APPENDIX 1-1: Information Requirements Table – Springer Expansion

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
1. INTRODUCTION AND PROJECT OVERVIEW			
1.1. Application Background	Required ☒ Methods ☐	The scope of this application includes the following activities: • SERDS extension • Springer Pit expansion • Quesnel Lake Discharge [Operational] • Northwest PAG Stockpile Disposal Date • Alternative discharge concepts (Upstream Drain) (possibly; to be determined) • Reducing the NPR from 2 to 1.6 for Springer Deep and WX zones • Updating ML/ARD management procedures to account for the effects of mineral partitioning during blast fractionation for Springer Deep and WX zones. The effects assessment for this application will include: • surface water quantity – Include surface water quality in this section as well. • The methodology by which a reduction in NPR from 2 to 1.6 is developed. • Information on potential changes to material handling procedures for placing material from Springer Deep and WX zones with an NPR between 1.6 and 2 in Not Potentially Acid Generating (NAG) storage facilities. • Information on potential changes to material handling procedures to account for the effects of mineral partitioning during blast fractionation for material from Springer Deep and WX zones.	1.1 Application Background
1.2. Proponent Information	Required ☒ Methods ☐		1.2 Proponent Information
1.3. Project Overview			
1.3.1. Project History	Required ☒ Methods ☐		1.3.1 Project History
1.3.2. Overview of Products and Markets, and Projected Project Benefits	Required ☒ Methods ☐	Project benefits will be discussed	1.3.2 Overview of Products and Markets, and Projected Project Benefits
1.3.3. Location, Access, and Land Use	Required ☒ Methods ☐	A summary description of the Project location and access, including a figure, will be included in the Application. Coordinates for the location of the Project will be provided in the Application. Figures will be developed to illustrate the following: • The location of Mount Polley Mine • Mount Polley Mine layout • Project Footprint • Relevant infrastructure	1.3.3 Location, Access, and Land Use
1.3.4. Mine Components and Off-Site Infrastructure	Required ☒ Methods ☐	The components of the Project will be described in the Application. A figure will be provided for context.	1.3.4 Mine Components and Off-Site Infrastructure
1.3.5. Mine Development and Operations	Required ☒ Methods ☐	Details regarding how the Project fits into permitted mine plan will be provided in the Application.	1.3.5 Mine Development and Operations
1.3.6. Mine Design and Assessment Team	Required ☒ Methods ☐		1.3.6 Mine Design and Assessment Team
1.3.7. Spatial Data	Required ☒ Methods ☐	Relevant spatial data will be provided as maps, including maps of Project and Project component locations. Maps of environmental monitoring and sampling stations will be provided in relevant baseline and monitoring sections.	1.3.7 Spatial Data
1.3.8. Concordance with Environmental Assessment Conditions	Required ☒ Methods ☐	For context discussion of conditions and commitments in the existing EAC will be included in the Application. If there are no relevant commitments, then a statement will be included in the Application indicating that there are no applicable commitments.	1.3.8 Concordance with Environmental Assessment Conditions
1.4. Regulatory Framework	Required ☒ Methods ☐	A summary of authorizations / approvals required for the Project will be provided. Existing authorizations that govern aspects of the Project will be identified.	1.4 Regulatory Framework
1.5. Indigenous Engagement			
1.5.1. Background	Required ☒ Methods ☐	MPMC operates in the territory of the William's Lake First Nation and the Xatśūll First Nation. Summary of previous and planned engagement activities with these First Nations will be provided.	1.5.1 Background
1.5.2. Asserted and Established Rights and Interests	Required ☒ Methods ☐	See 1.5.1	1.5.2 Asserted and Established Rights and Interests

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
1.5.3. Engagement Efforts	Required ☒ Methods ☐	See 1.5.1.	1.5.3 Engagement Efforts
2. BASELINE INFORMATION			
2.1. Summary	Required ☒ Methods ☐	Baseline conditions will be described and will focus on parts of the environment that may be affected by the Project. The scope of the baseline information will be to support assessment consistent with the scope of this Application. Baseline information will be summarized from existing monitoring programs.	2.1 Summary
2.2. Meteorology and Climate	Required ☒ Methods ☐	A summary of relevant meteorological and climate information will be provided, based on existing monitoring data. The baseline information will include parameters relevant for the design and construction of the Project, such as precipitation, snowpack, temperature, and evapotranspiration. The Application must include an assessment of historic climatic conditions at the Project and include general short- and long-term predictions or assumptions related to precipitation, snowpack, temperature, and evapotranspiration that may impact water quantity and quality modelling results.	2.2 Meteorology and Climate
2.3. Geology			
2.3.1. Regional Geology	Required ☒ Methods ☐		2.3.1 Regional Geology
2.3.2. Deposit (Ore) Geology	Required ☒ Methods ☐	A summary of the geological setting will be provided. .	2.3.2 Deposit (Ore) Geology
2.3.3. Surficial Geology, Terrain, and Geohazard Mapping	Required ☒ Methods ☐	A geotechnical evaluation, including assessment of terrain stability and description of natural hazards relevant to the Project activities will be provided.	2.3.3 Surficial Geology, Terrain, and Geohazard Mapping
2.3.4. Natural and Seismic Hazards Assessments	Required ☒ Methods ☐	See 2.3.3	2.3.4 Natural and Seismic Hazards Assessments
2.3.5. Soil Survey and Soil Characterization for Reclamation	Required ☒ Methods ☐	The Project will occur within the M-200 permit boundary. Soil disturbance is anticipated for a small portion of natural ground. Soil survey and soil characterization will be provided for natural areas that may be disturbed.	2.3.5 Soil Survey and Soil Characterization for Reclamation
2.4. Geochemical Characterization and Source Terms	Required ☒ Methods ☐	A QP assessment outlining the estimated time to onset of acid rock drainage and how it relates to the proposed timeline of the Project and the rehandling of PAG material to the existing pit will be provided. The Application will include available static and kinetic laboratory analytical results for PAG material encountered to date and anticipated to be excavated from Phase 4 of the Cariboo-Springer Pit mining operations.	2.4 Geochemical Characterization and Source Terms
2.4.1. Geochemical Characterization	Required ☒ Methods ☐	A QP discussion regarding geochemical characterization of PAG material will be provided. The Application must include a breakdown of geochemical characteristics of previously mined zones as well as zones that may be mined as part of the Springer Pit Expansion.	2.4.1 Geochemical Characterization
2.4.2. Geochemical Source Terms	Required ☒ Methods ☐	Source terms have been updated based on the Springer Pit Expansion (considers more recent data and zones that will be mined as part of the expansion). Source terms for the NAG waste rock dumps will be reviewed by SRK based on the modified NPR.	2.4.2 Geochemical Source Terms
2.5. Topography and Surface Drainage Features	Required ☒ Methods ☐	Existing topography and surface drainage features relevant to the Project components addressed in this Application will be described. A figure showing an overview of surface drainage will be provided.	2.5 Topography and Surface Drainage Features
2.6. Water Quantity			

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	**Requirements**	**Comments**	**Location in Final Application**
2.6.1.Surface Water Quantity	Required ☒ Methods ☐	The hydrology baseline information for the Project will be provided, with references to existing studies, where applicable, and previously published hydrological datasets. The baseline information will be summarized from data collection programs already in place. The Application will include historic and current surface water quantity for the PAG Stockpile. The Application will include information on surface water quantity of NAG storage facilities that are intended to receive material with an NPR between 2 and 1.6.	2.7.1 Surface Water Quantity
2.6.2.Groundwater Quantity	Required ☒ Methods ☐	The groundwater baseline information for the Project will be provided, with references to existing studies, where applicable, and previously published groundwater datasets. The baseline information will be summarized from data collection programs already in place.	2.6.2 Groundwater Quantity
2.7. Water Quality			
2.7.1.Surface Water Quality	Required ☒ Methods ☐	A summary of relevant surface water quality baseline information will be provided. This section will be prepared by summarizing available data and from reports associated with the sites water quality monitoring programs. This section will include receiving environment, Quesnel Lake, data from 2015 to present, and compare it with reference, baseline data. Additionally: - parameters used to calculate guidelines will be provided in table foot notes - presenting graphs will indicate applicable water quality guidelines on the graph itself - where chronic water quality guideline is not applicable to any sampling locations due to monthly sampling, the results will still be compared with chronic guideline - raw data will be provided in an additional appendix For additional reference, this section will provide a summary of data described above for Hazeltine Creek or note where this information has been presented/addressed for reference. The Application will include historic and current surface water quality for the PAG Stockpile. The Application will include an assessment of current surface water quality as it compares to established water quality predictions and timeframes of ML/ARD onset and characteristics. The Application must include information on surface water quality of NAG storage facilities that are intended to receive material with an NPR between 2 and 1.6.	2.7.1 Surface Water Quality
2.7.2.Groundwater Quality	Required ☒ Methods ☐	A summary of relevant groundwater quality baseline information will be provided. This section will be prepared by summarizing available data from reports associated with the site's existing monitoring program.	2.7.2 Groundwater Quality
2.8. Sediment Quality	Required ☒ Methods ☐	In support of the Quesnel Lake Operational Discharge Extension, a summary of relevant sediment quality data from the receiving environment, Quesnel Lake, will be provided. This section will include data from 2015 to present, and compare it with reference, baseline data. Additionally, all sediment toxicity data available to present will be provided along with a comparison to reference conditions. For additional reference, this section will provide a summary of data described above for Hazeltine Creek or note where this information has been presented/addressed for reference.	2.7.3 Sediment Quality
2.9. Fisheries and Aquatic Resources			

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
2.9.1. Periphyton and Benthic Invertebrate Community Measures	Required ☒ Methods ☐	A summary of relevant biological monitoring data from the receiving environment, Quesnel Lake, monitoring locations will be provided. This will include a summary of all relevant periphyton and benthic invertebrate, plankton community measurements from the receiving environment from 2015 to present, along with a comparison to reference, pre-breach/baseline data will be provided. This section will also include all available tissue quality data to present from the applicable receiving environment locations. For additional reference, this section will provide a summary of data described above for Hazeltine Creek or note where this information has been presented/addressed for reference.	2.9.1 Periphyton and Benthic Invertebrate Community Measures
2.9.2. Fish and Fish Habitat	Required ☒ Methods ☐	A summary of the receiving environment, Quesnel Lake, fish habitat condition and use of this habitat by fish populations will be provided.	2.9.2 Fish and Fish Habitat
2.9.3. Tissue Residues	Required ☒ Methods ☐	A summary of all available tissue residue data to present from the applicable sampling location from the relevant receiving environment will be provided.	2.9.3 Tissue Residues
2.10. Ecosystems and Wildlife	Required ☒ Methods ☐	The Project will occur within the M-200 permit boundary. A summary of terrestrial biodiversity will be provided to characterize the baseline conditions, with cross-references to existing reports.	2.10 Ecosystems and Wildlife
2.11. Land Status and Use	Required ☒ Methods ☐	A summary of land status and use will be provided.	2.11 Land Status and Use
2.12. Archaeology	Required ☒ Methods ☐	The Project will occur within the M-200 permit boundary. A summary of relevant archaeological resources will be provided, with cross-references to existing reports.	2.12 Archaeology
2.13. Cultural Use	Required ☒ Methods ☐	The application will contain a brief statement that there is no current cultural resource use of the area, based on existing studies.	2.13 Cultural Use
3. MINE PLAN		This section will include a detailed discussion on the mine plan for the Project. It will include figures outlining development, estimated material volumes, and a discussion on the potential implications of an extended temporary shutdown. No change to the permitted mine boundary is anticipated as part of the Project.	3. MINE PLAN
3.1. Mine Plan Overview	Required ☒	A high-level overview of current mining in the area will be provided in the Application. A description of how the Project will interact with mining will be provided. A description of the Project will be presented to provide context for the assessment of potential effects of the Project and support regulatory review of the Application. Figures will be included.	3.1 Mine Plan Overview
3.2. Existing Development	Required ☒	The existing site conditions described in the Application. The existing environment will be described in Section 2 in the context of the Project. Integration of the Project with the mine site will be described in other sections.	3.2 Existing Development
3.3. Life of Mine Plan	Required ☒		3.3 Life of Mine Plan
3.4. Detailed Five Year Mine Plan	Required ☐		3.4 Detailed Five Year Mine Plan
3.5. Mine Facility Designs and Development	Required ☒		
3.5.1. Open Pits	Required ☒	A QP assessment outlining the estimated time to onset of acid rock drainage and how it relates to the proposed timeline of the Project and the rehandling of PAG material to the existing pit will be provided.	3.5.1 Open Pits
3.5.2. Underground Workings	Required ☐		3.5.2 Underground Workings
3.5.3. Processing Plant (Mill) and Associated Facilities	Required ☐	Existing mill and associated facilities will be used to support the Project. No changes.	3.5.3 Processing Plant (Mill) and Associated Facilities
3.5.4. Tailings Storage Facility and Associated Infrastructure	Required ☐	Modifications needed to support the expansion of the TSF needed to support the Project will be covered under a separate application. A description of this project linkage will be provided in the application.	3.5.4 Tailings Storage Facility and Associated Infrastructure

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
3.5.5. Waste Rock Dumps	Required ☒	This will include discussion from a QP assessment outlining the estimated time to onset of acid rock drainage and how it relates to the proposed timeline of the Project and the rehandling of PAG material to the existing pit will be provided. A description of the permitted Temporary NW PAG Stockpile will be provided.	3.5.5 Waste Rock Dumps
3.5.6. Water Management Structures	Required ☒	A description of existing water management structure relevant to the Project will be provided.	3.5.6 Water Management Structures
3.5.7. Ore, Overburden, Soil and Construction Stockpiles	Required ☒	A description of material stockpiles associated with the Project will be provided in the Application.	3.5.7 Ore, Overburden, Soil and Construction Stockpiles
3.5.8. Mine Access and Mine Haulage Roads	Required ☒	An overview of the access roads and the mine haulage roads relevant to the Project will be provided. The majority of activity will occur using existing infrastructure.	3.5.8 Mine Access and Mine Haulage Roads
3.5.9. Power Supply and Distribution Infrastructure	Required ☒	A summary of the existing facilities to be used will be described.	3.5.9 Power Supply and Distribution Infrastructure
3.5.10. Explosives Storage Facilities	Required ☒	A summary of the existing facilities to be used will be described.	3.5.10 Explosives Storage Facilities
3.5.11. Ancillary Facilities and Support Infrastructure	Required ☒	A summary of the existing facilities to be used will be described.	3.5.11 Ancillary Facilities and Support Infrastructure
4. RECLAMATION AND CLOSURE PLAN			
4.1. End Land Use and Capability Objectives	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project. The footprint and capacity of the Temporary NW PAG Stockpile is not being modified as part of this Project. No change to the reclamation and closure plan presented in the 2017 Mine Reclamation and Closure Plan is required. Disposal of PAG will still occur in pit.	4.2 End Land Use and Capability Objectives
4.2. Reclamation Approaches			
4.2.1. Soil Resources	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.3.1 Soil Resources
4.2.2. Landform Design and Erosion Control	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.3.2 Landform Design and Erosion Control
4.2.3. Revegetation Strategy	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.3.3 Revegetation Strategy
4.2.4. Progressive Reclamation/Sequencing	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.3.4 Progressive Reclamation/Sequencing
4.2.5. Reclamation Research	Required ☐	Reclamation research will not be possible, as these areas will be continuously disturbed during the 8 years of operation.	4.3.5 Reclamation Research
4.2.6. Reclamation Monitoring	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.3.6 Reclamation Monitoring
4.2.7. Habitat Compensation Works	Required ☐	All work will be within the M-200 permit boundary. Habitat offsets, if needed to offset impacts on Bootjack Creek habitat will be handled directly by DFO.	4.3.7 Habitat Compensation Works
4.3. Trace Element Uptake in Soils and Vegetation	Required ☐ Methods ☐		4.4 Trace Element Uptake in Soils and Vegetation
4.4. Contaminated Sites, Human Health and Ecological Risk Assessment	Required ☒ Methods ☐	Human Health and Ecological Risk Assessments that have been done on performed on site will be summarized.	4.5 Contaminated Sites, Human Health and Ecological Risk Assessment
4.5. Disposal of Chemicals, Reagents, Hazardous Materials and Contaminated Materials	Required ☒ Methods ☐	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.6 Disposal of Chemicals, Reagents, Hazardous Materials and Contaminated Materials
4.6. Groundwater Well Decommissioning	Required ☐ Methods ☐	No additional groundwater wells are currently expected as part of the Project.	4.7 Groundwater Well Decommissioning
4.7. Reclamation and Closure Prescriptions-			
4.7.1. Structures and Equipment	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.8.1 Structures and Equipment
4.7.2. Waste Rock Dump Reclamation	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.8.2 Waste Rock Dump Reclamation
4.7.3. Tailings Storage Facility Reclamation	Required ☐		4.8.3 Tailings Storage Facility Reclamation
4.7.4. Open Pit Reclamation Prescriptions	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.8.4 Open Pit Reclamation Prescriptions

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
4.7.5. Watercourse Reclamation Prescriptions	Required ☒	A description for reclamation of Bootjack Creek will be provided in the Application if it will be impacted the SERDS expansion. However, if Bootjack Creek habitat cannot be avoided then it will be buried by the SERDS. It would be addressed through habitat offsets rather than reclamation.	4.8.5 Watercourse Reclamation Prescriptions
4.7.6. Road Reclamation	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.8.6 Road Reclamation
4.7.7. Schedule	Required ☒	An updated schedule for reclamation and closure will be provided based on Project schedule. No change to the reclamation and closure plan presented in the 2017 Mine Reclamation and Closure Plan is required.	4.8.7 Schedule
4.8. Detailed Five-Year Mine Reclamation Plan	Required ☒		4.9 Detailed Five-Year Mine Reclamation Plan
4.9. Temporary Shutdown	Required ☒	A discussion on the potential implications of an extended temporary shutdown or care and maintenance of the mine as it relates to management of surface water quality, quantity and the estimated onset of acid rock drainage in the temporary NW PAG stockpile will be provided. Additionally, this section will also include a contingency management plan for PAG material stored on site that cannot be backfilled into existing pits during extended temporary shutdowns. If additional mitigation measures are required during a temporary shutdown, details and associated cost estimates will also be provided.	4.10 Temporary Shutdown
4.10. Post-Closure Monitoring and Maintenance	Required ☒	Will be included in the Conceptual Reclamation and Closure Plan for the Project.	4.11 Post-Closure Monitoring and Maintenance
4.11. Reclamation Cost Estimate			
4.11.1. Conventional Reclamation and Closure	Required ☒	Reclamation cost estimates for closure scenario will be provided under separate cover.	4.12 Reclamation Cost Estimate
4.11.2. Post-Closure Monitoring	Required ☒	Reclamation cost estimates for closure scenario will be provided under separate cover.	4.12 Reclamation Cost Estimate
4.11.3. Post-Closure Maintenance (excluding Water Treatment)	Required ☒	Reclamation cost estimates for closure scenario will be provided under separate cover.	4.12 Reclamation Cost Estimate
4.11.4. Life of Mine Water Treatment	Required ☒	Reclamation cost estimates for closure scenario will be provided under separate cover.	4.12 Reclamation Cost Estimate
5. MODELLING, MITIGATION, AND DISCHARGES			
5.1. Summary	Required ☒	Qualitative hydrology and water quality assessments of the potential effects of the Project will be provided.	5.1 Summary
5.2. Conceptual Site Model	Required ☐ Methods ☐		5.2 Conceptual Site Model
5.3. Site-Wide Water Balance Model	Required ☒ Methods ☐	Quantitative model will be updated to reflect new LOM schedule. Updates include revisions to catchment boundaries, storage, and runoff impacted by mine development. Results will include facility level water volume and level projections and estimated discharge quantities from the site. Details on the operational efficiency and reliability of the WTP and a model sensitivity scenario that reflects recent operational data will be provided. No change to the site-wide water balance is associated with result of the Project. The capacity and surface area of the Temporary NW PAG Stockpile will not change. Water quantity will be discussed to provide context (Section 2.6.1).	5.3 Site-Wide Water Balance Model

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	**Requirements**	**Comments**	**Location in Final Application**
5.4. Surface Water Quality Model	Required ☒ Methods ☐	Details on the operational efficiency and reliability of the WTP and a model sensitivity scenario that reflects recent operational data will be provided. Updating the Surface Water Quality Model is not currently anticipated. However, the need for a site-specific excel based water quality model will be determined based on an evaluation of source terms by a QP. The Application must include an assessment on the potential changes of contaminant loading from the PAG Stockpile by lowering the cut-off for PAG classification from an NPR of 2 to 1.6. The Application must include an assessment on the potential changes of contaminant inputs originating from NAG storage facilities caused by the storage of material with an NPR between 2 and 1.6.	5.4 Surface Water Quality Model
5.5. Groundwater Model			
5.5.1.Conceptual Hydrogeologic Model	Required ☒ Methods ☐	As a component of the site-wide conceptual groundwater model, the application will confirm the understanding regarding the groundwater divide between Bootjack Lake and Springer Pit.	5.5.1 Conceptual Hydrogeologic Model
5.5.2.Numeric Hydrogeologic Model	Required ☒ Methods ☐	The application will include an update to the site-wide numerical hydrogeological model and a summary report which describes the model and its ability to simulate the current and future (both operational and closure) groundwater flow conditions that are relevant to this application. Model simulations must be used in the application to support a groundwater impact assessment and inform the groundwater monitoring, management, and mitigation efforts at the mine. If no update to the existing model is needed, supporting rationale from a QP will be provided.	5.5.2 Numeric Hydrogeologic Model
5.6. Mitigation Methods	Required ☐		
5.6.1.Best Available Technology Evaluation	Required ☐ Methods ☐		5.6.1 Best Available Technology Evaluation
5.6.2.Volume and Quantity Control Methods	Required ☐ Methods ☐		5.6.2 Volume and Quantity Control Methods
5.6.3.Geochemical Attenuation Processes	Required ☐ Methods ☐		5.6.3 Geochemical Attenuation Processes
5.6.4.Water Treatment		Information/discussions on the anticipated changes to water quantity and quality as informed by the Surface Water Balance and Surface Water Quality Models, and how it these predictions relate to the water treatment effectiveness and capacities will be provided. An update on water treatment technology and research development will be provided in the updated Water Management Plan submitted with the Application. This will include an implementation plan and schedule for water treatment technology development. current surface water monitoring program intended and that there are no proposed changes in the trigger values arising from the amendment application.	5.6.4 Water Treatment
5.6.4.1. Description	Required ☒	A description of the existing water treatment system will be provided in the Application. A discussion developed by a QP noting the existing WTPs ability to manage the potential impact of the Project will be included in the Application.	5.6.4.1 Description
5.6.4.2. Location	Required ☒	The location of the existing water treatment system will be provided in the Application.	5.6.4.2 Location
5.6.4.3. Detailed Design	Required ☐		5.6.4.3 Detailed Design
5.6.4.4. Treatment Effectiveness	Required ☒	Details on the operational efficiency and reliability of the WTP and a model sensitivity scenario that reflects recent operational data will be provided.	5.6.4.4 Treatment Effectiveness
5.6.4.5. Performance Risks	Required ☐		5.6.4.5 Performance Risks

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	**Requirements**	**Comments**	**Location in Final Application**
5.6.4.6. Influent and Effluent Water Quality	Required ☒	Predictions for changes to WTP influent volume and quality resulting from the Project will be provided. Additionally, this section will provide details on proposed mitigation, including WTP capacity, performance, and adequacy in mitigating the discharge.	5.6.4.6 Influent and Effluent Water Quality
5.6.4.7. Waste and By-Products	Required ☒		5.6.4.7 Waste and By-Products
5.6.4.8. Maintenance	Required ☐		5.6.4.8 Maintenance
5.6.4.9. Emergency Response Plans	Required ☐		5.6.4.9 Emergency Response Plans
5.6.4.10. Monitoring Plans	Required ☒	Existing monitoring plans and their relevance to the Project will be discussed in the Application. The Application will include: • Information on potential changes to material handling procedures for placing material from Springer Deep and WX zones with an NPR between 1.6 and 2 in Not Potentially Acid Generating (NAG) storage facilities. • Information on potential changes to material handling procedures to account for the effects of mineral partitioning during blast fractionation for material from Springer Deep and WX zones.	5.6.4.10 Monitoring Plans
5.6.4.11. Schedule	Required ☒		5.6.4.11 Schedule
5.6.4.12. Cost Estimate	Required ☐		5.6.4.12 Cost Estimate
5.7. Domestic Water/Sewage Treatment	Required ☐ Methods ☐		5.7 Domestic Water/Sewage Treatment
5.8. Effluent Discharge	Required ☒ Methods ☐	A description of effluent discharge will be included in the Application. This will be informed by updates to the Surface Water Balance, Surface Water Quality Models, and Water Management Plan. The potential for non-point discharge seepages to occur will be assessed, if identified a focused monitoring/mitigation program would be reviewed if required.	5.8 Effluent Discharge
5.9. Initial Dilution Zone	Required ☒ Methods ☐		5.9 Initial Dilution Zone
6. ENVRIONMENTAL ASSESSMENT PREDICTIONS			
6.1. Aquatic Resources	Required ☒ Methods ☐		6.1 Aquatic Resources
6.2. Terrestrial Resources	Required ☒ Methods ☐		6.2 Terrestrial Resources

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
7. ENVIRONMENTAL MONITORING		A list of the required changes to the existing Comprehensive Environmental Monitoring Plan based on the proposed Project and associated changes to water management on site will be provided. A summary of any new information and science available including but not limited to publications from QRCC will be provided and considered in the context of the proposed expansion project and the review of the CEMP. An interim update to the Water Management Progress Report required by condition 2.12 of PE-11678 will be provided with the Application. Updates will be provided for: - Site-wide water quality model; - Site-wide water balance model; - Water Management Plan (Mine Operations); - Annual Discharge Plan; - Any other plans that will require updates to reflect the proposed Springer Expansion. Revisions to the Flocculant Management Plan will be completed if necessary. Additional monitoring requirements will be noted, including those related to Bootjack Lake.	7. ENVIRONMENTAL MONITORING
7.1. Environmental Monitoring Program Design	Required ☒ Methods ☐	The existing Comprehensive Environmental Monitoring Plan will be discussed in the Application.	7.1 Environmental Monitoring Program Design
7.2. Mine Site Water Monitoring Program	Required ☒ Methods ☐	The existing Comprehensive Environmental Monitoring Plan will be discussed in the Application.	7.2 Mine Site Water Monitoring Program
7.3. Discharge Monitoring Program	Required ☒ Methods ☐	The existing Comprehensive Environmental Monitoring Plan will be discussed in the Application.	7.3 Discharge Monitoring Program
7.4. Environment Monitoring Program	Required ☒ Methods ☐	The existing Comprehensive Environmental Monitoring Plan will be discussed in the Application.	7.4 Environment Monitoring Program
7.5. Post-Closure Environmental Monitoring Program	Required ☒ Methods ☐	As informed by the 2022 Mine Plan and Reclamation Program.	7.5 Post-Closure Environmental Monitoring Program
7.6. Aquatic Effect Monitoring Program	Required ☒ Methods ☐	The existing Comprehensive Environmental Monitoring Plan will be discussed in the Application.	7.6 Aquatic Effect Monitoring Program
8. HEALTH AND SAFETY			
8.1. Occupational Health and Safety Program			
8.1.1. Occupational Health Risk Assessment	Required ☐		-
8.1.2. Ergonomics	Required ☐		-
8.1.3. Emergency Wash Facilities	Required ☐		-
8.1.4. Hazardous Dust	Required ☐		-
8.1.5. Lunchrooms, Mine Dry, and Sanitary Conveniences	Required ☐		-
8.2. Post Permitting Requirements			
8.2.1. Issued for Construction Plans	Required ☐		-
8.2.2. Letters of Assurance	Required ☐		-
8.2.3. Occupational Health Programs	Required ☐		-
8.2.4. Workplace Hazardous Materials Information System (WHMIS)	Required ☐		-
8.2.5. Additional Information and Certifications	Required ☐		-
9. MANAGEMENT PLANS			

Information (refer to "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits" for additional info on each section)	**Requirements**	**Comments**	**Location in Final Application**
9.1. Environmental Management System	Required ☒		9.1 Environmental Management System
9.2. Surface Erosion Prevention and Sediment Control Plan	Required ☒	Relevant information for surface erosion prevention and sediment control will be included in the Application.	9.2 Surface Erosion Prevention and Sediment Control Plan
9.3. Soil Management Plan	Required ☒	The existing Soil Management Plan will be used to inform the soil salvage and stockpile management.	9.3 Soil Management Plan
9.4. Construction Environmental Management Plan	Required ☐		9.4 Construction Environmental Management Plan
9.5. ML/ARD Management Plan	Required ☒	The ML/ARD Management Procedure Manual will be updated to reflect the reduced NPR. This update will be approved by QP.	9.5 ML/ARD Management Plan
9.6. Mine Site Water Management Plan	Required ☒	Information related to construction water management and the existing Mine Site Water Management Plan will be included in the Application.	9.6 Mine Site Water Management Plan
9.7. Discharge Management Plan	Required ☒		9.7 Discharge Management Plan
9.8. Vegetation Management Plan	Required ☐		9.8 Vegetation Management Plan
9.9. Invasive Plant Management Plan	Required ☒		9.9 Invasive Plant Management Plan
9.10. Wildlife Management Plan	Required ☒		9.10 Wildlife Management Plan

9.17. Waste (Refuse and Emissions) Management Plan	Required ☐		9.17Waste (Refuse and Emissions) Management Plan

APPENDIX 1-2: Information Requirements Table – TSF Interim Raise to 974 m

Joint Information Requirements Table

for

Mines Act and *Environmental Management Act* Permits

Prepared by:

British Columbia Ministry of Energy, Mines and Petroleum Resources

&

British Columbia Ministry of Environment and Climate Change Strategy

January 2024

Introduction

The Information Requirements Table (IRT) serves as the single list of information requirements for a *Mines Act* (MA) permit application, issued by the Ministry of Energy, Mines and Low Carbon Innovation (EMLI), and an effluent discharge permit application under the *Environmental Management Act* (EMA), by the Ministry of Environment and Climate Change Strategy (ENV). The IRT is intended to:

- Be used in conjunction with the document entitled, "Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits"[1] and is intended for use in the development of both new and/or permit amendment applications. The information contained within the IRT will be developed to meet the unique nature of each project.
- It is also to be used in conjunction with all other guidance provided by either ENV or EMLI.
- Inform clients of the detailed information required to support MA and EMA permit applications and ensure all the information necessary to support the MA and EMA applications is provided; and
- Aid ENV and EMLI technical staff during the screening phase.

Overview

The IRT is intended to aid proponents and reviewers through the coordinated authorizations review process: during the pre-application stage to determine the information requirements, prior to submitting an application, and in screening, to ensure the required information has been included in the application submission.

It is recommended that proponents carefully review the entire Joint Application Information Requirements for *Mines Act* and *Environmental Management Act* Permits and consider any possible information requirements that may apply to their project proposal. If a specific methodology from the Joint Application Information Requirements guidance document is being proposed, this should be identified in the IRT and initially be described at a high level by proponents during the pre-application stage. More detail or specific Information Requirements can be added by adding in new lines into the IRT in the appropriate section.

After proponents have created a first draft of the IRT, reviewers will carefully review the project proposal and draft IRT prior to meeting with proponents to identify any missing information requirements or areas that require further discussion. The pre-application phase is most often an iterative set of discussions between the proponent and technical reviewers, regarding the information requirements and any specifics and/or methodologies that may be required in a joint

MA/EMA permit application.

Once complete, the province will send the final IRT to proponents for their use in preparing their application. A copy of the IRT must accompany the application submission by proponents and must indicate the locations of each information requirement within the application (far right-hand column).

It is important to note that changes in a project proposal may occur during the pre-application, screening, and/or review phases of the process. These changes may require a reassessment of the information required for an application. Proponents and reviewers will work together to discuss these changes and identify any revisions or additional information requirements.

Abbreviations

CEMP	Construction Environmental Management Plan
CSM	Conceptual Site Model
EMA	*Environmental Management Act*
EMPR	Ministry of Energy, Mines and Petroleum Resources
ENV	Ministry of Environment and Climate Change Strategy
IFC	Issued for Construction
IRT	Information Requirements Table
MA	*Mines Act*
ML/ARD	Metal Leaching and Acid Rock Drainage
WHMIS	Workplace Hazardous Materials Information System

Information (refer to "Joint Application Information Requirements for Mines Act and Environmental Management Act Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
1. INTRODUCTION AND PROJECT OVERVIEW			
1.1. Application Background	Required ☒ Methods ☐	The scope of this application includes the following construction activities: • Extension of portions of the existing buttresses along the Main and Perimeter embankments • Resloping of the South, Main and Perimter embankments to 2H:1V. • Extension of the embankments at the south and north abutments • Construction of an upstream drain upstream of the till core along portions of the Main and Perimeter embankments.	
1.2. Proponent Information	Required ☒ Methods ☐		
1.3. Project Overview			
1.3.1. Project History	Required ☒ Methods ☐		
1.3.2. Overview of Products and Markets, and Projected Project Benefits	Required ☒ Methods ☐	Project benefits will be discussed.	
1.3.3. Location, Access, and Land Use	Required ☒ Methods ☐	A summary description of the Project location and access relative to MPMC, including a figure, will be included in the Application. Coordinates for the location of the Project will be provided in the Application. Figures will be developed to illustrate the following: • The location of MPMC • MPMC layout • Project Footprint • Relevant infrastructure	
1.3.4. Mine Components and Off-Site Infrastructure	Required ☒ Methods ☐	The components of the Project will be described in the Application. Stamped and signed (Issued for Permitting) engineering drawings will be provided at a suitable level of detailed design.	
1.3.5. Mine Development and Operations	Required ☒ Methods ☐	Details regarding how the Project fits into the permitted and future mine plan will be provided in the Application.	
1.3.6. Mine Design and Assessment Team	Required ☒ Methods ☐		
1.3.7. Spatial Data	Required ☒ Methods ☐	Relevant spatial data will be provided as maps, including maps of Project and Project component's locations.	
1.3.8. Concordance with Environmental Assessment Conditions	Required ☒ Methods ☐	Information relevant to the proposed Project will be provided in the Application. If no relevant commitments, then a statement will be included in the Application indicating that there are no applicable commitments.	
1.4. Regulatory Framework	Required ☒ Methods ☐	A summary of authorizations / approvals required for the Project will be provided. Existing authorizations that govern aspects of the Project will be identified.	
1.5. Indigenous Engagement			
1.5.1. Background	Required ☒ Methods ☐	MPMC operates in the territory of the William's Lake First Nation and the Xatśūll First Nation. Summary of previous and planned engagement activities with these First Nation's will be provided.	
1.5.2. Asserted and Established Rights and Interests	Required ☒ Methods ☐	See 1.5.1	
1.5.3. Engagement Efforts	Required ☒ Methods ☐	See 1.5.1.	
2. BASELINE INFORMATION			

Information (refer to "Joint Application Information Requirements for Mines Act and Environmental Management Act Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
2.1. Summary	Required ☒ Methods ☐	Baseline conditions will be described and will focus on parts of the environment that may be affected by the Project. The scope of the baseline information will be to provide information to support assessment consistent with the scope of this Application. Baseline information will be summarized from existing monitoring programs.	
2.2. Meteorology and Climate	Required ☒ Methods ☐	A summary of relevant meteorological and climate information will be provided, based on existing monitoring data. The baseline information will include parameters relevant for the design and construction of the Project, such as precipitation, snowpack, temperature, and evapotranspiration.	
2.3. Geology			
2.3.1. Regional Geology	Required ☒ Methods ☐	A foundation characterization report that meets the intent of the EGBC site characterization for dam foundation guidelines will be provided.	
2.3.2. Deposit (Ore) Geology	Required ☐ Methods ☐		
2.3.3. Surficial Geology, Terrain, and Geohazard Mapping	Required ☒ Methods ☐	See 2.3.1	
2.3.4. Natural and Seismic Hazards Assessments	Required ☒ Methods ☐	See 2.3.1	
2.3.5. Soil Survey and Soil Characterization for Reclamation	Required ☒ Methods ☐	The TSF expansion is expected to occur in a largely disturbed area within the M-200 permit boundary; however, the associated water management infrastructure will extend beyond the M-200 permit boundary requiring a boundary extension. Soil survey and soil characterization will be provided for all natural areas that may be disturbed.	
2.4. Geochemical Characterization and Source Terms	Required ☐ Methods ☐		
2.4.1. Geochemical Characterization	Required ☒ Methods ☐	The existing geochemical characterization results used for the tailings will be provided.	
2.4.2. Geochemical Source Terms	Required ☒ Methods ☐	The existing geochemical source terms used for the tailings will be provided.	
2.5. Topography and Surface Drainage Features	Required ☒ Methods ☐	Existing topography and surface drainage features relevant to the Project components addressed in this application will be described. A figure showing an overview of surface drainage will be provided.	
2.6. Water Quantity			
2.6.1. Surface Water Quantity	Required ☒ Methods ☐	The hydrology baseline information for the Project will be provided, with references to existing studies, where applicable, and previously published hydrological datasets. The baseline information will be summarized from data collection programs already in place. Project-related effects on the surface water environment and site water management will be developed based on the results of existing modelling analyses. Relevant maps will be provided.	
2.6.2. Groundwater Quantity	Required ☒ Methods ☐	Existing groundwater conditions relevant to the Project will be provided, with references to existing studies, where applicable, and previously published hydrological datasets. The baseline information will be summarized from data collection programs already in place.	

