and the point of discharge are as shown in the attached Site Plan A.

2. GENERAL REQUIREMENTS

2.1. Maintenance of Works and Emergency Procedures

2.1.1 The authorized works must be inspected regularly and maintained in good working order. In the event of an emergency or condition beyond the control of the permittee which prevents effective operation of the authorized works or leads to an unauthorized discharge, the permittee must take appropriate remedial action and notify the director immediately. The director may require the permittee to reduce or suspend operations to protect the environment until the authorized works have been restored, and/or corrective steps taken to prevent unauthorized discharges.

2.1.2 All ponds, ditching, and other runoff or seepage collection and diversion works must be inspected at least twice per year, once in the spring after freshet and once in the fall before freeze-up. Records of these inspections must be maintained and made available for inspection by the Ministry immediately upon request.

2.1.3 The authorized works must be complete and in operation while discharging.

2.2. Bypasses

Any bypass of the authorized works is prohibited unless prior approval of the director is obtained and confirmed in writing.

2.3. Process Modifications

The director must be notified prior to implementing changes to any process that may affect the quality and/or quantity of the authorized discharges. The notification must be submitted to the Ministry's Routine Environmental Reporting Submission Mailbox envauthorizationsreporting@gov.bc.ca or as otherwise instructed by the director. Despite notification under this section, permitted limits and objectives must not be exceeded.

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

2.4. **Surface Runoff and Mine Drainage Control**

2.4.1 Unless required for operational purposes, surface runoff from undisturbed areas and groundwater pumped from up gradient of pits or other undisturbed areas, must be diverted so that it does not flow to the tailings storage facility, or to the mine and mill areas.

2.4.2 Seepage and runoff from the open pits, rock disposal sites, and from down gradient of the tailings storage facility must be collected and conveyed to treatment works, the tailings storage facility, mill or open pits.

2.4.3 Inactive open pits may be used for storage of mine water, tailings storage facility supernatant or mill site runoff, provided records of volumes transferred to any pit are maintained and reported quarterly.

2.4.4 Recycling of on-site water and evaporation enhancing techniques must be practiced.

2.4.5 Surface water control works must be provided for all areas disturbed by roads, open pits, rock disposal/storage sites, the mill site and ore storage sites. The surface water control works must be designed to convey all flows up to a 1 in 10 year 24-hour storm event and must be designed to withstand all flows up to a 1 in 200 year 24-hour storm event, without significant damage.

2.4.6 The tailings storage facility must provide adequate storage, beach width and freeboard as required by *Mines Act* Permit M-200.

2.5. **Reporting of Storm Events**

2.5.1 In the event that the permittee reports an incident to the director that is the result of a storm event that is considered to exceed the 1 in 10 year 24-hour storm event or 1 in 200 year 24-hour storm event, the permittee must cause a Qualified Professional to complete a flow analysis to demonstrate the estimated magnitude and corresponding return period of the storm event.

2.5.2 The flow analysis must be submitted to the director 60 days following the reporting of the storm event.

2.5.3 The permittee must provide all available supporting information used in the flow analysis, including but not limited to:

(a) Date, time, and duration of storm event,

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

(b) Total precipitation measured during storm event including source of data,

(c) Available measured flow data including source of data,

(d) Map showing the site watershed location and drainage area (in km^2) in proximity to any relevant regional watersheds used in the return period flow analysis, and

(e) Any other applicable supporting information.

2.6. **Erosion and Sediment Control Plan**

2.6.1 The permittee must maintain and implement the most recent version of the Erosion and Sediment Control Plan (ESCP) dated December 7, 2021. The objective of the ESCP is to outline management practices to prevent erosion and minimize transport of sediment laden water to the receiving environment that could result in exceedances at monitoring stations of water quality guidelines for aquatic life for non-filterable residue (Total Suspended Solids) in British Columbia Approved Water Quality Guidelines (BC WQGs): Aquatic Life, Wildlife & Agricultures (2021 version) or most recent version.

2.6.2 The permittee must cause a Qualified Professional to conduct a review of the ESCP and develop an ESCP Review Report based on the findings of the review. The first review must be conducted in 2023 and then every five years thereafter or earlier if proposed change(s) to the ESCP may affect the quality and/or quantity of the authorized discharges, as stated in section 2.3 of this permit. The permittee must submit the ESCP Review Report as part of the annual report required by section 4.2 for the year in which the review was required to be conducted.

2.6.3 The ESCP Review Report must include, but is not limited to:

(a) An assessment of whether the ESCP methods being employed on site are being undertaken in accordance with the most recent ESCP,

(b) An assessment of the effectiveness of the ESCP in achieving the objective of the plan,

(c) Recommended improvements to the ESCP, and

(d) Any comments, recommendations, or observations the Qualified Professional considers would be relevant to achieving the objective of the plan.

2.6.4 The permittee must cause a Qualified Professional to update the ESCP based on the recommended modifications included in the ESCP Review

Report and submit the updated ESCP to the director within 90 days of submission of the annual report that included the ESCP Review Report. The permittee must provide justification where any of the recommended modifications have not been included in the updated ESCP as part of a cover letter for the updated ESCP.

2.6.5 The permittee must maintain the most recent approved version of the ESCP onsite for inspection by the Ministry.

2.6.6 The permittee must cause a Qualified Professional to modify or amend the ESCP as required by the director and the permittee must, within the timeframe specified by the director, resubmit to the director the ESCP with required modifications or amendments.

2.7. **Environmental Emergency Response Plan**

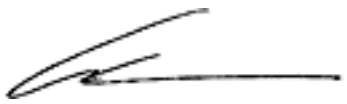
2.7.1 The permittee must maintain and implement an up to date Environmental Emergency Response Plan by January 31st of each year. The Environmental Emergency Response Plan must include all of the following:

(a) Adequate procedures for responding to all probable environmental emergencies, including spills,

(b) Permit exceedances associated with the Mount Polley Mine operations and mine site area,

(c) Procedures for the suspension of the effluent discharge to Quesnel Lake, and

(d) A notification protocol for immediate advising the Xatśūll First Nation, the Williams Lake First Nation, the Cariboo Regional District, and the community of Likely of significant emergency events, and permit exceedances at the mine site.



2.7.2 The permittee must ensure mine personnel are trained on the contents of the Emergency Response Plan and is reviewed annually.

2.8. **Annual Discharge Plan**

2.8.1 The permittee must maintain and implement an Annual Discharge Plan approved by the director for the discharge authorized in section 1.2 above. The plan must include the following:

(a) An outline of the expected volume, timing, and duration of effluent released to Quesnel Lake,

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

(b) Consideration and account of hydrology and snowpack information, mine water balance information, Polley Lake discharge control, and background water quality information,

(c) Demonstrate how the objectives, set out in column 3 of Table 1 above, will be met at the Edge of Quesnel Lake IDZ in Quesnel Lake,

(d) A maximum turbidity target(s), as measured at the outlet of the treatment plant, which requires immediate reporting to the director should the turbidity target(s) be exceeded for longer than one hour in duration,

(e) A trigger response plan for treatment system shutdown(s), and/or for suspension or reduction of discharge, and for the resumption of the discharge, if the effluent discharge limits at the outlet of the treatment plant cannot be met, or if an objective for the Edge of Quesnel Lake IDZ in Quesnel Lake cannot be met,

(f) Identification of the sources of mine water and the percent of each source in the total effluent discharge for each day,

(g) Demonstrate how the discharge will be managed to minimize suspended solids deposition into Quesnel Lake, and,

(h) Identification of equipment, including calibration and maintenance schedules related to continuous measurements of flow, turbidity, specific conductance and temperature.

2.8.2 The Annual Discharge Plan must be reviewed at least once each year, and any necessary updates to the plan must be submitted to the director for approval at least 30 days prior to adoption.

2.9. **Nitrogen Management Plan**

The permittee must maintain and implement a Nitrogen Management Plan developed by a Qualified Professional. The plan must describe measures that prevent the loss of nitrogen species into the environment arising from the use of explosives and handling of waste rock. Any update to the plan must be provided to the director within 30 days of implementation.

2.10. **Flocculant Management Plan**

2.10.1 The permittee must cause a Qualified Professional to develop a Flocculant Management Plan (FMP) for the Veolia Actiflo treatment system, and the permittee must submit the FMP to the director by March 31, 2023. The objective of the FMP is to describe the method for

settling of solids while optimizing the use of coagulants and/or flocculants (settling aids) and limiting potential detrimental effects such as toxicity in the receiving environment.

2.10.2 The FMP must include, but is not limited to:

(a) A clear objective statement,

(b) A list of settling aids used and safety data sheets for each settling aid,

(c) Identification of locations where settling aids are applied,

(d) Description of works used for adding settling aids to waste streams,

(e) A plan for ensuring that sufficient inventory of settling aids is on site while avoiding excessive quantities of hazardous chemicals being on site and avoiding settling aids from becoming less effective due to age,

(f) Application rates at all locations for which settling aids are used and how toxicity in the discharge will be prevented,

(g) Justification for choice in settling aids and associated management works,

(h) Defined inspection schedule for works used to manage settling aids,

(i) Defined monitoring procedures; including inflow rates, outflow rates and dosing applications,

(j) Monitoring procedures of the influent and effluent to determine appropriate application rates, and

(k) Defined procedures for determining when settling aids will be used and when their use must be terminated, or dosages adjusted.