Information (refer to "Joint Application Information Requirements for Mines Act and Environmental Management Act Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
2.7. Water Quality			
2.7.1. Surface Water Quality	Required ☒ Methods ☐	A summary of relevant surface water quality baseline information will be provided. This section will be prepared by summarizing available data and from reports associated with the sites water quality monitoring programs.	
2.7.2. Groundwater Quality	Required ☐ Methods ☐	Existing groundwater conditions relevant to the Project will be provided, with references to existing studies, where applicable, and previously published hydrological datasets. The baseline information will be summarized from data collection programs already in place.	
2.8. Sediment Quality	Required ☐ Methods ☐		
2.9. Fisheries and Aquatic Resources			
2.9.1. Periphyton and Benthic Invertebrate Community Measures	Required ☐ Methods ☐		
2.9.2. Fish and Fish Habitat	Required ☐ Methods ☐		
2.9.3. Tissue Residues	Required ☐ Methods ☐		
2.10. Ecosystems and Wildlife	Required ☒ Methods ☐	The Project TSF expansion is expected to occur in a largely disturbed area within the M-200 permit boundary; however, the associated water management infrastructure will extend beyond the M-200 permit boundary.	
2.11. Land Status and Use	Required ☒ Methods ☐	A summary of land status and use will be provided.	
2.12. Archaeology	Required ☒ Methods ☒	The Project TSF expansion is expected to occur in a largely disturbed area within the M-200 permit boundary; however, the associated water management infrastructure will extend beyond the M-200 permit boundary.. Archaeological resources for the site have previously been identified and will be summarized based on that report.	
2.13. Cultural Use	Required ☒ Methods ☐	The application will contain a brief statement that there is no current cultural resource use of the tailings storage area.	
3. MINE PLAN			
3.1. Mine Plan Overview	Required ☒	A high-level overview of current mining will be provided in the Application. A description of how the Project will interact with mining will be provided. The following figures are planned: • Site General Arrangement Plan • Project Overall Plot Plan	
3.2. Existing Development	Required ☒	The existing environment will be described in Section 2 in the context of the Project. Integration of the Project with the mine site will be described in other sections.	
3.3. Life of Mine Plan	Required ☒	An overview of the permitted life of mine plan will be provided,.	
3.4. Detailed Five Year Mine Plan	Required ☒		
3.5. Mine Facility Designs and Development	Required ☐		
3.5.1. Open Pits	Required ☐		
3.5.2. Underground Workings	Required ☐		
3.5.3. Processing Plant (Mill) and Associated Facilities	Required ☒	A high-level description of the processing plant, as it relates to the production of tailings, will be provided in the Application.	
3.5.4. Tailings Storage Facility and Associated Infrastructure	Required ☒	A detailed design report for the TSF interim raise to elevation 974 m will be provided in the Application.	
3.5.5. Waste Rock Dumps	Required ☐		

Information (refer to "Joint Application Information Requirements for Mines Act and Environmental Management Act Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
3.5.6. Water Management Structures	Required ☒	A description of how the Project will interact with existing water management structures will be provided. Designs for modifications to these structures will be included in the Application.	
3.5.7. Ore, Overburden, Soil and Construction Stockpiles	Required ☒	Descriptions of the soil and construction materials associated with the Project will be provided in the Application.	
3.5.8. Mine Access and Mine Haulage Roads	Required ☒	An overview of the access to the Project will be provided.	
3.5.9. Power Supply and Distribution Infrastructure	Required ☐		
3.5.10. Explosives Storage Facilities	Required ☐		
3.5.11. Ancillary Facilities and Support Infrastructure	Required ☐		
4. RECLAMATION AND CLOSURE PLAN			
4.1. End Land Use and Capability Objectives	Required ☒	The Application will include reclamation and closure information for the Project based on the latest update to the Mine Reclamation and Closure Plan	
4.2. Reclamation Approaches			
4.2.1. Soil Resources	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.2.2. Landform Design and Erosion Control	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.2.3. Revegetation Strategy	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.2.4. Progressive Reclamation/Sequencing	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.2.5. Reclamation Research	Required ☐		
4.2.6. Reclamation Monitoring	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.2.7. Habitat Compensation Works	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.3. Trace Element Uptake in Soils and Vegetation	Required ☐ Methods ☐		
4.4. Contaminated Sites, Human Health and Ecological Risk Assessment	Required ☐ Methods ☐		
4.5. Disposal of Chemicals, Reagents, Hazardous Materials and Contaminated Materials	Required ☐ Methods ☐		
4.6. Groundwater Well Decommissioning	Required ☐ Methods ☐		
4.7. Reclamation and Closure Prescriptions			
4.7.1. Structures and Equipment	Required ☐		
4.7.2. Waste Rock Dump Reclamation	Required ☐		
4.7.3. Tailings Storage Facility Reclamation	Required ☒	The Application will include reclamation and closure information for the Project and based on the latest update to the Mine Reclamation and Closure Plan	
4.7.4. Open Pit Reclamation Prescriptions	Required ☐		
4.7.5. Watercourse Reclamation Prescriptions	Required ☒		

Information (refer to "Joint Application Information Requirements for Mines Act and Environmental Management Act Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
4.7.6. Road Reclamation	Required ☐		
4.7.7. Schedule	Required ☒		
4.8. Detailed Five-Year Mine Reclamation Plan	Required ☒	The Application will include reclamation and closure information for the Project.	
4.9. Temporary Shutdown	Required ☒		
4.10. Post-Closure Monitoring and Maintenance	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.11. Reclamation Cost Estimate			
4.11.1. Conventional Reclamation and Closure	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.11.2. Post-Closure Monitoring	Required ☒	As informed by the Mine Reclamation and Closure Plan	
4.11.3. Post-Closure Maintenance (excluding Water Treatment)	Required ☒		
4.11.4. Life of Mine Water Treatment	Required ☒		
5. MODELLING, MITIGATION, AND DISCHARGES			
5.1. Summary	Required ☒		
5.2. Conceptual Site Model	Required ☐ Methods ☐		
5.3. Site-Wide Water Balance Model	Required ☒ Methods ☐	An updated water balance will be provided with the Application.	
5.4. Surface Water Quality Model	Required ☒ Methods ☐	An updated water quality model will be provided with the Application.	
5.5. Groundwater Model			
5.5.1. Conceptual Hydrogeologic Model	Required ☐ Methods ☐		
5.5.2. Numeric Hydrogeologic Model	Required ☒ Methods ☐	Existing numerical model for the TSF will be updated	
5.6. Mitigation Methods	Required ☐		
5.6.1. Best Available Technology Evaluation	Required ☐ Methods ☐		
5.6.2. Volume and Quantity Control Methods	Required ☒ Methods ☒		
5.6.3. Geochemical Attenuation Processes	Required ☐ Methods ☐		
5.6.4. Water Treatment			
5.6.4.1. Description	Required ☒	A brief description of the existing water treatment system will be provided in the Application. A high-level description of the proposed modifications will be provided as part of the Application.	
5.6.4.2. Location	Required ☒	A brief description of the existing water treatment system will be provided in the Application. A high-level description of the proposed modifications will be provided as part of the Application.	
5.6.4.3. Detailed Design	Required ☒		
5.6.4.4. Treatment Effectiveness	Required ☒		
5.6.4.5. Performance Risks	Required ☒		
5.6.4.6. Influent and Effluent Water Quality	Required ☒		

Information (refer to "Joint Application Information Requirements for Mines Act and Environmental Management Act Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
5.6.4.7. Waste and By-Products	Required ☒		
5.6.4.8. Maintenance	Required ☒		
5.6.4.9. Emergency Response Plans	Required ☒		
5.6.4.10. Monitoring Plans	Required ☒	Existing monitoring plans and their relevance to the Project will be discussed in the Application.	
5.6.4.11. Schedule	Required ☒		
5.6.4.12. Cost Estimate	Required ☒		
5.7. Domestic Water/Sewage Treatment	Required ☐ Methods ☐		
5.8. Effluent Discharge	Required ☐ Methods ☐		
5.9. Initial Dilution Zone	Required ☐ Methods ☐		
6. ENVRIONMENTAL ASSESSMENT PREDICTIONS			
6.1. Aquatic Resources	Required ☐ Methods ☐		
6.2. Terrestrial Resources	Required ☒ Methods ☐	The Project TSF expansion is expected to occur in a largely disturbed area within the M-200 permit boundary; however, the associated water management infrastructure will extend beyond the M-200 permit boundary..	
7. ENVIRONMENTAL MONITORING			
7.1. Environmental Monitoring Program Design	Required ☐ Methods ☐		
7.2. Mine Site Water Monitoring Program	Required ☒ Methods ☐	The existing Mine Site Water Monitoring Program will be discussed in the Application.	
7.3. Discharge Monitoring Program	Required ☐ Methods ☐		
7.4. Environment Monitoring Program	Required ☐ Methods ☐		
7.5. Post-Closure Environmental Monitoring Program	Required ☒ Methods ☐	As informed by the Mine Reclamation and Closure Plan	
7.6. Aquatic Effect Monitoring Program	Required ☐ Methods ☐		
8. HEALTH AND SAFETY			
8.1. Occupational Health and Safety Program			
8.1.1. Occupational Health Risk Assessment	Required ☒	The existing site wide Construction Environmental Management Plan will be used to support the Project.	
8.1.2. Ergonomics	Required ☐		
8.1.3. Emergency Wash Facilities	Required ☐		
8.1.4. Hazardous Dust	Required ☐		
8.1.5. Lunchrooms, Mine Dry, and Sanitary Conveniences	Required ☐		

Information (refer to "Joint Application Information Requirements for Mines Act and Environmental Management Act Permits" for additional info on each section)	Requirements	Comments	Location in Final Application
8.2. Post Permitting Requirements			
8.2.1. Issued for Construction Plans	Required ☒		
8.2.2. Letters of Assurance	Required ☐		
8.2.3. Occupational Health Programs	Required ☐		
8.2.4. Workplace Hazardous Materials Information System (WHMIS)	Required ☐		
8.2.5. Additional Information and Certifications	Required ☐		
9. MANAGEMENT PLANS			
9.1. Environmental Management System	Required ☐		
9.2. Surface Erosion Prevention and Sediment Control Plan	Required ☒	Relevant information for surface erosion prevention and sediment control will be included in the Application.	
9.3. Soil Management Plan	Required ☒	The existing Soil Management Plan will be used to inform the soil salvage and stockpile management	
9.4. Construction Environmental Management Plan	Required ☒	Management of materials to be used on site during construction will be addressed through the Construction Environmental Management Plan.	
9.5. ML/ARD Management Plan	Required ☒		
9.6. Mine Site Water Management Plan	Required ☒	Information related to construction water management will be included in the Application.	
9.7. Discharge Management Plan	Required ☐		
9.8. Vegetation Management Plan	Required ☒		
9.9. Invasive Plant Management Plan	Required ☒		
9.10. Wildlife Management Plan	Required ☒		
9.11. Archaeological Management and Impact Mitigation Plan	Required ☒		
9.12. Mine Emergency Response Plan	Required ☒		
9.13. Mine Site Traffic Control Plan	Required ☒		
9.14. Fuel Management and Spill Control Plan	Required ☒		
9.15. Combustible Dust Management Plan	Required ☐		
9.16. Chemicals and Materials Storage, Transfer, and Handling Plan	Required ☐		
9.17. Waste (Refuse and Emissions) Management Plan	Required ☐

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) has retained WSP Canada Inc. (WSP) to complete a detailed design to raise the tailings storage facility (TSF) at Mount Polley Mine. This report presents the detailed design to support raising the TSF from its currently permitted elevation of 970 m to a crest elevation of 974 m. The design crest elevation 974 m is an interim design to enable the TSF to be raised while design efforts for a potential raise of the TSF to contain the life of mine (LoM) tailings is advanced. The following are included in this report:

- design of the TSF raise to elevation 974 m, including the following design assessments:
  - site and deposition technology
  - storage capacity
  - seepage through the embankment and foundation
  - filter compatibility
  - upstream drain capacity
  - slope stability and deformation
  - water balance
  - risk review and design controls
- review and update of the TSF pond management, spillway design, and freeboard requirements
- construction drawings and technical specifications
- material quantities
- closure considerations

This report should be read in conjunction with the most recent TSF site characterization report (WSP 2023).

This design supports regulatory permit application, and hence satisfies the BC Ministry of Energy, Mines and Low Carbon Innovation requirements outlined in the Health, Safety and Reclamation Code for Mines in British Columbia (EMLI 2022). Design drawings of the TSF raise are provided in Appendix A, and the construction technical specification is provided in Appendix B.

MPMC defined and uses the coordinate system tailings grid for the TSF. All coordinates and elevations are presented in tailings grid.

2.0 BACKGROUND

Mount Polley Mine is a copper and gold mine near Williams Lake, British Columbia (BC), operated by MPMC, a subsidiary of Imperial Metals Corporation. The TSF is located about 3 km southeast of the mill and includes one embankment that is approximately 4.8 km in length (Drawing 02, Appendix A). The embankment is subdivided into three sections: the Main Embankment, Perimeter Embankment, and South Embankment (Drawing 03, Appendix A). The embankment has incorporated a staged expansion design utilizing modified centreline and centreline construction methods. The general zoning of the TSF embankment consists of the following:

- upstream fill comprising tailings sand and select fill (e.g., rockfill)
- low-permeability till core
- filter zone
- transition zone
- rockfill

Rockfill forms the downstream wedge of the embankments and the downstream buttress along the Perimeter and Main embankments.

Mount Polley Mine began production in 1997 and operated until October 2001 when operations were suspended for economic reasons. In March 2005, the mine restarted, and was in operation up to the time of the TSF breach in August 2014. The embankment crest was near elevation 968 m at the time.

In 2015, the Freshet Embankment was constructed to elevation 950 m through the breach area to allow the capture and temporary storage of the 2015 and 2016 freshet flows. The construction of buttresses along the Perimeter and Main embankments was completed in October 2016 (Golder 2015a, 2017a).

The June 23, 2016, amendment of *Mines Act* Permit M-200 authorized the return to full operations at the mine, including construction of the TSF to elevation 970 m (Golder 2015b) and deposition of tailings. Construction to raise the Freshet Embankment at Corner 1 to elevation 970 m started in June 2016. By September 2018, construction had been completed to elevation 968 m (Golder 2019b).

Mining operations at Mount Polley Mine were halted between May 2019 and Q4 2021 for economic reasons. In June 2022, the mill restarted operations and tailings deposition into the TSF resumed. Construction to raise the South, Main, and Perimeter embankments to elevation 970 m was restarted in July 2022 and was completed in 2023.

A feasibility design for raising the embankment of the TSF to an elevation of 984 m was completed in 2014 (Golder 2015c). The aim of the feasibility assessment was to identify potential considerations, constraints, or conflicts that may limit the elevation to which the TSF could be raised. The results of the study indicated that a raise of the facility is feasible. In 2021, MPMC updated the LoM plan, and a crest elevation of approximately 987 m was determined to be required to store the LoM tailings. An additional geotechnical investigation and laboratory testing is ongoing to assess potential strength gains from reconsolidation of the upper glaciolacustrine unit (UGLU) that sheared during the breach in 2014. This interim design to elevation 974 m was developed assuming no strength gains of the UGLU that sheared in 2014. A remoulded undrained shear strength equal to the average minus one standard deviation of the measured values as part of the forensic investigation in 2014 was adopted as in previous analyses and designs (Golder 2015b,e). An interim design elevation of 974 m was selected to enable short-term operations of the TSF.

3.0 BASIS OF DESIGN

The design basis for the raise of the TSF is summarized in this section, including the design and operation philosophy and key design criteria. The design of the TSF raise is consistent with applicable regulatory documents and guidelines from MPMC, WSP, and national and international organizations, where applicable (e.g., Canadian Dam Association [CDA], International Commission on Large Dams). The following regulations apply to this study:

- *Health, Safety and Reclamation Code (HSRC) for Mines in British Columbia* (EMLI 2022).
- Guidance Document for Revisions to Part 10 of the HSRC for Mines in BC (BC MEM 2016).

The design of the TSF is also consistent with the following guidelines, where applicable:

- CDA *Dam Safety Guidelines* (CDA 2013).
- *Technical Bulletin: Application of CDA Dam Safety Guidelines to Mining Dams* (CDA 2019).
- *Global Industry Standard for Tailings Management* (Global Tailings Review 2020).
- Mining Association of Canada *Guide to the Management of Tailings Facilities* (MAC 2021).

The complete design basis and design criteria are included in Appendix C.

3.1 Design and Operation Philosophy

The design of the TSF follows the principles set out by the Mining Association of Canada in its Towards Sustainable Mining program and the recommendations made by the Independent Expert Engineering Investigation and Review Panel (IEEIRP 2015). The following approaches have been used for the design of the TSF:

- **Limit the amount of surface water to that required for operation**—This will be achieved through maintaining storage capacity within the external water management ponds and ongoing discharge of water from the mine site.
- **Promote unsaturated conditions in the tailings**—Wide sub-aerial beaches will be maintained upstream of the embankments, and upstream drains will be constructed to create a zone of unsaturated tailings adjacent to the embankments.
- **Promote consolidation of tailings upstream of the TSF embankment**—Upstream drains will be constructed to create a zone of unsaturated tailings adjacent to the embankments.
- **Reduce the hydraulic gradient across the till core**—This will be achieved through maintaining wide sub-aerial beaches along the embankments and the construction of upstream drains.

Operation of the TSF is to follow the above philosophy. Quantitative performance objectives (QPOs) have been defined to confirm that operation of the TSF follows the operation philosophy.

3.2 Design Basis and Criteria

Key design basis and criteria are summarized in Table 1. The complete design basis and criteria are included in Appendix C. Specific design criteria for each design component are provided within those sections in the report.

Table 1: Design Basis and Criteria

Criteria	Unit	Value	Source/Comment
General			
Nominal Tailings Production Rate	t/day	20,000	MPMC (2021)
TSF storage capacity	-	minimum to allow continuity of operation until 2026	Includes the remaining storage capacity of the permitted 970 m raise based on the 2019/2020 survey of the tailings surface 8.0 Mt deposited between June 2022 and December 2023
Dam classification	-	Significant	Refer to Appendix C
Design earthquake event	AEP	1:2,475	HSRC Guidance Document Section 3.3.1 (BC MEM 2016) Other criteria include: ▪ Between 1:100 and 1:1,000 AEP (CDA 2019) ▪ 1:1,000 AEP recommended by GISTM (Global Tailings Review 2020) Consistent with WSP's best practice, an earthquake event of 1:10,000 AEP will be used to assess sensitivity of the analyses
Static (long term)	FoS	1.5	HSRC Guidance Document Section 3.3.1 (BC MEM 2016) CDA (2019) Table 3-4
Static (during or at end of construction)	FoS	1.5	HSRC Guidance Document Section 3.3.1 (BC MEM 2016) Other criteria include: >1.3 recommended by CDA (2019) Table 3-4
Pseudo-static	FoS	1.0	Informed by Table 3-5 of CDA (2019)
Post-earthquake	FoS	1.2	Informed by Table 3-5 of CDA (2019)
Overall downstream slope no steeper than	-	2H:1V	HSRC Guidance Document Section 3.3.1 (BC MEM 2016)

Table 1: Design Basis and Criteria

Criteria		Unit	Value	Source/Comment
Tailings Characteristics				
Solids content of tailings slurry discharged to TSF		%wt	Nominally ~35	Provided by MPMC
Tailings average dry density after deposition		t/m^3	1.35	Assumed by WSP 1.36 t/m^3 by KP (2005)
Tailings beach slope		%	Sub-aerial – 0.5% Sub-aqueous – 2%	Based on available topographic and bathymetric surveys since 2016
Water Management				
IDF	Operations	-	72-hour PMF	PMF runoff volume will be estimated considering the annual 72-hour PMP rainfall plus snowmelt, which was selected consistent with WSP's best practice. Other criteria include: ▪ 1/3 between 1-in-975-year and PMF for a minimum duration of 72 hours required by HSRC Guidance Document Section 3.3.1 (BC MEM 2016). ▪ Between 1-in-100 and 1-in-1,000-year return period recommended by CDA (2019). ▪ 1-in-1,000-year return period recommended by GISTM (2020).
EDF	Operations	years	24-hour 1:200 year precipitation and snowmelt	Typical EDF return periods range from 1-in-50 years to 1-in-200 years (CDA 2019).

Table 1: Design Basis and Criteria

Criteria		Unit	Value	Source/Comment
Freeboard	Normal	-	No overtopping by 95% of waves caused by the most critical wind with a frequency of 1:1,000 year with reservoir at maximum normal elevation	CDA (2013)
	Minimum	-	No overtopping by 95% of waves caused by the most critical wind when the reservoir is at its maximum level during the IDF	CDA (2013)
Water Management				
Operating pond volume range		million m^3	1.5 to 1.7	Minimum provided by MPMC for operation of the mill Maximum adopted to maintain wide sub-aerial beaches
Beach width		m	100	Minimum during normal operating conditions Portion of beach above operating pond level

TSF = tailings storage facility; Mt = million tonnes; HSRC = Health, Safety and Reclamation Code; AEP = annual exceedance probability; GISTM = Global Industry Standard for Tailings Management; FoS = factor of safety; %wt = weight percent; IDF = inflow design flood; EDF = environmental design flood; PMF = probable maximum flood; PMP = probable maximum precipitation.

4.0 SITE CONDITIONS

The Mount Polley TSF site characterization report (WSP 2023) presents the TSF site conditions with respect to climate, geology, seismicity, geotechnical, hydrogeology, and geochemistry.

The Engineers and Geoscientists British Columbia (formerly The Association of Professional Engineers and Geoscientists of British Columbia, APEGBC) site characterization for dam foundation guidelines (APEGBC 2016) were followed during the preparation of the Mount Polley TSF site characterization report. It is intended that the TSF site characterization report be updated with data from future site investigations, and with observations and data from construction and operation of the TSF. Should the understanding and interpretation of site conditions change with time, then the TSF design will be reassessed incorporating the site condition changes.

A summary of the TSF site conditions is presented in this section to provide context for the design and to define conditions and design parameters for analyses including climate and earthquake events. Foundation material properties adopted for seepage and stability modelling are presented in Sections 7.5 and 7.7.

4.1 Site Location and Geomorphology

Mount Polley Mine is located approximately 56 km northeast of Williams Lake, BC, between Polley Lake and Bootjack Lake.

The region is located on the eastern edge of the Interior Plateau, at the boundary between the Quesnel Highlands and the Fraser Plateau. Terrain and geomorphology of the region comprises flat and gently rolling topography with hummock bedrock exposures, dissected by a network of streams and lakes. Surface drainage patterns are influenced by bedrock topography; most of the stream valleys in the region have a northwest orientation and drain southward toward the lowland area north of the western arm of Quesnel Lake (Bichler and Bobrowsky 2003).

In the TSF area, the gentle topography and surface expression of the lowland area at the head of the west arm of Quesnel Lake is the result of glacial advance followed by glacial retreat and inundation by meltwater. The regional surficial geology is dominantly the result of erosion and deposition associated with the most recent glaciation (WSP 2023).

4.2 Climate

The site experiences high summer precipitation due to summer storms, and the lowest monthly precipitation occurs in February. Precipitation typically occurs as snowfall starting in November, which accumulates until March. Average annual precipitation at the site is estimated to be 612 mm, with a standard deviation of 118 mm based on precipitation records for the site from 1974 to 2021. Typically, the increase of temperatures over 0°C starts in March, leading to freshet until June.

A summary of the baseline climate parameters is provided in Table 2. An evaluation of future climate change projections indicates future climate at the site will likely be warmer and wetter, with larger variations throughout the months.

Table 2: Summary of Key Climate Parameters for Mount Polley Mine

Parameter	Value
Mean annual total precipitation (mm)	612
1:2-year 24-hour rainfall (mm)	33
1:10-year 24-hour rainfall (mm)	47
1:200-year 24-hour rainfall (mm)	69
Projected annual total precipitation anomaly from baseline for 2050s (%)	+5

Table 2: Summary of Key Climate Parameters for Mount Polley Mine

Parameter	Value
Projected annual total precipitation anomaly from baseline for 2080s (%)	+8
Mean annual temperature (°C)	3.9
Average winter season (sub-zero mean monthly temperatures)	November to March
Mean snow water equivalent for the month of March (mm)	185
Projected annual air temperature anomaly from baseline for 2050s (°C)	+1.8
Projected annual air temperature anomaly from baseline for 2080s (°C)	+2.7
Mean annual shallow lake evaporation (mm)	673
Mean annual potential evapotranspiration (mm)	863

Note: Statistics are based on reviewed historical records from multiple climate stations and measured and derived data (where applicable).

The five-year update of the climate baseline for the site is presented in WSP Golder (2022a) and includes precipitation, air temperature, relative humidity, solar radiation, evaporation, snow depths, wind speed and direction, and updated climate change projections.

4.3 Hydrology

The mine site is drained by three main watersheds: Hazeltine Creek, Edney Creek, and Morehead Lake. The Hazeltine Creek watershed includes Polley Lake and conveys all water from Polley Lake, the east side of Mount Polley, and the area surrounding the TSF. In general, the hydrology of Hazeltine Creek (and by extension, the mine area and TSF) can be described as snowmelt driven, with the majority of annual runoff occurring during the spring snowmelt in April and May freshet (KP 2014).

4.4 Geology

The regional surficial geology is predominantly the result of erosion and deposition associated with the late Pleistocene (Wisconsinan) glacial episode referred to as the Fraser Glaciation (Clague 1987, 1988). The stratigraphic sequence identified in the area of the TSF can be generalized in order of increasing depth as follows:

- fill and anthropogenic materials
- ablation till, including glaciolacustrine and glaciofluvial sub-units
- basal till, including glaciolacustrine and glaciofluvial sub-units
- bedrock

This stratigraphic sequence is generally applicable to the mine area and TSF, with local variations associated with the depositional and erosional history of a particular area. The surficial geological units of the TSF area are interpreted to represent two main stages of the Fraser Glaciation: the advance stage and the recessional stage (Bichler and Bobrowsky 2003). Basal till is punctuated by glaciofluvial and glaciolacustrine deposits that typify the early stages of deposition (the advance stage), represented in the TSF area by basal till and associated sub-units. The ablation till and some layers of the glaciofluvial and glaciolacustrine sub-units were likely deposited during the recession stage of glaciation.

Available mapping indicates the TSF area is underlain by altered, deformed, and brecciated volcanic and intrusive igneous rocks of the Late Triassic Nicola Group, with local sandstone and conglomerate of the Kamloops Group, Dragon Mountain Formation and some unnamed sediment groups (Logan et al. 2007).

4.5 Seismicity

The site is located in an area of relatively low seismicity for BC. WSP developed a site-specific seismic hazard model for the Mount Polley Mine site based on source models developed for the 6th Generation Canadian National Seismic Hazard Model (Canada SHM6) and a review of geological and paleoseismological features (WSP 2023a). Both near-field, moderate-magnitude crustal earthquakes and far-field subduction interface earthquakes contribute to the site seismic hazard. The shallow crustal earthquake sources are dominated by moderate-magnitude earthquakes (**M**6.0 to **M**6.5) close to the site (i.e., less than 60 km) at all annual exceedance probabilities (AEPs). The contribution to hazard at the site from the Cascadia subduction zone is from large earthquakes (**M**8+) at 450 to 550 km from the site at all AEPs and spectral periods of interest.

Probabilistic analysis results from site-specific hazard model are listed in Table 3.

Table 3: Peak Ground Accelerations (5%-damped) for Selected Annual Exceedance Probabilities at the Mount Polley Tailings Storage Facility Site (V_{S30} = 849 m/s)

Annual Exceedance Probability (AEP)	Mean Acceleration (g)
1:1,000	0.026
1:2,475	0.048
1:5,000	0.076
1:10,000	0.116

V_{S30} = time-averaged shear-wave velocity (VS) to a depth of 30 m.

For dams impounding tailings with a Significant consequence classification, the HSRC Guidance Document (BC MEM 2016) defines a minimum earthquake design ground motion with a 1:2,475 AEP.

4.6 Geotechnical Conditions

A detailed description of geotechnical conditions in the area of the TSF embankment is provided in WSP (2023a). Typically, the stratigraphic units in the foundations of the TSF can be characterized as follows:

- **Till**—The till is generally a mixture of gravel, sand, and low plastic fines ranging from silt to silty clay. The material is generally cohesive with a consistency from firm to hard.
- **Glaciofluvial units**—The glaciofluvial units are generally gravelly sandy silt to silty sand with trace gravel. The fines content ranges from about 4% to 100% and are generally non-plastic. The material is generally non-cohesive with a compactness ranging from compact to very dense.
- **Glaciolacustrine units (GLUs)**—The GLUs are generally silty clay to clay with trace to some sand. The fines are generally low to high plasticity. The material is generally cohesive with a consistency ranging from firm to very stiff. The sensitivity of the glaciolacustrine soil interpreted from the cone penetration testing (CPT) data generally ranges between 2 and 3.
    - **Main Embankment**—A semi-continuous layer of glaciolacustrine soil is present at an elevation of approximately 900 to 910 m and extends along the length of the Main Embankment. A shallower layer of glaciolacustrine soil near elevation 920 m was identified near Stn. 2+455 and 2+695. The Main Embankment glaciolacustrine soil generally has a low to intermediate plasticity (silt to silty clay). The average water content is approximately 26%.

Consolidation tests indicate a range of preconsolidation pressures from 1,100 kPa to 4,000 kPa and CPT data generally indicates a minimum preconsolidation pressure of about 1,200 kPa at the elevation of the semi-continuous layer of glaciolacustrine soil. CPT data at the higher elevation glaciolacustrine soil layer shows an interpreted minimum preconsolidation pressure of about 850 kPa. The maximum excess pore pressures generated when rockfill was stockpiled on the Main Embankment in 2022 was equivalent to a B-bar of 0.13.

- **Perimeter Embankment**—The glaciolacustrine soil deposits along the Perimeter Embankment are not continuous, and their elevations generally range from about 885 to 935 m. The Perimeter Embankment glaciolacustrine soil generally has a low to intermediate plasticity (silt to silty clay). The average water content is approximately 21%. Consolidation tests indicate a range of preconsolidation pressures from 900 to 3,800 kPa.
- **Perimeter Embankment at Corner 1**—Upper and lower glaciolacustrine soil deposits are present at Corner 1.
  - The upper glaciolacustrine (UGLU) deposit is a semi-continuous layer between approximate elevation 918 and 925 m from approximately Stn. 4+000 to 4+285. The UGLU generally consists of silty clay to high plasticity clay, with trace to some sand, and is firm to stiff. The fines are generally an intermediate to high plastic material and range from silty clay to clay. The average water content of the UGLU is approximately 31% and is generally greater compared to the glaciolacustrine material encountered in the foundation of the other embankments. Consolidation tests indicate a range of preconsolidation pressures from about 300 kPa to 590 kPa. The maximum excess pore pressures generated during the construction of the 2015 Freshet Management Embankment were equivalent to a B-bar of 0.46. Excess pore water pressures take approximately one year to dissipate based on the rate of consolidation measured in the laboratory and the field.
  - The lower glaciolacustrine (LGLU) deposit is also a semi-continuous layer between approximate elevation 900 and 918 m. The LGLU fines generally consist of a low to intermediate plastic material and range from silty clay-clayey silt to silty clay. The average water content of the LGLU is approximately 22%. Consolidation tests indicate a range of preconsolidation pressures in the order of 700 to 1,200 kPa.
- **South Embankment**—A layer of low plasticity silty clay interpreted to have deposited in a glaciolacustrine environment was encountered directly above bedrock near Stn. 1+095 at the South Embankment; however, the geotechnical testing completed on the material is not representative of the intermediate or high plasticity GLUs found within the footprint of the Perimeter Embankment at Corner 1.

- **Highly weathered bedrock**—Generally weathered volcaniclastic conglomerate, volcanic debris or completely weathered bedrock.

Material properties for limit equilibrium stability analysis are presented in WSP (2023a) and included in Section 7.7.2.

4.7 Hydrogeology

The groundwater flow direction prior to the development of the TSF was inferred to be from the west and northwest towards the east and southeast. The water table was observed to be near ground surface, with artesian pressures measured within the TSF basin upstream of Corner 4 and upward groundwater flow gradients measured along the Main Embankment and Perimeter Embankment at Corner 1.

The current groundwater flow direction in the area of the TSF is inferred to be partly dependent on the existing TSF Pond level. Provided that surface water level elevations within the TSF are above the surrounding shallow groundwater level, groundwater flow will be radial from the TSF towards the southwest, southeast, and northeast. However, when the TSF pond level falls below the shallow groundwater levels on the west side of the TSF, then the TSF area becomes a flow-through environment, similar to pre-development conditions, with groundwater flow directed across the TSF from the west and northwest towards the east and southeast.

Based on in situ and laboratory testing, the hydraulic conductivity of the foundation till (ablation till and basal till) is variable, ranging from 1×10^{-5} m/s to 2×10^{-8} m/s. The range in hydraulic conductivity for the glaciofluvial units, 8×10^{-4} m/s to 2×10^{-6} m/s, confirms that these units are more permeable and may act as preferential pathways for seepage from the TSF. Conversely, the range in hydraulic conductivity for the glaciolacustrine deposits, 7×10^{-8} m/s to 2×10^{-10} m/s, confirms that these units have a low permeability and may act as barriers for seepage migration and/or as confining units where they occur directly above glaciofluvial units, and could potentially cause artesian pressures in the underlying glaciofluvial units.

Material properties for seepage analysis are included in Section 7.5.

4.8 Groundwater Geochemical Conditions

Baseline groundwater quality conditions are generally characterized by low concentrations of dissolved metals, sulphate, and nitrate and low to moderate hardness.

Over the last decade or so, although there were increasing parameter of interest concentration trends at some locations, significant changes to groundwater quality at the perimeter of the TSF has not been identified except with respect to sulphate. The concentration of sulphate in groundwater downgradient of the TSF at the Perimeter Embankment between Corner 1 and Corner 2 and at the South Embankment near Corner 3 approached or reached levels observed in the TSF pond water. The concentration of sulphate does not exceed the BC Ministry of Environment and Climate Change Strategy Contaminated Sites Regulation (BC ENV 1997) standards for protection of freshwater aquatic life and is monitored quarterly or semi-annually depending on location.

5.0 TAILINGS CHARACTERIZATION

5.1 Geotechnical Characterization

Typical characteristics of the tailings that have been deposited in the TSF are included in Table 4.

Table 4: Characteristics of Existing Tailings

Parameter		Value	Source/Comment
Gradation	Sand	31%–38%	Available particle size distributions are shown in Figure 1 In 2014, three particle size tests were undertaken on tailings samples collected from within the TSF near the Perimeter Embankment. The data indicate the tailings deposited near the embankment are generally silty sand/sandy silt (fines content 20% to 58%), likely due to varying degrees of segregation during deposition as conventional slurry
	Fines	62%–69%	
Plasticity		Non-plastic	Based on visual classification
Specific gravity of solids		2.7–2.8	Estimated based on KP (1990) and Golder (2015d)
Hydraulic conductivity		1×10^{-6} to 1×10^{-5} m/s	Considered to be representative of tailings deposited near the embankment Based on falling head laboratory testing (Golder 2015e) and estimated from available particle size distribution curves
Sub-aerial beach slope		0.5%–1%	Based on available topographic and bathymetric surveys since 2016
Sub-aqueous beach slope		2%–3%	Based on available topographic and bathymetric surveys since 2016
Average dry density after deposition		1.35 t/m^3	Assumed by WSP Assumed as 1.36 t/m^3 by KP (2005)

Three CPTs (CPT16-20, -21, and -22) were undertaken on the tailings beach in 2016 to maximum depths of up to 35 m below the tailings surface (Golder 2017b). The three tests were undertaken within 100 m of the upstream crest of the embankment. Using the Robertson (1990) soil behaviour type classification, the tailings materials were predominantly classified as interlayered silty sand, sandy silt, clayey silt, and silty clay. This classification is generally consistent with the findings of particle size tests undertaken on the tailings. The state parameter estimated for all CPTs was between about -0.2 and -0.1 for the first upper 5 to 10 m, and between about -0.1 and 0 below that depth, with the exception of a few thin layers with positive state parameter (Golder 2017b).

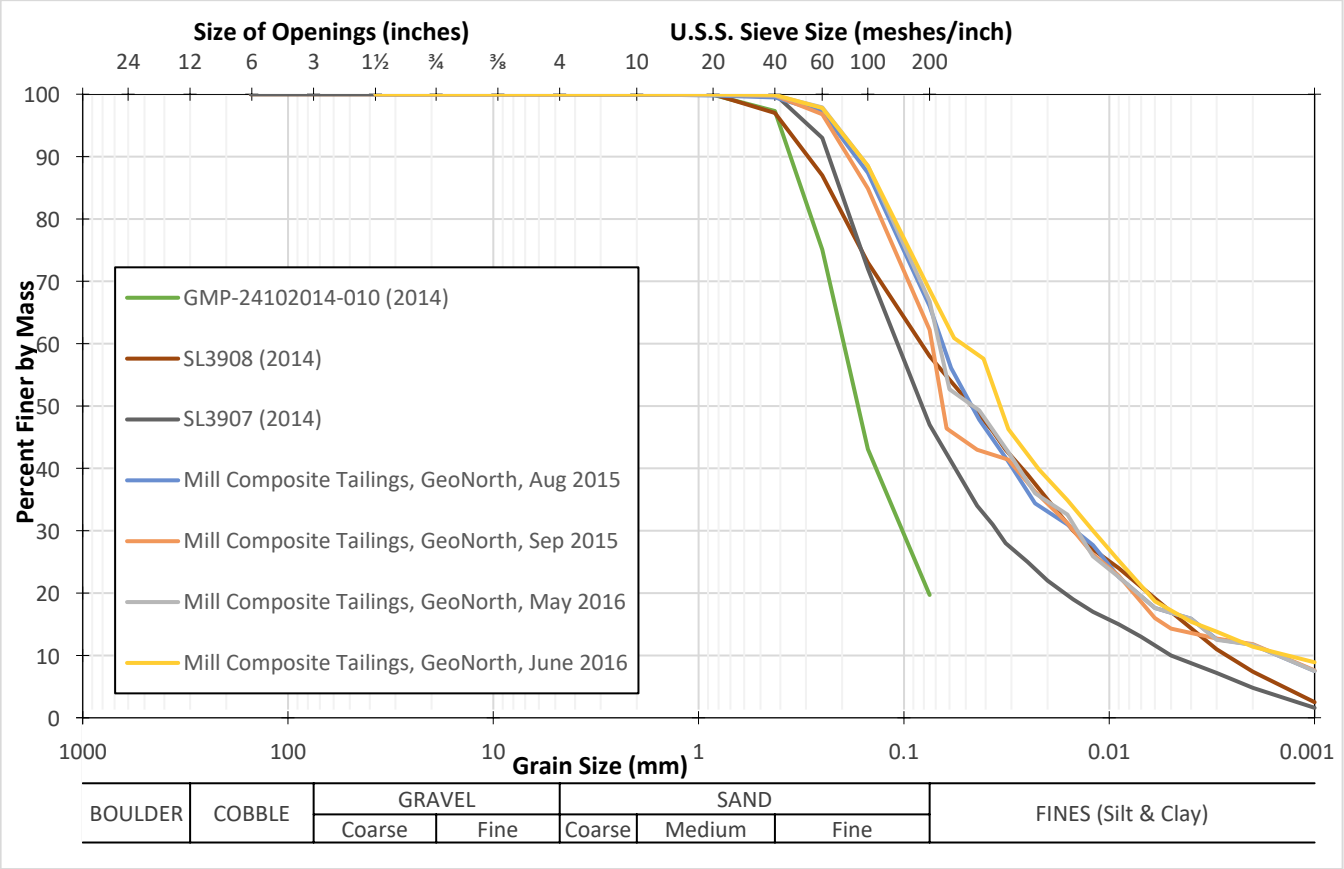

Figure 1: Gradation of Existing Tailings

5.2 Tailings Chemistry

The Mount Polley copper-gold porphyry deposit is classified as an alkalic porphyry copper gold deposit. The mined mineralized zones are enriched in copper and selenium relative to global norms. The tailings are lower in sulphide mineral content compared to the ore because most of the copper sulphides are removed through ore processing. In addition, mill process reagents, with the exception of lime, are not expected to be present within the tailings. Processing changes over time have been minimal and are not expected to affect the geochemical reactivity of the tailings; therefore, tailings geochemistry can be considered generally consistent over time (Kennedy et al. 2016; SRK 2022).

Mount Polley tailings are classified as non-acid generating based on operational monitoring and testing of tailings spilled into Hazeltine Creek in August 2014.

The leachate quality from humidity cell tests and column tests is described below:

- pH typically between 8.0 and 8.2
- sulphate concentrations initially on the order of 1,000 mg/L, with decreasing concentrations over time that reached lower stabilized values
- highest copper concentration of 0.15 mg/L in one test, but with typical maximum concentrations of 0.02 mg/L in humidity cell test leachates and 0.05 mg/L in column test leachates

- highest selenium concentrations were 0.01 mg/L in humidity cell test leachates and 0.06 mg/L in column test leachates
- molybdenum concentrations initially between 2 and 3 mg/L in column leachates

The measured concentrations at the TSF supernatant pond are generally below Permit limits, with the exceptions for total copper, total phosphorous, total arsenic, total zinc, and dissolved aluminium (WSP 2023d). The source of the increased concentrations in the monitoring data for these parameters is thought to be due to the discharge of leachate to the TSF from the onsite test heap leach facility in 2018 (Golder 2022), which has since been decommissioned. These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process.

6.0 DESIGN DESCRIPTION

This section includes a description of the design, materials and zoning, surface and foundation preparation, abutment details, water management, and details of the upstream drains and tailings management.

6.1 Overview of Embankment Raise

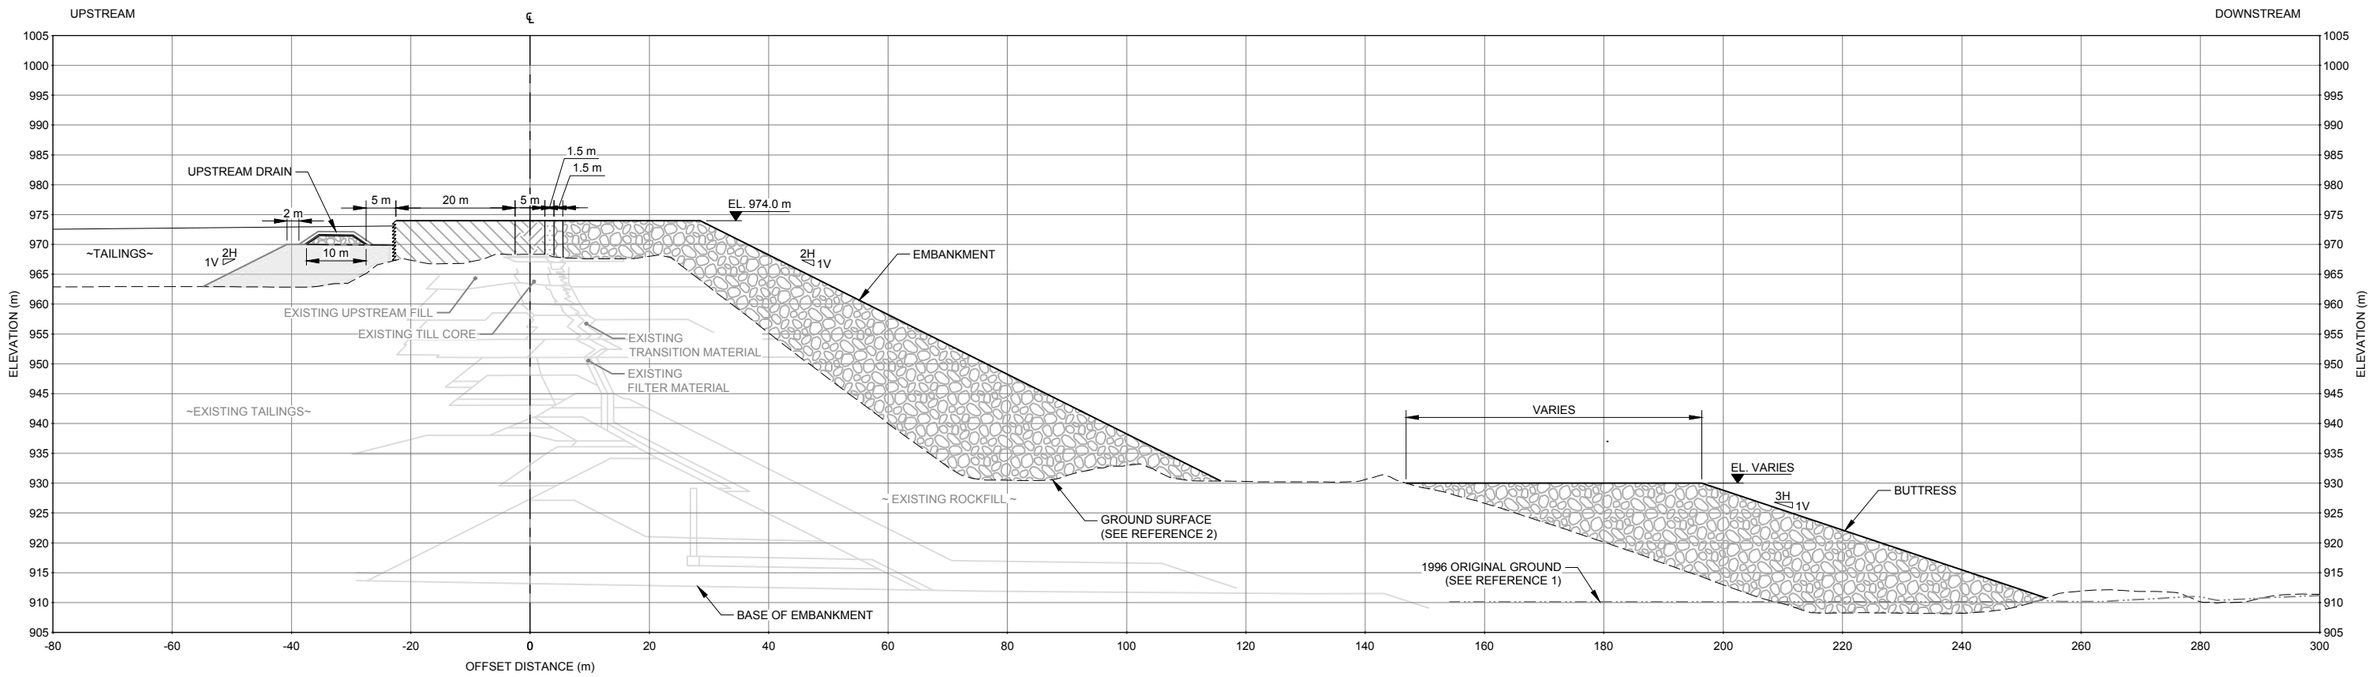
The TSF embankment (Main, Perimeter, and South embankments) is constructed to a maximum elevation of 970 m. The design of the TSF to elevation 974 m provides storage capacity for tailings production of approximately 24 million tonnes (Mt; based on current beach slopes and includes the remaining storage capacity of the permitted 970 m raise based on the 2019/2020 survey of the tailings surface).

The embankment raise to elevation 974 m includes:

- extension of portions of the buttresses along the Main and Perimeter embankments
- resloping of the South, Main, and Perimeter embankments to 2H:1V
- extension of the embankments at the south and north abutments
- construction of a drain upstream of the till core along the embankments

The facility will require a rate of rise of about 2 m per year (i.e., to about elevation 972 m in 2024 and to 974 m in 2025) to accommodate the planned tailings production.

6.2 Embankment Materials and Zoning



The embankment raises will consist of the components detailed in Table 5. A typical section is shown in Figure 2. Technical specifications detailing placement and compaction and quality assurance and quality control requirements for the materials listed in Table 5 are included in Appendix B.

Table 5: Embankment Zoning

Name	Zone	Description and Purpose
Upstream fill	U	Minimum 20 m wide fill zone to provide upstream support to Zone S (till core)
Till core	S	Minimum of 5 m wide low hydraulic conductivity element, placed upstream of Zone F (filter)
Filter	F	Minimum of 1.5 m wide, placed upstream of Zone T (transition) and downstream of Zone S (till core). Zone F is designed to be filter compatible with Zone S and the foundation till and prevent erosion of Zone S and foundation till into the voids of Zone T
Transition	T	Minimum of 1.5 m wide, placed upstream of Zone C (compacted embankment rockfill) and downstream of Zone F (filter). Zone T is designed to be filter compatible with Zone F and prevent erosion of Zone F into the voids of Zone C
Compacted embankment rockfill	C	Minimum 10 m wide, placed downstream of Zone T (transition) and compacted in 1 m layers
Embankment rockfill	-	13 m wide at elevation 974 m, placed downstream of Zone C (compacted embankment rockfill). The downstream face of the embankment rockfill will be 2 horizontal to 1 vertical (2H:1V)
Buttress rockfill	-	3H:1V downstream face, which will impose a low shear stress on the foundation soils due to the flatter downstream slope and increase the length of potential slip surfaces passing through the foundation soils, thereby resisting force and improving stability

Note: Materials are listed in order from upstream to downstream of the embankment. Materials for construction of the upstream drain are included in Section 6.6.

The gradation envelops of embankment construction materials are presented in Figure 3. All fill materials will be non-acid generating.

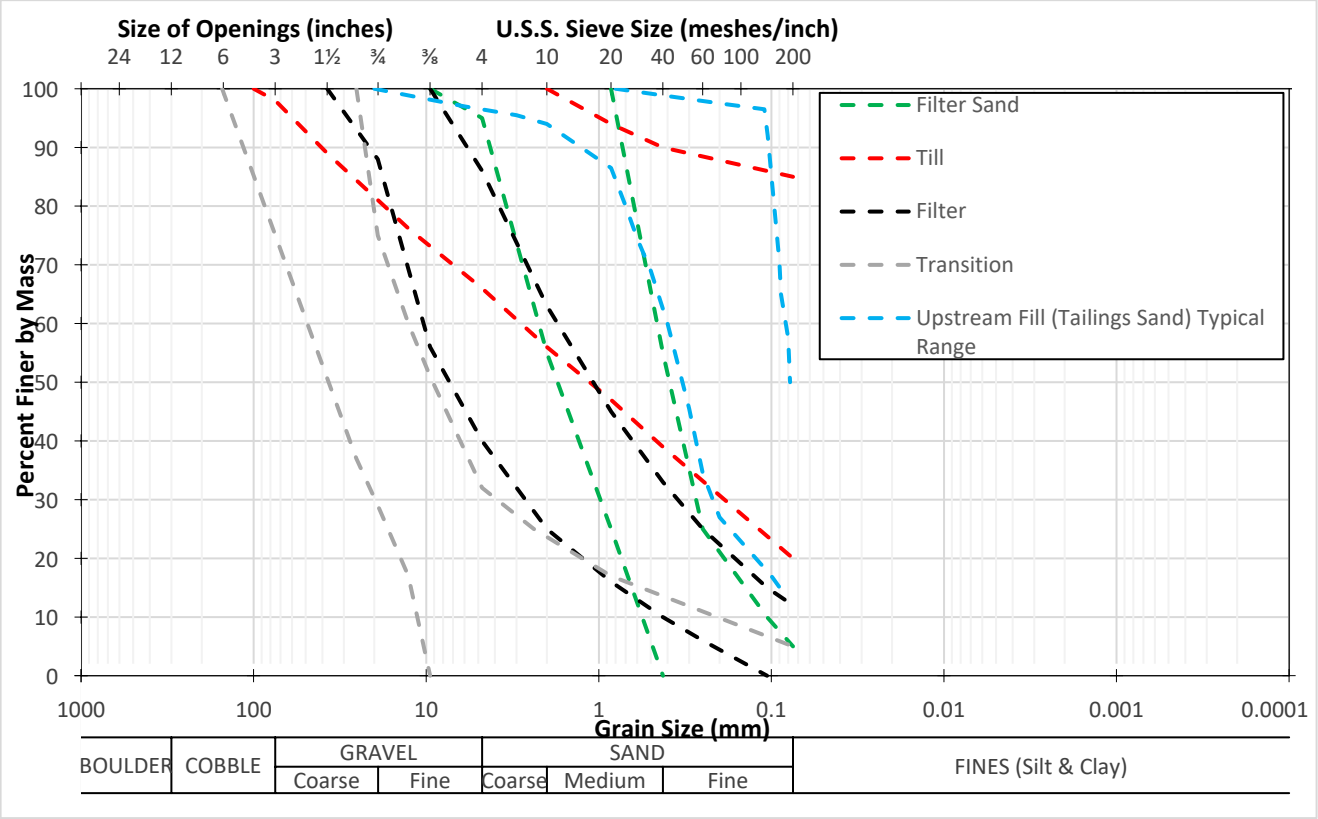

Figure 3: Embankment Construction Material Particle Size Distribution Envelopes

The filter, filter sand, and transition materials have been designed to meet modern filter criteria (USBR 2011; FEMA 2011; Fell et. al 2015; USDA 2017) with a modification on the maximum sand content (i.e., 40%) in the filter band based on laboratory testing (Eldridge and Gilmer 2002). The laboratory testing was carried out on crushed aggregates with a similar gradation under hydraulic gradients much greater than those expected in the Mount Polley TSF.

The filter, filter sand, and transition gradation envelope requirements for construction of the embankment to elevation 974 m remain unchanged from the filter, filter sand, and transition gradation envelopes specified for construction of the embankment to elevation 970 m (Golder 2015b). Fill materials will be produced, stockpiled, hauled, and spread in a manner to minimize segregation. Materials not complying with the specification will not be used in the construction.

6.3 Foundation Preparation

Foundation preparation is required at the following locations prior to any fill placement:

- at the north and south abutments
- along the foundation of the South Embankment reslope
- along the foundation of the Main and Perimeter embankments buttress extension

Stockpiled material, vegetation, and topsoil is to be stripped along the footprint of the abutments, South Embankment reslope, and buttress extensions. Stripped material will be managed in accordance with MPMC soil management programs. The extent of the foundation preparation is shown in Drawings 05, 09, 15, and 20 (Appendix A), and details are provided in the technical specification (Appendix B).

6.3.1 North and South Abutments

The embankment will extend onto natural ground at the north and south abutments (i.e., Corner 4 and Corner 5). The abutment details will consist of the till core tied into competent till or onto bedrock. A filter blanket is to be placed downstream of the till core, along the till foundation. The embankment design at the abutments is shown in Drawing 25, Appendix A. Foundation preparation will consist of removal of topsoil, organics, and soft or loose soil to expose competent till. Where the till foundation is greater than 2 m thick, the till core will be keyed into the till. Where the till is less than 2 m, the till core is to extend down to competent bedrock. The depth of the till foundation will be confirmed by the excavation of test pits.

Where excavation is required to bedrock, highly fractured and weathered bedrock overlying sound bedrock is to be removed. The surface of the exposed bedrock is to be cleaned of all soil and loose bedrock. Depending on the condition of the bedrock and the opinion of the geotechnical engineer, additional treatment may be required, which may consist of the placement of bentonite, shotcrete, or slush grout.

The biosolids stockpile at the north abutment is to be excavated to the extents necessary for foundation preparation. The final limits of foundation preparation at the abutments will be confirmed by the geotechnical engineer during construction.

Placement of a till blanket may be required at the south abutment after foundation preparation is completed to grade the surface so it drains downstream from the till core.

6.4 Water Management

The Mount Polley Mine site has an annual net water surplus, and discharge from the mine site is necessary to manage the mine site water and to prevent accumulation of water on the mine site year over year.

Water management will be consistent with practice to date. Temporary detention of water is necessary in the TSF to manage runoff volumes generated during the freshet; however, the fundamental basis of the water management plan is to not accumulate water on site (including the TSF) by treating and discharging water and to not carry over water from year to year even under extreme wet conditions.

The majority of water inflows into the TSF are pumped and are therefore in the direct control of the operator. The inflows into the TSF are as follows:

- water discharged with the tailings slurry, at approximately 35% solids by weight
- water pumped from the site water management structures for temporary detention in the TSF during freshet or high precipitation events

The water inflows to the TSF that are not pumped, and therefore not in the direct control of the operator, are as follows:

- precipitation on the direct footprint of the TSF (approx. 2.38 km^2)
- runoff from the catchment directly above the TSF (approx. 1.19 km^2)

Outflows from the TSF consist of the following:

- reclaim water pumped to the mill or Perimeter Embankment Till Borrow Pond by means of a floating barge within the TSF pond
- seepage through the embankment, upstream drains and foundation to the seepage collection ponds
- evaporation losses from the TSF pond and wet tailings beaches
- water retained in the newly placed tailings

The TSF will be managed by maintaining the pond volume within the normal operating range (i.e., 1.5 to 1.7 million m^3) for reclaim water and make-up water.

6.5 Tailings Management and Deposition

Tailings management and deposition will be consistent with practice to date. Tailings will be deposited as a slurry with approximately 35% solids by weight. The tailings will be discharged along the embankment crest and will form an average beach slope of approximately 0.5% to 1%. The sub-aqueous tailings will form a steeper slope of approximately 2% to 3%. It is assumed that the maximum pond depth during normal operation is about 4 m at the location of the reclaim barge.

Deposition of the tailings will be planned to maintain the pond near the centre of the facility and against the natural topography on the western perimeter. A minimum beach length of 100 m will be maintained between the TSF pond and the embankment during normal operations. To enable management of the pond against the natural ground and to maintain a minimum beach length of 100 m, the barge will need to be relocated to a central location between Corner 4 and Corner 5.

The location of the pond over the period of operations up to elevation 974 m for the TSF is shown in the tailings deposition figures in Appendix F.

6.6 Upstream Drain

The hydraulic head imposed on the embankments will be controlled by the construction of an upstream drain along the upstream side of the embankments. The upstream drain will be constructed at about elevation 970 m along the Main Embankment and from Corner 1 to Corner 2 at the Perimeter Embankment. Along the South Embankment and at the Perimeter Embankment at Corner 1, the upstream drain may be constructed higher up to elevation 972 m.

The upstream drain will collect water from the tailings in the TSF and will discharge the water outside of the TSF into the downstream water management infrastructure. The upstream drain will also promote drainage and consolidation of newly placed tailings.

The upstream drain has been sized to convey flows for a crest elevation of 987 m. Details for the upstream drain are included in Section 7.6.

7.0 DESIGN ANALYSES AND ASSESSMENTS

The design of the Mount Polley TSF raise to elevation 974 m was informed by the studies and assessments presented in this section:

- site and deposition technology selection
- water balance
- storage capacity analysis
- filter compatibility assessment
- seepage analysis
- upstream drain design
- slope stability analysis
- stress-deformation analysis
- freeboard and spillway design
- closure considerations
- risk review and design controls

7.1 Siting and Deposition Technology

Typically, a single consolidated TSF is preferred over multiple smaller TSFs; however, there are cases where multiple TSFs may be a preferred option. This section provides a summary on the selection of a site for tailings management at the Mount Polley Mine site and on best available technology and best applicable practices for tailings deposition as it relates to Mount Polley Mine. The study is provided in Appendix D.

7.1.1 Objectives

In selecting potential locations and technologies for the storage of tailings, the following objectives are to be met (BC MEM 2016):

- Provide secure and permanent storage facility.
  - physical stability
  - chemically and biologically stable, or be designed to mitigate transport of contaminants into the receiving environment
- Minimize additional land disturbance (i.e., additional footprint of the facility).
- Maximize in-pit or underground backfill.
- Minimize impacts to receiving environment.
- Minimize social impact (e.g., negative public perceptions, disruption of traditional land use).
- Minimize cost, including the costs for investigation, design, procurement, construction, operation, and closure.

- Incorporate post-closure land use objectives.
- Limit the amount of free water within the impoundment.

7.1.2 Site Alternatives and Available Deposition Technologies

A siting and deposition technology assessment was completed as part of the Mount Polley TSF elevation 984 m LoM feasibility design (Golder 2015c). The study included a review of available tailings deposition technologies; a review of potential sites to deposit tailings; and an assessment of the alternatives based on environmental, social, technical, and economic indicators. Deposition of the remaining LoM tailings (i.e., about 70 Mt at the time) as a slurry within the existing TSF was identified as the best available option in 2015 (Golder 2015c).

The site and deposition technology assessment was revisited in 2022 to incorporate updated conditions, including tailings deposition since the restart of operation in 2016 (i.e., about 20 Mt), and remaining LoM production (i.e., 62.8 Mt) and to assess the alternative of co-disposal of hydro-cyclone underflow in the southeast rock disposal site. This is included in Appendix D.

The potential sites identified for the TSF included:

- existing TSF
- new TSF location (four potential locations were identified)
- lake deposition (e.g., Polley Lake, Bootjack Lake, Quesnel Lake)
- open pit deposition (e.g., Springer Pit, Cariboo Pit, Wight Pit, Bullion Pit)
- underground deposition
- co-disposal with waste rock (e.g., southeast rock disposal site)

The existing Mount Polley open pits and underground working were eliminated from further consideration as these are either active mining areas or used for site water management.

The available tailings management technologies are differentiated primarily by the water content of the tailings, which determines the transportation method and the deposition method. The following technologies are available and were included in the 2022 assessment:

- low solids content tailings slurry (i.e., conventional tailings or unthickened tailings)
- thickened (non-segregating) tailings
- paste tailings
- filter tailings
- hydro-cyclone classified tailings

7.1.3 Findings and Recommended Site and Deposition Technology

The findings from the 2022 siting and deposition assessment regarding the range of options considered were as follows:

- The best available option is to store the tailings produced in the remaining LoM within the existing TSF as conventional slurry. This is because:
  - The existing TSF has the best-studied foundation conditions of any of the potential TSF locations. A new land-based TSF footprint is unlikely to offer advantages over the existing TSF footprint. Using a different land-based site would require significant investigation, add to the disturbed area of the mine, and require more closure work at the completion of mining.
  - Conventional tailings can be operated in a manner that reduces both the likelihood (conservative assessment of soil strength and adoption of conservative design criteria resulting in wide buttresses along the embankments) and consequence of failure (wide beaches, relatively dense tailings, and a small pond volume) provided accumulation of water does not occur.
- Separating the tailings into fine (overflow) and coarse (underflow) fractions with hydro-cyclones could reduce the amount of tailings to be stored in the TSF by 10% to 30% if the coarse fraction is placed in the southeast rock disposal site; however, a separate water management pond with a storage capacity of about 4 million m^3 to manage the 1:200-year freshet volume would be required. A separate water management pond would require significant investigation (foundation conditions would be required to be characterized to a sufficient level to enable appropriate design), add to the disturbed area of the mine, and require more closure work at the completion of mining.
- Thickened tailings offer limited advantages over conventional tailings as the mine site has an overall positive water balance and the TSF or a new dam would be required to manage freshet water.
- The high capital cost of a filter plant may not be economic given the relatively short remaining LoM. A separate water management pond with a storage capacity of about 4 million m^3 to manage the 1:200-year freshet volume would also be required.
- Deposition of tailings in deep lakes provides numerous advantages in terms of the physical and chemical stability of tailings; however, the permitting of such facilities is difficult, particularly when the lakes provide habitat for fish.
- The only advantage to using the Bullion Pit is that an area with significant historical mining disturbance could be restored to a landscape similar to the pre-mining condition. The delay to the mine operation related to the investigation and design of the containment structures and the seepage control system to minimize water loss to the Quesnel River, coupled with the increased costs for transporting the tailings to the Bullion Pit and water from the Bullion Pit to the mine and the need for an environmental impact assessment, make this alternative unattractive, and, likely would prevent continuation of operations.

The study recommends that the tailings produced in the remaining LoM be transported as conventional (slurry) tailings to the existing TSF and be managed using best applicable practices, including:

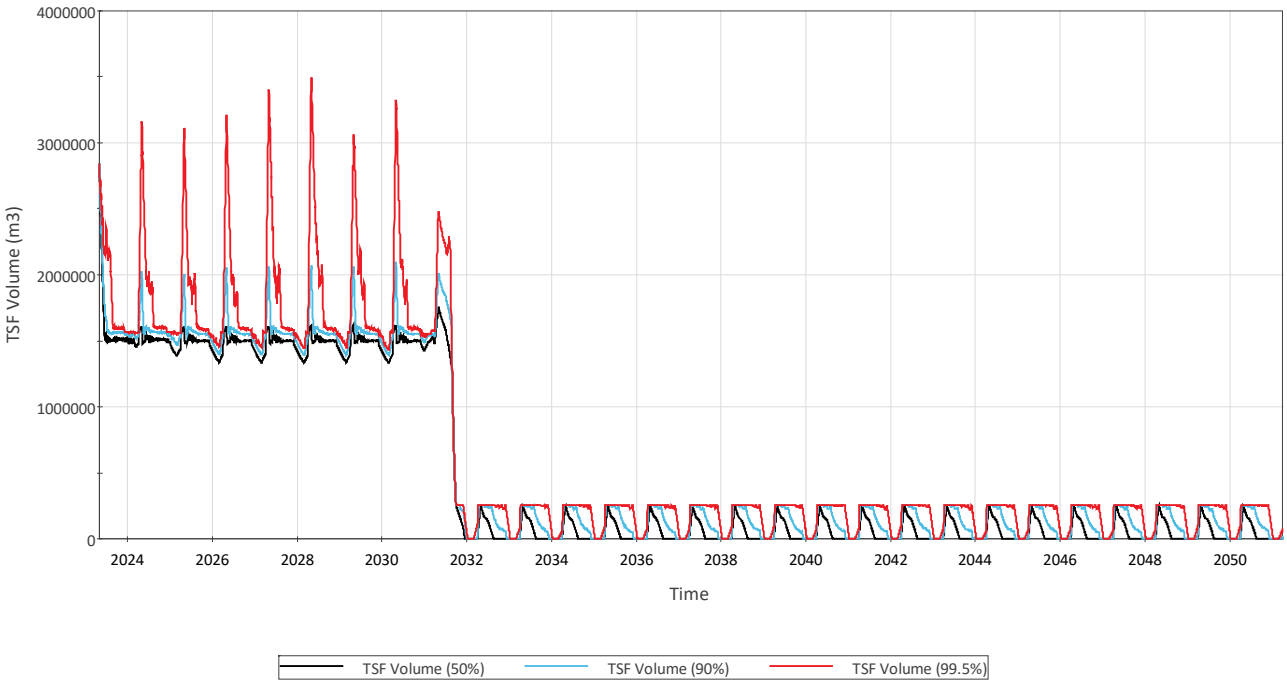
- routine and sustained discharge of mine water such that the volume of water stored in the TSF is maintained low

- managing the pond in the TSF such that beaches are maintained upstream of the embankments throughout the operational life of the TSF
- providing drainage to promote the desaturation and densification of the tailings

7.2 Tailings Storage Facility Water Balance

The SWWBM (site-wide water balance model) supports water management planning and the assessment of water quality and associated water treatment and discharge options. The last SWWBM was updated to reflect the Springer Expansion LoM plan during the operational phase and incorporates closure and post-closure phases for Mount Polley Mine (WSP 2023c), which include a hypothetical raise of the TSF to elevation 987 m.

The stage-storage curves projected up to a crest elevation of 987 m constitute a snapshot that changes with time as tailings are deposited.



The SWWBM was run with probabilistic monthly climate inputs for this assessment. To develop probabilistic inputs, monthly precipitation data in the *Mount Polley Mine Climate Baseline Update* (Golder 2022) were fitted to a log-normal probability distribution.

The minimum and maximum operational water volumes set in the SWWBM for the TSF under normal conditions are 1.5 million m^3 and 1.7 million m^3, respectively. The TSF pond volume in the SWWBM is set at 1.5 million m^3 prior to freshet. When the maximum normal operating volume of 1.7 million m^3 is exceeded the model starts pumping water out of the TSF to return the pond volume to the specified normal operating range after freshet.

During closure and post-closure, the TSF pond is modelled to discharge annually via a spillway, and the TSF pond volume will vary seasonally, limited by the spillway invert, to a maximum of approximately 0.25 million m^3.

Results of the SWWBM presented in Figure 4 show the water volume in the TSF throughout future operations and into closure until 10 years after post-closure. The TSF volume pattern shown for the 2041 to 2051 post-closure period is continued for the remaining 80 years of post-closure (until 2131).

It is important to point out that the SWWBM was run for the Springer Expansion LoM plan, which includes raising the TSF to 987 m. The TSF raise to elevation 974 m is expected to be reached by 2026. If the TSF were to initiate closure at elevation 974 m, the closure scenario, with the pond reduced to 0.25 m^3, is applicable and the results presented for closure and post-closure are expected to be similar.

TSF = tailings storage facility.

Figure 4: Tailings Storage Facility Water Volume from Operations to 10 Years after Post-closure – Springer Expansion Life of Mine Plan

Table 6 shows tabulated minimum, average, and maximum bounds for the three percentile trends shown in Figure 4. The bounds presented represent the minimum, average, and maximum values for each percentile during the operational period: TSF operation to crest elevation 987 m (2023–2031), closure period (2031–2041), and post-closure period (from 2041).

Table 6: Tailings Storage Facility Water Volume (m^3) – Springer Expansion Life of Mine Plan

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	1,331,000	1,392,000	1,434,000
	Average	1,478,529	1,562,418	1,796,559
	Maximum	1,624,000	2,097,000	3,504,000
Closure	Minimum	0	0	0
	Average	119,426	188,747	266,028
	Maximum	1,762,000	2,030,000	2,507,000
Post-closure	Minimum	0	0	0
	Average	50,748	115,988	182,703
	Maximum	252,571	252,571	252,571

7.3 Tailings Storage Capacity

Tailings storage capacity analysis was undertaken for the TSF to determine the volume of tailings that can be stored in the TSF with a crest elevation of 974 m and provide input to the embankment raise construction schedule. The tailings deposition was modelled using Muk3D v2022.1.1 developed by MineBridge Software Inc. The base surface used for the deposition modelling was generated by combining a topographic survey completed on October 18, 2019, and a bathymetric survey completed on June 17, 2020. Deposition of tailings into the TSF was halted prior to the topographic survey in October 2019 and resumed in June 2022.

The parameters adopted for the deposition model are presented in Table 7.

Table 7: Parameters Adopted for Tailings Storage Facility Deposition Modelling

Parameter	Value	Notes
Tailings slope	0.5% sub-aerial 2% sub-aqueous	Range based on available topographic and bathymetric surveys since 2016
	1% sub-aerial 3% sub-aqueous	
Operational pond volume	1.5 million m^3	Pond volume to be maintained during normal operating conditions
Pond depth	4 m (beneath the reclaim barge)	Estimated for normal operation conditions based on available bathymetric surveys since 2016

Modelling of the deposition was conducted such that the pond is maintained away from the embankments and against the natural topography on the western perimeter of the TSF. To enable management of the pond against the natural ground and to maintain a minimum beach length of 100 m, the reclaim barge will need to be relocated to a central area between Corner 4 and Corner 5. It is important to note that maintaining a minimum beach length of 100 m, as required by the quantitative performance objectives, becomes more challenging with shallow tailings slopes and it is not a desired condition.

The tailings storage capacity (tonnage) versus tailings discharge elevation for the adopted range of tailings slopes is presented in Table 8. Selected stages of the deposition modelling are presented in Appendix E. Deposition timelines and construction scheduling based on these tonnages are discussed in Section 10.0.

As discussed in Section 7.10, a tailings freeboard (i.e., elevation difference between the top of tailings and the crest of the embankment) of 0.9 m is required to maintain adequate water storage capacity for temporary retention of site water generated from large freshet or precipitation events. This tailings freeboard is based on a 0.5% sub-aerial beach slope, which is what has been achieved with recent operations. Tailings freeboard may be increased or reduced during operations based on actual tailings deposition slopes; the tailings freeboard will be included as part of the quantitative performance objectives and changes must be agreed upon with the Engineer of Record.

Table 8: Tailings Capacity vs Tailings Discharge Elevation for Tailings Storage Facility Crest Elevation 974 m

Tailings Elevation (m)	Tailings Slope: 0.5% Sub-aerial, 2% Sub-aqueous		Tailings Slope: 1% Sub-aerial, 3% Sub-aqueous	
	Volume (million m^3)	Tonnage (Mt)	Volume (million m^3)	Tonnage (Mt)
970.0	12.06	16.28	9.33	12.59
972.0	16.02	21.63	13.14	17.74
973.1	17.78	24.01	14.90	20.11

Mt = million tonnes.

It is important to note that shallow tailings slopes are not a desired condition as meeting the quantitative performance objectives will be increasingly challenging. Introduction of a tailings freeboard is a result of the approximate 0.5% sub-aerial beach slopes achieved during recent operations. The tailings freeboard could be reduced, and larger tailings storage capacity made available, if steeper beach slopes were achieved.

7.4 Internal Erosion

The purpose of the filter, filter sand, and transition zones is to prevent erosion of the till core and till foundation into the voids of the rockfill shell.

The specified gradations of filter, filter sand, and transition materials have been designed to meet modern filter criteria (USBR 2011; FEMA 2011; Fell et al. 2015; USDA 2017) with a modification to the maximum sand content (i.e., 40%) in the filter band based on laboratory testing (Eldridge and Gilmer 2002). The filter, filter sand, and transition gradation envelope requirements for construction of the embankment to elevation 974 m remain unchanged from the filter, filter sand and transition gradation envelopes specified for construction of the embankment to elevation 970 m (Golder 2015b).

A detailed assessment of the adequacy of the embankment filter and transition constructed prior to August 2014 is presented in Golder (2016b). A summary of the assessment is included in Sections 7.4.1 to 7.4.3.

7.4.1 Till Core – Filter Compatibility

The filter compatibility assessment between the till core and filter materials was carried out following the criteria presented in Fell et al. (2015) and representative envelope of grain size distribution curves for all stages of construction. Figure 5 shows the filter compatibility criteria and the grain size distribution envelopes for the till core and filter material. The results show a portion of the till core and filter grain size distributions as constructed do not meet filter compatibility criteria.

To assess filters on existing dams, Foster and Fell (2001) developed a method based on laboratory tests and analysis of dams that have experienced piping incidents, defining erosion boundaries:

- “No erosion – practically no erosion; i.e., <10 g of base material for cohesionless soils and no visible erosion of the preformed hole in cohesive soils.”
- “Some erosion and excessive erosion – filter seals after ‘some’ erosion of the base material.”
- “Continuing erosion – for the cases where the filter was too coarse to allow the eroded base materials to seal the filter, resulting in unrestricted erosion of the base soil.”

The no erosion, excessive erosion, and continuing erosion boundaries for the compatibility of the till core–filter materials are presented in Figure 5. In this case, the no erosion criteria coincide with the filter criteria. The results show that a portion of the filter grain size distributions as constructed is in between the no erosion and some erosion boundaries, and therefore the filter would seal after “some” erosion of the till core.

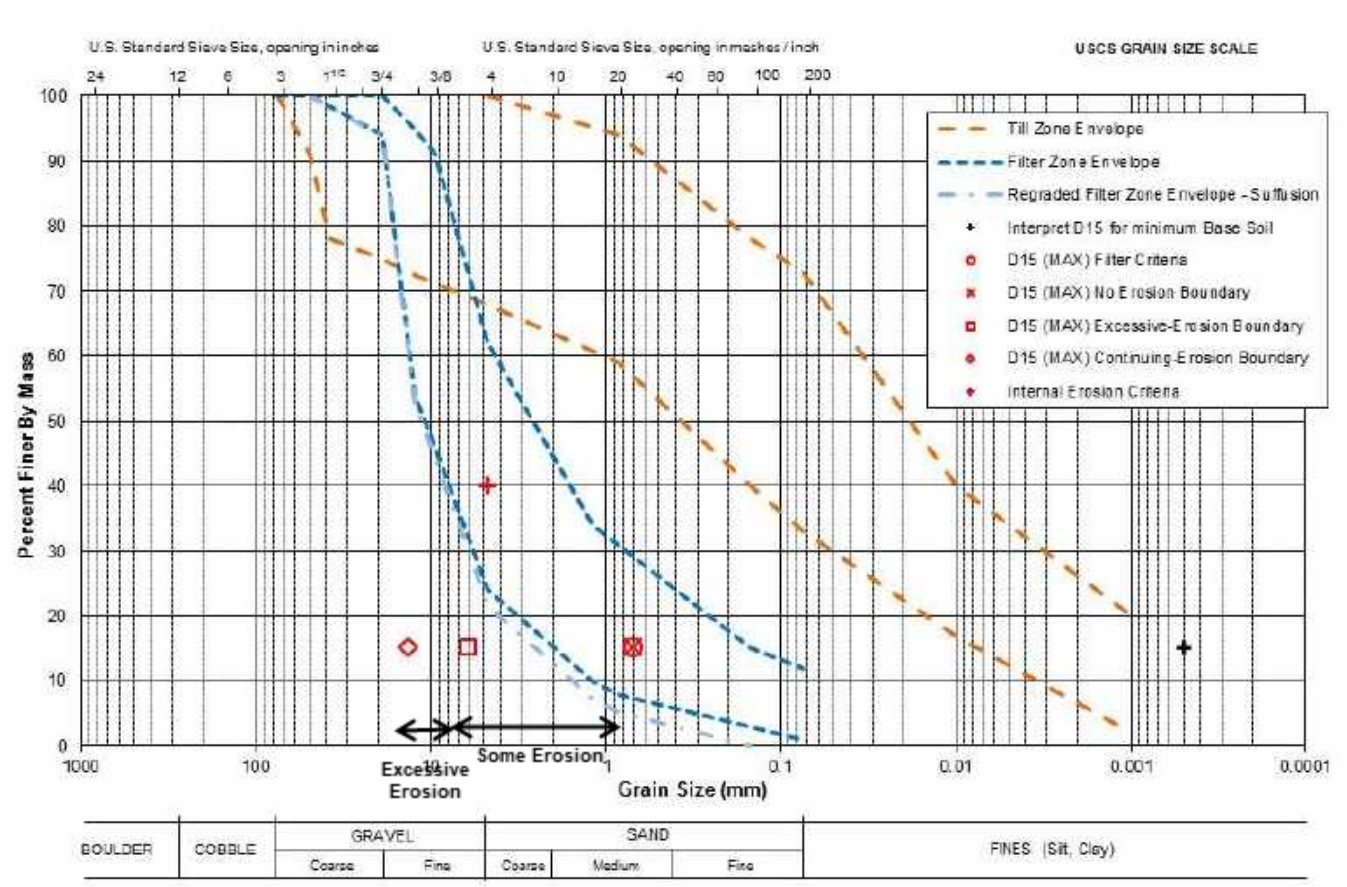


Figure 5: Filter Compatibility between Till Core and Filter Materials Constructed Prior to August 2014

Prior to the breach of the Perimeter Embankment, no signs of erosion or sinkholes were reported and the maximum hydraulic gradient imposed on the till core of the embankment was in the order of 5. As noted in International Commission on Large Dams (ICOLD) Bulletin 164, “The available evidence on the occurrence of global backward erosion (see Figure 2.7 in Section 2.3.2.2) in central core dams is that this internal erosion mode will only occur at relatively high gradients except when the core consists of cohesionless, internally unstable soil subject to suffusion.” The till core is considered not to be susceptible to suffusion due to its plasticity. As noted in Bulletin 164, “for practical purposes Fell et al. (2008) have concluded that based on the data described available soils with Plasticity Index > 7 should be considered not subject to suffusion at the gradients usually experienced in dams and their foundations” (ICOLD 2013).

Based on the filter criteria results and observations prior to the breach, if the hydraulic gradients were to raise to a level sufficient to initiate backward erosion of the till core, some erosion of the till core could be expected before the filter seals it.

To reduce the hydraulic gradient through the till core, minimum 100 m beaches are maintained upstream of the embankments and the size and depth of the pond are limited to the minimum required to operate the process plant. These operational requirements are part of the design and operational philosophy and are included in the QPOs of the TSF.

The TSF raise from elevation 970 to 974 m will result in a small increase of the hydraulic gradient imposed on the till core (i.e., less than 1); however, in consideration of potential future raises, the design includes upstream drains between elevation 970 and 972 m to control the hydraulic head upstream of the embankment and therefore the hydraulic gradient across the till core. The design of the upstream drains is presented in Drawings 25 to 28 in Appendix A.

7.4.2 Filter – Transition Compatibility

The filter and transition grain size distributions as constructed meet filter compatibility criteria. Figure 6 presents the filter compatibility criteria and the grain size distribution envelopes for the filter and transition materials. The no erosion boundary is also included in Figure 6.

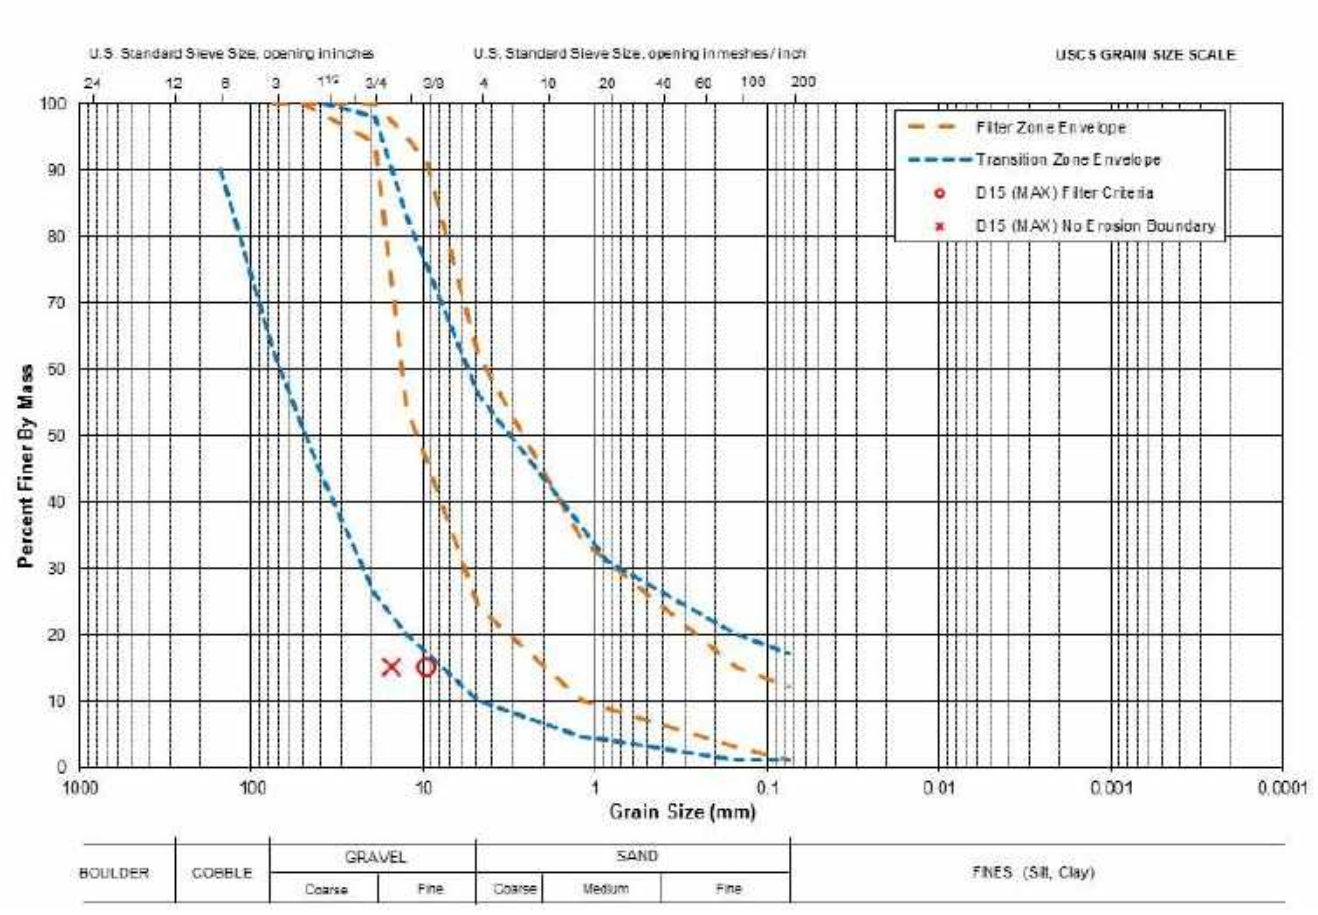

Figure 6: Filter Compatibility between Filter and Transition Materials Constructed Prior to August 2014

7.4.3 Transition – Rockfill Compatibility

The transition and rockfill grain size distributions as constructed meet filter compatibility criteria. Figure 7 presents the filter compatibility criteria and the grain size distribution envelopes for the transition and rockfill materials.

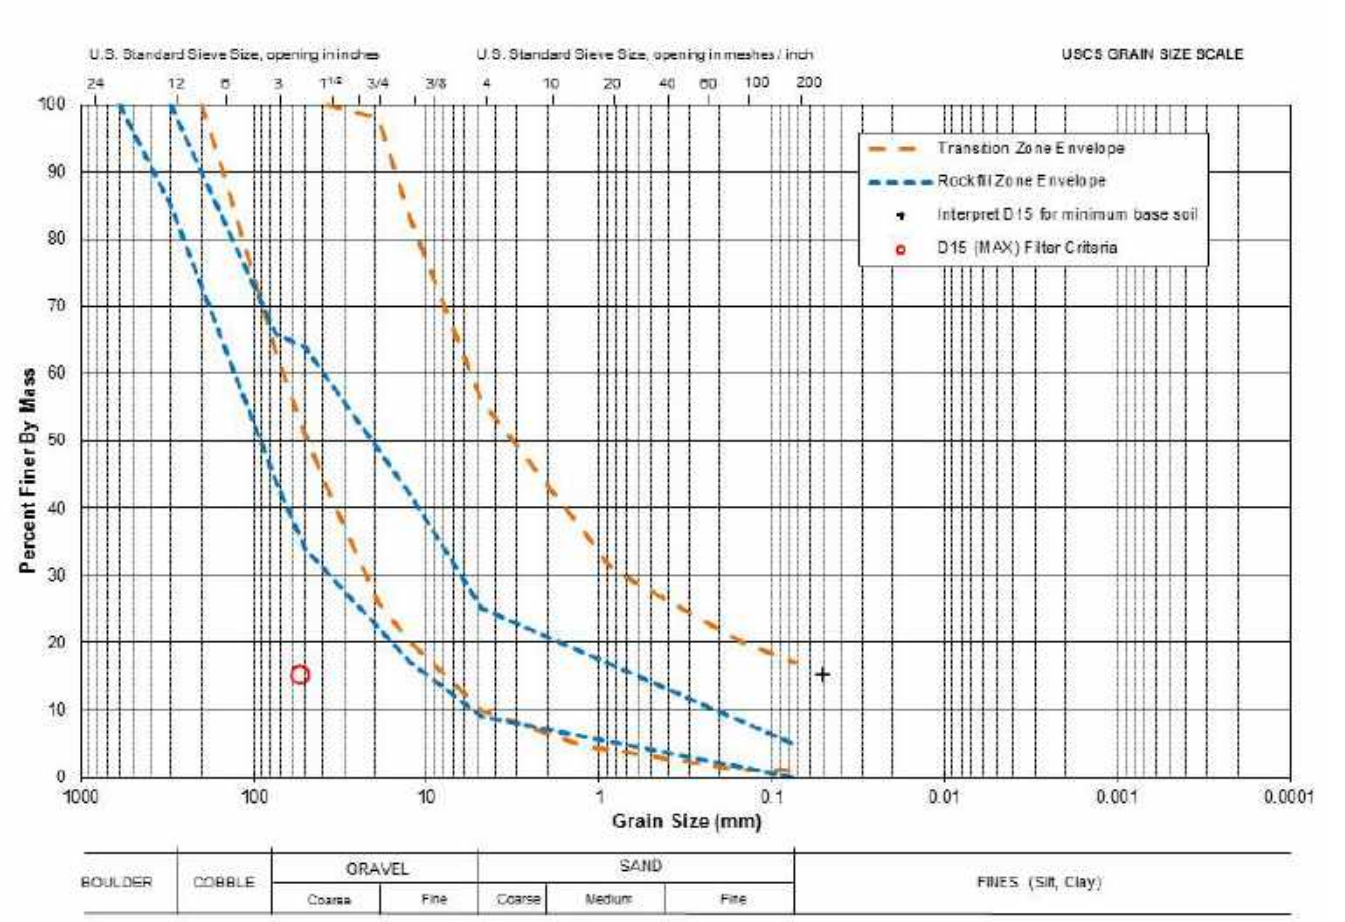

Figure 7: Filter Compatibility between Transition and Rockfill Materials Constructed Prior to August 2014

7.5 Seepage Analysis

Seepage analyses were carried out for typical sections of the elevation 974 m configuration of the South Embankment (Stn. 0+725), Main Embankment (Stn. 2+055), Perimeter Embankment (Stn. 3+765), and Perimeter Embankment at Corner 1 (Stn. 4+255) under steady-state conditions. The section at Corner 1 was analyzed to represent the portion of the embankment that includes a cut-off wall below elevation 950 m (from Stn. 3+996 to 4+464).