2.10.3 The permittee must implement the most recent version of the FMP.

2.10.4 The permittee must cause a Qualified Professional to conduct a review of the FMP every five years with the first review to be conducted in 2028 and develop an FMP Review Report based on the findings of the FMP review. The permittee must submit the FMP Review Report as part of the annual report required in section 4.2 for the year in which the review was required to be conducted.

2.10.5 The FMP Review Report must include, but is not limited to:

(a) An assessment of whether the settling aid management methods being employed on site are being undertaken in accordance with the most recent FMP,

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

(b) An assessment of the monitoring data to evaluate whether the objective of the FMP is being met,

(c) Recommended improvements to the FMP in achieving the objective of the plan, and

(d) Any comments, recommendations, or observations the Qualified Professional considers relevant to achieving the objective of the plan.

2.10.6 The permittee must cause a Qualified Professional to update the FMP based on the recommended updates included in the FMP Review Report and submit to the director within 90 days of submission of the annual report that included the FMP Review Report. The permittee must provide justification where any of the recommended updates have not been included in the updated FMP as part of a cover letter for the updated FMP.

2.10.7 The permittee must maintain the most recent approved version of the FMP onsite for inspection by the Ministry.

2.10.8 The permittee must cause a Qualified Professional to modify or amend the FMP as required by the director and the permittee must, within the timeframe specified by the director, resubmit to the director the FMP with required modifications or amendments.

2.11. **Water Treatment and Discharge Program**

The permittee must undertake a program to investigate new and/or improved treatment technologies and develop a water treatment and discharge program for all mine site water treatment works and source control optimization activities which includes the following:

2.11.1 Best Achievable Technology (BAT) Assessment

(a) The permittee must undertake a BAT assessment of any treatment technologies identified in the Water Management Plan dated November 27, 2020 or any new and/or improved treatment technologies retained for permitting. The permittee must submit to the director for approval by January 31st of each year a study plan that details bench and pilot scale testing that will be undertaken.

2.11.2 Water Treatment Plant Optimization

The permittee must operate and optimize the performance of the Veolia Actiflo Water Treatment Plant (WTP) to remove contaminants present

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

in the mine site contact water to meet the discharge requirements of section 1.2.4.

(a) "Numeric Performance Metric" (NPM) means a measurable value that quantifies the outcome or result of water treatment and the ability of the treatment to remove specified chemical constituent(s). It forms the basis for a numeric comparison of untreated water, to water that has been treated by the treatment system.

(b) The permittee must operate and optimize the design and performance of the WTP to target achievement of any prescribed NPM. The stated NPM target value represents WTP operation that achieves annual average effluent quality that is at or below any specified NPM. Assessment of the attainment of NPM values must be reported in an annual optimization update progress report appended to the annual report required in section 4.2. If the effluent quality does not achieve an NPM value specified by the director, the permittee must identify and propose response actions to bring the effluent quality toward meeting the target value in the annual optimization update progress report. Response action may include treatment plant optimization and/or source control and/or water management improvements, and a schedule for implementing the response action must be included in the annual optimization update progress report.

The following NPM is established:

Total copper 12 ug/L

(c) "Annual average effluent quality" means the effluent concentration of total copper based on a 52-week rolling average, using the average of the 52 weekly grab samples at HAD-3 when the WTP is discharging.

2.11.3 Source Control Optimization

The permittee must undertake ongoing maintenance and surveillance of on-site water management systems and activities undertaken to increase source control of any potential contaminants of concern.

(a) The permittee must undertake source control optimization yearly.

(b) The permittee must undertake an analysis of the treatment plant effluent to determine selenium species present and at a minimum determine the typical proportion of total selenium that is selenate,

selenite, and organoselenium. Based on these results the director may require additional analysis for selenium speciation of mine source waters.

2.11.4 Review of Discharge Alternatives

The permittee must review discharge alternatives for direct discharge of treated mine water on and around the mine site considering the following mine phases: operations, care and maintenance, closure, and post-closure.

The review of discharge alternatives must include consideration of:

(a) Passive and semi-passive water treatment options for distributed discharges across the mine site informed by the Water Management Plan dated November 27, 2020, and most recent Reclamation and Closure Plan for the site,

(b) Physical (geomorphological and hydrological), chemical, and biological characteristics of potential receiving environments, and

(c) The capacity of the proposed discharge locations to receive the additional discharges of treated water and meet applicable environmental benchmarks.

2.12. **Water Management Progress Reporting**

The permittee must report to the director on all aspects of section 2.11 every 6 months, beginning June 30, 2020, and continuing until such time as the director deems the reporting no longer required. The report must include, but is not limited to:

(a) Results of all BAT assessments,

(b) Bench and pilot testing of treatment systems,

(c) Progress on implementation of response action(s) for attainment of the NPM target value,

(d) Source control optimization studies,

(e) Summary and discussion of proposed alternative discharge locations that have the capacity to receive the treated water and changes from the previous progress reports,

(f) Documentation that the testing and piloting programs are relevant for all the different types of mine influenced water on site, and

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

(g) Any other studies related to the Water Treatment and Discharge Program outlined in section 2.11.

2.13. **Communication Plan**

The permittee must maintain and implement the Communication Plan dated March 20, 2016. The Communication Plan must demonstrate the sharing of environmental data with the Xatśūll First Nation, the Williams Lake First Nation, the Cariboo Regional District, and the community of Likely. Any changes to the communication plan must be discussed with the Public Liaison Committee and submitted to the director prior to adoption.

2.14. **Public Liaison Committee**

The permittee must maintain a Public Liaison Committee (PLC), in accordance with the approved Terms of Reference dated November 21, 2018. The permittee must submit any Terms of Reference updates to the director for approval 30 days prior to adopting them.

The Committee must meet at least quarterly to share and receive information about mine activities and the results of monitoring programs with interested members of the public, the Xatśūll First Nation, the Williams Lake First Nation, and regulating agencies.

2.15. **Posting of Security**

The permittee must maintain a Reclamation Security as required by *Mines Act* Permit M-200.

2.16. **Metal Contaminated Soil Milling**

Tailings from the processing of metal contaminated soils in the mill from off mine site sources may be discharged to the tailings storage facility subject to all the following:

(a) The soils must be contaminated only with metals.

(b) The permittee must notify the director 14 days prior to receiving these materials at the mine site and provide results of chemical analysis of the material at the time of notification.

(c) Records of the volumes processed must be maintained and reported as part of the annual reporting requirements.

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

2.17 **Qualified Professionals**

All documents submitted to the director must be signed by the author and where specifically required by this permit, authored, and signed by a Qualified Professional.

A “Qualified Professional", in relation to a duty or function under Ministry legislation, means an individual who:

(a) is registered in British Columbia with a professional association, is acting under that organization’s code of ethics, and

(b) through suitable education, experience, accreditation, and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.

3. MONITORING REQUIREMENTS

3.1. Springer-Cariboo Pit Hydrogeology Work Plan and Assessment

3.1.1 The permittee must submit a summary, when requested by and to the satisfaction of the director, of all hydrogeological work that has been completed downgradient of the Springer Pit and Cariboo Pit relevant to the Springer Pit filling and drawdown. The summary must describe all monitoring, modelling, and drilling investigations, and must provide recommendations by a Qualified Professional for additional hydrogeological investigations required to manage water in the pits during any future refilling and for mine closure. Recommendations must consider ongoing collection of water quality and geology data as the mine advances, review of the groundwater monitoring network, and hydrogeological model refinements, as appropriate.

3.1.2 Based on review of the summary, the director may require additional hydrogeological investigation and assessment of the hydrogeology along the seepage path from the Springer-Cariboo Pit to Bootjack Lake. Any additional monitoring recommended in the summary of hydrogeological work or required by the director must be incorporated into updates of the Comprehensive Environmental Monitoring Plan.

3.1.3 The recommendations of the summary of hydrogeological work required above, and all ongoing hydrogeological data collected must be re-assessed as part of the annual reporting requirements under section 4.2 of this permit. This includes an annual update to the characterization of the groundwater system in the area between the pit and the lake,

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

refinements, and updates to the seepage model near the pit and reporting on the groundwater monitoring network near the pit.

3.1.4 In addition, updated results and interpretations of the Springer-Cariboo Pit Hydrogeology Assessment, including an updated calibration and verification of the seepage model near the pit, must be prepared by a Qualified Professional, and must be submitted to the director prior to any planned refilling of Springer Pit above 1025 masl.

3.2. **Comprehensive Environmental Monitoring Plan**

3.2.1 The permittee must continue to develop, submit, and implement an ongoing Comprehensive Environmental Monitoring Plan (CEMP) to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas.

3.2.2 An updated CEMP must be submitted to the director for approval by March 31, 2020, and every three years thereafter.

3.2.3 The permittee must undertake monitoring in accordance with the approved CEMP immediately following its approval.

3.2.4 The CEMP must meet all the following requirements:

(a) Consolidate and integrate all the monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.
(b) At a minimum address, a three-year time span.
(c) At a minimum include all sampling sites, frequency of sampling, variables to be analysed, method detection limits, sampling methods, sample analysis methods, and data analysis methods.
(d) The updated CEMP must be approved by the director.

3.2.5 The permittee must provide all data and information collected under the CEMP to the director, in electronic format, on a quarterly basis.

3.2.6 The permittee must submit a three-year detailed monitoring program interpretive report to the director by March 31, 2022, and every three years thereafter.