The analyses were conducted using GeoStudio 2023.1 from GEOSLOPE International Ltd. The objectives of the seepage analyses were as follows:

- to quantify anticipated seepage rates through the foundation, embankment, and proposed upstream drains
  - to assess sensitivity of the seepage rate through the embankment and foundation and the flow rate through the upstream drain for a range of beach widths (i.e., distance from the embankment to the pond: 0, 50, 100, 200 and 300 m)
- to determine phreatic surface geometries for use in stability analyses

Sensitivity analyses were undertaken to assess the flow rate through the upstream drain for the anticipated range of tailings hydraulic conductivity.

7.5.1 Material Properties Calibration

The tailings and foundation material properties were calibrated using available monitoring data at Corner 1 of the Perimeter Embankment (Stn. 4+255) and near the middle section of the Main Embankment (Stn. 2+055).

Section 4+255 (old Stn. 20+265; Golder 2015a) was selected for calibration of the hydraulic conductivity of the tailings using the estimated upstream drain flows and associated beach width and piezometric data. The hydraulic conductivity of the tailings was calibrated within a range of 1.0×10^{-4} m/s to 1.0×10^{-6} m/s, estimated from laboratory hydraulic conductivity tests and estimations based on particle size distribution (Section 5.1). Tailings anisotropy was estimated to have a horizontal to vertical permeability ratio of kh/kv = 0.1 based on interlayering typical of slurry-deposited tailings.

Section 2+055 (old Stn. 2+060) was selected for the calibration of the hydraulic conductivity of foundation materials and tailings using available vibrating wire piezometer (VWP) data and associated beach width. Material properties for both tailings and foundation materials were calibrated using various combinations to obtain a reasonable comparison between the available VWP data and the calculated phreatic surface in the model.

A distinction is made in the calibration model between tailings materials above and below elevation 960 m to reflect tailings that drained and consolidated following the 2014 embankment breach and tailings deposited since 2016.

The hydraulic conductivities assigned to foundation materials were calibrated within the ranges reported in the site characterization report (WSP 2023a).

The recorded seepage reporting to the Main Embankment Seepage Collection Pond was only used as reference in the calibration as reported flows include a combination of seepage through the embankment, flow through an upstream drain, flow from depressurization wells, and runoff.

The results of the calibration modelling are illustrated in Figures F-2 and F-3 in Appendix F. Calibrated material properties for the seepage analyses are presented in Table 9.

Table 9: Material Properties Used for Seepage Modelling

Name	Material Model	Saturated Hydraulic Conductivity K (m/s)	Anisotropy Ratio K_x'/K_y'	Notes
Foundation – glaciofluvial and till	Saturated only	1×10^{-6}	0.1	Adopted based on foundation characterization (WSP 2023a) and model calibration Glaciofluvial: 8×10^{-6} to 2×10^{-4} m/s Ablation till: 6.4×10^{-8} to 2×10^{-6} (mean 2×10^{-7}) Basal till: 4×10^{-8} to 2×10^{-6} (mean 3×10^{-7})
Foundation – glaciolacustrine	Saturated only	5×10^{-10}	1	Adopted based on foundation characterization (WSP 2023a) and model calibration HydrogeoSieveXL: 2×10^{-10} to 7×10^{-8} (mean 7×10^{-9}) From CPT: 3×10^{-9} to 6×10^{-8} (mean 2×10^{-8})
Rockfill	Saturated only	1×10^{-2}	1	Assumed by WSP

Table 9: Material Properties Used for Seepage Modelling

Name	Material Model	Saturated Hydraulic Conductivity K (m/s)	Anisotropy Ratio K_x'/K_y'	Notes
Tailings deposited since 2016	Saturated / unsaturated	1×10^{-5}	0.1	Estimated based on model calibration
Tailings deposited prior to August 2014	Saturated / unsaturated	1×10^{-6}	0.1	Estimated based on model calibration Available permeability test on tailings sample collected upstream of Corner 1 in 2014 = 2×10^{-6} m/s Estimated hydraulic conductivity using Hazen and Kozeny-Carman for a range of tailings gradations near the embankment = 4×10^{-5} to 8×10^{-6} m/s
Till core	Saturated / unsaturated	1×10^{-8}	1	Based on forensic investigation data and characterization of foundation till (WSP 2023a)
Filter, transition and upstream drain rock	Saturated / unsaturated	1×10^{-2}	1	Assumed by WSP
Upstream fill	Saturated / unsaturated	1×10^{-5}	1	Estimated based on model calibration of tailings
Cut-off wall	Saturated only	1×10^{-8}	1	Upper bound based on the hydraulic conductivity testing of samples taken from the cut-off wall (Golder 2015a)

Kx'/Ky' = horizontal hydraulic conductivity over vertical hydraulic conductivity

7.5.2 Boundary Conditions

The following boundary conditions were used:

- total head boundaries within the facility to define pond elevations for various beach length configurations
- zero-pressure boundaries along the ground surfaces beyond the buttress toe
- zero-flow boundaries within the upstream drain
  - A zero-flow boundary within the upstream drain acts as a sink, pulling water out of the model. This assumes the drain has enough capacity to maintain the phreatic surface at the elevation of the drain.
  - The flow rate at the point of zero-flow within the upstream drain does not report to the embankment buttress toe.
  - The upstream drain at elevation 950 m at Corner 1 was assumed to not be operating.

7.5.3 Seepage Analysis Results

The results of the seepage analyses are presented in Appendix F and summarized in Sections 7.5.3.1 to 7.5.3.3. The analyses were undertaken using the calibrated material properties in Table 9 and considering a range of beach widths (i.e., 0, 50 and 100, 200, and 300 m) to reflect variations in operational and upset conditions. The maximum beach width of 300 m represents a scenario where the operational (1.5 to 1.7 million m^3) pond is against the natural ground to the west of the TSF and there is even beach distributed across each of the embankments.

7.5.3.1 Phreatic Level and Hydraulic Gradient

Table 10 presents the phreatic level of the pond against the till core and the hydraulic gradient through the till core. The results presented are for a scenario where no upstream drain is constructed and with an upstream drain at elevation 970 m.

Table 10: Phreatic Level against the Till Core and Hydraulic Gradient across the Till Core

Embankment	Configuration	Phreatic Level and Hydraulic Gradient (K) at Till Core									
		No Beach		50 m Beach		100 m Beach		200 m Beach		300 m Beach	
		Phreatic Level (elev., m)	K	Phreatic Level (elev., m)	K	Phreatic Level (elev., m)	K	Phreatic Level (elev., m)	K	Phreatic Level (elev., m)	K
South Embankment	Without drains	973.6	4.5	972.0	4.2	970.4	3.9	967.1	3.2	963.6	2.5
	With drain at elev. 970 m	971.2	4.0	970.0	3.8	970.0	3.8	-	-	-	-
Main Embankment	Without drains	973.4	7.3	971.4	6.9	969.4	6.5	964.7	5.5	957.6	4.1
	With drain at elev. 970 m	970.7	6.7	970.0	6.6	970.0	6.6	-	-	-	-
Perimeter Embankment	Without drains	972.7	6.3	969.4	5.7	965.8	5.0	956.1	3.0	946.3	1.1
	With drain at elev. 970 m	970.2	5.8	-	-	-	-	-	-	-	-
Perimeter Embankment at Corner 1	Without drains	972.4	3.9	970.3	3.5	968.6	3.1	964.3	2.3	959.1	1.2
	With drain at elev. 970 m	971.0	3.6	970.0	3.4	-	-	-	-	-	-

Note: Till core elevation corresponds to 5 m till core width at elevation 951 m for the South Embankment, elevation 937 m for the Main Embankment and elevation 941 m for the Perimeter Embankment. The Perimeter Embankment at Corner 1 elevation 953 m is used where cut-off wall transitions to a 5 m wide till core.

Grey shaded cells indicate where phreatic level and hydraulic gradient are not reported for cases with drain at elevation 970 m where the phreatic level is lower than the drain.

The results show that the phreatic level and hydraulic gradient can be managed by maintaining wide tailings beaches upstream of the embankments and that the hydraulic gradient remains relatively low for normal operating and upset conditions.

The analyses also show that the upstream drains will start capturing water when the pond encroaches the embankment (i.e., 100 m beach or less). As discussed in Section 7.4, the upstream drains have been included in the design in consideration of potential future raises above elevation 974 m that would increase the hydraulic gradient imposed on the till core of the embankment. Changes to the hydraulic gradient through the till core will be relatively small (< 1) for the TSF raise from elevation 970 to 974 m. The intent of the upstream drains is to limit increases to hydraulic head upstream of the embankment, and hydraulic gradient through the till core, for crest elevations above 974 m and up to elevation 987 m.

7.5.3.2 Flow Rates through Upstream Drain

Seepage analyses were undertaken to quantify anticipated flows through the upstream drain at elevation 974 m to inform the design of downstream water management infrastructure. The results of the seepage analyses for flow through the upstream drain per embankment are summarized in Table 11.

The upstream drain has been designed to consider potential future raises of the TSF, up to elevation 987 m. Flows used to size the upstream drain are presented in Section 7.6.

Table 11: Flow through Upstream Drains at Tailings Storage Facility Elevation 974 m

Embankment	Total Flow through Upstream Drain per Embankment									
	No Beach		50 m Beach		100 m Beach		200 m Beach		300 m Beach	
	m^3/s	L/s	m^3/s	L/s	m^3/s	L/s	m^3/s	L/s	m^3/s	L/s
South Embankment	3.7×10^{-2}	36.9	5.7×10^{-3}	5.7	1.3×10^{-3}	1.3	-	-	-	-
Main Embankment	3.8×10^{-2}	38.3	5.1×10^{-3}	5.1	2.3×10^{-4}	0.2	-	-	-	-
Perimeter Embankment	5.1×10^{-2}	51.0	2.6×10^{-3}	2.6	-	-	-	-	-	-
Perimeter Embankment at Corner 1	1.3×10^{-2}	13.2	1.1×10^{-3}	1.1	-	-	-	-	-	-

Total flow through upstream drain per embankment calculated based on total length of upstream drains at each embankment:
South Embankment drain length of 1,050 m used to calculate flows.
Main Embankment drain length of 1,200 m used to calculate flows.
Perimeter Embankment drain length of 1,600 m used to calculate flows (includes section west of Corner 1 to Corner 5).
Perimeter Embankment at Corner 1 drain length of 400 m used to calculate flows.
Grey shaded cells indicate that the phreatic level is lower than the drain and negligible flows are observed through the upstream drains.

The existing upstream drain at elevation 950 m at Corner 1 was assumed to not be operational in the analyses to assess the potential flows that the upstream drain at elevation 970 m could experience.

The analysis shows that little to no flow is expected through the upstream drains for beach widths greater than 50 m. The upstream drain has been incorporated to account for future raises above 974 m and is not a critical control for managing hydraulic gradient at TSF elevation 974 m.

7.5.3.3 Seepage Rates through Embankment and Foundation

Seepage analyses were undertaken to quantify seepage rates through the embankment and foundation and to inform the design of downstream water management infrastructure. The results of the seepage analyses for seepage through the embankment and foundation are summarized in Table 12 and shown for the Main Embankment in Figure 8. The seepage values reported do not include flows through upstream drains.

Table 12: Flow through the Embankment and Foundation

Embankment		Total Seepage through Embankment and Foundation per Embankment									
		No Beach		50 m Beach		100 m Beach		200 m Beach		300 m Beach	
		m^3/s	L/s	m^3/s	L/s	m^3/s	L/s	m^3/s	L/s	m^3/s	L/s
South Embankment	Without drain	4.6×10^{-3}	4.6	4.3×10^{-3}	4.3	4.1×10^{-3}	4.1	3.6×10^{-3}	3.6	3.1×10^{-3}	3.1
	With drain	4.3×10^{-3}	4.3	4.1×10^{-3}	4.1	4.0×10^{-3}	4.0	3.6×10^{-3}	3.6	3.1×10^{-3}	3.1
Main Embankment	Without drain	8.4×10^{-3}	8.4	8.1×10^{-3}	8.1	7.8×10^{-3}	7.8	7.1×10^{-3}	7.1	6.1×10^{-3}	6.1
	With drain	8.1×10^{-3}	8.1	7.9×10^{-3}	7.9	7.8×10^{-3}	7.8	7.1×10^{-3}	7.1	6.1×10^{-3}	6.1
Perimeter Embankment	Without drain	1.5×10^{-2}	15.5	1.5×10^{-2}	14.6	1.4×10^{-2}	13.5	1.1×10^{-2}	10.9	8.4×10^{-3}	8.4
	With drain	1.5×10^{-2}	14.8	1.4×10^{-2}	14.4	1.4×10^{-2}	13.5	1.1×10^{-2}	10.9	8.4×10^{-3}	8.4
Perimeter Embankment at Corner 1	Without drain	9.4×10^{-3}	9.4	9.0×10^{-3}	9.0	8.6×10^{-3}	8.6	7.6×10^{-3}	7.6	6.3×10^{-3}	6.3
	With drain	9.1×10^{-3}	9.1	8.9×10^{-3}	8.9	8.6×10^{-3}	8.6	7.6×10^{-3}	7.6	6.3×10^{-3}	6.3

South Embankment length of 1,050 m used to calculate total toe seepage in L/s.

Main Embankment length of 1,200 m used to calculate total toe seepage in L/s.

Perimeter Embankment length of 1,300 m used to calculate flows (section west of Corner 1 to Corner 2). The Perimeter Embankment section modelled includes the Perimeter Embankment Till Borrow Pond and is considered an upper bound for seepage and not representative of the full length of the embankment.

Perimeter Embankment at Corner 1 length of 450 m used to calculate flows (one drainage panel).

The upstream drain has been modelled at elevation 970 m.

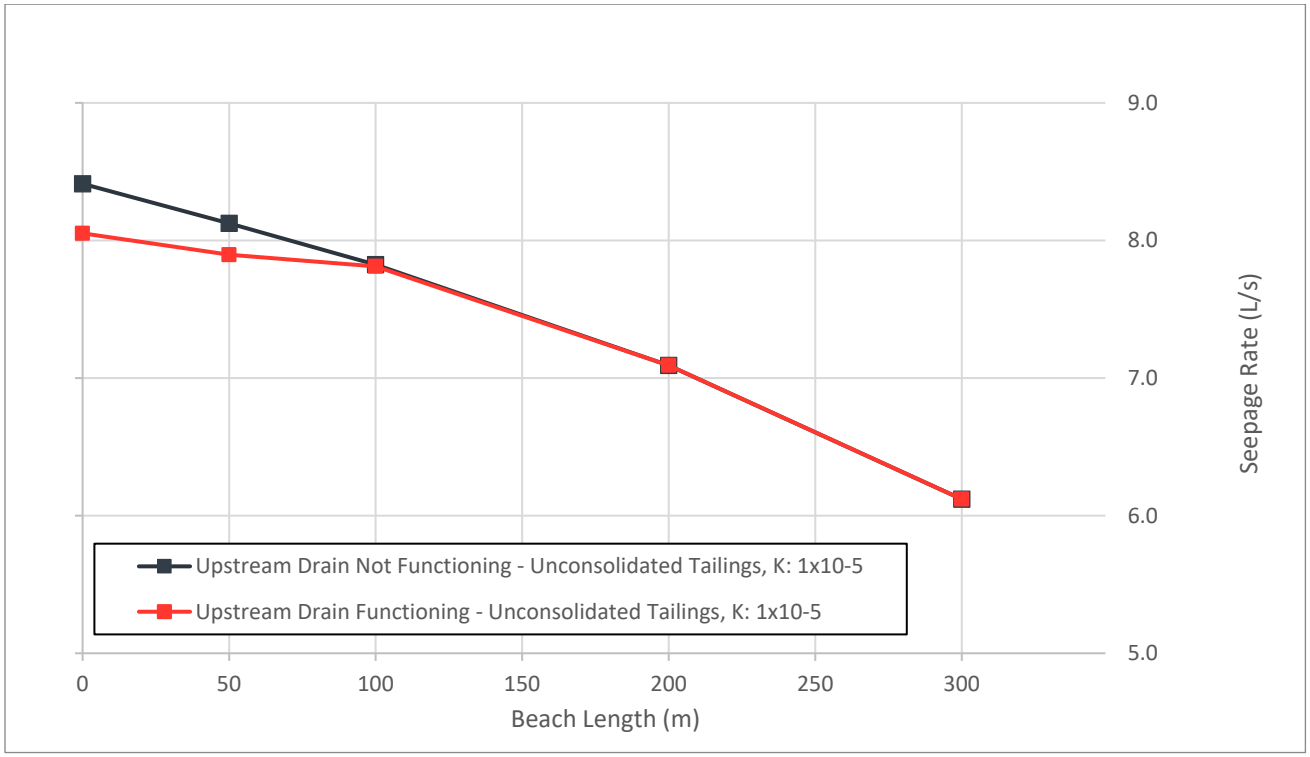

Figure 8: Main Embankment (Stn. 2+055) Total Seepage through Toe/Foundation

The seepage analyses carried out on typical sections of the embankment show that seepage from the TSF will not significantly increase by raising the TSF from elevation 970 to 974 m (WSP 2023b). The seepage rate will be dependent on the length of the tailings beach.

7.6 Upstream Drain Design

This section presents the upstream drain design capacity and layout. Design objectives for the upstream drain system are primarily for potential future raises above elevation 974 m and are to:

- control the hydraulic gradient across the till core by limiting the hydraulic head upstream of the embankment
- promote unsaturated conditions in the tailings above the drain
- promote consolidation of tailings above the drain and upstream of the TSF embankment

These objectives will be met by providing passive drainage of water from the tailings deposited upstream of the till core to the downstream water management infrastructure.

The upstream drainage system design is based on the configuration of the existing Perimeter Embankment upstream drain at Corner 1 and will consist of the following:

- A minimum of 1 m thick and 10 m wide layer of drain rock wrapped on a non-woven geotextile and placed on general fill. Bedding material will be placed under the geotextile at the base and over the drain rock.

- A series of pipe “panels” installed within the drain rock. Each panel consists of six to eight perforated high-density polyethylene (HDPE) drainpipes that connect to a solid HDPE connector pipe, which then conveys flow in one central solid HDPE pipe through the till core and to the downstream water management structures.
  - Each perforated drainpipe (sized as 6-inch DR9 HDPE) will be 10 m long and will be placed 50 m apart and perpendicular to the embankment. The drainpipes will be installed at a grade of 0.5% to 1%.
  - The solid HDPE connector pipe (sized as 12-inch DR17 HDPE) will be installed within the drain rock, parallel to the embankment and at a grade of 0.5% to 1%.
  - The solid HDPE collector pipe (also sized as 12-inch DR17 HDPE) will be installed at a minimum grade of 1% and maximum of 12%.

The upstream drain will be offset 25 m from the till core.

Filter sand will be placed around the HDPE collector pipe on the upstream and downstream side of the till core.

Tailings deposition above the upstream drains must occur in a way to prevent erosion of the constructed upstream drains, either through pipeline discharge location, erosion control measures, spigots, or some combination.

Details of the upstream drain panel are shown in Drawings 25 to 28 in Appendix A and included in the technical specifications in Appendix B.

7.6.1 Pipe Sizing

The drain, connector, and collector pipes were sized to accommodate the estimated flow for an elevation 987 m TSF configuration. Pipe flow capacities were calculated using Manning’s equation with a Manning’s coefficient equal to 0.01 for the HDPE pipes.

The design flow for each pipe was estimated from 2D seepage modelling for the TSF at elevation 987 m. The results of the analyses are presented in Table 13. The criteria adopted to estimate the design flow were a tailings hydraulic conductivity of 1×10^{-5} m/s and a 50 m beach width. A factor of safety (FoS) of 3 was applied to the estimated design flow.

Table 13: Flow through Upstream Drains at Tailings Storage Facility Elevation 987 m with a 50 m Beach

Embankment	Flow per Drain Pipe[(a)] (m^3/s)	Flow per Drain Pipe[(a)] (L/s)
South Embankment Stn. 0+725	1.6×10^{-3}	1.63
Main Embankment Stn. 2+055	1.6×10^{-3}	1.57
Perimeter Embankment Stn. 3+765	1.4×10^{-3}	1.42
Perimeter Embankment at Corner 1 Stn. 4+255	2.0×10^{-3}	2.02

(a) Reported flows consider a lateral catchment area of 50 m per drain pipe.

As shown in Table 13, the results of the 2D seepage model ranged between 1.42 and 2.02 L/s. Considering an applied FoS of 3, the upstream drain pipes require a capacity up to 6.1 L/s. The adopted design flow for sizing of drain pipes installed with 50 spacing was 6.8 L/s.

A typical drainage panel comprises eight upstream drain pipes, which are routed through a singular discharge pipe. The adopted design flow for sizing of the discharge pipe was 54 L/s.

7.7 Stability Analysis

Two-dimensional limit equilibrium slope stability analyses were conducted using GeoStudio 2023.1. The objective of the stability analyses was to confirm that the FoS for short-term and long-term stability meet the design criteria presented in Section 7.7.1.

7.7.1 Design Criteria for Slope Stability

The minimum FoS criteria are summarized in Table 14.

Table 14: Slope Stability Analysis Design Criteria

Criteria	Unit	Value	Source
Static (long term)	FoS	1.5	HSRC Guidance Document Section 3.3.1 (BC MEM 2016), CDA (2019) Table 3-4
Static (during or at end of construction)	FoS	1.5	HSRC Guidance Document Section 3.3.1 (BC MEM 2016) Other criteria include: >1.3 recommended by CDA (2019) Table 3-4
Pseudo-static	FoS	1.0	Informed by Table 3-5 of CDA (2019)
Post-earthquake	FoS	1.2	Informed by Table 3-5 of CDA (2019)
Design earthquake event	-	1:2,475 AEP	HSRC Guidance Document Section 3.3.1 (BC MEM 2016) Other criteria include: ▪ Between 1:100 and 1:1,000 (CDA 2019) ▪ 1:1,000 AEP recommended by GISTM (Global Tailings Review 2020) Consistent with WSP's best practice, an earthquake event of 1:10,000 AEP is used to assess sensitivity of the analyses
Design earthquake peak ground acceleration	g	0.048	For earthquake event of 1:2,475 AEP 0.116 g for earthquake event of 1:10,000 AEP
Seismic coefficient for limit equilibrium pseudo-static analysis	-	0.5	Hynes-Griffin and Franklin (1984) 20% strength reduction applied to GLUs as recommended by Hynes-Griffin and Franklin (1984) for clays

FoS = factor of safety; HSRC = Health, Safety and Reclamation Code; AEP = annual exceedance probability; GISTM = Global Industry Standard for Tailings Management; GLU = glaciolacustrine unit.

7.7.2 Material Properties

7.7.2.1 Embankment Fill Materials

Strength parameters to be used in the stability analyses for embankment fill materials have been selected based on interpretation of the available field and laboratory test data and are consistent with strength parameters adopted for previous design analyses (i.e., Golder 2015b,c, 2017c).

Table 15: Embankment Material Properties for Stability Analysis

Material	Unit Weight (kN/m^3)	Shear Strength	Notes
Rockfill	21.5	$T = 1.726\ \sigma'_n{}^{0.899}$	Based on Leps (1970) average rockfill (Golder 2016a)
Transition	20		
Tailings	17	Drained: $\phi' = 25°$ c = 0 kPa Undrained: $T/\sigma_v' = 0.1$	Assumed by Golder (2015b, 2017c) Undrained shear strength adopted for post-earthquake analysis. Assumes liquefied tailings.
Upstream fill	20	$\phi' = 32°$ c = 0 kPa	Assumed by Golder (2015b, 2016a) based on Campaña (2011)
Till core	20.5	$\phi' = 33°$ c = 0 kPa	Based on triaxial testing of two recompacted samples of till (KP 1995) and triaxial testing (KCB 2015a, 2015b)
Filter and cut-off wall aggregate	20	$\phi' = 30°$ c = 0 kPa	Based on triaxial testing (Golder 2015e)

T = shear strength; σ_v' = effective vertical stress; ϕ' = friction angle; σ'_n = effective normal stress; c = cohesion.

Post-earthquake analyses use an undrained strength ratio for the tailings, which is representative of a liquefied strength. The relatively small magnitude of ground acceleration anticipated during the design earthquake event is unlikely to trigger widespread liquefaction in the tailings. Thus, using a post-liquefied undrained strength for the tailings represents a worst-case scenario for post-earthquake tailings strength.

7.7.2.2 Foundation Soils

Strength parameters used to represent foundation soils in the stability analyses are presented in Table 16.

Till and glaciofluvial materials vary in gradation depending on location, elevation, and depositional history; however, the results of the laboratory testing show a relatively consistent high strength. The shear strength parameters selected for the foundation till and glaciofluvial layers represent an average for the materials. The strength parameters are consistent with the parameters used in previous design analyses, testing results and analyses of the Perimeter Embankment breach at Corner 1 carried out by the IEEIRP (2015), and the results of laboratory testing completed by KCB (2015b).

Glaciolacustrine soils were analyzed using total stress (undrained) strength parameters. The total stress approach uses the SHANSEP (Stress History and Normalized Soil Engineering Properties) model that accounts for the stress history of the soil. The preconsolidation pressure that was selected for modelling the strength of each of the glaciolacustrine soil layers is based on data collected for the specific layer and soils in the immediate area. The data used include the results of laboratory strength testing, CPT profiles, the response of the soils during in situ testing and sampling (e.g., not being able to push a shear vane into the soil layer and bending of Shelby tubes during sampling), and correlation with index testing. Along the Perimeter and Main embankments, the preconsolidation pressure values selected for the analyses were at or below the lower bound of the values obtained from the laboratory consolidation tests and estimated from the CPT profiles. The undrained shear strength ratio function used to characterize glaciolacustrine materials was refined from $\tau = 0.22\ \sigma'_v\ OCR^{0.8}$ (where τ = shear strength, σ'_v = effective vertical stress, and OCR = overconsolidation ratio) to $\tau = 0.22\ \sigma'_v\ OCR^{0.71}$ based on laboratory testing completed as part of the 2021/2022 investigation. The undrained shear strength ratio functions are presented in Figure G-2, Appendix G.

A remoulded undrained shear strength continues to be adopted to characterize the UGLU at Corner 1 in these analyses. The remoulded undrained shear strength was selected as the average minus one standard deviation of the measured values from field vanes and CPTs as part of the forensic investigation in 2014. Since then, the embankment was repaired and constructed to elevation 970 m (approx. 40 m high) over the area of UGLU that sheared. Potential strength gains from reconsolidation of the UGLU have not been included in the characterization and stability analyses.

The sensitivity (strain weakening) of the GLU was not incorporated into the limit equilibrium analyses. Stress- deformation analyses were completed to assess potential redistribution of stresses due to strain weakening of glaciolacustrine units. The results are presented in Section 7.9.

A layer of low plasticity silty clay interpreted to have deposited in a glaciolacustrine environment was identified directly above bedrock near Stn. 1+095 at the South Embankment; however, the geotechnical testing completed on the material showed that it is not representative of the intermediate or high plasticity GLUs found at the Main and Perimeter embankments, including Corner 1. For the purposes of stability modelling, this layer was assigned the same shear strength and preconsolidation pressure (1,200 kPa) as the GLU at the Main Embankment.

B-bar values (i.e., change in pore pressure over the change in confining stress [Skempton 1954]) were assigned to the till and the glaciofluvial and glaciolacustrine soils to account for the excess pore pressures that may be generated during construction (WSP 2023a). The B-bar values determined for each material are based on the maximum pore pressure response measured during construction since 2014.

A detailed summary of available geotechnical data and characterization of the TSF foundation is presented in the TSF dam site characterization report (WSP 2023a). The TSF dam site characterization report will be updated with data from future site investigations, and with observations and data from construction and operation of the facility over the life of the TSF. Should the understanding and characterization of foundation soils change with time, then required changes will be documented in future revisions of the TSF dam site characterization report and incorporated into this design report.

Table 16: Foundation Material Parameters for Stability Analysis

Material	Unit Weight (kN/m^3)	Shear Strength	Pore Pressure Coefficient B-bar	Notes
Foundation till	22	ϕ' = 34° c = 0 kPa	0.2	Triaxial testing of samples of till by IEEIRP (2015) and KCB (2015b)
Glaciofluvial	22	ϕ' = 34° c = 0 kPa	0.2	Triaxial testing of undisturbed glaciofluvial samples by Golder (2015d)
UGLU (Perimeter Embankment at Corner 1)	18	Peak: $T = 0.22\ \sigma_v' OCR^{0.71}$ Where σ_p' = 400 kPa Remoulded: S_{ur} = 22 kPa	0.46	Field and laboratory test programs by IEEIRP (2015) and KCB (2015a,b) including vane shear tests, CPT, direct simple shear, direct shear, and triaxial testing Remoulded undrained shear strength selected as the average minus one standard deviation of the measured undrained shear strength values
LGLU (Perimeter Embankment at Corner 1)	20	$T = 0.22\ \sigma_v' OCR^{0.71}$ Where σ_p' = 700 kPa	0.2	Field and laboratory test programs by IEEIRP (2015), KCB (2015a.b), and Golder (2017b, 2019a) including vane shear tests, CPT, direct simple shear, direct shear, and triaxial testing
GLU (Perimeter Embankment)	20	$T = 0.22\ \sigma_v' OCR^{0.71}$ Where σ_p' = 900 kPa	0.2	Consolidation testing by Golder on samples from boreholes GA15-06, GA21-03 and GA21-11 at Perimeter Embankment indicate preconsolidation stress from 900 to 3,600 kPa (excluding the samples assessed to be of very poor quality)
GLU (Main Embankment)	20	$T = 0.22\ \sigma_v' OCR^{0.71}$ Where σ_p' = 1,200 kPa	0.2	Field and laboratory test programs by KP (2007), AMEC (2012), Golder (2015d), and WSP Golder (2022b) including vane shear tests, CPT, direct simple shear, direct shear, and triaxial testing Consolidation tests indicate a range of preconsolidation pressure from 2,500 kPa to 4,000 kPa (excluding the samples assessed to be of very poor quality) and CPT data indicate a minimum preconsolidation pressure of about 1,200 kPa
		$T = 0.22\ \sigma_v' OCR^{0.71}$ Where σ_p' = 850 kPa (GLU at approx. elev. 922 Stn. 2+400 and 2+750)		Field and laboratory test programs by AMEC (2012), Golder (2015d), and WSP Golder (2022b) CPT21-07 data indicate a minimum preconsolidation pressure of about 850 kPa

Table 16: Foundation Material Parameters for Stability Analysis

Material	Unit Weight (kN/m^3)	Shear Strength	Pore Pressure Coefficient B-bar	Notes
Low plasticity silty clay (Stn. 1+095 South Embankment)	20	$T = 0.22\ \sigma_v' OCR^{0.71}$ Where $\sigma_p' = 1{,}200$ kPa	0.2	Index laboratory testing by Golder (2017b)

Source: WSP 2023a.
T = Shear strength; σ_v' = Effective vertical stress; ϕ' = Peak friction angle; OCR = overconsolidation ratio; σ_p' = Preconsolidation stress; c = cohesion; UGLU = upper glaciolacustrine unit; GLU = glaciolacustrine unit; LGLU = lower glaciolacustrine unit; CPT = cone penetration test; S_{ur} = Remolded Undrained shear strength.

7.7.3 Liquefaction Potential of Foundation Soils

Till and glaciofluvial materials vary in gradation, with the majority being a mixture of gravel, sand, and low plastic fines. A portion of glaciofluvial materials have a larger portion of sand (up to 85%) with some fines. While localized portions of the glaciofluvial units could be susceptible to seismic induced strength loss, these materials are typically laterally non-continuous and in a dense state and are not considered to be susceptible to liquefaction or cyclic softening.

7.7.4 Method and Scenarios Assessed

Nineteen sections, identified to represent the variability of the foundation and embankment conditions over the length of the TSF embankment, were chosen for stability analysis (Figure 9). Eighteen of these sections were used for previous stability modelling for the 970 m detailed design (Golder 2015b), design update (Golder 2017c) and Stn. 20+458 stability assessment (Golder 2018), and one section has been added at Stn. 0+725 in this assessment.

All sections were modelled for an embankment with a crest elevation of 974 m and a downstream slope of 2H:1V extending onto natural ground, or buttress. All sections were run for both normal operating conditions (i.e., minimum 100 m beach width and upstream drain functioning) and upset conditions (i.e., 0 m beach width and upstream drain not functioning). The upstream drain is included in the design for future raises of the TSF (Section 7.6) and has little effect for the raise of the TSF to elevation 974 m unless the pond encroaches to the embankment.

Where the design criteria presented in Table 7.7.1 were not met without modifications to the buttresses, iterative analyses were conducted to design a buttress that would meet the minimum FoS criteria. Where required, stability analyses were then re-run for the design configuration of the embankments and buttress.

The following scenarios were analyzed:

- static (end of construction)
  - In this case, the foundation soils are partially consolidated due to the applied load of the rockfill used for raising and resloping the embankment to elevation 974 m and buttress extension. B-bar values were assigned to the till and the glaciofluvial and glaciolacustrine units to account for the excess pore water pressures that may be generated during construction. The B-bar values used are based on measured pore pressure response during construction since 2014.

- Tailings were modelled to an elevation of 969 m.

- static (long term)
  - In this case, any excess pore water pressures generated during construction are considered to have dissipated and no B-bar values were assigned to the model.
  - Tailings were modelled to an elevation of 973 m.
- pseudo-static
  - A peak ground acceleration of 0.048 g corresponding to a 1:2,475 AEP was used for pseudo-static analyses. A seismic coefficient of 0.5 was selected for the pseudo-static analyses as recommended by Hynes-Griffin and Franklin (1984).
  - A 20% strength reduction factor was applied to glaciolacustrine deposits as recommended by Hynes-Griffin and Franklin (1984) for clays to account for strength loss during cyclic loading.
  - Tailings were modelled to an elevation of 973 m.
- post-earthquake
  - The post-earthquake case used an undrained strength for the tailings, which is representative of a liquefied strength.
  - A 20% strength reduction factor was applied to glaciolacustrine deposits to account for strength loss during cyclic loading.
  - Tailings were modelled to an elevation of 973 m.

7.7.5 South Embankment Stability Analysis Results

One section, at Stn. 1+095 (old Stn. 1+100), was used in previous stability analyses (Golder 2015a, 2017c) to represent the South Embankment in terms of geometry and foundation conditions (i.e., layer of low plasticity silty clay). No additional geotechnical investigations have been required at the South Embankment and the foundation characterization remains as per the design update in 2017 (Golder 2017c).

An additional section was analyzed at the tallest section of the South Embankment at Stn. 0+725. No GLUs were identified in the foundation along the South Embankment.

The results of the analyses are summarized in Table 17 and Figures G-3 to G-10 in Appendix G.

The results of the slope stability analyses show that the design criteria FoS are achieved for both normal operating conditions (i.e., 100 m beach width and upstream drain functioning) and upset conditions (i.e., 0 m beach width and upstream drain not functioning) for elevation 974 m with a 2H:1V downstream slope for the South Embankment.

Table 17: Stability Analysis Results – South Embankment

Section	Static (end of construction)		Static (long term)		Pseudo-static		Post-earthquake	
	0 m beach	100 m beach	0 m beach	100 m beach	0 m beach	100 m beach	0 m beach	100 m beach
0+725	2.0	2.0	2.1	2.1	2.0	2.0	2.1	2.1
1+095	1.8	1.8	1.8	1.8	1.4	1.5	1.5	1.6

7.7.6 Main Embankment Stability Analysis Results

Five sections, identified to represent the variability of the foundation and embankment conditions over the length of the Main Embankment, were previously chosen for stability analysis. The foundation characterization has been updated for the section at Stn. 2+455 based on results of the 2021/2022 geotechnical investigation. No revisions to the foundation characterization in other areas of the Main Embankment were required, and the other four analyzed sections remain as per the elevation 970 m TSF detailed design (Golder 2015b). The sections and details of the foundation characterization adjustments are as follows:

- Stn. 1+845 (old Stn. 1+850).
- Stn. 2+055 (old Stn. 2+060).
- Stn. 2+235 (old Stn. 2+240).
- Stn. 2+455 (old Stn. 2+460): A glaciolacustrine layer, about 0.5 to 1.6 m thick at about elevation 922 m was included in this section. The GLU was modelled with an 850 kPa preconsolidation value based on CPT data (WSP 2023b).
- Stn. 2+695 (old Stn. 2+700).

The results of the analyses are summarized in Table 18 and Figures G-11 to G-33 in Appendix G.

Table 18: Stability Analysis Results – Main Embankment

Section	Static (end of construction)		Static (long term)		Pseudo-static		Post-earthquake	
	0 m beach	100 m beach	0 m beach	100 m beach	0 m beach	100 m beach	0 m beach	100 m beach
1+845	1.5	1.5	1.5	1.5	1.1	1.1	1.2	1.2
2+055	1.5	1.6	1.5	1.5	1.2	1.2	1.3	1.3
2+235	1.5	1.5	1.5	1.5	1.1	1.1	1.1	1.2
2+455	1.5	1.6	1.5	1.6	1.1	1.2	1.3	1.3
2+695	2.6	2.6	2.5	2.6	2.3	2.4	2.5	2.5

The slope stability analyses required extending the buttress along the majority of the Main Embankment to meet the minimum FoS criteria described in Section 7.7.1. The FoS results presented in Table 18 are for the design buttress. The buttress design was controlled by the stability requirements of Stn. 1+845 through Stn. 2+455. The buttress geometry was maintained from Stn. 2+455 to Corner 2 and resulted in FoS values that largely exceed the minimum design criteria.

The sensitivity (strain weakening) of the GLU was not incorporated into the limit equilibrium analyses; however, as discussed in Section 7.9, the stress deformation model shows that strain-weakening of GLU is not predicted to occur at the Main Embankment.

In addition to the analyzed scenarios presented in Table 18, the following sensitivity analyses were performed on Main Embankment design sections:

- The undrained strength of the GLU layer at elevation 922 m between about Stn. 2+455 and 2+695 was characterized with an 850 kPa preconsolidation value based on CPT data. Sensitivity analyses were carried out for the section at Stn. 2+455, reducing the preconsolidation value to 700 kPa and 400 kPa. A preconsolidation of 700 kPa is representative of the LGLU at Corner 1 and 400 kPa is representative of the UGLU at Corner 1.
  - With a preconsolidation value of 700 kPa, the FoS remained at 1.5.
  - With a preconsolidation value of 400 kPa, the FoS reduced from 1.5 to 1.4. Even with the lowest preconsolidation stress identified in the area of the TSF (400 kPa), the FoS reduced slightly and the section was stable (FoS > 1.0).
- Artesian conditions were applied to the glaciofluvial foundation material at Stn. 2+055 (5 m artesian pressure elevation), Stn. 2+235 (8 m artesian pressure elevation), and Stn. 2+455 (11 m artesian pressure elevation) to represent a scenario where the existing Main Embankment vertical drain wells fail and artesian pressures are generated in the foundation. The FoS slightly decreased but remained at 1.5 at the three sections.
- A peak ground acceleration of 0.116 g, corresponding to an earthquake event of 1:10,000 AEP, was applied to Stn. 2+235 for the pseudo-static long-term, 100 m beach scenario. The FoS reduced from 1.2 to 1.0 and still met the minimum design criteria with a significantly larger seismic load.

7.7.7 Perimeter Embankment Stability Analysis Results

Eleven sections, identified to represent the variability of the foundation and embankment conditions over the length of the Perimeter Embankment, including Corner 1 (approx. Stn. 3+920 to 4+650), were previously chosen for stability analysis.