3.2.7 During the period of treated effluent discharge authorized by section 1.2 above, the director may require expedited sampling, testing, and

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

reporting of treated effluent discharged during the spring freshet (March through July annually).

3.2.8 The director may require revisions to the CEMP based on review of monitoring data and/or any other relevant information.

3.3. **Effluent Toxicity Testing**

Acute and chronic toxicity testing of discharges to Quesnel Lake authorized under section 1.2 of this permit must be conducted as follows:

Acute Bioassay	**Frequency**	**Source for Sample Collection**
96-hr LC50 Rainbow Trout	Monthly	HAD-03 - Effluent discharged to Quesnel Lake (E304230)
48-hr LC50 Daphnia magna	Monthly	HAD-03 - Effluent discharged to Quesnel Lake (E304230)
Chronic Bioassay	**Frequency**	**Source for Sample Collection**
7-day Ceriodaphnia dubia survival and reproduction, and 7-day ELS toxicity test with a salmonid fish and/or other tests specified by the director	Quarterly or as required by the approved CEMP	as specified in the approved CEMP when discharging direct to Quesnel Lake

3.4. **Water Flow Measurement**

3.4.1 The permittee must provide and maintain suitable flow measuring devices and record staff gauge measurements, during open water, at surface water stations at W1B (Morehead Creek), W4A (North Dump Creek), W5 (Bootjack Creek) W12 (6K Creek), H1 (continuous, Upper Hazeltine Creek), H3 (Edney Creek), H4 (Polley Lake outlet) and H2 (continuous, Lower Hazeltine Creek), located approximately as shown on the attached Site Plan B, or at alternative monitoring stations satisfactory to the director.

3.4.2 Springer Pit water level elevation must be monitored and recorded on a monthly basis.

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

3.4.3 Staff gauge readings must be taken at the same time as stream flow measurements and/or water quality sampling are collected at the same or associated sites.

3.4.4 A stage discharge curve must be developed for all staff gauges.

3.4.5 All staff gauges and flow measuring devices must be checked and calibrated once per year, after June 15th but prior to August 31st of each calendar year.

3.5. **Outfall and Pipeline Commissioning and Inspection**

3.5.1 The permittee must develop and implement a monthly visual inspection program for the pipeline from the Actiflo treatment plant to the outfall in Quesnel Lake. The monthly visual inspection program must include all of the following:

(a) The pipeline corridor must be visually inspected every month.

(b) Records of the monthly visual inspections must be made available for inspection by the Ministry immediately upon request.

3.5.2 The permittee must conduct a comprehensive annual inspection of the pipeline corridor by October 1st of each year.

3.5.3 The permittee must conduct an underwater inspection of the diffusers every 5 years to ensure they remain in good working order.

3.5.4 An annual inspection report with recommended remedial actions must be prepared by a Qualified Professional and submitted to the director within 60 days of completion of the comprehensive inspection.

3.5.5 The pipeline and outfall must have all the following signage:

(a) A sign must be maintained along the alignment of the outfall facing Quesnel Lake above the high water mark.

(b) Signs must identify the nature of works.

(c) Signs must be posted along the effluent pipeline right-of-way at points of public access to identify the right-of-way.

(d) All signs must include emergency contact information.

3.6. **Climate Monitoring**

The permittee must maintain meteorological stations and measure continuous daily precipitation; daily maximum, minimum and mean temperature; and

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

daily evaporation calculation or suitable alternative as approved by the director. Climate Monitoring sites are as shown in Site Plan C.

3.7. Sampling and Analytical Procedures

3.7.1 The permittee must carry out sampling in accordance with the procedures described in the "British Columbia Field Sampling Manual, (2013 Edition)" or most recent edition, or by alternative procedures as authorized by the director.

3.7.2 The permittee must carry out analyses in accordance with procedures described in the "British Columbia Environmental Laboratory Manual (2020 Edition)", or the most recent edition or by alternative procedures as authorized by the director.

Copies of the above manuals are available on the Ministry web page at https://www2.gov.bc.ca/gov/content/environment/research-monitoring-reporting/monitoring/laboratory-standards-quality-assurance/bc-field-sampling-manual

3.7.3 Bioassays must be conducted using the following methods:

(a) The "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Rainbow Trout", Report EPS 1/RM/13 December 2000;

(b) The "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Daphnia magna", Reference Method EPS 1/RM/14 December 2000;

(c) The "Biological Test Method: Toxicity Tests Using Early Life Stages of Salmonid Fish (Rainbow Trout)", Report EPS 1/RM28, July 1998 -Embryo/Alevin;

(d) The "Biological Test Method: Test of Reproduction and Survival Using the Cladoceran Ceriodaphnia dubia", Report EPS l/RM/21, February 2007; or,

(e) By suitable alternative procedures as authorized by the director.

3.8. Quality Assurance

3.8.1 The permittee must maintain and implement a "Quality Assurance Manual" consistent with "British Columbia Field Sampling Manual (2013 Edition)", or most recent edition. The permittee must ensure that all data submitted as a requirement of this permit is produced in accordance with the Quality Assurance Manual, that data is handled and

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

reviewed in accordance with protocols established in the Manual and is accompanied by quality assurance data required by the Manual. The permittee must provide the director with any updates to this Manual within 30 days of adoption.

3.8.2 Analysis of samples for parameters designated under the Environmental Data Quality Assurance Regulation must be at a laboratory registered for the designated parameter under the Regulation. In addition, the permittee must participate in quality assurance audits as required by the Regulation.

4. REPORTING

4.1. Routine Reporting

4.1.1 In each month that discharge occurs as authorized by section 1.2 above, the permittee must submit a monthly report, suitably tabulated in a table, and formatted, to the director summarizing:

(a) The volume of treated effluent discharged,

(b) A summary of continuous Turbidity readings of the treated effluent discharged,

(c) The most recently available water quality results for the effluent discharged, including toxicity test results,

(d) Water quality results compared to the applicable permit limits and objectives specified in Table 1 and/or BC WQGs,

(e) Any exceedances of respective permit limits, objectives and/or BC WQGs must be clearly highlighted, and

(f) Any missed sampling events/missing data must be identified with an explanation provided.

4.1.2 Each monthly report must be submitted within seven days of the end of previous month via email to envauthorizationsreporting@gov.bc.ca. Each monthly report must also contain and present all data submitted in the previous 2 monthly reports in a manner that would identify potential trends.

4.1.3 Each monthly report must also be provided to the Williams Lake First Nation and Xatśūll First Nation and be made available to the Public Liaison Committee.

4.1.4 The permittee must cause each data submission required by this Authorization to include a statement outlining the number of

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

exceedances of permitted discharges that occurred during the reporting period, the dates of each such exceedance, an explanation as to the cause of the exceedances, and a description of the measures taken by the permittee to rectify the cause of each such exceedance. If no exceedances occurred over the reporting period, the required statement may instead indicate that no exceedance of permitted discharges occurred during the reporting period.

4.1.5 The permittee must submit all data required to be submitted under this section by email to envauthorizationsreporting@gov.bc.ca or as otherwise instructed by the director. For guidelines on how to properly name the files and email subject lines or for more information visit the Ministry website: https://www2.gov.bc.ca/gov/content/environment/waste-management/waste-discharge-authorization/data-and-report-submissions/routine-environmental-reporting-submission-mailbox

4.1.6 The director may require modification to the monitoring program based on the evaluation of the monthly and annual reports and on any other information that pertains to the operations and/or discharges.

4.1.7 The permittee must upload monitoring data associated with this permit to the Ministry's Environmental Monitoring System (EMS) database, within 45 days of the end of the three-month period in which the data is collected.

4.2. **Annual Report**

4.2.1 The permittee must also submit by March 31st of each year, a comprehensive annual report of all monitoring via email to the above email address, in a format suitable for public release. The annual report must include:

(a) All monitoring sample results required under the permit,

(b) Evaluation of quality assurance, including collection, sampling, and data handling protocols,

(c) Water quality results from HAD-3 and QUL-58 compared to the applicable permit limits and objectives specified in Table 1, and BC WQGs,

(d) Any exceedances of respective permit limits, objectives and/or BC WQGs must be clearly highlighted,

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

(e) Any missed sampling events/missing data must be identified with an explanation provided,

(f) Evaluation of the treatment plant operation and control,

(g) Evaluation of the impacts of the mining operation on the receiving environment from the previous year,

(h) Summary of any non-compliance with the permit and other incidents that may have led to impacts to the receiving environment,

(i) Updates of the water balance, and a calibration assessment of the water balance and water quality models,

(j) Assessment of the outfall dispersion and dispersion modelling for the Quesnel Lake discharge,

(k) Update to any modeling relating to the Springer Pit groundwater seepage and its impacts on Bootjack Lake as described in section 3.1,

(l) Review and update of the assessment of acid rock drainage (ARD) potential and water quality impacts from mine waste management,

(m) Comparison of monitoring data with water quality guidelines, predictions, and targets,

(n) Update on the progress of reclamation and any updates to the reclamation plan that impact on site water quality,

(o) Evaluation of the effectiveness of the Surface Runoff and Mine Drainage Control programs,

(p) Summary of the Public Liaison Committee meetings, including any issues and concerns presented,

(q) Evaluation of the Outfall and Pipeline Inspection program,

(r) Trend analysis (graphs) of water monitoring data at each site for the past 5 years, and,

(s) Assessment of attainment of the NPM target value:

i. Using the HAD-3 monitoring data, evaluate the average annual effluent quality and trends as defined in section 2.11.2 (c),

ii. If the average annual effluent quality exceeds the NPM target value or if trend suggest NPM target value may be

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

exceeded within the next annual review cycle, provide an explanation of the most probable cause(s),

iii. Summary of proposed response action(s), and

iv. Progress update with respect to implementation of any response action(s).

4.2.2 Monitoring data and the analysis of that data, as it will be presented in the annual report, must be reviewed by a third party Qualified Professional.

4.2.3 A groundwater monitoring program review, including but not limited to sampling, well locations, site water balance, interpretation of data trends and possible environmental impacts, and suitable recommendations, must be completed for the entire mine site at least every three years, with the next review required by March 31, 2025.

4.2.4 A copy of the annual report must be provided to the Williams Lake First Nation, Xatśūll First Nation and the Public Liaison Committee within 30 days of the report being submitted to the director.

4.3 Veracity of Data

The permittee must ensure that all information submitted as a requirement of this permit is accurate and free from mistakes or misleading statements. The permittee must include in any submission required under this permit an explanation for any data that:

(a) Is required under the permit but is missing from the submission, and

(b) The permittee considers to be not representative of the actual discharge, conditions, or other circumstances the data is intended to measure.

4.4. Non-compliance Reporting

4.4.1 The permittee must immediately notify the director or designate of any non-compliance with the requirements of this permit and take appropriate remedial action. Written confirmation of all non-compliance events, including available test results is required within 24 hours of the original notification unless otherwise directed by the director.

4.4.2 Both the initial notice and the confirmation must also be emailed to EnvironmentalCompliance@gov.bc.ca.

4.4.3 Within 30 days of any non-compliant event, the permittee must submit a follow-up report to the director and the above mailbox that includes, but not limited to the following:

Date issued: May 30, 1997
Date amended: December 1, 2022
(most recent)

Luc Lachance, P.Eng
for Director, *Environmental Management Act*

(a) All relevant test results related to the non-compliance instance(s),

(b) An explanation of the most probable cause(s) of the non-compliance(s); and,

(c) Remedial actions taken and planned to prevent similar non-compliance(s).

4.4.4 A copy of the initial compliance notice, written confirmation and follow-up report must also be provided to the Williams Lake First Nation, Xatśūll First Nation, and the Public Liaison Committee.

4.5 **Reporting of Toxicity Failure**

4.5.1 The permittee must immediately notify the director of any toxicity failure according to the Non-Compliance Reporting requirements in section 4.4. For the purpose of this section, a sample is considered to have failed the specific toxicity test if:

(a) 96-hr LC50 Rainbow Trout: Using 100% effluent concentration, more than 50% of the fish die within a 96 hour test period,

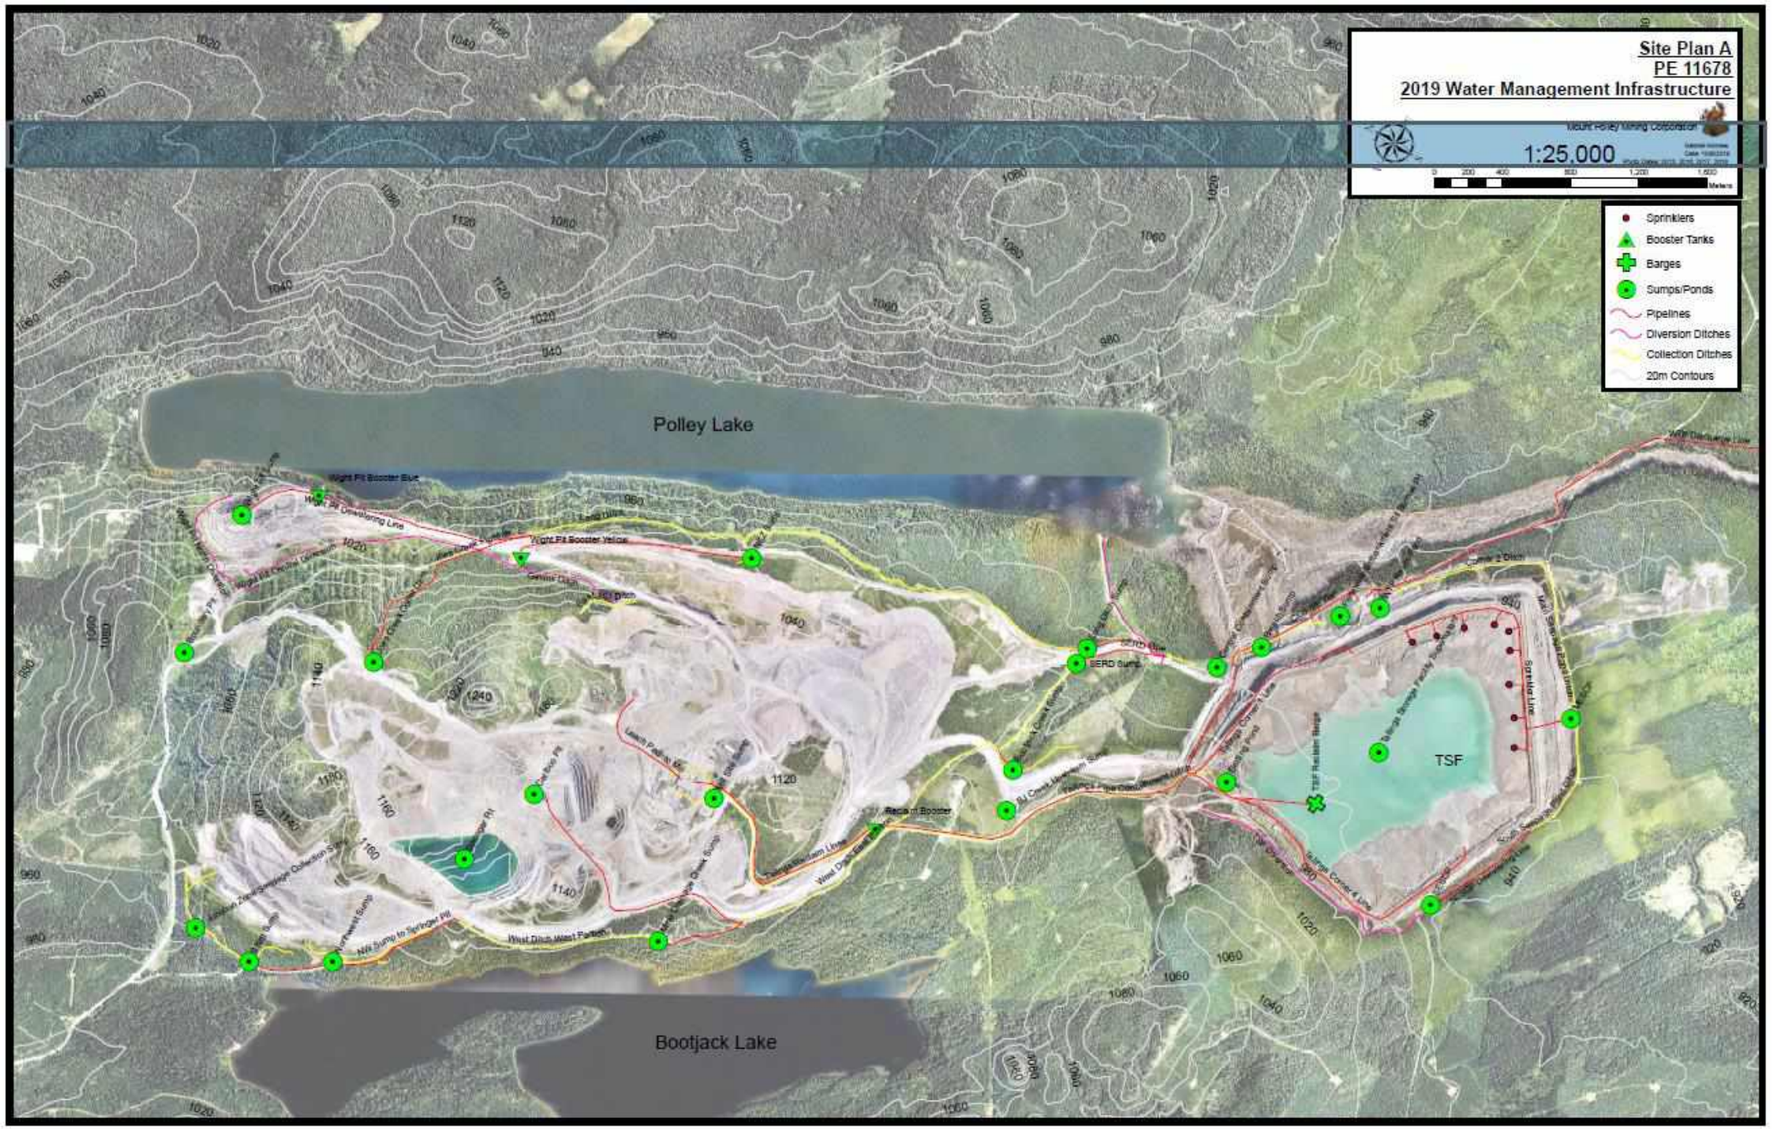
(b) 48-hr LC50 Daphnia magna: Using 100% effluent concentration, more than 50% of the organisms die within a 48 hour test period,

(c) 7-day Ceriodaphnia dubia reproduction: The water is determined to cause greater than 25% inhibition of survival and reproduction; or,

(d) 7-day ELS toxicity test with a salmonid fish: The water is determined to cause greater than 25% non-viable embryos.