The foundation characterization was updated for five sections at Stn. 2+850, 3+270, 3+395, 3+765, and 4+255 based on results of the 2021/2022 geotechnical investigation (WSP Golder 2022b).

The foundation characterization was also updated on the west side of Corner 1 based on results of the 2018 geotechnical investigation, and an additional section at Stn. 4+410 was analyzed (Golder 2018). The section at Stn. 4+540 was modified based on the changes at Stn. 4+410 for the current analysis.

No revisions to the foundation characterization in other areas of the Perimeter Embankment were required, and the sections at Stn. 3+185, 3+530, 4+000, 4+175, and 4+285 remain as per the elevation 970 m TSF detailed design (Golder 2015a, 2017c).

The sections and details of the foundation characterization adjustments are as follows:

- Stn. 2+850 (old Stn. 2+850): The GLU, approximately 3 m thick, at about elevation 913 to 916 m, was truncated downstream of the toe of the existing buttress based on borehole GA21-06 completed as part of the 2021/2022 geotechnical investigation.
- Stn. 3+185 (old Stn. 3+190).
- Stn. 3+270 (old Stn. 3+275): The thickness of the GLU was increased to 4 m based on boreholes GA21-03 and GA21-11 completed downstream of the existing buttress.
- Stn. 3+395 (old Stn. 3+400): The two closely spaced GLUs were combined into a single unit between approximate elevation 903 and 909.5 m based on borehole GA21-02.
- Stn. 3+530 (old Stn. 3+535).
- Stn. 3+765 (old Stn. 3+770): A 0.3 m thick GLU was included under the buttress and downstream at elevation 912.5 m based on borehole GA21-01.
- Stn. 4+000 (old Stn. 20+005).
- Stn. 4+175 (old Stn. 20+180).
- Stn. 4+255 (old Stn. 20+265): The UGLU near elevation 920 m at Stn. 4+230 (old Stn. 20+240 in Golder 2015a) was added to the section at Stn. 4+255 (Golder 2017c) to combine both sections.
- Stn. 4+285 (old Stn. 20+295).
- Stn. 4+410 (old Stn. 20+458).
- Stn. 4+540 (old Stn. 4+525): The GLU near elevation 930 m at Stn. 4+410 was added to the section at Stn. 4+540.

The results of the analyses are summarized in Table 19 and Figure G-34 to G-82 in Appendix G.

Table 19: Stability Analysis Results – Perimeter Embankment

Section	Static (end of construction)		Static (long term)		Pseudo-static		Post-earthquake

(a) Corner 1 upstream drain at elevation 950 m operational for 100 m beach normal operational case. The 0 m beach case assumes an upset condition where upstream drain is not functional.

The slope stability analyses required extending the buttress from about Stn. 3+200 to 3+450 and within the Perimeter Embankment Till Borrow Pond from about Stn. 3+580 to 3+920 to meet the minimum FoS criteria described in Section 7.7.1. The FoS results presented in Table 19 are for the design buttress.

The buttress design at Corner 1, from about Stn. 3+920 to 4+650 is controlled by the results of the stress-deformation modelling (Section 7.9). The stress-deformation analyses undertaken at Stn. 4+175 showed that strain weakening in the UGLU propagates under the embankment and buttress if the buttress is designed to meet the FoS criteria using limit equilibrium analyses assuming peak undrained shear strength. As such, the buttress configuration at Corner 1 was designed using the stress-deformation model and result on higher FoS using limit equilibrium analyses assuming peak undrained shear strength.

In addition to the analyzed scenarios presented in Section 7.7.3, the following sensitivity analyses were performed on Perimeter Embankment design sections:

- Additional analyses were carried out to determine the sensitivity of the FoS to the peak undrained shear strength of the GLU. Analysis was undertaken for the Perimeter Embankment section at Stn. 3+395, with lower preconsolidation pressures only identified at Corner 1 (i.e., 400 and 700 kPa). An FoS of 1.4 was achieved when the preconsolidation pressure was reduced from 900 kPa to 700 kPa, for the long-term, 0 m beach scenario and 1.3 when the FoS was reduced to 400 kPa. Even with the lowest preconsolidation stress identified in the area of the TSF (400 kPa), the FoS reduced to 1.3 and the section was stable (FoS > 1.0).
- A peak ground acceleration of 0.116 g, corresponding to an earthquake event of 1:10,000 AEP was applied to Stn. 3+395 and 4+175 for the pseudo-static long term, 100 m beach scenario. The FoS reduced from 1.2 to 1.1, and from 1.3 to 1.1, for the two sections respectively, and still met the minimum design criteria with a significantly larger seismic load.

7.7.8 Upstream Stability Analysis Results

A post-earthquake analysis was performed for upstream embankment stability, which assumes the tailings (excluding the upstream fill) has liquefied. The tailings were modelled with an undrained shear strength of $T/\sigma_v' = 0.1$. The analysis was conducted considering a 3 m elevation difference between the crest of the embankment and the tailings beach. The pond was modelled to be against the embankment (0 m beach) to represent an upset operations case. The result of the analysis is presented in Figure G-32 in Appendix G and shows an FoS of 1.2, which meets the minimum post-earthquake design criteria.

Potential seismic deformations of the upstream fill are discussed in 7.9.2.

7.8 Static Deformations

Vertical deformations resulting from consolidation/settlement of embankment fill materials under static conditions were monitored with a survey monument during construction of the Perimeter Embankment raise from elevation 966 to 970 m at Corner 1 (from 2017 to 2023). The recorded settlement at the crest of the rockfill shell has been in the order of 10 cm, which is within the expected range for a 40 m high rockfill structure. Future raises are anticipated to be consistent with previous annual raise rates (i.e., 2 to 3 m per year), and it is anticipated that settlements will remain low within the previously recorded range. Considering the freeboard allowance (Section 7.10), overtopping of the TSF due to settlement is considered to be a non-credible hazard. It is also noted that any settlements are corrected as part of yearly embankment raises.

Horizontal deformations are anticipated to be minor and distributed along the embankment crest broadly proportionally to the height of the embankment (i.e., would not occur as horizontal shear at a single location). Anticipated deformations would not compromise the integrity of the 5 m wide till core or continuity of the 1.5 m filter and transition zones.

7.9 Stress Deformation Modelling

A stress-deformation analysis was carried out on section 2+055 of the Main Embankment and section 4+175 of the Perimeter Embankment at Corner 1 using the commercially available computer code FLAC Version 8.1 (Cundall 2012). The section at the Main Embankment represents the tallest section of the facility and includes the semi-continuous layer of glaciolacustrine soil in the foundation. The section at the Perimeter Embankment includes the portion of the foundation that failed in 2014 and that has the GLU with lower preconsolidation stress.

These sections also correspond to those controlling the design of the buttress at each embankment based on limit equilibrium analyses.

The analyses were performed to assess the stability and potential deformations of the embankments at elevation 974 m (static analysis) and under the 2,475-year earthquake load (seismic analysis), including the potential for strain-weakening of GLUs. One crustal motion and one subduction interface motion were used as input ground motions in the seismic analysis.

The analysis procedure, characterization of the foundation and embankment materials for modelling purposes, and the static and seismic deformation analyses results are included in Appendix H. A summary of the findings of the analyses is presented in Sections 7.9.1 and 7.9.2.

7.9.1 Static Analysis

Section 2+055 of the Main Embankment and section 4+175 of the Perimeter Embankment at Corner 1 are predicted to be stable at the end of construction up to elevation 974 m under the analyzed conditions. The FoS computed at the end of construction is 1.6 for section 2+055 and 1.7 for section 4+175.

Strain-weakening is not predicted to be initiated in the GLU at section 2+055 of the Main Embankment during construction up to elevation 974 m.

Assuming a constant 22 kPa remoulded undrained shear strength for the UGLU that sheared during the failure in 2014 (i.e., no inclusion of potential strength gains from reconsolidation), a shear band about 3 m long with a maximum plastic shear strain of about 10% is predicted to develop below the downstream slope of the Perimeter Embankment at Corner 1 at section 4+175. However, the predicted degree of strain-weakening is relatively low (about 6% strength reduction in a 3 m long shear band) and does not have a significant impact on the stability of the elevation 974 m embankment.

7.9.2 Seismic Analysis

Section 2+055 of the Main Embankment and section 4+175 of the Perimeter Embankment at Corner 1 are predicted to be stable under the action of the 2,475-year earthquake ground motion.

The maximum permanent horizontal displacement in the downstream direction is less than 5 cm in the embankments and buttresses of both analysed sections.

Strain-weakening is not predicted to be initiated in the GLU at section 2+055 of the Main Embankment under the action of the 2,475-year earthquake ground motion.

Assuming a constant 22 kPa remoulded undrained shear strength for the UGLU that sheared during the failure in 2014 (i.e., no inclusion of potential strength gains from reconsolidation), a relatively low level of strain-weakening (less than 1.5% strength reduction) is predicted in the UGLU under the downstream slope of the Perimeter Embankment at section 4+175 during the 2,475-year earthquake ground motion. This degree of weakening is relatively low (less than 1.5% strength reduction) and does not have a significant impact on the seismic stability of the embankment.

Settlement of the upstream fill (up to 0.5 m) may occur if the phreatic surface upstream of the till core is relatively shallow (e.g., 100 m beach width and phreatic surface at the elevation of the drain) and the seismic loading is enough to trigger liquefaction in the tailings and upstream fill. This deformation mechanism was predicted under the action of the subduction interface motion; the crustal motion was not sufficient to trigger liquefaction. The maximum permanent horizontal and vertical displacements predicted at the centreline of the embankment in both analyzed sections are less than 4 cm at the end of the 2,475-year earthquake ground motion. The serviceability of the till core is not expected to be affected by this level of displacement; however, the displacements associated with this deformation mechanism could potentially affect the serviceability of the upstream drain at elevation 970 m. As indicated in Section 7.5, the seepage analyses show that little to no flow is expected through the upstream drains during normal operations (i.e., beach widths greater than 100 m) to elevation 974 m. The upstream drains have been incorporated to account for future raises above 974 m and are not a critical control for managing hydraulic gradient at TSF elevation 974 m.

7.10 Water Management Infrastructure

7.10.1 Tailings Storage Facility Freeboard and Emergency Spillway

The inflows that directly contribute to the TSF are from precipitation on the footprint of the TSF and runoff from the catchment directly upstream of the TSF. The major contribution to TSF supernatant volume is pumped from the site contact water facilities including the Central Collection Sump and Perimeter Embankment Till Borrow Pond.

A freeboard is required to prevent overtopping of the TSF embankment. The freeboard calculations follow the procedures and equations discussed in the CDA (2013, 2019) guidelines. Wind speeds, pond depth, and embankment slope geometry were considered to determine the greatest wave uprush value for the normal and minimum freeboard scenarios. The calculated minimum freeboard is 0.7 m and controls the freeboard requirement. Freeboard calculations are included in Appendix I.

The TSF emergency spillway will be constructed on the north side of the TSF to protect the embankment during the inflow design flood (IDF) event, which considers the probable maximum flood (PMF). The emergency spillway invert elevation has been calculated to prevent exceedance of the required minimum freeboard during passage of the design IDF event. Hydrologic calculations are included in Appendix I.

Inflow volumes to the TSF were estimated using the United States Department of Agriculture Soil Conservation Service method. Rainfall-runoff models were developed using the Conservation Service method implemented with Hydrologic Engineering Center – Hydrologic Engineering Center (HEC-HMS) software (version 4.11) (USACE 2023).

The PMF for the TSF was estimated using the annual 72-hour probable maximum precipitation (PMP) rainfall plus snowmelt. The runoff volume generated by the IDF was 1.3 million m^3. The peak IDF discharge conveyed by the emergency spillway assumed that the TSF has no storage capacity at the beginning of the event, therefore will discharge all of the IDF runoff volume.

The design of the emergency spillway has a broad-crested weir geometry, with a cross-section that includes a base width of 6 m and 7H:1V side slopes to allow a trafficable surface, and a slope of 0.3% across the embankment crest. The spillway invert is required to be 1.1 m below the embankment crest for conveyance of the peak IDF discharge plus minimum freeboard. Table 20 summarizes the spillway invert, resulting water levels, and peak discharge during the passage of the IDF at an embankment crest elevation of 974 m.

Table 20: Summary of the Emergency Spillway Arrangement and Flood Routing Results for Inflow Design Flood

Embankment Crest Elevation (m)	Spillway Invert Elevation (m)	Spillway Base Width (m)	TSF Peak Discharge (m^3/s)	Peak Water Level Elevation (m)	Minimum Freeboard (m)
974.0	972.9	6.0	2.8	973.3	0.7

The emergency spillway location and alignment was selected considering potential future embankment raises above elevation 974 m and closure.

The emergency spillway is to be constructed for each interim embankment raise between elevation 970 m and 974 m. The emergency spillway entrance and chute will need to be raised as the embankment is raised.

The general layout, plan, profile, and typical sections of the emergency spillway are included in Appendix A. The emergency spillway technical specifications are included in Appendix B.

Emergency Spillway Channel Sizing

The spillway channel was sized using the Manning's equation assuming uniform flow conditions and accounting for superelevation in the curves. The channel conveys the peak flow with 0.3 m of freeboard. Flow velocities were estimated using the Manning's equation to size erosion protection.

The spillway channel material was selected based on the normal flow velocity for the stability scenario and maximum permissible velocity of the lining material. The Manning's roughness coefficients, channel dimensions, normal flow depth, and normal flow velocity for each segment are summarized in Table 21.

Superelevation for each curve of the spillway channel alignment was estimated using the US Army Corps of Engineers (USACE 1972) method and results from the Manning's equation.

Table 21: Summary of the Emergency Spillway Channel Design

Spillway Channel Segment (Approximate Station PVI [m])	Design Consideration	Max Slope (%)	Channel Bed Material	Manning's Roughness Coefficient ($s/m^{1/3}$)		Side Slopes (XH:1V)	Bottom Width (m)	Channel Depth (m)	Normal Flow Depth[a] Including Superelevation (m)	Normal Flow Velocity[b] (m/s)	Freeboard (m)
				Capacity	Stability						
Entrance/crest (10+031–10+122)	Trafficable side slopes	0.3	Granular Road Gravel	0.030	0.022	7H:1V	6.00	1.1–1.4	0.4	1.00	0.7–1.0
Chute (10+122–10+142)	Maximum slope	16.7	100 kg Class Riprap[c]	0.044	0.039	2H:1V	6.00	0.6	0.3	2.9	0.3
Stilling basin (10+142–10+145)	Contain hydraulic jump	0	100 kg Class Riprap[c]	0.044	0.039	2H:1V	6.00	1.0	0.5[d]	n/a	0.5
Stilling basin to road crossing (10+145–10+174)	Channel capacity	0.5	10 kg Class Riprap[c]	0.038	0.034	2H:1V	6.00	1.0	0.4	1.0	0.6
Road crossing (10+174–10+240)	Trafficable side slopes	0.5	Granular Road Gravel	0.030	0.022	10H:1V	6.00	0.7	0.3	1.1	0.4

		10.0	50 kg Class Riprap[c]	0.042	0.037				0.4	3.3	0.6
Discharge apron (10+800-10+817)	Topographic slope	2.0	10 kg Class Riprap[c]	0.038	0.034	2H:1V	2.00-20.0	0.3-1.0	0.14-0.50[e]	1.00-1.85	0.2-0.5[e]

(a) Normal flow depth for capacity scenario.

(b) Normal flow velocity for stability scenario.

(c) BC MOTI 2020.

(d) Flow depth is representative of the hydraulic jump estimated to be developed within the stilling basin structure.

(e) Flow depth at station 10+817 is calculated using Manning's equation assuming normal flow conditions. However, the flow depth will be less and the freeboard will be greater due to the steep natural slope (33%) beginning at station 10+817.

PVI = Point of Vertical Intersection; n/a = not applicable.

The spillway chute was designed to convey flow from the embankment crest to existing ground with a maximum slope of 6H:1V. A precast concrete weir with a 6.0 m base width and 2H:1V side slopes will be installed at the chute entrance. The spillway chute has a base width of 6.0 m and will be lined with 900 mm of 100 kg class riprap.

The stilling basin structure was sized using the results from the Manning's equation and three hydraulic design methods: Department of the Interior Bureau of Reclamation (USBR 1984), USACE (1977), and Prairie Farm Rehabilitation Administration (PFRA 1979). The length of the stilling basin and the depth of the channel were designed to contain the hydraulic jump (conjugate depth) expected to occur at the outlet of the spillway chute. The conjugate depth was calculated using the Manning's equation and is estimated to be 0.45 m. The resulting length of the stilling basin for each method is provided in Table 22.

Table 22: Spillway Stilling Basin Length

Hydraulic Design Method	Stilling Basin Length (m)
USBR (1984)	2.16
USACE (1977)	2.20
PFRA (1979)	2.52

The stilling basin length was selected as 3.0 m for increased energy dissipation prior to discharge into the spillway channel downstream and improve constructability of the structure. The stilling basin base width will be 6.0 m with 2H:1V side slopes and it will be lined with 900 mm of 100 kg class riprap.

The segment of the spillway from the stilling basin to the road crossing was designed with a 6.0 m base width for continuation between the stilling basin and the road crossing and will be lined with 400 mm of 10 kg class riprap.

The road crossing was designed to convey flow across the haul road as a shallow ford. The road crossing has a base width of 6.0 m, with 10H:1V side slopes to provide adequate crossing geometry for haul trucks. The road crossing will be lined with 200 mm of angular road gravel (75 mm minus) above 400 mm of 10 kg class riprap.

The spillway outlet channel base width, from the road crossing to the discharge apron, will be 2.0 m with 2H:1V side slopes. The spillway outlet channel will be lined with 400 mm of 10 kg class or 680 mm of 50 kg class riprap based on the slope as presented in Table 21.

The discharge apron was designed to disperse flow and reduce energy prior to discharge into Bootjack Creek. The discharge apron channel depth will transition from 1.0 m to 0.3 m and the base width will widen from 2.0 m to 20.0 m at the crest of the natural steep slope. The discharge apron will be lined with 400 mm of 10 kg class riprap. The discharge apron will convey flow onto riprap placed at grade down Bootjack Creek's left downstream bank. The riprap placed at grade shall be field fit and will continue to widen down the bank and terminate prior to Bootjack Creek's main channel.

7.10.2 Tailings Storage Facility Seepage Collection Channels and Ponds

Diversion and collection channels and ponds are currently in place around the TSF. The elevation 974 m TSF raise design will affect portions of the existing surface collection and diversion channels and structures around the TSF. These channels and structures will be partially or fully covered by the TSF embankment or buttress. The following modifications to existing water management infrastructure around the TSF will be required:

- relocation of the South Embankment Seepage Collection Pond and Main Embankment Seepage Collection Pond, as well as relocation of portions of the collection channels that feed these ponds
- expansion of the Perimeter Embankment Till Borrow Pond and relocation of portions of the channels that feed this pond

The inflow to the ponds includes seepage, runoff and flow from the upstream drains that will be collected by the collection channels and direct precipitation to the ponds. New ponds are designed to store the peak flow generated from the 1:10-year 24-hour rain plus snowmelt event and will include 0.5 m of dead storage and 0.5 m of freeboard above the storm event water surface elevation.

The collection channels are proposed to convey the peak flow generated from 1:200-year 24-hour storm event plus seepage and upstream drain flow rates. The channels include a minimum of 0.3 m freeboard.

A diversion channel is required at Corner 4 to capture surface runoff from a relatively small catchment upstream of the TSF. The diversion channel is to be sized to convey the peak flow generated from 1:200-year 24-hour storm event, while maintaining a minimum 0.3 m freeboard.

The design report for the TSF diversion channel, collection channels and ponds will be provided in a separate document.

7.11 Tailings Storage Facility Closure and Reclamation

The closure philosophy will be consistent with the most recent Mine Reclamation and Closure Plan (MPMC 2022). The TSF will remain a permanent structure, which will be reclaimed and given productive land use.

Prior to cover soil placement on the 2H:1V embankment slopes, an assessment will be conducted to determine which species can successfully revegetate the TSF embankments. This assessment will also investigate which species and revegetation/reclamation techniques will maximize overall cover soil stability and minimize erosion and future maintenance requirements.

Following cover soil placement, the TSF will be revegetated. A spillway, sized with capacity for the probable maximum flood, will also be constructed during active closure, so that a desirable long-term pond level will be maintained.

7.12 Geotechnical Risk Review and Design Controls

Potential failure mechanisms that must be addressed in the design of a tailings storage facility are summarized in Table 23 with the designer's assessment of each mechanism. The designer's assessment was made against typical dam failure modes presented in the ICOLD tailings dam safety bulletin (ICOLD 2022).

The design and operational philosophy and controls incorporate the findings and recommendation of the IEEIRP (2015) *Report on Mount Polley Tailings Storage Facility Breach*. These are to limit the amount of surface water to only that required for operation, promote unsaturated conditions in the tailings with drainage provisions, and promote consolidation of tailings upstream of the embankments.

Mount Polley Mine has an active failure modes and effects analysis for the TSF that is updated annually with the Engineer of Record. The failure modes and effects analysis includes a likelihood and risk review for failure modes and effects related to dam safety, environment, health and safety, and mine operations. Table 23 incorporates failure modes that could result in a potential breach of the TSF.

Failure modes presented in Table 23 have been assessed as credible or non-credible. A credible failure mode has been defined as a feasible failure mode that could result in a potential breach of the TSF with controls in place. A non-credible failure mode is a failure mode that cannot be triggered by the design criteria external loading conditions and/or operational upset conditions.

Table 23: Summary of Tailings Storage Facility Failure Modes Assessment

Failure Modes (adapted from ICOLD 2022)		Designer's Assessment		
Mechanism	**Typical Failure Mode**	**Discussion**	**Identified Controls**	**Assessment (if constructed as designed with operational mitigative controls)**
Instability due to foundation failure	Undetected weak foundation materials	Multiple field investigations have been completed along the foundation of the embankments and buttresses to delineate the extent and characterize the foundation materials. Golder/WSP has carried out four geotechnical investigations since 2014 along the South, Main, and Perimeter embankments (Golder 2015d, 2017b, 2018; WSP Golder 2022b). Two site investigations were undertaken by others following the breach in 2014 (KCB 2015; IEEIRP 2015). Prior investigations include KP (1990, 1995, 1997) and AMEC (2012). Foundation characterization has been completed per EGBC guidelines (WSP 2023a). The design criteria factors of safety for limit-equilibrium stability are met for all embankments.	Design of the elevation 974 m TSF raise has been undertaken incorporating a 2H:1V minimum overall downstream slope and wide buttresses are constructed along the Perimeter and Main embankments. Buttress width and height has been maintained along portions of the embankment irrespective of limit equilibrium analyses (i.e., FoS greater than minimum criteria along portions of the embankment). Instrumentation has been installed to monitor foundation response (SI, IPI, SAA and VWPs). Quantitative performance objectives (QPOs) including trigger levels and monitoring frequency, are in place for the existing TSF and will be updated for the TSF above elevation 970 m.	Credible
	Incorrect strength characterization	Multiple field investigations have been completed along the foundation of the embankments and buttresses to characterize the foundation materials. Golder/WSP has carried out four geotechnical investigations since 2014 along the South, Main, and Perimeter embankments (Golder 2015d, 2017b, 2018; Golder WSP 2022). Two site investigations were undertaken by others following the breach in 2014 (KCB 2015; IEEIRP 2015). Prior investigations include KP (1990, 1995, 1997) and AMEC (2012). Foundation material properties have been assigned based on in situ and laboratory testing. Shear strength parameters selected for the foundation till and glaciofluvial layers represent an average for the materials. Glaciolacustrine soils have been analyzed using total stress (undrained) strength parameters. The preconsolidation pressure values selected for the analyses are at or below the lower bound of the values calculated from the laboratory consolidation tests and estimated from the CPT profiles. Foundation characterization has been completed per EGBC guidelines (WSP 2023a). The design criteria FoS for limit-equilibrium stability are met for all embankments. Limit equilibrium analyses completed for a range of GLU strengths to assess sensitivity to potential variability. Stress-deformation analyses completed to assess potential redistribution of stresses due to strain weakening of GLU.	Design of the elevation 974 m TSF raise has been undertaken incorporating a 2H:1V minimum overall downstream slope and wide buttresses are constructed along the Perimeter and Main embankments. Buttress width and height has been maintained along portions of the embankment irrespective of limit equilibrium analyses (i.e., FoS greater than minimum criteria along portions of the embankment). Instrumentation has been installed to monitor foundation response (SI, IPI, SAA and VWPs). QPOs, including trigger levels and monitoring frequency, are in place for the existing TSF and will be updated for the TSF above elevation 970 m.	Credible
	Unexpected pore pressure generation	Excess pore water pressures may develop in the foundation under the buttress and embankment reslope during construction. However, extensive field and laboratory investigations have been completed to characterize the foundation, and the pore pressure response has been monitored during construction of the embankment and buttresses since 2014. The measured maximum pore pressures responses were used in the short-term stability analyses (e.g., during or at the end of construction). The design criteria FoS for limit-equilibrium stability are met for all embankments. The annual embankment crest raise is small, in the order of 2 to 3 m per year.	Construction sequence (buttress extension and embankment reslope prior to raising the embankment) Instrumentation (VWPs) has been installed to monitor foundation response. QPOs, including trigger levels and monitoring frequency, are in place for the existing TSF and will be updated for the TSF above elevation 970 m.	Not credible

Table 23: Summary of Tailings Storage Facility Failure Modes Assessment

Failure Modes (adapted from ICOLD 2022)		Designer's Assessment		
Mechanism	**Typical Failure Mode**	**Discussion**	**Identified Controls**	**Assessment (if constructed as designed with operational mitigative controls)**
Instability due to foundation failure continued	Artesian pore pressure generation	Upward gradients and artesian pressures are present at glaciofluvial units in the Main Embankment foundation. Four vertical drain wells installed under the Main Embankment help relief some of the artesian pressure. Limit equilibrium analyses completed with artesian pressures show little sensitivity to artesian pressures (if vertical drain wells were to fail and pore pressures increase).	Vertical drain wells have been installed in the foundation of the Main Embankment. Instrumentation (VWPs) has been installed to monitor pore pressure in the foundation. QPOs, including trigger levels and monitoring frequency, are in place for the existing TSF and will be updated for the TSF above elevation 970 m.	Not credible
	Liquefaction of cohesionless soils and cyclic softening of cohesive soils	The site is in an area of relatively low seismicity (peak ground acceleration equal to 0.048g for design earthquake event with a 1:2,475 AEP). Laboratory testing has been completed on glaciolacustrine samples to characterize the cyclic response (WSP 2023a). A 20% strength reduction factor has been applied in the pseudo-static and post-seismic limit equilibrium analyses to glaciolacustrine deposits to account for potential strength loss during cyclic loading. The dense till foundation materials are considered to not be susceptible to liquefaction or cyclic softening. The glaciofluvial foundation materials are typically not continuous layers.	Design of the elevation 974 m TSF raise has been undertaken incorporating a 2H:1V minimum overall downstream slope and wide buttresses are constructed along the Perimeter and Main embankments. Buttress width and height has been maintained along portions of the embankment irrespective of limit equilibrium analyses (i.e., FoS greater than minimum criteria along portions of the embankment).	Not credible
	Incorrect seismic hazard/response analysis	The site is in an area of relatively low seismicity. A site-specific probabilistic seismic hazard assessment undertaken for the TSF in 2022 (WSP 2023a). Limit equilibrium analyses were completed for an earthquake event with a 1:10,000 AEP to assess sensitivity to potential variability. Results show FoS equal to or greater than 1. Stress-deformation analyses were completed to confirm stability of the facility due to seismic loading.	Design of the elevation 974 m TSF raise incorporates sensitivity analysis to extreme earthquake event (1:10,000 AEP).	Not credible
	Erosion at the toe due to nearby water courses	Hazeltine Creek is over 200 m away from the toe of the embankment; its flow can be regulated by a weir. Hazeltine Creek is not considered an erosion risk to the buttress and embankment. The elevation 974 m South Embankment will extend across an unnamed creek at Corner 4. The catchment of the creek is small (approx. 0.15 km^2) and its flow is not considered an erosion risk to the embankment. Foundation preparation and potential till blanket placement will be completed so water drains away from the till core. The design includes diversion of water away from the embankment (refer to water management design).	Design of the elevation 974 m TSF raise has been undertaken incorporating Corner 4 creek catchment and diversion. Construction quality assurance / quality control (QA/QC) will be performed to confirm foundation preparation and potential till blanket placement is completed so water drains away from the till core and water is diverted away from the south abutment.	Not credible
	Excavation at the toe for seepage collection ditches or sumps	Water management infrastructure will be relocated in some areas to near the toe of the embankment and buttress; however, seepage collection ditches are shallow (approximately 1 m deep) and ponds are offset from the toe of the embankment and buttress.	Construction QA/QC will be performed. Inspections will be carried out by MPMC and the EoR.	Not credible
	Landslide at an abutment	Foundation at abutments comprises competent till and bedrock. Glaciolacustrine deposits have not be encountered at the abutments. Additional test pits are excavated as part of foundation preparation to confirm foundation conditions. Surficial organic or weak soils are removed as part of foundation preparation. Natural slope grades at the abutments and upstream are gentle (less than 30%). No evidence of historical landslides has been observed.	Construction QA/QC will be performed.	Not credible

Table 23: Summary of Tailings Storage Facility Failure Modes Assessment

Failure Modes (adapted from ICOLD 2022)		Designer's Assessment		
Mechanism	**Typical Failure Mode**	**Discussion**	**Identified Controls**	**Assessment (if constructed as designed with operational mitigative controls)**
Instability of the TSF slope	Inclusion of weak materials in the structural portion of the TSF, possibly due to lack of compaction and/or poor drainage	Design of the TSF raise is consistent with previous raises. Rockfill forms the downstream wedge of the embankments and the downstream buttress along the Perimeter and Main embankments. Rockfill is mainly fresh, intrusive rock with a relatively high internal friction angle (Golder 2016a). Construction of safety berms at different stages of construction may have resulted in localized slivers of loose rockfill or finer rockfill. Some ravelling has been observed on the angle of repose slope; however, the slope will be resloped to 2H:1V as part of the raise using a bottom-up construction method.	Design of the elevation 974 m TSF raise has been undertaken incorporating a 2H:1V minimum overall downstream slope, and wide buttresses are constructed along the Perimeter and Main embankments. Construction QA/QC will be performed.	Not credible
	Liquefaction of non-cohesive soils and cyclic softening of cohesive soils	Tailings upstream of the embankment are susceptible to liquefaction. The upstream fill consists of compacted tailings sand. The upstream fill below approx. elev. 968 m includes layers of rockfill and has undergone consolidation due to dewatering of the TSF in 2014. Post-earthquake limit equilibrium analyses indicate an FoS equal to 1.2 for the upstream slope. Stress-deformation analyses indicate that the till core would experience minor deformations (< 4 cm) if the tailings and upstream fill liquefy. No loss of containment is expected. The till core, filter, transition, and rockfill are mechanically placed and compacted and are not susceptible to liquefaction or cyclic softening.	The amount of surface water is limited to only that required for operation (i.e., lower phreatic surface upstream of the embankment). Construction QA/QC will be performed.	Not credible
Overtopping	Large flood that exceeds capacity of spillway	The spillway is designed to pass the 72-hour annual PMP plus snowmelt. The catchment reporting to the TSF is small and well defined. The majority of water inflows into the TSF are pumped and are therefore in the direct control of the operator.	QPOs, including freeboard trigger levels and monitoring frequency, are in place for the existing TSF and will be updated for the TSF above elevation 970 m. Design includes a freeboard contingency of 0.3 m.	Not credible
	Large flood with blocked spillway (by debris, ice or pipelines)	The spillway invert is wide; the design includes a 6 m invert width and 7:1 side slopes. Freeboard contingency of 0.3 m	Inspection of the facility by owner and EoR team is planned. Design includes a freeboard contingency of 0.3 m. QPOs are in place for the existing TSF and will be updated for the TSF above elevation 970 m. Inspections will include assessment of spillway conditions.	Not credible
	Wave action	Deposition of the tailings is planned to maintain the pond near the centre of the facility and against the natural topography on the western perimeter. The TSF is managed by maintaining the pond volume within the operating range for reclaim water and make-up water. During large freshet events, the pond could encroach onto the upstream fill of the embankment. A minimum of 20 m of upstream fill is compacted upstream of the embankments. Progression of erosion has been slow and can be addressed before it reaches the core.	The pond is maintained away from the embankments, near the centre of the facility against the natural topography. There is 20 m wide compacted fill upstream of the till core. Design includes a freeboard contingency of 0.3 m. QPOs, including minimum beach width trigger levels and monitoring frequency, are in place for the existing TSF and will be updated for the TSF above elev. 970 m.	Not credible

Table 23: Summary of Tailings Storage Facility Failure Modes Assessment

Failure Modes (adapted from ICOLD 2022)		Designer's Assessment		
Mechanism	**Typical Failure Mode**	**Discussion**	**Identified Controls**	**Assessment (if constructed as designed with operational mitigative controls)**
Overtopping continued	Operational upset (improper water management)	The majority of water inflows into the TSF are pumped and are therefore in the direct control of the operator. The catchment reporting to the TSF is small and well defined. Water can be temporarily stored in open pits if required.	Design of the elev. 974 m TSF raise incorporates a spillway and upstream drains to draw down phreatic surface as pond approaches the embankment. Inspections of the facility and water management infrastructure by the owner are planned. QPOs, including minimum beach width, freeboard and pond volume trigger levels and monitoring frequency, are in place for the existing TSF and will be updated for the TSF above elevation 970 m.	Not Credible
	Uncontrolled rupture of a tailings slurry delivery or water reclaim pipeline	The tailings pipeline is located in ditches and along upstream crest of embankments in the TSF.	Inspections of the facility and water management infrastructure by owner are planned.	Not credible
	Landslide into reservoir (rock, snow, or soil)	The slope above the TSF is less than 30 degrees and heavily vegetated. No rock outcrop is present. There is no evidence of historical landslides.	-	Not credible
	Settlement of crest (due to static and/or seismic deformations)	Minor settlement will mainly occur after TSF raises as a result of consolidation of the embankment and foundation. Construction to raise the embankment to elev. 974 m is expected to occur in 2 to 3 consecutive years. Any settlements are corrected as part of construction. Stress-deformation analyses completed to assess deformation due to static and seismic loading show relatively small deformations due to earthquake loading (< 4 cm).	Freeboard contingency is included. Topographic surveys of the facility are completed twice per year.	Not credible
Internal erosion (piping)	Material incompatibility between low and high hydraulic conductivity zones of the embankment	A portion of the filter constructed before 2014 does not meet modern filter criteria. The till core is not expected to initiate backward erosion for the gradients that will be imposed on the core, and that if backward erosion were initiated, the filter as constructed prior to 2014 would prevent ongoing erosion. Pond elevation prior to 2014 reached a maximum elevation of 966.45 m and the pond was in contact with the embankments in some areas. No signs of erosion or sinkholes were reported prior to the breach. The filter and transition zones designed and constructed since 2014 follow modern filtering criteria. Filter extends 25 m downstream in area of breach where foundation cracking/disruption is known to have occurred. Deposition of the tailings is planned to maintain the pond near the centre of the facility and against the natural topography on the western perimeter. The TSF is managed by maintaining the pond volume within the operating range for reclaim water and make-up water. The existing upstream drain at elev. 950 m limits the hydraulic head against the Perimeter Embankment at Corner 1.	Construction of an upstream drain at an elevation of 970 m along the Main and Perimeter embankments and 972 m along the South Embankment and at Corner 1. QPOs (trigger levels, monitoring frequency and actions): - minimum beach width - pond volume - toe drain flow - toe drain turbidity - piezometric levels	Credible

Table 23: Summary of Tailings Storage Facility Failure Modes Assessment

Failure Modes (adapted from ICOLD 2022)		Designer's Assessment		
Mechanism	**Typical Failure Mode**	**Discussion**	**Identified Controls**	**Assessment (if constructed as designed with operational mitigative controls)**
Internal erosion (piping) continued	Elevated pore water pressures and increased hydraulic gradient	Pond elevation prior to 2014 reached a maximum elevation of 966.45 m, and the pond was in contact with the embankments in some areas. During normal operation, the pond will reach a maximum elevation of 971.4 m and will be a minimum 100 m from the embankments.	The existing upstream drain is at elevation 950 m at Corner 1. An upstream drain will be constructed at an elevation of 970 m along the Main and Perimeter embankments and 972 m along the South Embankment and at Corner 1. QPOs (trigger levels, monitoring frequency and actions): - minimum beach width - pond volume - toe drain flow - toe drain turbidity - piezometric levels	Credible
	Hydraulic fracturing due to stress distribution within the TSF, differential settlement, or resulting from deformations due to seismic events	Foundation conditions do not rapidly vary along the embankment. GLUs are typically thin (<1 to 2 m) or overconsolidated (>1,200 kPa at the Main Embankment) Stress-deformation analyses completed to assess deformation due to seismic loading show relatively small deformations due to earthquake loading (< 4 cm). The cut-off wall is designed to allow deformation. Plastic concrete is resistant to erosion. Cutoff aggregate upstream of the wall has fines that will migrate into a crack and plug it.	QPOs (trigger levels, monitoring frequency and actions): - minimum beach width - pond volume - toe drain flow - toe drain turbidity - piezometric levels	Not credible
	Pipes through the TSF, including decant towers and pipes (seepage along the pipe, collapse of the pipe)	Design of upstream drains at elevation 970 and 972 m incorporate uniformly graded filter sand around conduits upstream and downstream of the till core. Upstream drain at Corner 1 at elevation 950 m incorporates uniformly graded filter sand around conduits downstream of the till core. Older upstream drains between about elevation 936 and 950 m incorporate filters around the conduits downstream of the till core. Pond elevation prior to 2014 reached a maximum elevation of 966.45 m, and the pond was in contact with the embankments in some areas. During normal operation, the pond will be a minimum 100 m from the embankments and the phreatic level against the embankment is expected to be at or below the elevation of the new upstream drains and pipe crossings at elevation 970 to 972 m. The new drains will limit the hydraulic head upstream of the pipe crossings. Monitoring data at the upstream drain at Corner 1 at elevation 950 m show that the drain is effective maintaining the pore pressures upstream of the till core at the elevation of the drain. HDPE pipes can accommodate the extra load of the facility raise to elevation 974 m.	Construction of upstream drains at an elevation of 970 m along the Main and Perimeter embankments and 972 m along the South Embankment. Uniformly graded filter sand around conduits upstream and downstream of the till core. QPOs (trigger levels, monitoring frequency and actions): - minimum beach width - pond volume - toe drain and upstream drain flow - toe drain and upstream drain turbidity - piezometric levels	Credible
	Underground features that could cause internal erosion	Development of preferential flow pathways in the foundation soils (e.g., glaciofluvial layers) or bedrock lead to increased seepage through the foundation. Foundation layers are typically non-continuous, with a wide range of hydraulic conductivity. Foundation check (test pits/trenches) are completed during foundation preparation at the Corner 4 and 5 abutments. Filter blanket is installed over the foundation along the embankment downstream of the till core.	QPOs (trigger levels, monitoring frequency and actions): - minimum beach width - pond volume - toe drain flow - toe drain turbidity - piezometric levels	Not credible

EGBC = Engineers and Geoscientists British Columbia; TSF = tailings storage facility; SI = slope inclinometer; IPI = in-place inclinometer; SAA = shape acceleration array; VWP = vibrating wire piezometer; QPOs = Quantitative Performance Objectives; CPT = cone penetration test; FoS = factor of safety; GLU = glaciolacustrine unit; AEP = annual exceedance probability; QA/QC = quality assurance / quality control; MPMC = Mount Polley Mining Corporation; EoR = Engineer of Record; PMP = probable maximum precipitation.

BC MEM (2016) requires assessment of failure modes by specific analyses, which are listed in Table 24 with references to report sections and the designer's assessment.

Table 24: Failure Modes Required to Be Assessed

Failure Modes	Report Section	Assessment
Geotechnical		
Slope stability	7.7 and 7.9	Design meets criteria
Seepage	7.5	Seepage is not a credible failure mode; design raise is 4 m and seepage rates are expected to be slightly higher than for the existing TSF
Internal erosion and piping	7.4	Design includes mitigation of internal erosion and piping by limiting the hydraulic gradient across the till core with operational controls and the use of upstream drains
Static and dynamic liquefaction	7.7 and 7.9	Design meets criteria for stability assuming tailings liquefy under seismic loading
Characterization of the footprint area as well as upstream areas	4.0	Included
Site-specific seismic hazards	4.5 and 7.7	Design meets criteria for stability considering the site-specific seismic hazard
Minimum acceptable factors of safety	7.7.1 and 7.9	Design meets criteria for stability
Long-term consolidation settlements	7.7.8	Consolidation is not a credible failure mode
Short-term and long-term deformations	7.9	Deformation of the embankment is not a credible failure mode
Hydrotechnical		
Flow capacity	7.10	Spillway designed to pass the 72-hour PMF
Surface erosion	-	Not a credible failure mode during operation if OMS controls are implemented. Closure design to consider erosion.
Water balance	6.4 and 7.10	Included
Hydrogeological		
Hydraulic fracturing	-	Not a credible failure mode; design includes management of the hydraulic gradient across the foundation and till core
Seepage through the foundation and abutments	7.5	The 4 m embankment raise is not expected to significantly increase the current seepage rates at the TSF
Geochemical		
Acid generation from tailings or dam construction materials	5.2	Assessment of geochemistry is excluded from the scope of this report. Refer to Kennedy et al. (2016) and SRK (2022).