4.5.2 The permittee must investigate each toxicity failure to determine the cause(s). Reasonable efforts must be made to obtain preliminary and in progress results from the analytical laboratory during the toxicity testing. The permittee must make immediate arrangements to retest in the event of potential and confirmed failures. The director may require additional toxicity testing based on the evaluation of results from toxicity testing and the causes of failure.

4.6. **Other Documents**



All documents to be submitted to the director must be sent as a separate document and named according to the name listed in this permit. The documents must be submitted to envauthorizationsreporting@gov.bc.ca or as otherwise instructed by the director.

Annual Status Report

Annual Status Form

AUTHORIZATION NUMBER: 11678

AUTHORIZATION TYPE: Effluent, Permit

LEGAL AUTHORIZATION HOLDER NAME: Mount Polley Mining Corporation

AUTHORIZED PERSON NAME: Alicia Lalonde

AUTHORIZED PERSON SIGNATURE: 

SIGNATURE DATE: March 31, 2024

I understand that it is an offense to mislead a government official, and I declare that all of the information presented is accurate and true.
I have been given the authority by the authorization holder to sign this form.

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
1.1.1	The monthly average rate of discharge tailings slurry is 55,500 cubic metres per day.	Yes	N/A
1.1.2	The authorized discharge period is continous.	Yes	N/A
1.1.3	The characteristics of the discharge must be typical concentrator tailings from the milling of ore or metal contaminated soil, mill site runoff, rock disposal site runoff, open pit water, and septic tank effluent from a copper-gold mine and mill complex.	Yes	N/A
1.1.4	The authorized Works are the following: a septic tank, tailings discharge line, open pits, tailings storage facility, water treatment and discharge system, seepage collection and recycle system, surface water collection works, tailings supernatant recycle systems; sediment pond(s); and related appurtenances located approximately as shown on Site Plan A.	Yes	N/A
1.1.5	The location of the facilities from which the discharge originates is within Mineral Leases No. 345731, No. 410495, No. 524068, No. 573346, No.933970, and No.933989 as well as Mineral Claims No. CB16 204475, No. PM5 206540, No. POL2 411010, No. 514039 and No. 514044, Cariboo Mining Division, Cariboo Land District.	Yes	N/A
1.1.6	The location of the point of discharge (tailings storage facility) is on Mineral Claim No. 514039, Cariboo Mining Division, Cariboo Land District.	Yes	N/A
1.2.1	The authorized annual average rate of discharge is 29,000 m^3/day.	Yes	Discharge commenced January 2023; see Section 4.12

Authorized Person Initial:_____ Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
1.2.2	The maximum rate of discharge is 52,000 m^3/day.	Yes	Discharge commenced January 2023; see Section 4.12
1.2.3	The discharge period is authorized until June 30, 2025.	Yes	N/A
1.2.4	The characteristics of the discharge at the treatment plant outlet must be equivalent to or less than the values specified in column 2 of Table 1.	Yes	There were no exceedances in 2023; see Section 4.12.2.4
1.2.5	The Annual Discharge Plan required under Section 2.8 must show how the concentrations of the parameters meet the objectives for the "Edge of Quesnel Lake Initial Dilution Zone (IDZ)" in Quesnel Lake as specified in column 3 of Table 1.	Yes	N/A
1.2.6	The Permittee must implement the response steps set out in the approved trigger response plan under Section 2.8(e) without delay if either: a) the effluent monitoring at the outlet of the treatment plant indicates that trigger levels set out in the approved trigger response plan are reached for any parameter in Table 1 or; b) An objective set for the Edge of Quesnel Lake IDZ in Table 1 is exceeded, or is predicted to be exceeded, as determined in accordance with procedures in the approved trigger response plan. Where the Permittee must cease discharging, the discharge may resume only in accordance with the approved trigger response plan. The requirement to implement the trigger response plan does not authorize an exceedance of the maximum values specified in Section 1.2.4 for the characteristics of the discharge at the outlet of the treatment plant.	Yes	Trigger response plans are included in the approved Annual Discharge Plan
1.2.7	The discharge is authorized from the Authorized Works, which are the settling pond(s), tailings storage facility, mine contact water collection system, the Veolia Actiflo treatment system, flow control valve(s), continuous flow meter, pipeline and outfall system and associated appurtenances as generally shown in the Site Plans.	Yes	N/A
1.2.8	The location of the facilities from which the discharge originates is the same as in Section 1.1.5.	Yes	N/A
1.2.9	The location of the discharge is the Quesnel Lake outfall at a point within Mineral Claim No. 501479 when discharging to Quesnel Lake.	Yes	N/A
1.3.1	The Permittee must maintain Springer Pit water levels at less than 1,025 meters above sea level (masl) to limit seepage towards Bootjack Lake.	Yes	The Springer Pit did not exceed 1,025 masl in 2023
1.3.2	The characteristics of the discharge must be typical of site runoff and seepage water.	Yes	N/A
1.3.3	The authorized works are Springer Pit, and its associated water management works and related appurtenances.	Yes	See Section 3.3
1.3.4	The location of the facilities from which the discharge originates and the point of discharge are shown in Site Plan A.	Yes	N/A
2.1.1	The authorized works must be inspected regularly and maintained in good working order. In the event of an emergency or condition beyond the control of the Permittee which prevents effective operation of the authorized works or leads to an unauthorized discharge, the Permittee must take appropriate remedial action and notify the Director immediately. The Director may require the Permittee to reduce or suspend operations to protect the environment until the authorized works have been restored, and/or corrective steps taken to prevent unauthorized discharges.	Yes	One unauthorized discharged occurred in 2023. See Section 3.7.2.

Authorized Person Initial:_____

Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
2.1.2	All ponds, ditching, and other runoff or seepage collection and diversion works must be inspected at least twice per year, once in the spring after freshet and once in the fall before freeze-up. Records of these inspections must be maintained and made available for inspection by the Ministry immediately upon request.	Yes	See Section 3.3.6
2.1.3	The authorized works must be complete and in operation while discharging.	Yes	N/A
2.2	Any bypass of the authorized works is prohibited unless prior approval of the Director is obtained and confirmed in writing.	Yes	One unauthorized discharged occurred in 2023. See Section 3.7.2.
2.3	The Director must be notified prior to implementing changes to any process that may adversely affect the quality and/or quantity of the authorized discharges. Despite notification under this section, permitted levels must not be exceeded.	Yes	N/A
2.4.1	Unless required for operational purposes, surface runoff from undisturbed areas and groundwater pumped from up gradient of pits or other undisturbed areas, must be diverted so that it does not flow to the tailings storage facility, or to the mine and mill areas.	Yes	N/A
2.4.2	Seepage and runoff from the open pits, rock disposal sites, and from down gradient of the tailings storage facility must be collected and conveyed to treatment works, the tailings storage facility, mill or open pits.	Yes	N/A
2.4.3	Inactive open pits may be used for storage of mine water, tailings storage facility supernatant or mill site runoff, provided records of volumes transferred to any pit are maintained and reported quarterly.	Yes	N/A
2.4.4	Recycling of on-site water and evaporation enhancing techniques must be practiced.	Yes	N/A
2.4.5	Surface water control works must be provided for all areas disturbed by roads, open pits, rock disposal/storage sites, the mill site and ore storage sites. The surface water control works must convey all flows up to a 1 in 10 year 24-hour storm event, and must designed to withstand all flows up to a 1 in 200 year 24-hour storm event, without significant damage.	Yes	See Sections 3.3 and 3.3.6
2.4.6	The tailings storage facility must provide adequate storage, beach width and freeboard as required by Mines Act Permit M-200.	Yes	N/A
2.5.1	In the event that the Permittee reports an incident to the Director that is the result of a storm event that is considered to exceed the 1 in 10 year 24 hour storm event or 1 in 200 year 24 hour storm event, the Permittee must cause a Qualified Professional to complete a flow analysis to demonstrate the estimated magnitude and corresponding return period of the storm event.	Yes	N/A
2.5.2	The flow analysis must be submitted to the Director 60 days following the reporting of the storm event.	Yes	N/A
2.5.3	The Permittee must provide all available supporting information used in the flow analysis, including but not limited to: (a) Date, time and duration of storm event, (b) Total precipitation measured during storm event including source of data, (c) Available measured flow data including source of data (d) Map showing the site watershed location and drainage area (in km2) in proximity to any relevant regional watershed used in the return period flow analysis, and (e) Any other applicabale supporting information.	Yes	N/A