Table 24: Failure Modes Required to Be Assessed

Failure Modes	Report Section	Assessment
Metal leaching from tailings or dam construction materials	5.2	Assessment of geochemistry is excluded from the scope of this report. Refer to Kennedy et al. (2016) and SRK (2022).
Water treatment effectiveness and capacity	-	Not a credible failure mode because the design does not rely on water treatment to prevent failure and is not anticipated to influence the effectiveness or capacity of the treatment plant
Mechanical		
Tailings transport pressure and flow capacity	-	Assessment of tailings transport is undertaken by MPMC and excluded from the scope of this report.
Water conveyance pressure and flow capacity	6.6	Upstream drain pipes have been sized for expected flows for a TSF crest at elevation 987 m. Flow is by gravity only. Assessment of other water conveyance in pipelines is excluded from the scope of this report (e.g., reclaim barge; conveyance from Perimeter Embankment Till Borrow Pond to TSF
Loading conditions that should be considered in stability analyses include		
Initial and interim and long-term construction stages	7.7	The design meets stability criteria for short- and long-term construction stages
Impounding of water	7.7	The design meets stability criteria assuming an upset condition with no tailings beach (i.e., the pond against the embankment)
Impoundment of tailings	7.7	The design considers impounded tailings to elev. 973 m
Rapid drawdown (if possible, for the facility)	-	Not a credible failure mode; no mechanism to rapidly draw down the pond
Earthquake impact on dam	7.7	Design meets stability criteria considering the site seismic hazard
Earthquake induced liquefaction of retained tailings	7.7	Design meets stability criteria assuming tailings liquefy
Extreme climatic events (precipitation, temperature, and wind)	3.2 and 7.10	IDF design criteria is the 72-hour annual PMP plus snowmelt

Source: BC MEM 2016.

TSF = tailings storage facility; IDF = inflow design flood; PMP = probable maximum precipitation; - = not applicable.

The Engineers and Geoscientists British Columbia (EGBC) guide to the standard for documented independent review of high-risk professional activities or work (EGBC 2023) were followed and a Type I independent review was completed. The independent review checklist and signoff is included in Appendix J.

8.0 INSTRUMENTATION

A geotechnical instrumentation and monitoring system is in place for the Mount Polley TSF in conjunction with established QPOs to monitor performance of the facility.

The monitoring system has been established, and is reviewed on a regular basis, based on failure modes and critical controls identified as part of risk reviews and the design and operational philosophy. The intention of the monitoring system is to provide early warning indications of changing conditions that may affect the safe and effective management of the TSF.

The TSF instrumentation is monitored and assessed against the QPOs by MPMC staff. The Engineer of Record team reviews and interprets the instrumentation data provided by MPMC periodically. MPMC personnel is responsible for implementation of specific actions and responses in the event of anomalous data or QPO exceedances, including informing the Engineer of Record when the QPO thresholds are triggered.

As part of the design for the raise of the TSF to elevation 974 m, the existing TSF instrumentation monitoring system will be retained. Instrumentation, where required, will be relocated or extended during construction.

Geotechnical instrumentation and monitoring will follow the requirements set out in the existing Operation, Maintenance and Surveillance Manual for the TSF. The Operation, Maintenance and Surveillance Manual is reviewed annually and updated as required to reflect changing conditions for the TSF.

Slope inclinometer casing and VWP and shape acceleration array cables will be extended and raised as part of the construction to reslope and raise the embankment. Raising inclinometer casings and standpipe wells through the rockfill buttress can be challenging, and some of the existing inclinometers and standpipes may be damaged during construction. Instrumentation coverage will be reviewed if existing instrumentation is damaged. The need to replace instrumentation will be assessed in a case-by-case basis.

The survey monument installed at the crest of the Perimeter Embankment at Corner 1 was decommissioned during construction of the embankment in 2023. Readings of the remaining survey monument (SM17-02) installed on the Perimeter Embankment buttress at Corner 1 have been unreliable, and the survey monument should be decommissioned prior to raising the embankment above elevation 970 m.

Existing and proposed new instrumentation for the TSF is presented in Table 25. Specifications for the instrumentation are included in Appendix B, and coordinates and typical details are presented in Drawings 29 and 30 in Appendix A.

Table 25: Existing and Proposed Instrumentation for Monitoring of Tailings Storage Facility Failure Modes

Failure Mode	Existing Instrumentation to be Retained	New Instrumentation	Comment
Instability due to foundation failure	■ Twenty-two SIs are to be extended vertically and protected from damage (SI16-15, SI15-10, SI15-14, SI15-17, SI15-18, SI16-01, SI16-03, SI16-06, SI18-01, SI18-03, SI18-04, SI23-01, SI23-02, SI15-01, SI15-02, SI21-01, SI21-02, SI21-03, SI12-02, SI15-07, SI15-08, and SI21-06). ■ Four SAA cables (SAA15-01, SAA15-02, SAA16-01, and SAA16-02) are to be extended and protected from damage. ■ One hundred and twenty-three VWPs installed in the foundation are to be extended and protected from damage.	■ Five SAAs are to be installed in new boreholes in the foundation under the South and Main embankments. ■ VWPs are to be installed in boreholes drilled to install new SAAs. Elevations will be confirmed by the EoR. ■ Seven SAAs are to be retrofitted within existing SI casing on the Main and Perimeter embankments (SI15-12, SI15-15, SI23-03, SI15-04, SI15-06 and SI21-05). SAAs may not be able to be retrofitted in all proposed SIs due to consolidation of the existing casing. Drilling an adjacent borehole may be required in some cases.	■ Installation of SAAs in new boreholes is to be planned so the embankment can be adequately monitored during construction. SIs to be retrofitted with SAAs prior to the bulk of rockfill placement for embankment resloping. New SAAs to be installed within 2 months of completion of resloping of each embankment, or within 3 months of decommissioning of SIs. ■ The following SIs will need to decommissioned as they will be inaccessible to safely read following resloping of the embankments: SI15-19, SI15-20, SI16-16, SI15-03, SI15-05, and SI15-09. ■ SIs within footprint of ramp (SI15-10 and SI15-18) may be decommissioned, if required.
Overtopping	■ Freeboard and pond volume are monitored by survey of the pond level and tailings surface. ■ Minimum beach width and general location of the pond are monitored by visual inspection and satellite images.		
Internal erosion (piping)	■ Thirty-two VWPs installed in the embankment and upstream tailings are to be extended and protected from damage.	■ Forty-six VWPs are to be installed upstream of the till core to monitor the phreatic surface upstream of the till core and the performance of the upstream drains. ■ Manual flow rate and turbidity readings are to be taken on upstream drain discharge points.	■ VWPs to be installed during construction of the upstream drains. ■ Manual flow rate and turbidity readings are to continue for the Perimeter Embankment at Corner 1 upstream drain, South Embankment toe drain, and east and west Main Embankment toe drains. Turbidity readings are to continue at the Freshet Embankment seepage collection ditch and the north and south diversion ditches.

TSF = tailings storage facility; VWP = vibrating wire piezometer; SI = slope inclinometer; SAA = shape acceleration array; EoR = Engineer of Record.

9.0 MATERIAL QUANTITIES

The estimated material quantities required for construction of the embankments and emergency spillway to a crest elevation of 974 m are summarized in Table 26. Quantities include construction of the upstream drain. The estimated fill volumes are based on the August 25, 2023, survey. All fill quantities are estimated after spreading and compaction. No allowances for constructability or bulking factors have been included in the material quantity estimates. All geotextile and pipe quantities are for after installation only and do not include any allowances. Actual quantities may vary based on conditions encountered in the field.

Table 26: Material Quantities for Tailings Storage Facility Raise to Elevation 974 m

Task	Unit	Quantity
Embankment		
Foundation preparation	m^2	140,000
Till core	m^3	104,000
Filter[(a)]	m^3	32,000
Transition[(a)]	m^3	30,000
Raise and reslope rockfill	m^3	3,576,000
Buttress rockfill	m^3	1,609,000
Upstream fill	m^3	378,000
General fill for upstream drain and upstream fill below 970 m[(b)]	m^3	421,000
Drain rock	m^3	50,000
Drain rock transition	m^3	15,000
Filter sand	m^3	100
Geotextile 800 g/m^2	m^2	60,000
Geotextile 340 g/m^2	m^2	68,000
6-inch diameter perforated, SDR 9 HDPE pipe, PE4710	m	850
12-inch diameter solid, SDR 17 HDPE pipe, PE4710[(c)]	m	4,900
12-inch by 12-inch by 12-inch tee, SDR 17 HDPE, PE4710	ea	11
12-inch by 12-inch by 6-inch reducing tee, HDPE, PE4710	ea	85
12-inch end cap, SDR 17 HDPE, PE4710	ea	22
6-inch end cap, SDR 9 HDPE, PE4710	ea	85
Spillway[(d)]		
Riprap (10 kg class)	m^3	1,400
Riprap (50 kg class)	m^3	2,400
Riprap (100 kg class)	m^3	200
Geotextile 340 g/m^2	m^2	300
Granular Road Gravel	m^3	600
Till Liner	m^3	1,200
Fine Bedding	m^3	2,200
Coarse Bedding	m^3	100

Table 26: Material Quantities for Tailings Storage Facility Raise to Elevation 974 m

Task	Unit	Quantity
Native Fill	m^3	1,700
Rockfill	m^3	5,600
Excavation	m^3	13,600

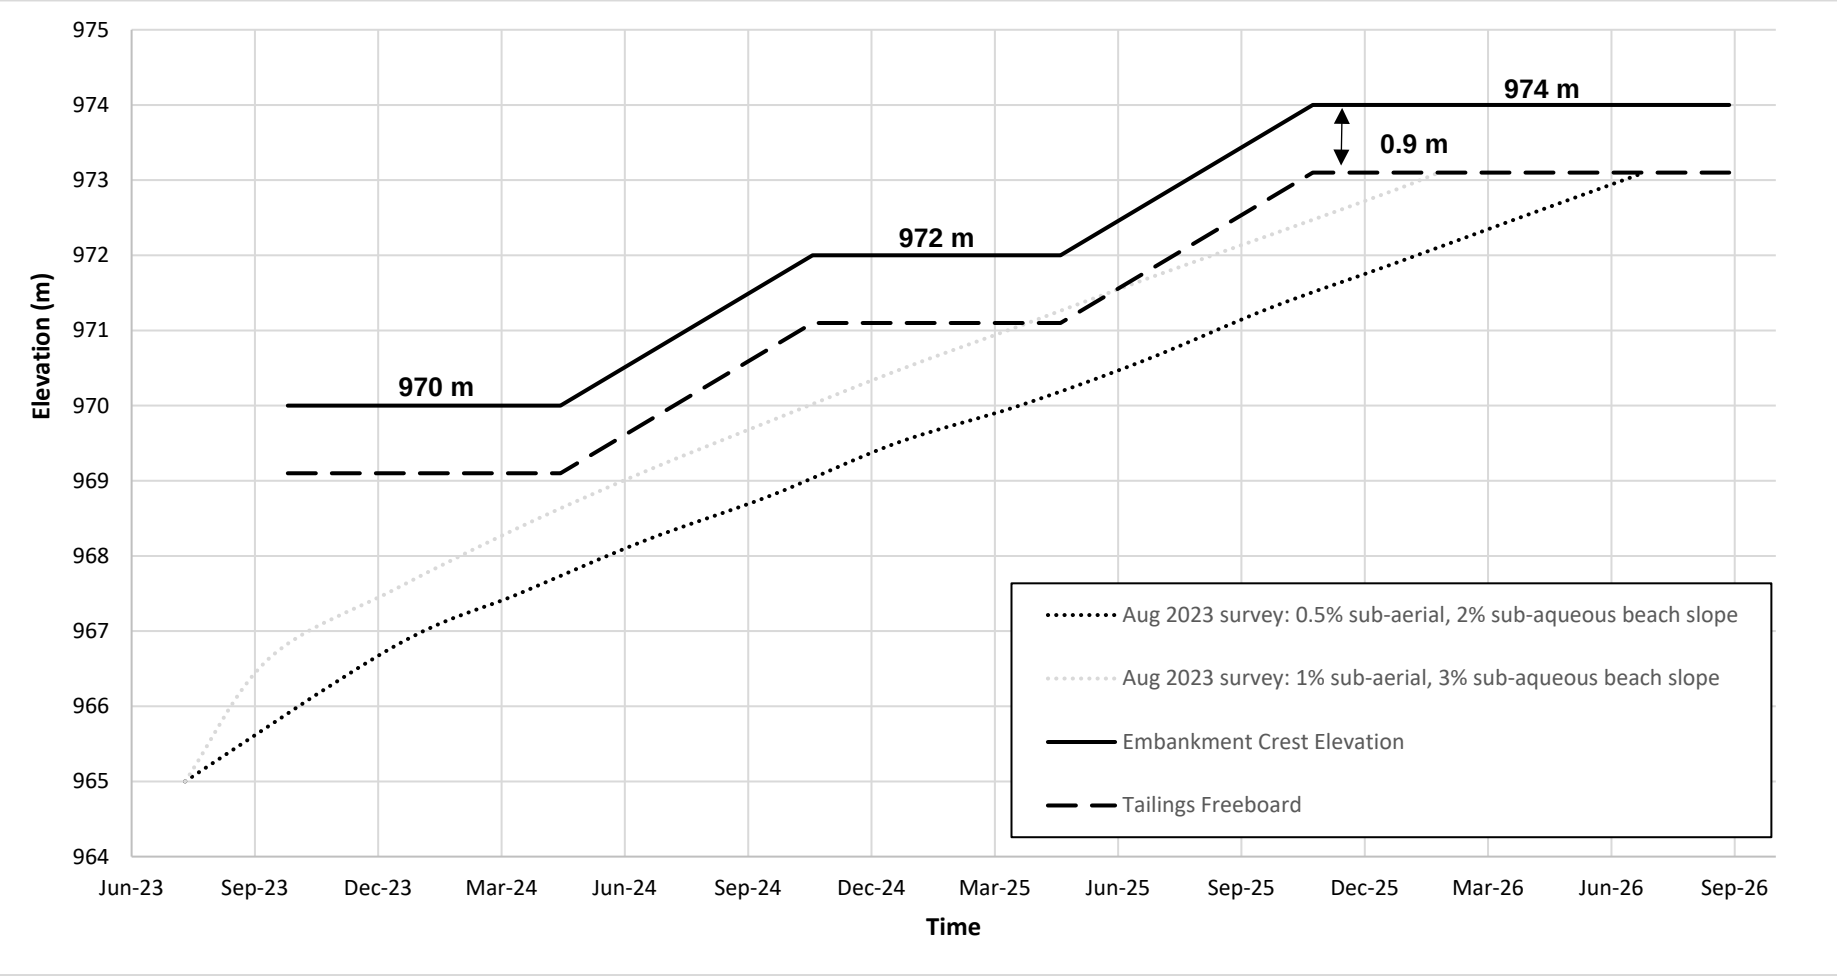
(a) Filter and transition quantities around drainpipes downstream of till core and within the upstream drain are not included.

(b) Based on topographic survey completed in August 2023. Ongoing tailings deposition has filled some of this volume.

(c) The length of pipe required from the downstream crest of the embankment to the downstream water management infrastructure is not included in the quantities in the table.

(d) Rounded up to the nearest 100.

SDR = standard dimension ratio; HDPE = high-density polyethylene.



10.0 CONSTRUCTION

10.1 Construction Schedule

Construction of the till core should be limited to when temperatures are above freezing. Generally, that is from April to October. Construction of the rockfill buttresses and rockfill shell can occur year round provided measures are taken to manage snow, ice, and surface water. A minimum tailings freeboard of 0.9 m (top of tailings surface to crest of embankment) is to be maintained.

The base surface used for the deposition modelling was generated by combining a topographic and bathymetry survey completed on August 25, 2023. Tailings deposition from August 2023 was modelled using actual production values from August to December 2023 and MPMC mine plan tonnages reported in the Design Basis from January 2024 onwards (Appendix C).

Figure 10 shows the embankment construction sequence to 974 m crest elevation from the current crest elevation of 970 m, along with the planned tailings deposition schedule considering a 0.5% and a 1% sub-aerial tailings beach slope. The construction sequence assumes that the construction season is limited to the period between May and October each year due to weather conditions. Note that this figure is based on actual production and the time frame differs from the mine plan presented in Appendix C.

Tailings freeboard is based on a 0.5% sub-aerial beach slope, which is what has been achieved with recent operations. Tailings freeboard may be increased or reduced during operations based on actual tailings deposition slopes; the tailings freeboard will be included as part of the quantitative performance objectives and changes must be agreed upon with the Engineer of Record.

Figure 10: Tailings Storage Facility Embankment Tailings Deposition and Construction Schedule

10.2 Construction Sequence

The following construction sequence is proposed for construction of the TSF to elevation 974 m, although some activities will be performed simultaneously:

- **Instrumentation**—relocation and/or protection of all existing geotechnical instrumentation that may be affected during construction.
- **Foundation preparation**—removal of any unsuitable material.
- **Toe buttress extension**—buttress construction must be completed prior to raising the embankment.
- **Embankment reslope and crest widening at elevation 970 m**—rockfill placement to reslope the embankment to 2H:1V. Buttress extension construction must be completed prior to resloping of the embankment.
- **Abutment foundation preparation**—removal of unsuitable materials and excavation to the underlying competent native till or bedrock to provide suitable tie-in for the till core.
- **Upstream drain construction**—till core crossing must occur at the elevations indicated in the drawings and specifications.
- **Raise of embankment**—till core construction from elevation 970 m, including surrounding upstream fill, filter transition, and rockfill.
- **Spillway construction**—spillway invert to be constructed 1.1 m below embankment crest elevation. Spillway to be constructed after each embankment raise and before freshet.

Sufficient construction material must be stockpiled or available during the construction to allow the sequential raising of the embankment with upstream fill, till, filter, transition, and rockfill.

The quality assurance and quality control requirements are described in detail in the *Embankment Construction to Elevation 974 m Technical Specification* (Appendix B). The Quality Assurance Manager will be present full time on site during construction activities and will be responsible for the quality assurance activities.

11.0 CLOSURE

The reader is referred to the Study Limitations, which precedes the text and forms an integral part of this report. We trust the above information is sufficient for your needs at this time. Should you have any questions or require clarification, please do not hesitate to contact the undersigned.

- FILTER SAND
- GENERAL FILL
- 2024 VIBRATING WIRE PIEZOMETER INSTALLED IN UPSTREAM FILL AND TAILINGS BEACH (SEE NOTE 5)

NOTES

1. ALL UNITS ARE IN METRES UNLESS NOTED OTHERWISE.
2. ELEVATIONS SHOWN ARE REFERENCED TO TAILINGS GRID.
3. REFER TO TILL CORE CROSSING CONTROL POINTS IN DRAWING 26 AND 27.
4. A MAXIMUM TILL CORE CROSSING ELEVATION AT 972 m IS ALLOWED FOR PANEL 1 TO 3 AND 10 TO 11.
5. SEE DRAWING 30 FOR VIBRATING WIRE PIEZOMETER PLACEMENT.
6. RECORD DRAWINGS FOR TSF CONSTRUCTION TO ELEVATION 970 m ARE IN PROGRESS. ZONE F AND ZONE T CONNECTION TO EXISTING FILTER AND TRANSITION TO BE CONFIRMED BY QA MANAGER DURING CONSTRUCTION. A MINIMUM 2.0 m WIDE ZONE F IS REQUIRED TO AT LEAST 0.5 m BELOW THE ELEVATION OF THE BOTTOM OF THE FILTER SAND. A MINIMUM 2.0 m WIDE ZONE T IS REQUIRED TO AT LEAST 0.5 m BELOW THE ELEVATION OF THE BOTTOM OF THE 2.0 m WIDE ZONE F.

REFERENCE

1.0 SCOPE

These Specifications provide the technical information for construction of the TSF embankments from elevation 970 m to 974 m, at the Mount Polley Mine near Likely, British Columbia. The scope of this Work includes but is not limited to the following:

- Foundation preparation
- South, Main and Perimeter embankments re-slope
- South, Main and Perimeter embankments raise
- Extension of the rockfill buttress along the Main and Perimeter embankments
- Sourcing and placement of fills for the upstream drain
- Sourcing and placement of fills for the spillway
- Supply and installation of pipe materials
- Supply and installation of instrumentation
- Control of water during construction.

These Specifications shall be read in combination with the latest revision of the Drawings. The work is to be constructed in accordance with and to the lines and grades shown on the Drawings, and as directed by the MPMC Construction Manager and the Geotechnical Engineer's QA Manager.

2.0 GENERAL

2.1 Definitions

The definitions used in this Specification are given in Table 2-1.

Table 2-1:List of Definitions

Term	Definition
Approval	A written engineering or geotechnical opinion, concerning the progress and completion of the work.
ASTM	ASTM International
Drain Rock	Screened rockfill used within the upstream drain and meeting the requirements of these Specifications.
Drawings	The most recent revision of the Issued for Construction (IFC) Tailings Storage Facility Drawings prepared by the Geotechnical Engineer.
General Fill	Fill consisting of mainly tailings and meeting the Specifications.

Table 2-1:List of Definitions

Term	Definition
Geotechnical Engineer	WSP Canada Inc.
Fill	A general terminology to describe soil or rockfill materials placed during the construction.
Filter (Zone F)	Material produced from crushing or screening NPAG rockfill to be placed in contact with the till core, filter sand and transition, and meeting the requirements of these Specifications.
Filter Sand	Granular material to be placed upstream in contact with the upstream fill and till core and downstream in contact with the till core and filter where the upstream drain pipes pass through the till core, and meeting the requirements of these Specifications.
NPAG	Non-Potentially Acid Generating.
Owner	Mount Polley Mining Corporation (MPMC).
PAG	Potentially Acid Generating.
Quality Assurance	Planned and systematic activities that provide confidence to the Owner (MPMC) and various stakeholders that quality control is being implemented effectively.
Quality Control	A planned system of inspection and testing carried out according to accepted standard specifications to ensure the quality of the work meets the design requirements.
Riprap	Armour rock used for erosion protection within water infrastructure
Rockfill or Zone C	Run-of-Mine NPAG rock material meeting the Specifications.
Specifications	The most recent revision of the Tailings Storage Facility technical specifications prepared by the Geotechnical Engineer.
TSF	Tailings Storage Facility.
Till (Zone S)	Soil consisting of sizes ranging from clay to cobbles that will be placed and compacted to form a low hydraulic conductivity layer, and meeting the requirements of these Specifications.
Till Foundation	Natural soil layer consisting of sizes ranging from clay to cobbles that form the foundation of the facility.
Transition (Zone T)	Material produced from crushing or screening NPAG rockfill to be placed in contact with the filter and rockfill, and meeting the requirements of these Specifications.
Upstream Fill (Zone U)	Fill consisting of mainly tailings and meeting the Specifications.
Work	The construction works, or additional work, required to complete construction of the Tailings Storage Facility as defined in the Drawings and Specifications.

2.2 Drawings

Table 2-2 presents a list of the Drawings.

Where a discrepancy exists between these Specifications and the Drawings, the Geotechnical Engineer shall be notified upon discovery of the discrepancy, and a formal written Request for Information (RFI) shall be issued to the Geotechnical Engineer to clarify the design intent.

The user is responsible to confirm that they are using the most recent version of the Specifications and Drawings.

2.3 Standards

Work shall conform to, but not be limited to, the requirements of the latest edition of the standards listed in Table 2-. Work included in this Specification shall conform to the applicable provisions in these publications, except as modified by the requirements specified herein or as indicated in the Drawings. Each publication shall be the most recent revision in effect at the time of issue of the bid package for this work.

Table 2-3: List of Standards

Standard	Description
ASTM C117	Standard Test Method for Materials Finer than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing.
ASTM C136	Standard Test Method for Sieve Analysis of Fine and Coarse Aggregates.
ASTM D75	Standard Practice for Sampling Aggregates
ASTM D422	Standard Test Method for Particle-Size Analysis of Soils
ASTM D698	Standard Test Methods for Laboratory Compaction Characteristics of Soil Using Standard Effort.
ASTM D6938	Standard Test Methods for In-Place Density and Water Content of Soil and Soil-Aggregate by Nuclear Methods (Shallow Depth).
ASTM D2216	Standard Test Methods for Laboratory Determination of Water (Moisture) Content of Soil and Rock by Mass.
ASTM D2321	Standard Practice for Underground Installation of Thermoplastic Pipe for Sewers and Other Gravity-Flow Applications.
ASTM D2657	Standard Practice for Heat Fusion Joining of Polyolefin Pipe and Fittings.
ASTM D3350	Standard Specification for Polyethylene Plastics Pipe and Fittings Materials.
ASTM D4318	Standard Test Methods for Liquid Limit, Plastic Limit, and Plasticity Index of Soils.
ASTM D4355	Standard Test Method for Deterioration of Geotextiles by Exposure to Light, Moisture and Heat in a Xenon Arc Type Apparatus.
ASTM D4533	Standard Test Method for Trapezoid Tearing Strength of Geotextiles.
ASTM D4632	Standard Test Method for Grab Breaking Load and Elongation of Geotextiles.
ASTM D4751	Standard Test Method for Determining Apparent Opening Size of a Geotextile.
ASTM D5240	Standard Test Method for Evaluation of the Durability of Rock for Erosion Control Using Magnesium Sulfate.
ASTM D5261	Standard Test Method for Measuring Mass per Unit Area of Geotextiles.
ASTM D6241	Standard Test Method for Static Puncture Strength of Geotextiles and Geotextile-Related Products Using a 50 mm Probe.
ASTM D6473	Standard Test Method for Specific Gravity and absorption of rock for erosion control.
ASTM D6913	Standard Test Methods for Particle-Size Distribution (Gradation) of Soils Using Sieve Analysis
ASTM D6928	Standard Test Methods for resistance of coarse aggregate to degradation by abrasion in the micro-deval apparatus

If materials are offered which conform to a standard other than that specified then the standard offered shall be equal to or superior, when tested, to the specified standard and full details of the difference between the standard offered and the standard specified shall be given.

2.4 Roles and Responsibilities

Table 3 presents a summary of the key roles and associated responsibilities and authorities. The roles and responsibilities of each position shall be reviewed, documented, and agreed upon prior to the start of work for each stage of the project.

Table 2-4: Table of Responsibilities

Role	Responsibility	Authority
MPMC TSF Construction Team		
MPMC TSF Qualified Person	▪ Coordinates the design, construction and overall management of the TSF with the EoR and MPMC construction manager, as well as internal and external resources.	▪ Designated by mine manager for safe management of the TSF.
MPMC Construction Manager	▪ Defines the scope of the project. ▪ Provides all materials, including water, and site access. ▪ Obtains all relevant permits. ▪ Provides reasonable access to the general open areas around the work site. ▪ Provision of survey for set-out and for construction record. ▪ Coordinates all project communications. ▪ Arranges coordination and progress meetings, as required. ▪ Leads problem resolution meetings for all QA and QC issues.	▪ Retains the Contractor to complete the project. ▪ Directs the scope of work to complete the project. ▪ Has the authority to stop work due to non-compliance (which shall resume only after a plan for corrective action has been approved by the MPMC Construction Manager and QA Manager).
Contractor	▪ Retained by the MPMC Construction Manager. ▪ Assigned tasks by the MPMC Construction Manager to bring the Work, or additional work, to final completion. ▪ Ensure that the Work is done in accordance with the Drawings and Specifications. ▪ Follows the QC Plan. ▪ Reports to the MPMC Construction Manager. ▪ Request information, as necessary, to clarify the design intent.	▪ Directs work.

Table 2-4: Table of Responsibilities

Role	Responsibility	Authority
Quality Control Laboratory	▪ Reports to the MPMC Construction Manager. ▪ Responsible for performing the QC laboratory and in-situ tests outlined in Section 5.0.	▪ Reports test results to the MPMC Construction Manager and the QA Manager.
Engineering Team		
Engineer of Record (Engineer)	▪ Ensures that the works are constructed in accordance with the design intent. ▪ Conducts site visits at key points to check on progress of work and support the QA team. ▪ Responsible to oversee the QA program to confirm that the works are constructed in accordance with the design intent. ▪ Responsible for the design and preparation of the Drawings and Specifications. ▪ Responsible for all design changes through updates to the Drawings and Specifications, including modifications or clarifications required during construction. ▪ Responsible for review of the construction record report. ▪ Prepares deviance accountability report. ▪ Fulfils the requirements of the Engineer of Record as defined in 10.1.5 of the Code.	▪ Overall supervision and coordination of QA team. ▪ Evaluates the adequacy of the as-built facility relative to the design as well as applicable standards, criteria and guidelines. ▪ Signs construction record.
Quality Assurance (QA) Manager	▪ Reports to the Engineer and represents the Engineer on site. ▪ Responsible for performing the QA tasks outlined in Section 5.0.Responsible for monitoring the Quality Control program to confirm that the works are constructed in accordance with the design intent. ▪ Review of QC data and sign-offs provided for compliance with the design intent, Drawings and Specifications. ▪ Attends site meetings and conducts site inspections. ▪ Assesses site design and construction issues or non-compliances and prepares recommendations for review by the Engineer. ▪ Prepares draft site documentation for review by the Engineer.	▪ Approves work as meeting the design intent, as set out in the Drawings and Specifications. ▪ Rejects work which fails to meet the design intent as set out in the Drawings and Specifications. ▪ Signs as the QA Manager on the construction checklists. ▪ Reports non-conformance of Work to the MPMC Construction Manager and the Engineer.

3.0 CARE OF WATER

3.1 Scope

This Section describes Care of Water during the construction, which consists of all work required to control water from any sources, including groundwater, surface water, snowmelt and precipitation, in order to complete the Work in accordance with the Drawings and Specifications, and in accordance with all environmental and safety controls established by MPMC. Care of water shall include the following:

- Managing water before, during and after excavating, preparing, placing, and compacting embankment fill material. Water management is also to be conducted in designated waste areas, access roads, stockpiles, and when undertaking any other part of the Work.
- Dewatering foundations and associated working areas. Providing, operating and maintaining any channels, flumes, drains, sumps, pumps and other drainage facilities and equipment necessary to divert or to remove water from construction areas.
- Constructing and maintaining any embankments and other protective works required to divert water away from areas required for the Work, and where applicable, removing such structures upon completion of the Work.

3.2 General

Surface water shall be temporarily diverted and managed during construction of the Work. Appropriate channel, ditch, dike and other facilities required to divert surface water from any area required to complete the Work shall be constructed.

Pumps, hoses, culverts and any other equipment required to dewater and maintain all parts of the construction site free from water shall be furnished, installed, maintained, and operated.

Temporary diversion and protective works and pumping stations shall be adequately operated and maintained. These shall also be readily accessible at all times.

Temporary dikes and other temporary works shall be removed promptly when they are no longer required at the direction of the Owner's Construction Manager. Materials from such removal shall be hauled to disposal areas designated by the Owner's Construction Manager.

Excavations shall be dewatered prior to performing work in the excavations, to the extent determined acceptable by the QA Manager. This includes the Perimeter Embankment Till Borrow Pond, Main Embankment till borrow area, Main Embankment Seepage Collection Pond, South Embankment Seepage Collection Pond and seepage collection ditches.

4.0 SURFACE AND FOUNDATION PREPARATION

4.1 Scope

This Section provides the requirements for surface and foundation preparation for raising the TSF embankments. The surface and foundation preparation for the South, Main and Perimeter embankments includes:

- expose and prepare the surface of the Till Core, Filter, and Transition materials along the crest of the embankments
- expose and prepare the surface of the buttress within the embankment re-slope footprint
- clearing, stripping and preparing the foundation within the embankment re-slope and buttress extension footprint
- clearing, stripping and preparing the foundation at the embankment abutments
- loading, hauling, dumping, and disposing of excavated materials.

4.2 General

Excavation shall be carried out in accordance with the Drawings and Specifications using ground support and water control measures required for safe and effective operation. Excavation procedures shall be such that the stability of adjacent fill or cut slopes or of completed Work shall not be at risk.

The excavation shall be laid out, subject to inspection by the QA Manager, prior to commencing any excavation. Excavation shall not start on any part of the Work until the proposed methodology and construction sequence has been approved by the Owner's Construction Manager.

Survey shall be performed to confirm the elevations and coordinates shown on the Drawings.

Excavation work may begin only after the necessary infiltration and runoff control measures have been completed in accordance with Section 3.0, and the necessary equipment, elements and materials for protection of surface excavations are available at the site. Temporary drainage and pumping systems shall be provided, operated and maintained, as required, to direct water away from the excavation areas, as specified in Section 3.0.

The location of the exposed material boundaries and exposed surface shall be surveyed.

4.3 Clearing and Stripping

Any area to be cleared and stripped shall require prior approval by the Owner's Construction Manager and the MPMC Environmental Department.

Clearing and stripping shall consist of removing stockpile material, topsoil, vegetation and other deleterious materials, including trees, brush, stumps, roots, and debris, and loading, hauling and dumping such materials into stockpiles within designated waste areas.

Competent foundation material, as determined by the QA Manager, shall be exposed. Foundation material considered unsuitable by the QA Manager shall be excavated and removed.

Vegetation shall not be disturbed beyond the boundaries shown on the Drawings unless so directed by the Owner's Construction Manager. Waste materials shall not be deposited into any riverbed or other water channel.

The QA Manager will determine if the fill material, containing organics, along the toe of the South Embankment needs to be progressively excavated in 20 m wide panels perpendicular to the embankment. In this case, the fill in each panel is to be removed down to competent foundation material, and Embankment Rockfill (Zone C) placed to replace the excavated material, prior to the excavation of the adjacent panel.

4.4 Foundation Preparation

Following clearing and stripping, the surface of the foundation shall be proof-rolled, as directed by the QA Manager. Where movements are observed which are deemed unacceptable by the QA Manager, the area shall be excavated, as directed by the QA Manager.

The foundation preparation and proof-rolling may be adjusted in the field to suit actual conditions, as defined by the QA Manager.

Fill placement shall not commence until preparation works have been completed, and written approval to proceed has been provided by the QA Manager.

4.5 Surface Preparation Along the Crest of the Embankments

The existing Till Core, Filter and Transition material along the crest of the embankments are to be exposed, as directed by the QA Manager. All deleterious materials are to be removed and hauled to a designated waste area.

Frost affected material along the crest of the Till Core shall be removed as directed by the QA Manager. After removal of frost affected material, the exposed surface of the till core shall be re-compacted with a sheep’s foot roller. The exposed till core may need to be moisture conditioned, as directed by the QA Manager.

Loose upstream fill material along the crest of the embankment shall be moisture conditioned and re-compacted as directed by the QA Manager.

4.6 Perimeter and South Embankments Abutments

Stockpiled material, topsoil, vegetation, and other deleterious materials, including trees, brush, stumps, roots, and debris is to be removed at the South Embankment abutment and Perimeter Embankment abutment. The material is to be loaded, hauled and dumped into stockpiles within designated waste areas.

The thickness of competent till is to be confirmed by the excavation of test pits, as directed by the QA Manager. The test pits are to be excavated along the Till Core and Upstream Fill footprint.

Where a minimum of 2 m of competent till exists above bedrock, the Till Core will be keyed into the foundation till by the excavation of a 0.5 m deep and 2.0 m wide trench.

Where the depth of foundation till to bedrock is less than 2 m, the Till Core shall be placed directly onto bedrock. The bedrock surface will be prepared to receive Till by the removal of all residual soil to fully expose the bedrock. Relatively loose, diggable bedrock is to be excavated and the surface cleaned by high pressure jets. Depending

on the condition of the bedrock surface, the QA Manager may request additional preparation which could include placement of bentonite, shotcrete or slush grout.

Foundation preparation at the abutment shall be completed in such a way that water drains away from the Till Core. This may require placement of a till blanket downstream of the Till Core.

4.7 Designated Waste Areas

Surplus and unsuitable materials shall be disposed of at waste areas designated by the Owner's Construction Manager. Such materials shall be loaded, hauled and placed into such waste areas, and shaped into waste piles. Waste piles shall be constructed such that drainage of surface water and groundwater is not impeded, and such that the piles are stable as defined by the Owner's Construction Manager.

Vegetation, topsoil and other materials resulting from clearing and stripping operations shall be stockpiled separately from other soil or rock materials at designated waste areas, avoiding obstruction of any natural or man- made water flows. All vegetation beyond the limits of such storage areas shall be preserved.

Upon completion of the work, the designated waste area shall be shaped in accordance with the requirements of the Owner's Construction Manager.

5.0 FILL PLACEMENT

5.1 Scope

This section comprises the requirements for placement of fills in the Works to the lines and grades shown on the Drawings, or as directed by the Owner's Construction Manager and QA Manager.

5.2 General

Fill placement shall be to the lines, grades and cross-sections shown on the Drawings and in accordance with the Specifications.

Dam embankment materials shall not encroach upon adjacent zones any further than allowed by the tolerances shown on the Drawings.

Water control measures such as temporary drainage and pumping systems shall be operated and maintained as required to direct water away from the fill placement areas as specified in Section 3.0.

Access to the Work will be provided and coordinated by the Owner's Construction Manager.

No fill shall be placed on any portion of the Works until excavation and surface and foundation preparation, as specified in Section 4.0, has been completed and such portions have been approved in writing by the QA Manager.

Fill shall not be placed on a surface where ice, snow or excessive moisture has accumulated. A previously approved foundation or fill surface, which in the opinion of the QA Manager, has deteriorated shall be repaired prior to any fill placement.

Fill shall consist of unfrozen material that is free of organic or other deleterious material, as approved by the QA Manager.

Fill which, while acceptable at the time of selection has, in the opinion of the QA Manager, deteriorated for any reason such that it no longer meets the Specifications for that material shall not be incorporated in the Works.

Construction traffic shall be routed such that no ruts are formed on the surface of excavated or placed fill areas. If ruts are formed, the ruts shall be graded level and re-compacted to the relevant degree of compaction for the particular fill type as required by the Specification.

5.3 Fill Materials

The material zones of the embankment are shown on the Drawings and described in this Specification.

Materials used in the construction are to be non-potentially acid generating (NPAG). Acceptance of all fill materials based on geochemical properties shall be the responsibility of the Owner's Construction Manager.

The particle size envelopes shown in these Specifications shall apply to the as-placed materials and in the stockpile.

Fill materials shall be well-graded within the specified gradation limits; i.e., they shall contain an even distribution of all sizes of particles within the designated envelope, without significant deficiency in any sizes. Fill material gradations shall meet the specification gradation within the envelope drawn between the specified points and not just at the specified points. Any unsuitable material from the fill shall be excavated and removed.

5.3.1 Till (Zone S)

The Till (Zone S) shall be a well graded Till with a minimum fines content of approximately 20% by weight (particles finer than 0.075 mm). The Till will be sourced from designated borrow areas. The Till shall have a minimum plasticity index (PI) of 7.

The Till shall meet the gradation in Table 5-1.

Table 5-1: Gradation Limits for the Till (Zone S)

Size (mm)	Sieve Size (USS)	Percent Passing (%)
100	4”	100
75	3”	98–100
37.5	1.5”	89–100
19	0.75”	81–100
12.5	0.5”	76–100
4.75	#4	66–100
2	#10	56–100
0.85	#20	47–94
0.425	#40	39–90
0.075	#200	20–85

Particles larger than 150 mm shall be removed from the material prior to compaction.

USS = United States Standard Sieve Size.

5.3.2 Filter Material (Zone F)

The Filter (Zone F) material is to be placed downstream of the till core. The material shall consist of hard, durable mineral particles, without organic matter, clay, soft particles, snow, ice, or any other unsuitable material.

The Filter shall meet the gradation in Table 5-2.

Table 5-2: Gradation Limits for the Filter Material (Zone F)

Size (mm)	Sieve Size (USS)	Percent Passing (%)
37.5	1.5”	100
19.1	0.75”	88-100
9.5	3/8”	56-100
4.75	#4	40-86
2	#10	25-63
0.85	#20	16-45
0.425	#40	10-33
0.25	#60	6-25
0.106	#140	0-15
0.075	#200	0-12

USS = United States Standard Sieve Size.

5.3.3 Transition Material (Zone T)

The Transition (Zone T) material shall be used as a transition zone between the Filter and Rockfill. The material shall consist of a mix of processed boulders, cobbles, gravel and sand produced by crushing or screening rockfill. The material shall consist of hard, durable mineral particles, without organic matter, clay, soft particles, snow, ice, or any other unsuitable material.

The Transition material shall meet the gradation in Table 5-3.

Table 5-3: Gradation Limits for the Transition Material (Zone T)

Size (mm)	Sieve Size (USS)	Percent Passing (%)
152.4	6”	100
25.4	1”	37-100
19.1	0.75”	29-75
12.7	0.5”	17-60
9.5	3/8”	0-51
4.75	#4	0-32
2.38	#8	0-25
0.85	#20	0-17
0.075	#200	0-5

USS = United States Standard Sieve Size.

5.3.4 Upstream Fill (Zone U)

The Upstream Fill (Zone U) shall consist of sandy tailings material or other granular material approved by the Engineer. The upstream fill is to be excavated from within the TSF and placed mechanically in lifts or by depositing the tailings into cells.

Till may be used if conditions allow compaction, and subject to the approval of the QA Manager. Filter material, Transition material or Rockfill may be used in select locations subject to the approval of the QA Manager.

5.3.5 Embankment Rockfill (Zone C) and Buttress Rockfill

Rockfill used in construction of the Embankment (Zone C) and Embankment Buttresses are to be non-potentially acid generating (NPAG). Acceptance of all fill materials based on geochemical properties shall be the responsibility of the Owner's Construction Manager.