Authorized Person Initial:_____ Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
2.6.1	The Permittee must maintain and implement the most recent version of the Erosion and Sediment Control Plan (ESCP) dated December 7, 2021. The objective of the ESCP is to outline management practices to prevent erosion and minimize transport of sediment laden water to the receiving environment that could result in exceedances at monitoring stations of water quality guidelines for aquatic life for non-filterable residue (Total Suspended Solids) in British Columbia Approved Water Quality Guidelines (BC WQGs): Aquatic Life, Wildlife & Agricultures (2021 version) or most recent version.	Yes	N/A
2.6.2	The Permittee must cause and Qualified Professional to conduct a review of the ESCP and develop an ESCP Review Report based on the findings of the review. The first review must be conducted in 2023 and then every five years thereafter or earlier if proposed change(s) to the ESCP may affect the quality and/or quantity of the authorized discharges, as stated in section 2.3 of this permit. The Permittee must submit the ESCP Review Report as part of the annual report required by section 4.2 for the year in which the review was required to be conducted.	Yes	The ESCP Review Report is included in Appendix X.
2.6.3	The ESCP Review Report must include, but is not limited to: (a) An assessment of whether the ESCP methods being employed on site are being undertaken in accordance with the most recent ESCP, (b) As assessment of the effectiveness of the ESCP in achieving the objective of the plan, (c) Recommended improvements to the ESCP, and (d) Any comments, recommendations, or observations the Qualified Professional considers would be relevant to achieving the objective of the plan.	Yes	The ESCP Review Report is included in Appendix X.
2.6.4	The Permittee must cause a Qualified Professional to update the ESCP based on the recommended modifications included in the ESCP Review Report and submit the updated ESCP to the Director within 90 days of submissions of the annual report that included the ESCP Review Report. The Permittee must provide justification where any of the recommended modifications have not been included in the updated ESCP as part of a cover letter for the updated ESCP.	Yes	Recommended modifications will be made to the ESCP by the QP within 90 days of annual report submission.
2.6.5	The Permittee must maintain the most recent approved version of the ESCP onsite for inspection by the Ministry.	Yes	N/A
2.6.6	The Permittee must cause a Qualified Professional to modify or amend the ESCP as required by the Director and the Permittee must, within timeframe specified by the Director, resubmit to the Director the ESCP with required modifications or amendments.	Yes	N/A
2.7.1	The Permittee must maintain and implement an up to date Environmental Emergency Response Plan by January 31st of each year. The Environmental Emergency Response Plan must include all of the following: a) adequate procedures for responding to all probable environmental emergencies, including spills, b) permit exceedances associated with the Mount Polley Mine operations and mine site area, c) procedures for the suspension of the effluent discharge to Quesnel Lake and d) a notification protocol for immediate advising the Xatsull First Nation, Williams Lake First Nation, the Cariboo Regional District, and the community of Likely of significant emergency events, and permit exceedances at the mine site.	Yes	Submitted October 18, 2018 and maintained in 2023
2.7.2	The Permittee must ensure mine personnel are trained on the contents of the Emergency Response Plan and it is reviewed annually.	Yes	The Environmental Emergency Response Plan was reviewed in 2023.

Authorized Person Initial:_____

Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
2.8.1	The Permittee must maintain and implement an Annual Discharge Plan approved by the Director for the discharge authorized in section 1.2. The plan must include the following: (a) An outline of the expected volume, timing, and duration of effluent released to Quesnel Lake, (b) Consideration and account of hydrology and snowpack information, mine water balance information, Polley Lake discharge control, and background water quality information, (c) Demonstrate how the objectives, set out in column 3 of Table 1, will be met at the edge of the IDZ in Quesnel Lake, (d) A maximum turbidity target(s), as measured at the outlet of the treatment plant, which requires immediate reporting to the Director should the turbidity target(s), be exceeded for longer than one hour in duration, (e) A trigger response plan for treatment system shutdown(s), and/or for suspension or reduction of discharge, and for the resumption of the discharge, if the effluent discharge limits at the outlet of the treatment plant cannot be met, or if the objectives for the Edge of Quesnel Lake IDZ in Quesnel Lake cannot be met, (f) Identification of the sources of mine water and the percent of each source in the total effluent discharge for each day, (g) Demonstrate how the discharge will be managed to minimize suspended solids deposition into Quesnel Lake, and, (h) Identification of equipment, including calibration and maintenance schedules related to continuous measurements of flow, turbidity, specific conductance and temperature.	Yes	N/A
2.8.2	The Annual Discharge Plan must be reviewed at least once each year, and any necessary updates submitted to the Director for approval at least 30 days prior to adoption.	Yes	The Annual Discharge Plan was reviewed in 2023.
2.9	The Permittee must maintain and implement a Nitrogen Management Plan developed by a Qualified Professional. The plan must describe measures that prevent the loss of nitrogen species into the environment arising from the use of explosives and handling of waste rock. Any update to the plan must be provided to the Director within 30 days of implementation.	Yes	N/A
2.10.1	The Permittee must cause a Qualified Professional to develop a Flocculant Management Plan (FMP) for the Veolia Actiflo treatment system, and the Permittee must submit the FMP to the Director by March 31, 2023. The objective of the FMP is to describe the method for settling of solids while optimizing the use of coagulants and/or flocculants (settling aids) and limiting potential detrimental effects such as toxicity in the receiving environment.	Yes	The FMP was submitted on March 31, 2023.
2.10.2	The FMP must include, but is not limited to: (a) A clear objective statement, (b) A list of settling aids used and safety data sheets for each settling aid, (c) Identification of locations where settling aids are applied, (d) Description of works used for adding settling aids to waste streams, (e) A plan for ensuring that sufficient inventory of settling aids is on site while avoiding excessive quantities of hazardous chemicals being on site and avoiding settling aids from becoming less effective due to age, (f) Application rates at all locations for which settling aids are used and how toxicity in the discharge will be prevented, (g) Justification for choice in settling aids and associated management works, (h) Defined inspection schedule for works used to manage settling aids, (i) Defined monitoring procedures; including inflow rates, outflow rates and dosing applications, (j) Monitoring procedures of the influent and effluent to determine appropriate application rates, and (k) Defined procedures for determining when settling aids will be used and when their use must be terminated, or dosages adjusted.	Yes	N/A
2.10.3	The Permittee must implement the most recent version of the FMP.	Yes	N/A
2.10.4	The Permittee must cause a Qualified Professional to conduct a review of the FMP every 5 years with the first review to be conducted in 2028 and develop an FMP Review Report based on the findings of the FMP review. The Permittee must submit the FMP Review Report as part of the annual report required in section 4.2 for the year in which the review was required to be conducted.	Yes	N/A

Authorized Person Initial:_____ Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
2.10.5	The FMP Review Report must include, but is not limited to: (a) An assessment of whether the settling aid management methods being employed on site are being undertaken in accordance with the most recent FMP, (b) An assessment of the monitoring data to evaluate whether the objective of the FMP is being met, (c) Recommended improvements to the FMP in achieving the objective of the plan, and (d) Any comments, recommendations, or observations the Qualified Professional considers relevant to achieving the objective of the plan.	Yes	N/A
2.10.6	The Permittee must cause a Qualified Professional to update the FMP based on the recommended updates included in the FMP Review Report and submit to the Director within 90 days of submission of the annual report that included the FMP Report. The Permittee must provide justification where any of the recommended updates have not been included in the updated FMP as part of a cover letter for the FMP.	Yes	N/A
2.10.7	The Permittee must maintain the most recent approved version of the FMP onsite for inspection by the Ministry.	Yes	N/A
2.10.8	The Permittee must cause a Qualified Professional to modify or amend the FMP as required by the Director and the Permittee must, within timeframe specified by the Director, resubmit to the Director the FMP with required modifications or amendments.	Yes	N/A
2.11/2.11.1	The Permittee must undertake a program to investigate new and/or improved treatment technologies and develop a water treatment and discharge program for all mine site water treatment works and source control optimization activities which includes the following: Best Achievable Technology (BAT) Assessment a) The Permittee must undertake a BAT assessment of any treatment technologies identified in the Water Management Plan dated November 27, 2020 or any new and/or improved treatment technologies retained for permitting. The Permittee must submit to the Director for approval by January 31st of each year a study plan that details bench and pilot scale testing that will be undertaken.	Yes	The 2023 BAT Assessment Plan was submitted on January 31, 2023.
2.11.2	The Permittee must operate and optimize the performance of the Veolia Actiflo Water Treatment Plant (WTP) to remove contaminants present in the mine site contact water to meet the discharge requirements of section 1.2.4. (a) "Numeric Performance Metric" (NPM) means a measurable value that quantifies the outcome or result of water treatment and the ability of the treatment to remove specified chemical constituent(s). It forms the basis for a numeric comparison of untreated water, to water that has been treated by the treatment system. b) The Permittee must operate and optimize the design and performance of the WTP to target achievement of any prescribed NPM. The stated NPM target value represents WTP operation that achieves annual average effluent quality that is at or below any specified NPM. Assessment of the attainment of NPM values must be reported in an annual optimization update progress report appended to the annual report required in section 4.2. If the effluent quality does not achieve an NPM value specified by the Director, the Permittee must identify and propose response actions to bring the effluent quality toward meeting the target	Yes	See Section 4.12.1.1 and Progress Reports #12 and #13 included in Appendix W.
2.11.3	The Permittee must undertake ongoing maintenance and surveillance of on-site water management systems and activities undertaken to increase source control of any potential contaminants of concern. a) The Permittee must undertake source control optimization yearly. b) The Permittee must undertake an analysis of the treatment plant effluent to determine selenium species present and at a minimum determine the typical proportion of total selenium that is selenate, selenite and organoselenium. Based on these results the Director may require additional analysis for selenium speciation of mine source waters.	Yes	N/A

Authorized Person Initial:_____ Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
2.11.4	The Permittee must review discharge alternatives for direct discharge of treated mine water on and around the mine site considering the following mine phases: operations, care and maintenance, closure, and post-closure. The review of discharge alternatives must include consideration of: a) Passive and semi-passive water treatment options for distributed discharges across the mine site informed by the Water Management Plan dated November 27, 2020, and most recent Reclamation and Closure Plan for the site, (b) Physical (geomorphological and hydrological), chemical, and biological characteristics of potential receiving environments, and (c) The capacity of the proposed discharge locations to receive the additional discharges of treated water and meet applicable environmental benchmarks.	Yes	N/A
2.12	The Permittee must report to the Director on all aspects of section 2.11 every 6 months, beginning June 30, 2020, and continuing until such time as the Director deems the reporting no longer required. The report must include, but is not limited to: (a) The results of all BAT assessments, (b) Bench and pilot testing of treatment systems, (c) Progress on implementation of response action(s) for attainment of the NPM target value, (d) Source control optimization studies, (e) Summary and discussion of proposed discharge locations that have the capacity to receive the treated water and changes from the previous progress reports, (f) Documentation that the testing and piloting programs are relevant for the different types of mine influenced water on site, and (g) Any other studies related to the Water Treatment and Discharge Program outlined in section 2.11.	Yes	See Progress Reports #12 and #13 included in Appendix W.
2.13	The Permittee must maintain and implement the Communication Plan dated March 20, 2016. The Communication Plan must demonstrate the sharing of environmental data with the Xatsull First Nation, the Williams Lake First Nation, the Cariboo Regional District, and the community of Likely. Any changes to the plan must be discussed with the Public Liaison Committee and submitted to the Director prior to adoption.	Yes	N/A
2.14	The Permittee must maintain a Public Liaison Committee (PLC), in accordance with the approved Terms of Reference dated November 21, 2018. The Permittee must submit any Terms of Reference updates to the Director for approval 30 days prior to adopting them. The Committee must meet at least quarterly to share and receive information about mine activities and the results of monitoring programs with interested members of the public, Xatsull First Nation, the Williams Lake First Nation, and regulating agencies.	Yes	2023 PLC meeting minutes are included in Appendix C.
2.15	The Permittee must maintain a Reclamation Security as required by Mines Act Permit M-200.	Yes	N/A
2.16	Tailings from the processing of metal contaminated soils in the mill from off mine site sources may be discharged to the tailings storage facility subject to the following: a) The solids must be contaminated only with metals b) The Permittee must notify the Director 14 days prior to receiving these materials at the mine site and and provide results of chemical analysis of the material at the time of notification. c) Records of the volumes processed must be maintained and reported as part of the annual reporting requirements	Yes	N/A
2.17	All documents submitted to the Director must be signed by the author and where specifically required by this permit, authored, and signed by a Qualified Professional. A "Qualified Professional", in relation to a duty or function under Ministry legislation, means an individual who: (a) Is registered in BC with a professional association, is acting under that organization's code of ethics, and (b) through suitable education, experience, accreditation and knowledge, may reasonably be relied on to provide advice within his or her area of expertise, which area of expertise is applicable to the duty or function.	Yes	See Section 1.4

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
3.1.1	The Permittee must submit a summary, when requested by and to the satisfaction of the Director, of all hydrogeological work that has been completed downgradient of the Springer Pit and Cariboo Pit relevant to the Springer Pit filling and drawdown. The summary must describe all monitoring, modelling, and drilling investigations, and must provide recommendations by a Qualified Professional for additional hydrogeological investigations required to manage water in the pits during any future refilling and for mine closure. Recommendations must consider ongoing collection of water quality and geology data as the mine advances, review of the groundwater monitoring network, and hydrogeological model refinements, as appropriate.	Yes	N/A
3.1.2	Based on the review of the summary, the Director may require additional hydrogeological investigation and assessment of the hydrogeology along the seepage path from the Springer-Cariboo Pit to Bootjack Lake. Any additional monitoring recommended in the summary of hydrogeological work, or required by the Director must be incorporated into updates of the Comprehensive Environmental Monitoring Plan.	Yes	N/A
3.1.3	The recommendations of the summary of hydrogeological work required above, and all ongoing hydrogeological data collected must be re-assessed as part of the annual reporting requirements under section 4.2 of this permit. This includes an annual update to the characterization of the groundwater system in the area between the pit and the lake, refinements and updates to the seepage model near the pit, and reporting on the groundwater monitoring network near the pit.	Yes	See Section 4.9 and Appendix G
3.1.4	In addition, updated results and interpretations of the Springer-Cariboo Pit Hydrogeology Assessment, including an updated calibration and verification of the seepage model near the pit, must be prepared by a Qualified Professional, and must be submitted to the Director prior to any planned refilling of Springer Pit above 1,025 masl.	Yes	N/A
3.2.1	The Permittee must continue to develop, submit and implement an ongoing Comprehensive Environmental Monitoring Plan (CEMP) to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River and associated riparian and upland areas.	Yes	An updated CEMP was submitted on October 31, 2019 and was approved on February 10, 2021. A CEMP update was submitted on March 21, 2023 and is undergoing review.
3.2.2	An updated CEMP must be submitted to the Director for approval by March 31, 2020, and every three years thereafter.	Yes	A CEMP update was submitted on March 21, 2023 and is undergoing review.
3.2.3	The Permittee must undertake monitoring in accordance with the approved CEMP immediately following its approval.	Yes	N/A
3.2.4	The CEMP must meet all the following requirements: a) Consolidate and integrate all of the monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife. b) At a minimum address a three year time span. c) At a minimum include all sampling sites, frequency of sampling, variables to be analysed, method detection limits, sampling methods, sample analysis methods, and data analysis methods. d) The updated CEMP must be approved by the Director.	Yes	N/A
3.2.5	The Permittee must provide all data and information collected under the CEMP to the Director, in electronic format, on a quarterly basis.	Yes	N/A
3.2.6	The Permittee must submit a three-year detailed monitoring program interpretive report to the Director by March 31, 2022, and every three years thereafter.	Yes	N/A
3.2.7	During the period of treated effluent discharge authorized by section 1.2 , the Director may require expedited sampling, testing and reporting of treated effluent discharged during the spring freshet (March through July annually).	Yes	N/A

Authorized Person Initial:_____ Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
3.2.8	The Director may require revisions to the CEMP based on review of monitoring data and/or any other relevant information.	Yes	N/A
3.3	Acute and chronic toxicity testing of discharges to Quesnel Lake authorized under section 1.2 of this permit must be conducted as follows: Acute Bioassay : 96-hr LC50 Rainbow Trout and 48-hr LC50 Daphnia magna at HAD-03 Monthly (when effluent discharged to Quesnel Lake). Chronic Bioassay: 7-day Ceriodaphnia dubia survival and reproduction and 7-day ELS toxicity test with salmonid fish and or other tests specified by the Director Quarterly or as specified in the approved CEMP when discharging directly to Quesnel Lake.	Yes	See Section 4.12.3
3.4.1	The Permittee must provide and maintain suitable flow measuring devices and record staff gauge measurements, during open water, at surface water stations W1b (Morehead Creek), W4A (North Dump Creek), W5 (Bootjack Creek) W12 (6K Creek), H1 (continuous, Upper Hazeltine Creek), H3 (Edney Creek), H4 (Polley Lake outlet) and H2 (continuous, Lower Hazeltine Creek), located approximately as shown on Site Plan B, or at alternative monitoring stations satisfactory to the Director.	Yes	See Section 4.8
3.4.2	Springer Pit water level elevation must be monitored and recorded on a monthly basis.	Yes	See Table 3.3
3.4.3	Staff gauge readings must be taken at the same time as stream flow measurements and/or water quality sampling are collected at the same or associated sites.	Yes	See Section 4.8
3.4.4	A stage discharge curve must be developed for all staff gauges.	Yes	See Section 4.8 and Appendix L
3.4.5	All staff gauges and flow measuring devices must be checked and calibrated once per year, after June 15th but prior to August 31st of each calendar year.	Yes	See Section 4.8
3.5.1	The Permittee must develop and implement a monthly visual inspection program for the pipeline from the Actiflo treatment plant to the outfall in Quesnel Lake. The monthly visual inspection program must include all of the following: a) The pipeline corridor must be visually inspected every month. b) Records of the monthly visual inspections must be made available for inspection by the Ministry immediately upon request.	Yes	See Section 4.12.1.3
3.5.2	The Permittee must conduct a comprehensive annual inspection of the pipe line corridor by October 1st of each year.	Yes	See Section 4.12.1.3
3.5.3	The Permittee must conduct an underwater inspection of the diffusers every 5 years to ensure they remain in good working order.	Yes	The diffusers were inspected on November 2, 2023.
3.5.4	An annual inspection report with recommended remedial actions must be prepared by a Qualified Professional and submitted to the Director within 60 days of completion of the comprehensive inspection.	Yes	See Section 4.12.1.3
3.5.5	The pipeline and outfall must have the following signage: a) A sign must be maintained along the alignment of the outfall facing Quesnel Lake above the high water mark. b) Signs must identify the nature of the works. c) Signs must be posted along the effluent pipeline right-of-way at points of public access to identify the right-of-way. d) All signs must include emergency contact information.	Yes	N/A
3.6	The Permittee must maintain meteorological stations and measure continuous daily precipitation; daily maximum, minimum and mean temperature; and daily evaporation calculation or suitable alternative as approved by the Director. Climate Monitoring sites are shown in Site Plan C.	No	Both weather stations did not run continuously in 2023; see Section 4.6
3.7.1	The Permittee must carry out sampling in accordance with the procedures described in the "British Columbia Field Sampling Manual 2013 Edition", or most recent edition, or by alternative procedures as authorized by the Director.	Yes	See Section 4.3