The rockfill shall consist of well graded material with a maximum diameter of 1 m, obtained from run-of-mine NPAG rockfill. The material shall consist of hard, durable mineral particles, without organic matter, clay, soft particles, or any other unsuitable material. Any unsuitable materials from the rockfill shall be excavated and removed.

Select coarser rockfill, to be placed within the Main Embankment Seepage Collection Pond and Perimeter Embankment Till Borrow Pond, shall be uniformly graded with only a small proportion of gravel, sand and silt size particles, as approved by the QA Manager.

5.3.6 Drain Rock

The Drain Rock shall consist of screened rockfill with uniform particle sizes between 300 mm and 150 mm.

The material shall consist of hard, durable mineral particles, without organic matter, clay, soft particles, or any other unsuitable material.

5.3.7 Filter Sand

The Filter Sand shall be placed between the Till Core (Zone S) and Filter (Zone F) and between the Upstream Fill (Zone U) and Till Core (Zone S) where the upstream drain pipe crosses through the till core.

The material shall consist of hard, durable mineral particles, without organic matter, clay, soft articles, snow, ice, or any other unsuitable material.

The Filter Sand shall meet the gradation in Table 5-4.

Table 5-4: Gradation Limits for the Filter Sand

Size (mm)	Sieve Size (USS)	Percent Passing (%)
9.5	3/8”	100
4.75	#4	95-100
2	#10	55-100
0.85	#20	25-100
0.425	#40	0-55
0.25	#60	0-25
0.106	#140	0-10
0.075	#200	0-5

5.3.8 General Fill

General Fill material can be used to backfill the TSF tailings beach where the upstream drain will be constructed. If required by construction sequence, the General Fill can also be used to laterally support the 20 m wide Zone U Upstream Fill. General Fill shall consist of sandy tailings material or other granular material approved by the Engineer. General fill is to be placed mechanically in lifts.

5.4 Placement and Compaction

Fill materials shall be placed to the lines and elevations shown on the Drawings.

The placement of fill materials for the various zones of the embankment shall be scheduled as directed by the Owner's Construction Manager. To achieve this, the various fill materials shall be stockpiled so that they are available at the location of the fill placement when required.

The Owner's Construction Manager may require modifications to the fill construction program, depending upon conditions encountered during construction.

The embankments shall be constructed such that lenses, pockets, streaks and layers of materials differing substantially in gradation from the surrounding material within each zone are avoided.

Filter and Transition shall be hauled, placed and spread in such a manner as to prevent segregation. Any material placed which, in the opinion of the QA Manager, does not meet the specified requirements shall be removed or remixed, blended or otherwise reworked to produce a material which meets the specified requirements, whether or not such material has been covered by other fill material.

The fill shall be leveled prior to compaction by means of a tracked dozer, excavator or other suitable approved equipment to obtain an even surface with no depressions.

5.4.1 Till (Zone S)

The Till material shall be spread parallel to the axis of the embankment in horizontal lifts of uniform thickness not exceeding 0.3 m prior to compaction. Thinner lifts may be required if till compaction is carried out in freezing conditions.

Till shall only be placed in contact with the existing Till Core, Upstream Fill, Filter and Filter Sand. Till shall not be placed in direct contact with Transition material or Rockfill.

Precautions shall be taken to avoid any presence of particles greater than 150 mm. Oversize material shall be removed to the satisfaction of the QA Manager. Affected zones of Till material shall be removed at the direction of the QA Manager.

The Till shall be compacted with a sheep's foot drum roller to achieve a dry density of at least 95% of the Standard Proctor maximum dry density, as determined by ASTM D698 and within plus or minus 2% of the optimum moisture content.

Where the moisture content is outside these limits, the lift must be either dried or wetted as directed by the QA Manager. The compacted till surface shall be graded to prevent ponding water.

When placing Till adjacent to a slope of existing Till, the slope of the existing fill shall be benched, the bench height being equal to the fill lift thickness, to achieve a suitable contact surface between the ground and the new fill.

5.4.2 Filter Zone (Zone F)

The Filter (Zone F) material shall be placed in loose lift thicknesses of 0.3 m or less (prior to compaction).

Precautions shall be taken to prevent any contamination of the material. Any contaminated materials shall be removed and replaced. Contaminated material shall be removed to the satisfaction of the QA Manager prior to additional material being placed. Precautions shall be taken to prevent segregation of the Filter material during placement and spreading. Visibly segregated zones of Filter material shall be removed at the direction of the QA Manager.

Filter material shall only be placed in contact with compacted Till Core, Transition material, Filter Sand and existing Filter. Filter material shall not be placed in direct contact with Rockfill.

The Filter material shall be compacted with a smooth-drum roller to achieve a dry density of 95% of the Standard Proctor maximum dry density, as determined by ASTM D698. Over-compaction of the Filter is to be avoided to minimize particle breakage and production of fine particles.

The Filter (Zone F) material shall be raised simultaneously with the Till (Zone S), with no more than 0.6 m elevation difference between both zones. When the elevation difference is larger than 0.3 m, the downstream slope of the till is to be cut after compaction of the lifts. The Till (Zone S) layer shall be raised ahead of the Filter (Zone F) layer.

5.4.3 Transition Zone (Zone T)

The Transition (Zone T) material shall be placed in loose lift thicknesses of 0.6 m or less (prior to compaction).

The Transition material shall be compacted with six (6) passes of a smooth drum vibratory compactor having a static weight of at least twelve (12) tonnes.

The Transition (Zone T) and Filter (Zone F) material shall be raised with no more than one (1) Transition lift thickness between the elevations of both zones. The Zone F is to be placed ahead of the Zone T.

Transition material shall only be placed in contact with Filter and Rockfill. Transition shall not be placed in direct contact with the Till Core.

5.4.4 Upstream Fill (Zone U)

The Upstream Fill (Zone U) shall be placed within the 20 m wide zone adjacent to the Till Core.

The Zone U upstream fill shall be placed in nominal 0.6 m thick layers or less and compacted with a smooth-drum roller. The sandy tailings shall be compacted with a smooth drum vibratory compactor having a static weight of at least twelve (12) tonnes to achieve a dry density of at least 95% of the Standard Proctor maximum dry density, as determined by ASTM D 698.

Alternatively, Upstream Fill (Zone U) shall be tailings deposited in cells. A confining berm shall be constructed on the outside edges of the cells. A culvert is to be constructed through the berm at the end farthest from the tailings discharge point. The culvert will drain the water and finer tailings material into the TSF. Constant reworking of the tailings by a dozer shall be required to provide uniform distribution of the tailings within the cells.

5.4.5 Compacted Embankment Rockfill (Zone C)

The Rockfill (Zone C) next to the Transition (Zone T) shall be placed in a loose lift thickness of 1 m or less. The Zone C shall extend a minimum of 10 m downstream of the Zone T. Oversize boulders (greater than 1 m) shall not be incorporated in the fill. Such oversize materials shall be broken to size or moved to the downstream edge of the embankment.

The Rockfill shall be raised ahead of the Transition with no more than 1 m lift thickness between the elevation of both zones.

The Rockfill (Zone C) shall be compacted with six (6) passes of a smooth drum vibratory compactor having a static weight of at least twelve (12) tonnes.

5.4.6 Embankment Rockfill

The Rockfill shall be placed downstream of the compacted rockfill in a loose lift thickness of 3 m or less (prior to compaction). Routing of the loaded haul truck traffic on the rockfill shall be carried out such that compaction is obtained across the entire width of the fill.

Oversize boulders (greater than 1 m) shall not be incorporated in the fill. Such oversize materials shall be broken to size or moved to the downstream edge of the embankment.

All ramps constructed in rockfill shall be submitted to the Owner's Construction Manager for review. Ramp slopes for haul trucks shall not exceed 10%.

5.4.7 Buttress Rockfill

The rockfill shall be placed in a single lift, and dumped/pushed from the crest to toe, resulting in segregation of the rockfill. Coarser rockfill should collect along the base of the buttress. Select coarse rockfill is to be placed in a single lift within the Main Embankment Seepage Collection Pond and Perimeter Embankment Till Borrow Pond.

The rockfill placement for the buttress is to advance parallel to the existing buttress or where there is no existing buttress, to the downstream toe of the embankment, with the downstream crest overbuilt to allow re-slope of the downstream face of the buttress. A tracked dozer is to grade the downstream face of the placed rockfill to the required 3 horizontal: 1 vertical (3H:1V) grade as placement advances. The distance from the advancing rockfill face and the completed downstream reslope shall not exceed 100 m.

The completed rockfill surface shall be leveled by means of a tracked dozer or other suitable approved equipment to obtain an even surface with no depressions. All necessary steps shall be taken to avoid ponding of water on the fill.

All ramps constructed in rockfill shall be submitted to the Owner's Construction Manager for review. Ramp slopes shall not exceed 10%.

The existing instrumentation is to be raised and/or protected from damage during construction, as specified in Section 7.1 of this Specification.

The upstream toe drains are to be protected from damage.

The Main Embankment Toe Drain Collection Sump is to be relocated or extended.

The piping and pumping infrastructure at the Main Embankment Seepage Collection Pond is to be relocated or protected from damage during the construction.

5.4.8 Drain Rock

The Drain Rock shall be used for the construction of the upstream drain and within the breach pond channel.

The Drain Rock shall be placed in a single lift of 1.0 m (minimum). Traffic of construction equipment over the Drain Rock shall be limited to only what is required for placement of the material.

5.4.9 Filter Sand

The Filter Sand material shall be placed in loose lift thicknesses of 0.3 m or less (prior to compaction).

Precautions shall be taken to prevent any contamination of the material. Any contaminated materials shall be removed and replaced. Contaminated material shall be removed to the satisfaction of the QA Manager prior to additional material being placed. Precautions shall be taken to prevent segregation of the Filter Sand material during placement and spreading. Visibly segregated zones of Filter Sand material shall be removed at the direction of the QA Manager.

Filter Sand will only be placed in contact with Upstream Fill, Till Core and Filter material.

The Filter Sand material shall be compacted with a smooth-drum roller to achieve a dry density of 95% of the Standard Proctor maximum dry density, as determined by ASTM D 698. Over-compaction of the Filter Sand is to be avoided to minimize particle breakage and production of fine particles.

5.4.10 Pipe Bedding and Backfill Material

Till (Zone S), Filter (Zone F), Filter Sand, or Upstream Fill (Zone U) shall be used as pipe bedding and backfill material for the solid HDPE pipe. The bedding and backfill material to be used is as shown on the Drawings.

Where Till (Zone S) is used as pipe bedding and backfill:

- Particles greater than 20 mm shall be removed and the Till shall be wet of optimum (i.e., plus 2% of the optimum moisture content).
- The trench through the Till Core shall be sufficient width to allow proper placement and compaction of the bedding and backfill material.
- The pipe bedding shall be placed in a single minimum 0.1 m thick loose lift. The pipe haunch backfill shall be placed in a 75 mm loose lift. The embedment material shall be worked and tamped within the haunches of the pipe.
- The Till backfill shall be placed in 0.15 m minimum loose lifts. The 0.15 m loose lift shall be carried out after the backfill material has reached the pipe crown. The backfill material shall extend to a minimum of 0.6 m above the crest of the pipe.

- Compact Till bedding and backfill to achieve a dry density of at least 95% of the Standard Proctor maximum dry density, as determined by ASTM D 698 and at plus 2% of the optimum moisture content.

Where Filter Material (Zone F), Filter Sand, and Upstream Fill (Zone U) is used as pipe bedding and Backfill:

- The pipe bedding shall be placed in a single minimum 0.15 m thick loose lift and nominally compacted.
- The pipe haunch backfill shall be placed in a 75 mm loose lift and shall be nominally compacted. The embedment material shall be worked and tamped within the haunches of the pipe.
- Pipe backfill material shall be placed in 0.3 m loose lifts and compacted with a minimum of four (4) passes using hand-held compaction equipment. The 0.3 m loose lift shall be carried out after the backfill material has reached the pipe crown. The backfill material shall extend to a minimum of 0.6 m above the crest of the pipe.

A minimum 0.15 m thick layer of backfill material is to be placed over any pipe before hand-held equipment is operated above the pipe. A minimum 1.0 m thick layer of fill material is to be placed over any pipe before ride-on equipment or construction vehicles are operated above the pipe.

Transition Material (Zone T) shall be placed around the perforated corrugated polyethylene pipe (PCPE), unless directed otherwise.

- The pipe haunch backfill shall be placed in a 0.15 m loose lift and shall be nominally compacted. The embedment material shall be worked and tamped within the haunches of the pipe.
- Pipe backfill material shall be placed in 0.3 m loose lifts and compacted with a minimum of four (4) passes using hand-held compaction equipment. The 0.3 m loose lift shall be carried out after the backfill material has reached the pipe crown. The backfill material shall extend to a minimum of 0.5 m above the crest of the pipe.

5.5 Compaction Requirements

Each layer of spread fill material shall be compacted in a systematic, orderly and continuous manner to ensure that the entire fill is properly compacted. Layer thickness is defined as the thickness of the loose fill before compaction.

Compaction equipment shall generally travel parallel to the axis of the embankment being constructed, except where such routing is not practical, such as at turning areas or adjacent to instrumentation. In such areas, the compaction equipment shall be routed such that the best compaction can be attained.

Materials that cannot be adequately compacted by the specified compaction equipment because of location or space limitations shall be compacted with specified special compactors. Where such special compactors are required, fill layer thickness shall be modified, as required by the QA Manager.

One (1) pass shall mean a single traverse of a compactor across the surface of a layer in one direction. An overlap of at least 0.5 m shall be maintained between adjacent passes.

Vibratory rollers shall travel at an operating speed of no more than 70 m per minute. The operating speed of the compaction equipment is subject to review by the QA Manager, and will depend on the type of fill.

The compaction traffic pattern at fill zone boundaries or construction ramp joints shall be carried out such that the full number of roller passes extends completely across such boundaries.

5.5.1 Compaction Equipment

Sufficient compaction equipment of the types and sizes specified, as necessary for compaction of the various fill materials, shall be provided. This equipment shall be available and shall be maintained in good condition at all times.

Alternative compaction equipment may be used only if it can be demonstrated to the satisfaction of the QA Manager that such alternative equipment will compact the fill materials as effectively as the specified equipment, and also that the material after compaction meets the requirements of the Specifications.

5.5.2 Special Compactors

Special compactors shall include loaded dump trucks, hand-operated mechanical tampers and vibratory rollers, and any other compaction equipment not specified, subject to the approval of the QA Manager.

Special compactors shall be capable of producing the required compaction within a reasonable number of passes.

Hand-operated heavy-duty mechanical tampers shall be used under restricted space and access conditions. The operating frequency shall be such that previously compacted material is not disturbed. Operation shall proceed continuously until the specified level of compaction has been achieved.

A sufficient number of special compactors shall be available to compact inaccessible areas.

5.6 Protection and Maintenance

Any fill placed shall be maintained in a condition satisfactory to the QA Manager until completion of the Work. All necessary steps shall be taken to avoid ponding of water on the fill, or contamination of the fill by traffic or other causes. The surface and slopes shall at all times be kept free from rejected or unsuitable fill, or waste materials.

Should slides or erosion occur within or onto any placed fill, such materials and all other materials affected shall be removed, and the portion rebuilt as required.

5.7 Quality Control and Quality Assurance

Quality Control (QC) will be performed to ensure that the Work is constructed in accordance with the Drawings and Specifications.

Quality Assurance (QA) monitoring and testing will be carried out by the Engineer through their QA Manager, to satisfy themselves and MPMC that the Work is being carried out in accordance with the Drawings and Specifications.

The QC and QA testing requirements and frequency are listed in Table 5-5. At a minimum, all the required testing shall be performed to document the construction quality. The material testing listed in Table 5-5 shall be completed on record samples taken from placed material on the embankment to evaluate suitability of material and segregation during placement.

All necessary inspections, sampling and testing shall be performed to ensure that only materials of the specified composition, gradation and moisture content are supplied to the construction area. A sufficient number of control samples from the stockpile are to be tested prior to use to confirm the suitability of the material used.

The Owner's Construction Manager shall identify material stockpiles available for use in the construction.

Table 5-5: QA/QC Testing of Fill Placement

Material	Testing[a]		
	Test	QC Frequency	QA Frequency
Perimeter and South Embankment Abutment Foundation[b]	Water Content (ASTM D2216)	1 every 250 m^2 [c]	1 every 5 QC Tests
	Atterberg Limits (ASTM D4318)	1 every 250 m^2 [c]	1 every 5 QC Tests
	Gradation and Hydrometer (ASTM D422 & D6913)	1 every 250 m^2 [c]	1 every 5 QC Tests
Zone S Till Core Material	Water Content (ASTM D2216)	1 every 1,000 m^3	1 every 10 QC Tests
	Atterberg Limits (ASTM D4318)	1 every 2,000 m^3	1 every 10 QC Tests
	Gradation (ASTM D6913)	1 every 4,000 m^3	1 every 10 QC Tests
	Hydrometer (ASTM D422)	1 every 12,000 m^3	1 every 10 QC Tests
	Standard Proctor Maximum Dry Density (ASTM D698)	1 every 8,000 m^3	1 every 10 QC Tests
	In Situ Density by Portable Nuclear Gauge (D6938)	1 per each lift completed in a day and 1 every 300 m^3	1 every 10 QC Tests
	Lift Thickness	Measured continuously	Measured periodically
Zone F Filter Material	Water Content	1 every 1,000 m^3	1 every 10 QC Tests
	Wash Sieve Gradation (ASTM C136 & C117)	1 every 1,000 m^3	1 every 10 QC Tests
	Standard Proctor Maximum Dry Density (ASTM D698)	1 every 5,000 m^3	1 every 10 QC Tests
	In Situ Density by Portable Nuclear Gauge (D6938)	1 per each lift completed in a day and 1 every 100 m^3	1 every 10 QC Tests
	Lift Thickness	Measured continuously	Measured periodically

Table 5-5: QA/QC Testing of Fill Placement

Material	Testing[a]		
	Test	QC Frequency	QA Frequency
Zone T Transition Material	Wash Sieve Gradation (ASTM C136 & C117)	1 every 3,000 m^3	1 every 2 QC Tests
	Lift Thickness	Measured continuously	Measured periodically
	Number of Passes of Compactor	Measured continuously	Measured periodically
Zone C Rockfill	Lift Thickness	Measured continuously	Measured periodically
	Visual Gradation	Measured continuously	Periodical visual inspection
Zone U Upstream Fill (Tailings Sand)	Wash Sieve Gradation (ASTM C136 & C117)	1 every 10,000 m^3	1 every 10 QC Tests
	Standard Proctor Maximum Dry Density (ASTM D698)	1 every 20,000 m^3	1 every 10 QC Tests
	In Situ Density by Portable Nuclear Gauge (D6938) [d]	1 per each lift completed in a day and 1 every 2,500 m^3	1 every 10 QC Tests
	Lift Thickness	Measured continuously	Measured periodically
Filter Sand	Water Content	1 test per pipe installation	1 test
	Wash Sieve Gradation (ASTM C136 & C117)	2 tests per provider	1 test
	Standard Proctor Maximum Dry Density (ASTM D698)	2 tests per provider	None required
	In Situ Density by Portable Nuclear Gauge (D6938)	1 per lift	1 every 10 QC Tests
	Lift Thickness	Measured continuously	Measured periodically
Drain Rock	Visual Gradation	Continuously	Continuously

a) Frequencies based on in-place compacted volumes.
b) Samples for testing shall be collected from the foundation within the Till Core and Upstream Fill footprint. Frequency based on area defined by the Till Core and Upstream Fill footprint.
c) Minimum of two tests per abutment per construction year.
d) Small excavations may be required to test the in situ density of the bottom portion of the 0.6 m lifts as required by the QA Manager.

6.0 UPSTREAM DRAIN

6.1 Scope

This Section comprises all requirements for construction of the upstream drains, which includes the placement of Drain Rock and drain rock transition materials, and installation of geotextile and pipeline, according to the lines and grades shown on the Drawings or as directed by the Owner's Construction Manager and QA Manager.

6.2 General

6.2.1 Tolerances

Excavation limits are defined by the lines and elevations shown on the Drawings. Uniform gradients shall be maintained between adjacent spot elevations shown on the Drawings. The excavation shall be in a manner so that piping can be laid straight at a uniform grade, without sags or humps. The tolerances for the pipeline, unless otherwise approved by the QA Manager, shall be as follows:

- Line ± 150 mm; and
- Grade ± 30 mm.

6.2.2 Handling and Storage

Pipe and pipe fittings shall be stored on clean level ground, free of sharp objects which could damage these materials. Stacking shall be limited to a height that shall not cause excessive deformation of the bottom layers of pipe under anticipated temperature conditions. Where necessary, due to ground conditions, the pipe shall be stored on wooden sleepers, spaced suitably and of such width as not to allow deformation of the pipe at the point of contact with the sleeper or between supports.

During delivery to site, the geotextile shall be wrapped to protect it from ultraviolet (UV) light exposure, precipitation, mud, dirt, dust, puncture, or other damaging or deleterious conditions. Upon delivery at the job site, the geotextile rolls shall be handled and stored in accordance with the manufacturer's instructions to prevent damage, and in particular is to be protected from UV light exposure.

The QA Manager shall inspect the pipe, pipe fittings and geotextile prior to use, to verify that the proper material has been received. The material shall also be inspected to ensure they are free of flaws or damage occurring during manufacturing, shipping, or handling.

6.3 Materials

6.3.1 Polyethylene Pipe and Fittings

Pipes and fittings shall be homogenous throughout and free of visible cracks, holes (other than intentional manufactured perforations), foreign inclusions, or other deleterious effects, and shall be uniform in color, density, melt index, and other physical properties.

Fittings at the ends of pipes shall consist of polyethylene end cap.

The nominal size for the pipe and fittings is based on the nominal inside diameter of the pipe. Fittings supplied by manufacturers other than the manufacturer of the pipe shall not be permitted without the approval of the QA Manager.

The polyethylene pipe is to be perforated, where perforated pipe is shown on the Drawings. The perforations shall be drilled into the pipe after manufacture at the manufacturing plant.

The following pipe will be required for the works:

- 150 mm diameter perforated SDR 9 high-density polyethylene pipe (HDPE), PE4710 or equivalent approved, with smooth interior wall. The HDPE pipe shall be joined with split corrugated couplings.
- 300 mm diameter solid, SDR 17 HDPE pipe, PE4710.

6.3.2 Pipe Bedding and Backfill Material

Pipe bedding and backfill material shall meet the requirements of Section 5.4.10 of these Specifications.

6.3.3 Drain Rock Transition Material

Drain rock transition material shall meet the requirements of Section 5.4.10 of these Specifications.

6.3.4 Geotextile

An 800 g/m^2 non-woven needle punched geotextile shall be placed along the base of the Drain Rockfill and a 340 g/m^2 non-woven needle punched geotextile shall be placed over the Drain Rock transition. The geotextile shall be manufactured from prime quality virgin polymer. The geotextile shall meet or exceed all material properties listed in Table 6-1 and Table 6-2.

Table 6-1: Properties of 800 g/m^2 non-woven Geotextile

Property	Standard	Unit	Value
Mass per Unit Area	ASTM D 5261	g/m^2	812
Grab Tensile Strength	ASTM D 4632	N	2,000
Grab Elongation	ASTM D 4632	%	50
CBR Puncture Strength	ASTM D 6241	N	1,100
Trapezoidal Tear Strength	ASTM D 4533	N	890
UV Resistance	ASTM D 4355	% retained after 500 hours	70

Table 6-2: Properties of 340 g/m^2 non-woven Geotextile

Property	Standard	Unit	Value
Mass per Unit Area	ASTM D 5261	g/m^2	340
Grab Tensile Strength	ASTM D 4632	N	1,020
Grab Elongation	ASTM D 4632	%	50
CBR Puncture Strength	ASTM D 6241	N	530
Trapezoidal Tear Strength	ASTM D 4533	N	420
UV Resistance	ASTM D 4355	% retained after 500 hours	70

All rolls of the geotextile shall be identified with permanent marking on the roll or packaging, with the manufacturers name, product identification, roll number and roll dimensions.

6.4 Execution

6.4.1 Trench Excavation

The trench excavations shall be performed to the lines and grades shown on the Drawings or as directed by the QA Manager. Trench excavations shall not begin until the Surveyor has provided construction staking for the proposed work. The exposed subgrade along the trench shall be inspected by the QA Manager and approved prior to any fill being placed. Final surface shall be free of loose materials, clods, and other debris including grade stakes and hubs.

The trench excavations shall be graded and properly maintained to provide adequate drainage at all times. Work shall be suspended when, in the opinion of the QA Manager, the site is overly wet, muddy, or otherwise unsuitable for proper maintenance, until directed otherwise by QA Manager.

6.4.2 Fill Placement

All fill placement, including Drain Rockfill, drain rock transition, pipe bedding and backfill, shall be in accordance with Section 5.0 of these Specifications.

6.4.3 Piping

6.4.4 Handling and Placement

Care shall be exercised when transporting, handling and placing pipe and fittings, such that they are not cut, kinked, twisted, or otherwise damaged.

The pipe manufacturer’s recommendations for handling, storage, and installation of all polyethylene pipe fittings shall be complied with.

Ropes, fabric, or rubber-protected slings and straps shall be used when handling pipe. Slings and straps shall not be positioned at butt-fused joints. Chains, cables or hooks shall not be inserted into the pipe ends as a means of handling pipe.

Pipe or fittings shall not be dropped onto rocky or unprepared ground. Under no circumstances shall pipe or fittings be dropped into trenches, or dragged over sharp objects.

The maximum allowable depth of cuts, gouges or scratches on the exterior surface of pipe or fittings is 10 percent of the wall thickness. The interior of the pipe and fittings shall be free of cuts, gouges and scratches. All pipe and fittings shall be carefully examined for cracks, damage or defects before installation. The QA Manager shall inspect all pipes. Sections of pipe with excessive cuts, gouges or scratches shall be rejected and the rejected pipe shall be removed and replaced.

Whenever pipe laying is not actively in progress, the open end of pipe that has been placed shall be closed using a watertight plug.

6.4.5 Pipe Installation

All pipe and fittings shall be installed in accordance with this Specification, the pipe manufacturer's instructions, and ASTM D2321. All pipe and fittings shall be laid or placed to the grades and elevations shown in the Drawings with bedding and backfill as shown in the Drawings.

The interior of all pipe and fittings shall be inspected, and any foreign material shall be completely removed from the pipe interior before it is moved into final position.

Field-cutting of pipes, where required, shall be made with a machine specifically designed for cutting pipe. Cuts shall be carefully made, without damage to pipe or lining, so as to leave a smooth end at right angles to the axis of pipe. Cutter ends shall be tapered and sharp edges filed off smooth. Flame cutting shall not be allowed.

No pipe shall be laid until the QA Manager has observed the condition of the pipe.

No pipe shall be brought into position until the preceding length has been bedded and secured in its final position. Blocking under piping shall not be permitted unless specifically accepted by the QA Manager for special conditions.

Placement of overlying pipe backfill shall be carried out such that pipe is not damaged. The QA Manager may periodically request to prove that covered pipe has not been crushed.

The location and final elevation of the invert of the pipes shall be surveyed. The pipes shall be surveyed at ends and at approximately 20 m intervals between the ends.

6.4.6 Joints and Connections

All HDPE pipe shall be joined with thermal butt-fusion joints. All joints shall be made in strict compliance with ASTM D2657 and the pipe manufacturer's recommendations.

6.4.7 Geotextile Installation

The geotextile shall be installed in accordance with this Specification and the manufacturer's instructions. The geotextile shall be laid to the lines shown in the Drawings. The geotextile shall be placed after the drain rock transition has been placed, compacted and approved by the QA Manager.

The geotextile shall be handled in such a manner as to minimize damage during installation.

The geotextile panels are to overlap a minimum of 450 mm. No direct equipment trafficking over geotextile is permitted. The geotextile shall not be exposed to rain or snow precipitation prior to being installed and shall not be left exposed for more than 15 days after installation.

Damaged areas in the geotextile shall be repaired to the satisfaction of the QA Manager. Prior to repair, any soil or other materials that has penetrated the damaged geotextile shall be removed. The geotextile shall be repaired by placing a patch of the same type of geotextile that extends a minimum of 300 mm beyond any edge of the area to be repaired. Geotextile that cannot be repaired shall be replaced with new geotextile that complies with the project requirements.

6.5 Quality Assurance

QA monitoring will be carried out by the Geotechnical Engineer through their QA Manager, to satisfy themself and MPMC that the Work is being carried out in accordance with the Drawings and Specifications.

7.0 SPILLWAY

7.1 Scope

The emergency spillway during operations will be constructed on the north side of the TSF and will discharge to Bootjack Creek. Access to the Work will be provided and coordinated by the Owner's Representative.

This section comprises the requirements for construction of the emergency spillway during operations, which includes the placement and compaction of construction materials described in Section 7.3, according to the lines and grades shown on the Drawings or as directed by the Owner’s Construction Manager and QA Manager.

Surveys shall be performed to confirm the elevations and coordinates shown on the Drawings.

The locations of the exposed material boundaries and exposed surfaces shall be surveyed.

7.2 Materials

The materials to be used for spillway construction are shown on the Drawings and described in Sections 7.2.1 to 7.2.9.

7.2.1 Rockfill

Rockfill shall meet the requirements of Section 5.3.5 of these Specifications.

7.2.2 Native Fill

Native excavated material from the emergency spillway excavation can be used, as needed, for the construction of the emergency spillway channel between the Tailings Access Road and Bootjack Creek. Native Fill shall be free of organics, high plasticity clay, frozen or otherwise deleterious materials. Native Fill material shall be visually assessed by the QA Manager prior to placement to ensure it is suitable for placement. Soils with high moisture contents (i.e., saturated) shall not be placed without prior aeration and drying.

7.2.3 Till Liner

The Till Liner shall be a well graded till with a maximum particle size of 150 mm and a fines content between 20% and 70% by weight (particles finer than 0.075 mm). The Till Liner shall be sourced from designated borrow areas. Till Liner material shall be free of organics, high plasticity clay, frozen or otherwise deleterious materials.

7.2.4 Riprap

Riprap material shall be placed for the construction of the emergency spillway and meet the following standards. Riprap shall consist of well-graded, hard, durable, and angular rock which meets the gradation requirements set out in Table 7-1 and Table 7-2. Riprap material properties shall conform with requirements set out in Table 7-3). Riprap material is to be non-potentially acid generating (NPAG). Acceptance of all fill materials based on geochemical properties shall be the responsibility of the Owner's Construction Manager. Riprap is subject to the approval of the QA Manager prior to placement. Riprap QC and QA requirements are provided in Section 7.4.

Table 7-1: Mass Gradation for Riprap

Class of Riprap (kg)	Rock Gradation Percentage Smaller Than Given Rock Mass (kg)			
	15%	50%	85%	100%
10	1	10	1	10
50	5	50	5	50
100	10	100	10	100

Table 7-2: Dimension Gradation for Riprap

Class of Riprap (kg)	Approximate Average Dimension (Sg = 2.5) Equivalent Diameter (mm)			
	15%	50%	85%	100%
10	90	200	285	350
50	155	340	485	600
100	200	425	610	750

Table 7-3: Rip Rap Material Properties

Property	ASTM Test Designation	Allowable Value
Specific Gravity	D6473	≥2.50
Absorption	D6473	≤2%
Soundness By Use Of Magnesium Sulphate	D5240	≤10 % (Following 5 Cycles)
Micro-Deval Abrasion Loss Factor	D6928	≤20%

7.2.5 Fine Bedding

Fine Bedding shall be placed between the Ground Surface and Riprap with D_{50} less than or equal to 400 mm (10 kg Class Riprap, and 50 kg Class Riprap), as shown on the Drawings. Fine Bedding shall be well graded sand and gravel with maximum particle size of 100 mm and less than 12% passing 0.075 mm.

Fine Bedding used in construction of the emergency spillway is to be non-potentially acid generating (NPAG). Acceptance of all fill materials based on geochemical properties shall be the responsibility of the Owner's Construction Manager. The material shall consist of hard, durable mineral particles, without organic matter, clay, soft particles, or any other unsuitable material.

Fine Bedding QC and QA requirements are provided in Section 7.4.

7.2.6 Coarse Bedding

Coarse Bedding shall be placed below Riprap with D_{50} greater than 400 mm (100 kg class Riprap), as shown on the Drawings. The Coarse Bedding shall consist of well graded material with a maximum diameter of 0.2 m , less than 30% sand and less than 5% fines. Granular Bedding material is to be non-potentially acid generating (NPAG). Acceptance of all fill materials based on geochemical properties shall be the responsibility of the Owner's Construction Manager.

Coarse Bedding QC and QA requirements are provided in Section 7.4.

7.2.7 Granular Road Gravel

Granular Road Gravel shall consist of granular material approved by the QA Manager and the Owner's Construction Manager.

7.2.8 Geotextile

A 340 g/m^2 non-woven needle punched geotextile shall be placed along the base of the Coarse Bedding. The geotextile shall be manufactured from prime quality virgin polymer. The geotextile shall meet or exceed all material properties listed Table 6-2.

7.2.9 Precast Concrete Weir

Precast Concrete Weir to be Precon’s precast panel wall or equivalent weir to be approved by QA Manager.

7.3 Execution

Construction to raise the TSF embankment to elevation 974 m is expected to occur over 2 or more construction seasons. The emergency spillway shall be constructed before the end of the first construction season and then raised each season in accordance with the embankment raise.

7.3.1 Spillway Surface and Foundation Preparation

The spillway stripping, clearing, excavations, and foundation preparation shall meet the requirements of Section 4.2, 4.3, and 4.4.

7.3.2 Rockfill Placement and Compaction

The Rockfill placement and compaction for the emergency spillway shall be in accordance with Section 5.4.6.

7.3.3 Native Fill Placement and Compaction

Native Fill shall be placed in loose lift thicknesses of 0.3 m or less (prior to compaction).

Precautions shall be taken to prevent any contamination of the material. Any contaminated materials shall be removed and replaced. Contaminated material shall be removed to the satisfaction of the QA Manager prior to additional material being placed.

Native Fill material shall be compacted with a sheep's foot drum roller to achieve a dry density of at least 95% of the Standard Proctor maximum dry density, as determined by ASTM D698. The final surface of the Native Fill shall be compacted with a smooth drum vibratory roller to achieve an even surface.

7.3.4 Fine Bedding Placement and Compaction

The Fine Bedding shall be placed in loose lifts of 0.3 m or less (prior to compaction) to the extents shown in the Drawings.

The Fine Bedding material shall be compacted with six (6) passes of a smooth drum vibratory compactor having a static weight of at least twelve (12) tonnes.

7.3.5 Coarse Bedding Placement and Compaction

The Coarse Bedding shall be placed in loose lift of 0.3 m or less (prior to compaction) to the extents shown in the Drawings.

The Coarse Bedding material shall be compacted with six (6) passes of a smooth drum vibratory compactor having a static weight of at least twelve (12) tonnes.

7.3.6 Till Liner Placement and Compaction

The Till Liner material shall be spread parallel to the axis of the spillway in horizontal lifts of uniform thickness not exceeding 0.3 m prior to compaction.

Precautions shall be taken to avoid any presence of particles greater than 150 mm. Oversize material shall be removed to the satisfaction of the QA Manager. Affected zones of Till Liner material shall be removed at the direction of the QA Manager.

The Till Liner shall be compacted with a sheep's foot drum roller to achieve a dry density of at least 95% of the Standard Proctor maximum dry density, as determined by ASTM D698.

The compacted till surface shall be graded to prevent ponding water.

7.3.7 Riprap Placement

Riprap shall be placed in lifts, with the average thickness of each lift not to exceed the median rock diameter (D_{50}) of the riprap class being placed. Nominal riprap layer thickness at right angles to the slope shall be a minimum of 0.4 m for 10 kg Class riprap and 0.68 m for 50 kg Class riprap and 0.9 m for 100 kg Class riprap.

Riprap shall be placed with care to ensure adequate interlocking of the particles is achieved. Riprap placed adjacent to the pre-cast concrete weir shall be placed carefully to ensure the concrete is not damaged.

Riprap placed for the road crossing shall be void-filled after each lift washing in granular road gravel. Alternatively, void filling may be accomplished by pre-mixing the riprap with the granular road gravel and carefully placing the mix to ensure adequate interlocking of the riprap.

Riprap shall be placed to the extents, grades, and slopes indicated on the Drawings.

Riprap shall not be placed by end dumping, chutes, or being dropped from a height greater than 1.0 m from its final position.

7.3.8 Granular Road Gravel Placement

Granular Road Gravel shall be washed into the road crossing riprap. Placement and compaction requirements shall be determined by the QA Manager and the Owner's Construction Manager during construction.

7.3.9 Geotextile Installation

The geotextile shall be installed in accordance with this Specification and the manufacturer's instructions. The geotextile shall be laid to the lines shown in the Drawings. The geotextile shall be placed after the Till Liner transition has been placed, compacted and approved by the QA Manager.

The geotextile shall be handled in such a manner as to minimize damage during installation.

The geotextile panels are to overlap a minimum of 450 mm. No direct equipment trafficking over geotextile is permitted. The geotextile shall not be exposed to rain or snow precipitation prior to being installed and shall not be left exposed for more than 15 days after installation.

Damaged areas in the geotextile shall be repaired to the satisfaction of the QA Manager. Prior to repair, any soil or other materials that has penetrated the damaged geotextile shall be removed. The geotextile shall be repaired by placing a patch of the same type of geotextile that extends a minimum of 300 mm beyond any edge of the area to be repaired. Geotextile that cannot be repaired shall be replaced with new geotextile that complies with the project requirements.

7.3.10 Repair and Replacement of Damaged Precast Concrete Weir

For the repair and replacement of damaged concrete the following sequence of steps shall be followed:

- Replace any element that suffers structural damage including cracking or other damage that in the opinion of the QA Manager, compromises its strength, performance, or durability.
- Examine all concrete surfaces and clearly mark out spalled or other areas to be repaired. Obtain the QA Manager's authorization of the delineated repair areas and the proposed method and equipment to be used for the repairs prior to commencing the work.
- Completely remove all damaged concrete down to sound concrete. Remove microfractured surfaces resulting from the initial concrete removal process.
- Sawcut the perimeter perpendicular to the surface to a minimum depth of 25 mm. Do not use any repair method that produces a featheredge.
- Prior to placing repair mortar, clean and dampen the surfaces to obtain a saturated surface dry condition except where the repair technique requires a dry surface.
- Place the polymerized cementitious mortar in accordance with the manufacturer's written instructions. Treat the surface of the concrete to be repaired with a compatible acrylic bonding agent as authorized by the QA Manager prior to mortar filling.
- Construct the repair area slightly proud of the general surface and then grind it to match.
- Following repairs, promptly initiate curing and protection in accordance with CAN / CSA- A23.1.
- Provide completed repair areas that are tightly bonded to the underlying concrete and are free of shrinkage cracks or hollow void areas.

7.4 Spillway Quality Control and Quality Assurance

Quality Control (QC) will be performed to ensure that the Work is constructed in accordance with the Drawings and Specifications.

Quality Assurance (QA) monitoring and testing will be carried out by the Engineer through their QA Manager, to satisfy themselves and MPMC that the Work is being carried out in accordance with the Drawings and Specifications.

The QC and QA testing requirements and frequency for the emergency spillway materials are listed in Table 7-. At a minimum, all the required testing shall be performed to document the construction quality. The material testing listed in Table 7- shall be completed on record samples taken from placed material on emergency spillway to evaluate suitability of material and segregation during placement.

All necessary inspections, sampling and testing shall be performed to ensure that only materials of the specified composition, gradation and moisture content are supplied to the construction area. A sufficient number of control samples from the stockpile are to be tested prior to use to confirm the suitability of the material used.

The Owner's Construction Manager shall identify material stockpiles available for use in the construction.

Table 7-4: Spillway QA/QC Testing

Materials	Testing[a]		
	Test	QC Frequency	QA Frequency
Rockfill	Lift Thickness	Measured continuously	Measured periodically
	Visual Gradation	Measured continuously	Periodical visual inspection
Native Fill	Lift Thickness	Measured continuously	Measured periodically
	Visual Gradation	Measured continuously	Measured periodically
	Standard Proctor Maximum Dry Density (ASTM D698)	1 every 8,000 m^3	-
	In Situ Density by Portable Nuclear Gauge (D6938)	2 per each lift completed in a day	1 every 5 QC Tests
Till Liner Material	Water Content (ASTM D2216)	2 per borrow location and 1 every 1,000 m^3	Periodical visual inspection
	Gradation (ASTM D6913)	2 per borrow location and 1 every 4,000 m^3	1 every 5 QC Tests
	Standard Proctor Maximum Dry Density (ASTM D698)	1 per borrow location and 1 every 8,000 m^3	-
	In Situ Density by Portable Nuclear Gauge (D6938)	2 per each lift completed in a day	1 every 5 QC Tests
	Lift Thickness	Measured continuously	Measured periodically
Riprap	Visual Gradation	Measured continuously	Periodical visual inspection
	Lift Thickness	Measured continuously	Measured periodically
Fine Bedding and Coarse Bedding	Wash Sieve Gradation (ASTM C136 & C117)	1 every 3,000 m^3	1 every 2 QC Tests
	Lift Thickness	Measured continuously	Measured periodically
	Number of Passes of Compactor	Measured continuously	Measured periodically

a) Frequencies based on in-place compacted volumes.

8.0 INSTRUMENTATION

8.1 Scope

This Section describes the requirements for the supply, installation, testing, data acquisition and protection of instrumentation. The requirements include equipment and application software for the data acquisition, transmission and processing system.