Authorized Person Initial:_____ Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
3.7.2	The Permittee must carry out analyses in accordance with procedures described in the "British Columbia Environmental Laboratory Manual (2020 Edition)", or the most recent edition, or by alternative procedures as authorized by the Director.	Yes	N/A
3.7.3	Bioassays must be conducted using the following methods: a) The "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Rainbow Trout", Report EPS 1/RM/13 December 2000; b) The "Biological Test Method: Reference Method for Determining Acute Lethality of Effluents to Daphnia magna", Reference Method EPS 1/RM/14 December 2000; c) The "Biological Test Method: Toxicity Tests Using Early Life Stages of Salmonid Fish (Rainbow Trout)", Report EPS 1/RM28, July 1998 -Embryo/Alevin; d) The "Biological Test Method: Test of Reproduction and Survival Using the Cladoceran Ceriodaphnia dubia", Report EPS l/RM/21, February 2007; or e) By suitable alternative procedures as authorized by the Director.	Yes	N/A
3.8.1	The Permittee must maintain and implement a "Quality Assurance Manual" consistent with "British Columbia Field Sampling Manual (2013 Edition)", or most recent edition. The Permittee must ensure that all data submitted as a requirement of this permit is produced in accordance with the Quality Assurance Manual, that data is handled and reviewed in accordance with protocols established in the Manual, and is accompanied by quality assurance data required by the Manual. The Permittee must provide the Director with any updates to this Manual within 30 days of adoption.	Yes	N/A
3.8.2	Analysis of samples for parameters designated under the Environmental Data Quality Assurance Regulation must be at a laboratory registered for the designated parameter under the Regulation. In addition, the Permittee must participate in quality assurance audits as required by the Regulation.	Yes	N/A
4.1.1	In each month that discharge occurs as authorized by section 1.2, the Permittee must submit a monthly report, suitably tabulated in a table and formatted, to the Director summarizing: a) The volume of treated effluent discharged, b) A summary of continuous Turbidity readings of the treated effluent discharged, c) The most recently available water quality results for the effluent discharged, including toxicity test results, d) Water quality results compared to the applicable permit limits and objectives specified in Table 1 and/or BC WQGs, e) Any exceedance of respective permit limits, objectives and/or BC WQGs must be clearly highlighted, and f) Any missed sampling events/missing data must be identified with an explanation provided.	Yes	N/A
4.1.2	Each monthly report must be submitted within seven days of the end of previous month via email to EnvAuthorizationsReporting@gov.bc.ca . Each monthly report must also contain and present all data submitted in the previous 2 monthly reports in a manner that would identify potential trends.	Yes	N/A
4.1.3	Each monthly report must also be provided to the Williams Lake First Nation and Xatsull First Nation, and be made available to the Public Liaison Committee.	Yes	N/A
4.1.4	The Permittee must cause each data submission required by this Authorization to include a statement outlining the number of exceedances of permitted discharges that occurred during the reporting period, the dates of each such exceedance, an explanation as to the cause of the exceedances, and a description of the measures taken by the Permittee to rectify the cause of each exceedance. If no exceedances occurred over the reporting period, the required statement may instead indicate that no exceedance of permitted discharges occurred during the reporting period.	Yes	N/A
4.1.5	The Permittee must submit all data required to be submitted under this section by email to envauthorizationsreporting@gov.bc.ca or as otherwise instructed by the Director.	Yes	N/A

Authorized Person Initial:_____

Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
4.1.6	The Director may require modification to the monitoring program based on the evaluation of the monthly and annual reports and on any other information that pertains to the operations and or discharges.	Yes	N/A
4.1.7	The Permittee must upload monitoring data associated with this permit to the Ministry's Environmental Monitoring System (EMS) database, within 45 days of the end of the 3 month period in which the data is collected.	Yes	N/A
4.2.1	The Permittee must also submit by March 31st of each year, a comprehensive annual report of all monitoring via email to the above email address, in a format suitable for public release. The annual report must include: a) all monitoring sample results required under the permit, b) an evaluation of quality assurance, including collection, sampling, and data handling protocols, c) water quality results from HAD-3 and QUL-58 compared to the applicable permit limits and objectives specified in Table 1, and BC WQGs, d) any exceedances of respective permit limits, objectives and/or BC WQGs must be clearly highlighted, e) any missed sampling events/missing data must be identified with an explanation provided, f) evaluation of treatment plant operation and control, g) evaluation of the impacts of the mining operation on the receiving environment from the previous year, h) a summary of any non-compliance with the permit and other incidents that may have led to impacts to the receiving environment, i) updates of the water balance, and a calibration assessments of the water balance and water quality models, j) assessment of the outfall dispersion and dispersion modelling for the Quesnel Lake discharge, k) an update to any modeling relating to the Springer Pit groundwater seepage and its impacts on Bootjack Lake as described in section 3.1, l) a review and update of the assessment of acid rock drainage (ARD) potential and water quality impacts from mine waste management, m) a comparison of monitoring data with water quality guidelines, predictions and targets, n) an update on the progress of reclamation and any updates to the reclamation plan that impact on site water quality, o) an evaluation of the effectiveness of the Surface Runoff and Mine Drainage Control programs, p) a summary of the Public Liaison Committee meetings, including any issues and concerns presented, q) an evaluation of the Outfall and Pipeline Inspection program, r) trend analysis (graphs) of water monitoring data at each site for the past 5 years, and s) assessment of attainment of the NPM target value: i) Using the HAD-3 monitoring data, evaluate the average annual effluent quality and trends as defined in section 2.11.2 (c), ii) if the average annual effluent quality exceeds the NPM target value or if trends suggest NPM target value may be exceeded within the next annual review cycle, provide an explanation of the most probable cause(s), iii) summary of proposed response action(s), and iv) progress update with respect to implementation of any response action(s).	Yes	N/A
4.2.2	Monitoring data and the analysis of that data, as it will be presented in the annual report, must be reviewed by a third party Qualified Professional.	Yes	N/A
4.2.3	A groundwater monitoring program review, including but not limited to sampling, well locations, site water balance, interpretation of data trends and possible environmental impacts, and suitable recommendations, must be completed for the entire mine site at least every three years, with the next review required by March 31, 2025.	No	A groundwater review was completed March 31, 2022.
4.2.4	A copy of the annual report must be provided to the Williams Lake First Nation, Xatsull First Nation and Public Liaison Committee within 30 days of the report being submitted to the Director.	Yes	N/A

Authorized Person Initial:_____ Date:_____

CONDITION NUMBER	CONDITION DESCRIPTION	COMPLIANT? (Yes/No/ND)	ACTION TAKEN
4.3	The Permittee must ensure that all information submitted as a requirement of this permit is accurate and free from mistakes or misleading statements. The Permittee must include in any submission required under this permit an explanation for any data that: a) is required under the permit but is missing from the submission, and b) the Permittee considers to be not representative of the actual discharge, conditions, or other circumstances the data is intended to measure.	Yes	N/A
4.4.1	The Permittee must immediately notify the Director or designate of any noncompliance with the requirements of this Permit and take appropriate remedial action. Written confirmation of all non-compliance events, including available test results is required within 24 hours of the original notification unless otherwise directed by the Director.	Yes	N/A
4.4.2	Both the initial notice and the confirmation must also be emailed to EnvironmentalCompliance@gov.bc.ca	Yes	N/A
4.3.3	Within 30 days of any non-compliant event, the Permittee must submit a follow-up report to the Director that includes, but is not limited to the following: a) all relevant test results related to the non-compliance instance(s), b) an explanation of the most probable cause(s) of the noncompliance(s), and c) remedial actions taken and planned to prevent similar noncompliance(s).	Yes	See Sections 3.7.2 and 14.12.2.4
4.4.4	A copy of the initial compliance notice, written confirmation and follow-up report must also be provided to the Williams Lake First Nation, Xatsull First Nation, and the Public Liaison Committee.	Yes	N/A
4.5.1	The Permittee must immediately notify the Director of any toxicity failure according to the Non-Compliance Reporting requirements in section 4.4. For the purpose of this section , a sample is considered to have failed the specific toxicity test if: a) 96-hr LC50 Rainbow Trout: Using 100% effluent concentration, more than 50% of the fish die within a 96 hour test period, b) 48-hr LC50 Daphnia magna: Using 100% effluent concentration, more than 50% of the organisms die within a 48 hour test period, c) 7-day Ceriodaphnia dubia reproduction: The water is determined to cause greater than 25% inhibition of survival and reproduction, or d) 7-day ELS toxicity test with a salmonid fish: The water is determined to cause greater than 25% non-viable embryos.	Yes	No failures occurred in 2023, See Section 4.12.3
4.5.2	The Permittee must investigate each toxicity failure to determine the cause(s). Reasonable efforts must be made to obtain preliminary and in progress results from the analytical laboratory during the toxicity testing. The Permittee must make immediate arrangements to retest in the event of potential and confirmed failures. The Director may require additional toxicity testing based on the evaluation of results from toxicity testing and the causes of failure.	Yes	No failures occurred in 2023, See Section 4.12.3