The main items include installation of:

- vibrating-wire piezometers (VWPs);
- ShapeAccelArray (SAA) within existing inclinometers and new SAA installation; and
- data acquisition and processing equipment.

Also included is the extension of existing slope inclinometer casing and VWP and SAA cables that will be buried as part of the construction works.

The work shall include all labour, materials and equipment to complete the design as shown on the Drawings.

8.2 General

The locations for the instrumentation are shown in the Drawings, and installation procedures provided in this Specification. The location of all instruments and installation will be subject to approval by the QA Manager.

New instrumentation will be installed as shown in the Drawings. The existing instrumentation integrity shall be kept unless otherwise shown in the drawings.

The instrumentation and all materials required for the installation shall be brought to site at least 15 days in advance of installation, and the QA Manager shall review and approve them.

8.3 Submittals

A list of all instruments, cable, and casing lengths are to be submitted to the Geotechnical Engineer. A method for marking and identifying cables for individual instruments are to be included.

Manufacturer calibration sheets for all instruments to be installed are to be submitted to the Geotechnical Engineer.

Installation data including the installed location, the instrument identification number, the instrument serial number, and the installation date and time is to be provided to the Geotechnical Engineer. The data is to include the SAA azimuth corrections for software, and azimuth direction of X-marks.

8.4 Installation Procedures

Installation of the instruments shall be carried out in accordance with the Drawings, Specification and the instructions of the equipment manufacturer.

Readings of each instrument shall be taken to verify correct functioning. Backfill shall not be placed over the instruments or cable leads until the instruments have been tested and initial readings have been taken. An initial set of readings shall be taken immediately after installation.

Sufficient cable to route to the SAA and VWP data loggers or VWP connector boxes shall be purchased. The cable shall be long enough to provide adequate strain relief. Existing instrumentation shall be extended.

All cables shall be marked with identification tags at intervals of 15 m, or closer if required. In addition, each instrument shall be marked with the identification given to it on the Drawings or as identified by the QA Manager.

All instruments, cables, and connectors shall be protected from damage and displacement during progress of the work, and markers and barricades shall be provided as necessary.

Cables from the instruments to the SAA and VWP data loggers or VWP connector boxes shall be wrapped in geotextile and installed into trenches, as shown on the Drawings or as directed by the QA Manager. The instrumentation cables shall be protected from impact and damage during construction by hand-tamped sand backfill.

No traffic or equipment shall pass over any part of any instrument, cables or connections until at least 600 mm thickness of compacted material cover has been installed.

8.5 Electrical Protection and Safety

New and existing instrumentation shall be connected to the data acquisition system and it shall be confirmed that the system provides the following minimum protection for all electrical equipment:

- over-voltage peak suppressor;
- alternating current filter to eliminate interference; and
- Grounding system for lightning protection.

8.6 Voltage and Electrical Frequency

Facilities requiring permanent electrical power, including battery chargers and space heaters, shall be configured to operate at 110 V, alternating current at 60 Hz.

8.7 Protection

The instrumentation shall be protected with end caps and protective casing.

Cabins, supports and accessories necessary for the installation and protection of the instruments shall be provided.

8.8 Grout Mix

The grout mix in Table 8-1 shall be used for the VWP, inclinometer casing, and SAA installation.

Table 8-1: Grout Mix for Vibrating Wire Piezometer, SAA and Inclinometer Installation

Material	Quantity	Ratio by Weight
Portland Cement	42.5 kg	1
Water	107.5 L	2.5
Bentonite Powder	12.8 kg	0.3

The above quantities shall be adjusted to match the cement weight such that the mix comprises a unit number of bags of cement.

Mixing shall be carried out by first introducing the water into the mixer followed by the cement. The water cement mixture shall be thoroughly mixed before the bentonite is added. Bentonite powder and not pellets shall be used. Mixing shall continue until a stable, uniform slurry is achieved.

Grout shall be continuously agitated during pumping and grouting.

Instrumentation shall be backfilled from the bottom up. Grout shall be delivered into the hole by a threaded tremie PVC pipe.

8.9 Vibrating Wire Piezometers

8.9.1 General

Vibrating wire piezometers shall include the piezometer sensors, leads, the connector box, and all associated equipment and materials, including waterproof junction boxes, universal lead connectors, electrical protection systems and conduits, necessary for installation, testing, and operation. All such equipment shall be provided by the same manufacturer.

Data reading and recording shall be carried out manually during construction of the Work, and automatically thereafter.

Each piezometer shall have a sensor measuring range of up to 1 MPa, with a sensitivity of 0.025% and accuracy of ±0.1% of full-scale pressure (FS).

The following piezometers may to be installed:

- Model VW2100 manufactured by RST Instruments, or approved equivalent; or
- Model 4500S manufactured by Geokon Incorporated, or approved equivalent.

The connector boxes shall have capacity for simultaneous installation of all leads from the piezometers shown on the Drawings.

Additional piezometer cables may be required to connect to the existing piezometers, which will be buried as part of construction, to the connector boxes.

A read-out unit shall be provided to process signals from VWPs and to display the results.

8.9.2 Installation

Piezometers shall be installed according to the manufacturer's instructions, within the embankment fill, general fill (or tailings beach) and foundation at elevations shown on the Drawings or as directed by the QA Manager. Piezometers will be installed at the same time the inclinometer casing is been installed.

Prior to installation, the piezometer shall be immersed in de-aired water in accordance with the manufacturer's instructions.

The VWPs shall be attached, filter facing upward, to the outside of the inclinometer casing using duct or electrical tape.

The vibrating wire piezometer filter shall not be covered with the tape. An initial reading is required right after the readings have stabilized in the hole and before the hole is backfilled with grout.

Following installation, the hole shall be grouted with cement-bentonite from bottom to top using a tremie pipe. The grout mix to be used is defined in Section 8.9.

Installation of the piezometers shall be completed by connecting the leads to the connector boxes within the instrumentation cabin. The leads from the instruments to the connector boxes shall be wrapped in geotextile and installed into trenches, as shown on the Drawings or as directed by the QA Manager.

8.9.3 Extension of Vibrating Wire Piezometer Cables

As part of the embankment raise construction activities it will be necessary to relocate/extend the cable of VWP instrumentation so that they can be accessed from the raised embankment crest or buttress, as shown on the Construction Drawings, and specified in this section.

- Existing excess cable can be used where available and suitable
- All cable shall be inspected for suitability and tested, using a handheld read-out unit, prior to extension
- All extended VWP cables shall be laid horizontally or vertically within the embankment construction material
    - Cable shall be realigned so that it is a minimum of 0.75 m below the existing surface and/or lowest elevation of the till core, as shown in the construction drawings
    - At the initial location of cable realignment (i.e., initial 90-degree turn) the VWP cable shall be backfilled with a cement-bentonite mix to form a minimum 2 m long plug, as shown in the construction drawings
    - VWP cable shall be placed on a minimum bed of 0.1 m of hand placed bedding material (Section 5.4.10) with a maximum particle size of 20 mm and nominally compacted with hand operated equipment
    - VWP cable shall be backfilled to a minimum depth of 0.3 m above the cable with bedding material
    - The remaining 0.45 m above the cable shall be backfill with transition material and nominally compacted with light-duty compactor approved by the QA Manager.
- Where required, new cable shall be spliced in accordance with manufacturers instructions

- Spliced cable sections shall be placed horizontal so that they are located a minimum of 0.5 m from any cable bends, in any direction
- Spliced cable sections shall be backfilled with cement-bentonite mix

All relocated/extended cable shall be tested, using a handheld read-out unit, following relocation/extension to confirm it is operational.

8.10 Shape Acceleration Array Systems

8.10.1 General

This section covers furnishing and installing ShapeAccelArrays (SAAs) systems.

The SAA system shall be an SAAV, as manufactured by Measurand Inc. or approved equivalent. The SAA system shall have segment lengths of 500 mm. The lengths of each SAA system will be confirmed after drilling of the boreholes is completed.

A data acquisition system (DAS) shall be installed to collect data from the SAA instruments. Options include the DAS-1 and DAS-5. Both contain Campbell Scientific Inc. loggers, interface modules, and other components to automate data collection. Refer to the manufacturer for specific and additional components for each DAS. Batteries are not included with the DAS and shall be selected based on the manufacturer's specifications. Maximum cable lengths for SAAV vary; refer to the manufacturer for details. An SAA Surge Protection Device (SAASPD) shall be installed to protect the SAA from electrical surges caused by nearby lightning strikes. Refer to the manufacturer for details.

Twelve SAAs will be installed. Seven SAAs shall be installed on existing inclinometer casing located along the Main and Perimeter embankments. Drilling new boreholes will be required to install five SAAs along the South and Main embankments.

Only SAA splice kits, manufactured by Measurand Inc. shall be used for splicing SAA cables. Other splicing kits can only be used with SAA Manufacturer approval.

8.10.2 Installation

The SAA systems shall be installed in accordance with the manufacturer's handling and installation specifications. The vertical installation shall be done in accordance with the following procedure:

- The installation depth for the SAA shall be confirmed and documented by the QA Manager.
- A 70 mm SAA casing cap shall be placed on the inclinometer casing.
- The SAAV reel shall be set on the reel stand such that it unreels from the top. The reel shall be placed 1.0 m to 1.5 m away from the borehole. For SAAVs longer than 50 m, a sufficiently large reel stand (e.g., jack stands) shall be used to place the reel directly above the borehole.
- The insertion of the SAAV shall be done by at least two people: one person to guide the SAA instrument into the borehole, and the other to control the rate of descent by handling the reel.

- One extension tube shall be detached from the SAAV reel and attached to the springbox assembly. The X-mark on the extension tube should be in line with the X-mark on the SAAV. In cases where the SAAV is shorter than the borehole, several extension tubes may be required. See manufacturer's instructions for more details.
- Once the extension tube has been attached and the SAAV is resting on the bottom of the borehole, the SAAV shall be settled into the inclinometer casing (see manufacturer's instructions for more details):
  - The SAAV installation verification tool included in the Measurand SAA recorder software shall be used by connecting a computer to the SAA.
  - The casing cap shall be removed and set aside with enough slack cable to avoid interference with the settling process.
  - The SAAV shall be lifted until it is hanging in the casing with one segment touching the bottom. The angle reported by the SAAV Installation Verification tool should be 4-6 degrees.
  - Once the SAAV is resting on the bottom of the casing, the SAAV shall be dropped such that it falls straight into the casing. Approximately 5 lbs of downward pressure shall be applied to compress the SAAV within the casing. The compression value shall be recorded in the SAAV installation verification tool and sample data from the SAA recorder shall be collected.
  - The SAAV shall be lifted so only the last segment is resting on the bottom of the casing and dropped repeatedly until three sequential readings of compression do not change by more than 1 mm (10-15 drops).
  - The casing cap shall be replaced over the extension rods onto the top of the casing.
- The azimuth offset shall be determined using the X-mark protractor and methods described in the manufacturer's instructions.
- The SAAV casing cap shall be attached to the inclinometer casing using the method outlined in the manufacturer's instructions.
- The extension tube shall be cut by an amount determined by compressing the SAAV with 11 lbs of mass, and with the use of the extension tube anchor, the cutting location shall be marked.
- After cutting, the extension tube anchor shall be inserted into the top of the tube, and the extension tube shall be compressed until the bolt can be screwed into place.
- The SAAV cable shall be inserted into the cable grommet in the SAAV casing cap. The SAAV casing cap shall be closed and secured. See manufacturer's instructions for more details.

8.11 Inclinometers

8.11.1 General

A 70 mm diameter inclinometer casing manufactured by RST instruments or Durham Geo Slope Indicator (DGSI), or approved equivalent, shall be installed. The corresponding casing coupling manufactured by RST instruments or DGSI, or approved equivalent, shall be used to connect the inclinometer casings.

8.11.2 Installation

The borehole diameter should be large enough to accommodate the inclinometer casing and a tremie pipe so that grout can be pumped into the annulus from the bottom up.

Installation should closely follow the following procedure:

- Once the hole has been drilled to the required depth, the first length of casing shall be inserted, complete with bottom cap, anchor and attached tremie pipe. Additional lengths of casing are added until the desired depth is reached.
- Once the slope inclinometer casing is lowered into the hole to the required depth, a pair of grooves should be aligned in the expected direction of ground movement. This should be done only if it can be accomplished without applying excessive torque to the casing.
- Grout should be pumped through the tremie pipe into the hole, displacing any groundwater within the borehole.
- During casing installation, groundwater, drilling fluid, or fluid grout within the borehole may exert an uplift buoyancy force on the casing, lifting the casing out of the borehole. The following measures shall be used to prevent this uplift:
  - Anchor the casing at the bottom of the borehole prior to grouting by special accessory “casing anchors”.
  - Fill the inclinometer casing with water prior to grouting.
  - Grout the borehole in stages.
  - Blow all water from the inclinometer casing.
- Where there are no special constraints, the casing should stick up about 0.5 to 0.75 m.
- Spiral twisting of the grooves should not exceed 0.75 degrees per metre length of the tubing. Where considered necessary by the QA Manager (e.g., on very deep installations, typically >60 m) a spiral survey of the casing grooves shall be carried out after installation and an appropriate correction applied by the data reduction software.
- Upon completion of the installation, the inside of the casing should be kept clean so that the probe can travel accurately in the grooves all the way in and out of the casing. If the grooves become contaminated by grout, they should be cleaned by flushing with water and gentle brushing, and a dummy probe can be lowered to the bottom to check that the grooves are clear.

- After installation and curing of the grout, two sets of inclinometer readings should be taken to provide a reliable baseline. If the two sets show any apparent movement, additional readings should be taken.

8.11.3 Inclinometer Extensions

Existing inclinometer casings shall be extended. Inclinometer casing extensions shall be protected with fine crushed material before rockfill is placed around them. Inclinometer casing ends shall be capped while material is being placed to avoid clogging. Extension pipes, caps and fittings shall be provided in advance. The inclinometer casings shall be extended above the buttress construction surface.

8.11.4 Inclinometers Decommissioning

Eight inclinometer casings along the embankment will be decommissioned by backfilling the casing with grout. Grout mix is defined in Section 8.9.

The inclinometer casing shall be backfilled from the bottom up. Grout shall be delivered into the hole by a threaded tremie PVC pipe.

APPENDIX C

Design Criteria

TECHNICAL MEMORANDUM

DATE March 21, 2024 **Reference No.** 23590671-067-TM-Rev0-51393

TO Matt O'Leary
Mount Polley Mining Corporation

CC Don Parsons

FROM Sophie Bainbridge, Don Kidd, and Germán Pizarro **EMAIL sophie.bainbridge@wsp.com; don.kidd@wsp.com; german.pizarro@wsp.com**

MOUNT POLLEY MINE, BRITISH COLUMBIA – BASIS OF DESIGN AND DESIGN CRITERIA FOR TAILINGS STORAGE FACILITY RAISE TO ELEVATION 974 M

1.0 INTRODUCTION

WSP Canada Inc. (WSP) has developed this technical memorandum as part of a design to support the permit to raise the Mount Polley Mining Corporation (MPMC) tailings storage facility (TSF). This document presents the basis for design and the associated design criteria to be used by WSP for the issued for permit design for raising the existing TSF from its currently permitted elevation of 970 m to 974 m. This document provides the following:

- **project description**—Section 2.0
- **scope of work**—Section 3.0
- **design basis**—Section 4.0
- **design philosophy**—Section 5.0
- **design criteria**—Section 6.0

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

2.0 PROJECT DESCRIPTION

The Mount Polley Mine is a copper and gold mine operated by MPMC, a subsidiary of Imperial Metals Corporation. The site is located approximately 56 km northeast of Williams Lake, British Columbia, between Polley Lake and Bootjack Lake. The Mount Polley Mine began production in 1997 and operated until October 2001 when operations were suspended for economic reasons. In March 2005, the mine restarted and was in operation up to the time of the TSF breach in August 2014.

In 2015, the Freshet Embankment was constructed to elevation 950 m through the breach area to allow the capture and temporary storage of the 2015 and 2016 freshet flows. The construction of buttresses along the Perimeter and Main embankments was completed in October 2016 (Golder 2015a, 2017a).

The June 23, 2016 amendment of the *Mines Act* Permit M-200 authorized the return to full operations at the mine, including construction and operation of the TSF design to elevation 970 m (Golder 2015b). Construction to raise the Freshet Embankment at Corner 1 to elevation 970 m started in June 2016. By September 2018, construction of the Corner 1 Embankment had been completed to elevation 968 m (Golder 2019). The raise of the Freshet Embankment was referred to as the Corner 1 Embankment. Construction to raise the embankment to elevation 970 m was started in July 2022 and was completed in 2023.

Mining operations at the Mount Polley mine were halted between May 2019 and Q4 2021 for economic reasons. Deposition of tailings generated at the process plant into the TSF was resumed in June 2022. Dredging of tailings from the Springer Pit and deposition into the TSF started in March 2018 and was halted in October 2019.

The TSF is located about 3 km southeast of the mill and includes one embankment that is approximately 4.8 km in length. The embankment is subdivided into three sections: the Main Embankment, Perimeter Embankment, and South Embankment. The embankment has incorporated a staged expansion design utilizing modified centerline and centerline construction methods. The general zoning of the TSF embankment includes the following:

- upstream fill comprising select fill or tailings sand
- low-permeability till core
- filter zone
- transition zone

Rockfill forms the downstream wedge of the embankment and the downstream buttress along the Perimeter and Main embankments (sandy tailings reclaimed from Hazeltine Creek were also used in the construction of the downstream buttress at Corner 1).

The TSF Clean Water Ditch is located upstream of the TSF between Corner 4 and Corner 5 and diverts runoff into a small wetland downstream of the South Embankment.

In 2014, WSP, formerly Golder Associates Ltd. (Golder), completed a feasibility design for raising the embankment of the TSF to a maximum elevation of 984 m (Golder 2015c). The aim of the feasibility assessment was to identify potential considerations, constraints, or conflicts that may limit the elevation to which the TSF could be raised. The results of the study indicated that a raise of the facility is feasible. The life of mine (LoM) plan was updated in 2021 and a crest elevation of approximately 987 m is estimated to be required to contain the LoM tailings.

3.0 SCOPE OF WORK

The scope of work includes the following:

- update of site selection and technology review
- foundation characterization
- site-specific seismic hazard assessment
- 2D steady-state seepage analysis

- 2D limit equilibrium stability analysis
- 2D stress-deformation modelling
- filter compatibility assessment
- tailings deposition modelling
- review and update of the TSF pond management, spillway design, and freeboard requirements
- detailed design reporting including construction drawings and technical specifications

The battery limits for the study are assumed as:

- discharge of tailings into the TSF
- return water at the existing TSF
- the footprint boundaries of the existing TSF
- tie-in points to infrastructure and utilities (e.g., electrical power, access roads, data and communication, and network)

4.0 DESIGN BASIS

This basis of design is established in accordance with relevant design codes, standards, and guidelines.

4.1 Regulations, Standards, and Guidelines

The assessment of the TSF will be consistent with applicable regulatory documents and guidelines from Mount Polley, WSP, and national and international organizations, where applicable (e.g., Canadian Dam Association, International Commission of Large Dams). Regulations applicable to this study comprise the following:

- Health, Safety and Reclamation Code for Mines in British Columbia (EMLI 2022).
- Guidance Document for Revisions to Part 10 of the Health, Safety and Reclamation Code for Mines in British Columbia (BCMEM 2016).

The assessment of the TSF will also be consistent with the following guidelines, where applicable:

- Canadian Dam Association (CDA) Dam Safety Guidelines (2013).
- Technical Bulletin: Application of CDA Dam Safety Guidelines to Mining Dams (2019).
- Global Industry Standard for Tailings Management (GISTM 2020).
- Mining Association of Canada – A Guide to the Management of Tailings Facilities (2021)

Other internationally recognized codes and standards may be used, provided these codes and standards meet or exceed the referenced codes herein.

4.2 Dam Classification

Guidelines for the classification of dams are presented in the Canadian Dam Association (CDA) *Dam Safety Guidelines* (CDA 2013), *Technical Bulletin: Application of CDA Dam Safety Guidelines to Mining Dams* (CDA 2019) and *Technical Bulletin: Revision to Consequences of Failure – Environmental Consequence Classification* (CDA 2023). Tailings dams in British Columbia are regulated under the Health, Safety and Reclamation Code for Mines in British Columbia (BCMEM 2016; EMLI 2022), which references the 2013 CDA guidelines.

Consequence categories are based on the incremental losses that a failure of the dam might inflict on downstream or upstream areas or at the dam location itself. Incremental losses are those over and above losses that might have occurred in the same natural event or condition had the dam not failed. Infrastructure and economic consequences are based on third party losses. The consequences of a dam failure are ranked as Low, Significant, High, Very High, or Extreme for each of the loss categories. The classification assigned to a dam is the highest rank determined among the loss categories.

Table 1 presents the dam classification criteria by the CDA (2013, 2019).

Table 1: Dam Classification in Terms of Consequence of Failure

TS	Population at Risk[a]	Loss of Life[b]	Incremental Losses	
			Environmental and Cultural Values	Infrastructure and Economics
Low	None	0	▪ Minimal short-term loss. ▪ No long-term loss.	Low economic losses; area contains limited infrastructure or service.
Significant	**Temporary Only**	**Unspecified**	▪ **No significant loss or deterioration of fish or wildlife habitat.** ▪ **Loss of marginal habitat only.** ▪ **Restoration or compensation in kind highly possible.**	**Losses to recreational facilities, seasonal workplaces, and infrequently used transportation routes.**
High	Permanent	10 or fewer	▪ Significant loss or deterioration of important fish or wildlife habitat. ▪ Restoration or compensation in kind highly possible.	High economic losses affecting infrastructure, public transportation and commercial facilities.
Very High	Permanent	100 or fewer	▪ Significant loss or deterioration of critical fish or wildlife habitat. ▪ Restoration or compensation in kind possible but impractical.	Very high economic losses affecting important infrastructure or services (e.g., highway, industrial facility, storage facilities for dangerous substances).
Extreme	Permanent	More than 100	▪ Major loss of critical fish or wildlife habitat. ▪ Restoration or compensation in kind impossible.	Extreme losses affecting critical infrastructure or services (e.g., hospital, major industrial complex, major storage facilities for dangerous substances).

Source: CDA 2013, 2019.

(a) Definition for population at risk: None – there is no identifiable population at risk, so there is no possibility of loss of life other than through unforeseeable misadventure; Temporary – people are only temporarily in the dam-breach inundation zone (e.g., seasonal cottage use, passing through on transportation routes, participating in recreational activities); Permanent – the population at risk is ordinarily located in the dam-breach inundation zone (e.g., as permanent residents). Three consequence classes (high, very high, extreme) are proposed to allow for more detailed estimates of potential loss of life (to assist in decision-making if the appropriate analysis is carried out).

(b) Implications for loss of life: Unspecified – the appropriate level of safety required for a dam where people are temporarily at risk depends on the number of people, the exposure time, the nature of their activity, and other conditions. A higher class could be appropriate, depending on the requirements. However, the design flood requirement, for example, might not be higher if the temporary population is not likely to be present during the flood season.

The TSF is located between the Hazeltine Creek watershed (north of the TSF) and Edney Creek watershed (south of the TSF). Both watersheds flow on an approximate northwest to southeast direction to Quesnel Lake. The topographical features along the South edge of the Edney Creek watershed are up to 40 m higher than Edney Lake, and the topography along the north edge of the Hazeltine Creek watershed are up to about 30 m higher than Hazeltine Creek. The topography to the south and north of the TSF discourage the inundation extending outside of the Hazeltine Creek watershed and the Edney Creek watershed.

A dam breach and inundation study was carried out considering a flood-induced and sunny-day hypothetical failure of the Main Embankment and South Embankment with a crest elevation of 970 m (Golder 2017b).

- In the event of a breach at the Main Embankment, the runoff would flow southeast along Hazeltine Creek and Edney Creek to Quesnel Lake.
- In the event of a breach at the South Embankment, the runoff would flow south to Edney Lake and southeast along Hazeltine Creek and Edney Creek to Quesnel Lake.
- The runoff from a breach of the Perimeter Embankment would flow southeast along Hazeltine Creek or Edney Creek to Quesnel Lake, depending on the location of the breach.

The water treatment plant is the only permanent structure in these areas. The TSF South, Main, and Perimeter embankments have been evaluated according to the loss criteria.

- The loss of life is considered unspecified based on the limited exposure time of the general population and mine staff.
    - The area at risk for the general population is limited to the section of Gavin Lake Road downstream of the TSF, the bridge crossings on Edney Creek, and the area at the confluence of Hazeltine Creek and Edney Creek with Quesnel Lake. There is no permanent population in these areas.
    - The area at risk for mine staff is limited to the TSF (i.e., embankment crest and buttress) and the downstream water management infrastructure (i.e., WTP, SESCP, and MESCP). Mine staff conduct periodic inspections and maintenance activities at these locations but are not permanently in the area.
- Restoration of the fish habitat is possible, as demonstrated by the rehabilitation works that have been completed to date in the Hazeltine Creek channel.
- Third-party economic losses would be low.

The TSF would therefore be ranked as a significant consequence of failure facility.

As the TSF is raised there is an incremental increase in the volume and peak flow of tailings that could runout in the event of an embankment breach; however, the proposed embankment height raise from about 50 to 54 m (from elevation 970 to 974 m) is not expected to significantly impact the run-out zone and therefore the consequence classification.

4.3 Foundation Conditions

The geological setting of the Mount Polley TSF has been extensively investigated and a dam foundation characterization report has been developed for the TSF (WSP 2023). The foundation characterization report interprets all available information for the TSF foundation conditions. The stratigraphic sequence identified in the area of the TSF can be generalized in order of increasing depth as follows:

- fill and anthropogenic materials
- till, interpreted to represent materials deposited by meltwater and ice (ablation till)
- glaciolacustrine sediments
- glaciofluvial sediments
- basal till
- bedrock

4.4 Climate Data

Climate conditions for the site were estimated based on data from several meteorological stations in the region and at the site. MPMC has operated climate stations on site since 1995, although records are not continuous. Climate parameter statistics for the site were prepared using data from the three on-site climate stations (Mill Site Weather Station, Weather Station #1, Weather Station #2) and five regional climate stations operated by Environment and Climate Change Canada (Likely, Williams Lake A, Spokin Lake 4E, Barkerville, Quesnel A, Prince George A). The climate data were processed and analyzed to obtain a baseline climate information (Golder 2022b).

The Site experiences high summer precipitation due to summer storms, with the lowest monthly precipitation occurring in February. Precipitation typically occurs as snowfall starting in November and accumulates until March. Average annual precipitation at the Site is estimated to be 612 mm with a standard deviation of 118 mm based on precipitation records for the Site from 1974 to 2021. Typically, the increase of temperatures over 0°C starts in March, leading to freshet until June.

Table 2, Table 3 and Table 4 summarize the precipitation, evaporation, and temperature at the site, for different weather scenarios. These are results from a monthly frequency analysis considering data from 1974 to 2021.

Table 2: Monthly Precipitation Depths for the Site, 1974 to 2021

Month	Precipitation (mm)

Annual maximum series for 24-hour precipitation from the derived historical dataset was used to undertake a frequency analysis to provide rainfall design values (Table 5). The 24-hour, 3-day, and 10-day annual, spring, and summer probable maximum precipitation (PMP) depths (Table 6) were estimated using the Hershfield method (Golder 2022b).

Table 5: 24-hour Precipitation Depths for the Site, 1974 to 2021

Return Period (yr)	Depth (mm)
2	33
10	47
25	54
100	64
200	69
1,000	80

Table 6: Annual, Spring, and Summer Probable Maximum Precipitation Depths for the Site, 1974 to 2021

Period	Annual PMP (mm)	Spring PMP[(a)] (mm)	Summer PMP[(b)] (mm)
24-Hour	224	192	191
3-Day	339	272	294
10-Day	562	295	486

(a) Spring = March, April, and May.

(b) Summer = June, July, and August.

PMP = probable maximum precipitation.

4.5 Site Seismicity

Mount Polley is located in an area of relatively low seismicity for British Columbia. WSP developed a site-specific seismic hazard model for Mount Polley based on historical seismicity and a review of geological and paleoseismological features (WSP 2023). Probabilistic analysis results from site-specific hazard model are listed in Table 7.

Table 7: Site Seismic Hazard Values

Exceedance Probability	Return Period (years)	Peak Ground Acceleration (g)
5% in 50 years	1,000	0.026
2% in 50 years	2,475	0.048
1% in 50 years	5,000	0.076
½% in 50 years	10,000	0.116

Return periods are not exact representations of annual exceedance probabilities; rounding per Canadian Dam Association guidelines (CDA 2013, 2019) is shown.

5.0 DESIGN AND OPERATION PHILOSOPHY

The design and operation of the TSF will follow the principles set out by the Mining Association of Canada in its Towards Sustainable Mining program and the recommendations made by the IEERP (2015). The following approaches have been used for the design and operation of the TSF:

- Limit the amount of surface water to only that required for operation – this will be achieved through maintaining storage capacity within the external water management ponds and ongoing discharge of water from the mine site.
- Promote unsaturated conditions in the tailings – wide sub-aerial beaches will be maintained upstream of the embankments and upstream drains will be constructed to create a zone of unsaturated tailings adjacent to the embankments.
- Promote consolidation of tailings upstream of the TSF embankment –upstream drains will be constructed to create a zone of unsaturated tailings adjacent to the embankments.
- Reduce the hydraulic gradient across the till core – this will be achieved through maintaining sub-aerial beaches along the embankments and the construction of upstream drains.

Operation of the facility is to follow the above philosophy. The existing quantitative performance objectives will be revisited as part of the design to raise the TSF to elevation 974 and will be used to confirm that operation of the facility follows the operation philosophy.

6.0 DESIGN CRITERIA

The project-specific design criteria are detailed in Table 8.

Table 8: Design Criteria

Criteria	Unit	Value	Source/Comment
General			
Nominal Tailings Production Rate	t/day	20,000	MPMC (2021)
TSF Storage Capacity	-	Minimum to allow continuity of operation until 2026	Includes the remaining storage capacity of the permitted 970 m raise based on the 2019/2020 survey of the tailings surface 8.0 Mt deposited between June 2022 and December 2023
Dam classification	-	Significant	Refer to section 4.2
Coordinate system	-	Tailings grid	MPMC
Units	-	Metric	-
Design earthquake event	-	1:2,475 Annual Exceedance Probability (AEP)	HSRC Guidance Document Section 3.3.1 (BC MEM 2016) Other criteria include: ■ Between 1:100 and 1:1,000 (CDA 2019) ■ 1:1,000 AEP recommended by GISTM (2020) Consistent with WSP's best practice, an earthquake event of 1:10,000 AEP will be used to assess sensitivity of the analyses.
Design earthquake peak ground acceleration	g	0.048	for earthquake event of 1:2,475 AEP 0.116 g for earthquake event of 1:10,000 AEP
Seismic coefficient for limit equilibrium pseudo-static analysis	-	0.5	Hynes-Griffin and Franklin (1984) 20% strength reduction applied to glaciolacustrine deposits as recommended by Hynes-Griffin and Franklin (1984) for clays.
Static (long term)	FoS	1.5	HSRC Guidance Document Section 3.3.1 (BC MEM 2016), CDA (2019) Table 3-4
Static (during or at end of construction)	FoS	1.5	HSRC Guidance Document Section 3.3.1 (BC MEM 2016) >1.3 recommended by CDA (2019) Table 3-4
Pseudo-static	FoS	1.0	Informed by Table 3-5 of CDA (2019)
Post-earthquake	FoS	1.2	Informed by Table 3-5 of CDA (2019)

Table 8: Design Criteria

Criteria	Unit	Value	Source/Comment
Embankment Details			
TSF construction method	-	Centreline	Adopted
Low hydraulic conductivity element	-	Compacted till	Adopted
Overall downstream slope no steeper than	-	2H:1V	HSRC Guidance Document Section 3.3.1 (BC MEM 2016)
Embankment fill material	-	Non-acid generating	MPMC
Tailings Characteristics			
Solids content of tailings slurry discharged to TSF	%wt	Nominally ~ 35	Provided by MPMC
Tailings solids specific gravity	-	2.7	Estimated based on laboratory testing
Tailings average dry density after deposition	t/m^3	1.35	Assumed by WSP 1.36 t/m^3 in Knight Piesold (2005)
Tailings beach slope	%	sub-aerial – 0.5% Sub-aqueous – 2%	Estimated based on available topographic and bathymetric surveys since 2016

TSF = tailings storage facility; FoS = factor of safety.

A tailings deposition plan has been developed by MPMC from the restart of operations in July 2022. Annual tailings deposition into the TSF and cumulative tonnage for restart of operations until Q2 2026 (by which date storage capacity of the elevation 974 m facility will have been achieved, based on the tailings production plan) is included in Table 9.

Table 9: Tailings Production Plan July 2022 to Q2 2026

Period	Tailings Production (tonnes)	Cumulative Total Tonnage
July 2022	470,469	470,469
August 2022	620,000	1,090,469
September 2022	600,000	1,690,469
October 2022	620,000	2,310,469
November 2022	600,000	2,910,469
December 2022	620,000	3,530,469
January 2023	620,000	4,150,469
February 2023	560,000	4,710,469
March 2023	620,000	5,330,469
April 2023	600,000	5,930,469
May 2023	620,000	6,550,469
June 2023	600,000	7,150,469
July 2023	620,000	7,770,469
August 2023	620,000	8,390,469
September 2023	600,000	8,990,469
October 2023	620,000	9,610,469
November 2023	600,000	10,210,469
December 2023	620,000	10,830,469
January 2024	620,000	11,450,469
February 2024	560,000	12,010,469
March 2024	620,000	12,630,469
April 2024	600,000	13,230,469
May 2024	620,000	13,850,469
June 2024	600,000	14,450,469
July 2024	620,000	15,070,469
August 2024	620,000	15,690,469
September 2024	600,000	16,290,469
October 2024	620,000	16,910,469
November 2024	600,000	17,510,469
December 2024	620,000	18,130,469
Q1 2025	1,800,000	19,930,469
Q2 2025	1,820,000	21,750,469
Q3 2025	1,840,000	23,590,469
Q4 2025	1,840,000	25,430,469
Q1 2026	1,800,000	27,230,469
Q2 2026	1,820,000	29,050,469

Note: Some of this material is being deposited within the permitted 970 m TSF configuration. Cumulative total tonnage dates vary based on actual production quantities from July 2022 to date.

Ref. MPMC 2021.

6.1 Water Management Criteria

The Mount Polley Mine site has an annual net water surplus, and discharge from the mine site (after treatment) is necessary to manage the mine site water and to prevent accumulation of water on the mine site on a year over year basis. Temporary detention of water will be necessary to manage the large runoff volumes generated during the freshet; however, the fundamental basis of the water management plan is to not accumulate water on site (including the TSF) by treating and discharging water and to not carry over water from year to year even under extreme wet conditions.

The majority of water inflows into the TSF are pumped and are therefore in the direct control of the operator. These inflows are as follows:

- water discharged with the tailings slurry, at approximately 35% solids by weight
- excess water pumped from the water management structures for temporary detention in the TSF during the freshet and high flow events

Catchment areas directly contributing to the TSF are provided in Figure 1 and Table 10. This catchment delineation is the basis for the TSF spillway design. The water inflows to the TSF that are not pumped, and therefore not in the direct control of the operator, are as follows:

- precipitation on the direct footprint of the TSF
- potential runoff from the catchment directly above the west side of the TSF (catchment B and C in Figure 1) .
- potential runoff from the upstream catchment (catchment A in Figure 1) depending on the updates to the tailings pipeline ditch.

Outflows from the TSF consist of the following:

- reclaim water pumped to the mill by means of a floating barge within the TSF pond
- seepage through the embankment and foundation, including upstream drains, to the seepage collection ponds
- evaporation losses from the TSF pond and TSF wet tailings beaches
- water retained in the newly placed tailings

The TSF will be managed by maintaining the pond volume within the operating range for reclaim water and make-up water.

Deposition of the tailings will be planned in a manner that maintains the pond near the centre of the TSF facility and against the natural topography on the western perimeter.

Relevant parameters used as design criteria are summarized in Table 11.

Figure 1: TSF Catchment Areas

Table 10: TSF Catchment Areas

Catchment	Watershed Area (km^2)
TSF upstream contact A[(a)]	0.43
TSF upstream contact B	0.24
TSF upstream contact C	0.52
TSF	2.38

(a) The catchment area is to be refined as per update to the tailings pipeline ditch.

Table 11: Design Criteria for Tailings Storage Facility Water Levels and Emergency Spillway

Design Criteria		Value	Source / Comment
IDF	Operations	72-hour PMF	PMF runoff volume will be estimate considering the annual 72-hour PMP rainfall plus snowmelt, which was selected consistent with WSP's best practice. Other criteria include: • 1/3 between 1-in-975-year and PMF for a minimum duration of 72 hours required by HSRC Guidance Document Section 3.3.1 (BC MEM 2016). • Between 1-in-100 and 1-in-1,000-year return period recommended by CDA (2019). • 1-in-1,000-year return period recommended by GISTM (2020).
EDF	Operations	24-hour 1:200 year precipitation and snowmelt	Typical EDF return periods range from 1-in-50 years to 1-in-200 years (CDA 2019).
Freeboard	Normal	No overtopping by 95% of waves caused by the most critical wind with a frequency of 1:1000 year with reservoir at maximum normal elevation.	CDA (2013)
	Minimum	No overtopping by 95% of waves caused by the most critical wind when the reservoir is at its maximum level during the IDF.	CDA (2013)
Operating pond volume	Normal operating water level range	1.5 to 1.7 million m^3 (Mm^3)	Minimum provided by MPMC for operation of the mill. Maximum adopted to maintain wide sub-aerial beaches.
	Maximum prior to freshet	1.5 Mm^3	Lowest achievable volume provided by MPMC for operation of the mill.

Table 11: Design Criteria for Tailings Storage Facility Water Levels and Emergency Spillway

Design Criteria		Value	Source / Comment
Beach width	Minimum during normal operating conditions	100 m	Portion of beach above operating pond level.
Emergency Spillway during Operations	-	Spillway to pass the IDF; TSF to store the EDF.	CDA 2019
Climate change consideration	-	Not considered due to design life of the emergency spillway during operations.	The potential variation in precipitation under climate change is expected to be within the range of uncertainty in the PMP estimate. Therefore, the PMP will not be modified further to account for potential climate change effects.
Annual 72-hour PMP	-	339 mm	Section 4.4.
72-hour PMP snowmelt depth	-	54 mm	Snowmelts are determined using an energy balance method (Dunne and Leopold 1978) using 72-hour PMP rainfall and mean April temperature and wind speed.
24-hour 1:200-year precipitation and snowmelt	-	69 mm	Golder (2022b)
72-hour snowmelt distribution	-	Evenly distributed over 72-hour duration as baseflow.	Adopted
Erosion protection requirements	Emergency Spillway during operation	Specific erosion protection materials selected using peak velocities along the spillway alignment as calculated in the hydraulic calculations.	BC MOTI 2007
Upstream drain	Flow capacity	To maintain the phreatic level at the elevation of the drain when the pond encroaches 50 to100 m from the elevation 987 m TSF configuration	Adopted
Upstream drain pipelines capacity	FoS	3	Adopted

IDF = inflow design flood; EDF = environmental design flow; PMF = probable maximum flood; TSF = tailings storage facility; MPMC = Mount Polley Mining Corporation; FoS = factor of safety.

7.0 CLOSURE PHILOSOPHY

The closure philosophy will be consistent with the most recent Mine Reclamation and Closure Plan (*Mines Act* Permit M-200). The TSF will remain a permanent structure, which will be reclaimed and given productive land use. The final configuration of the TSF will include a small permanent pond and wetland area on the surface, with maximum 2H:1V embankment slopes and a spillway for pond water level control. The principal activities and areas for reclamation of the TSF will be as follows:

- removal of all infrastructure
- re-sloping and reclamation of embankments
- spillway construction to limit the pond volume to about 0.25 Mm^3
- reclamation of tailings surface (beach and pond)
- reclamation of till borrow pits, as required

Implementation of closure and its philosophy is feasible for the TSF with a 974 m crest elevation; however, the TSF is planned to be raise above elevation 974 m to provide storage capacity for the LoM.

8.0 CLOSURE

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this memorandum.

We trust that this technical memorandum provides sufficient information for your present needs. Please do not hesitate to contact us if you require any further elaboration or clarification.

APPENDIX D

Siting and Technology Study

TECHNICAL MEMORANDUM

DATE 27 October 2022 **Reference No.** 22514095-070-TM-Rev0-51343

TO Matt O'Leary
Mount Polley Mining Corporation

FROM Germán Pizarro and Ben Wickland **EMAIL German.Pizarro@wsp.com; Ben.Wickland@wsp.com**

SITE SELECTION AND TECHNOLOGY MEMO – MOUNT POLLEY MINE TAILING STORAGE FACILITY

In 2015, Golder Associates Ltd. (Golder), now a member of WSP (WSP Golder), completed a siting and deposition technology review as part of the Mount Polley tailings storage facility (TSF) elevation 984 m life of mine feasibility design (Golder 2015). The study included a review of available tailings deposition technologies, a review of potential sites to deposit tailings and an assessment of the alternatives based on environmental, social, technical, and economic indicators. Deposition of the remaining life of mine tailings (about 70 million tonnes) as a slurry within the existing TSF was recommended with operation using best applicable practices (BAP) of reduced water storage, maintaining beaches against the dams, and providing drainage to promote desaturation and drainage of the pond (Golder 2015).

Deposition of tailings as a slurry in the TSF re-started in June 2016 and continued until May 2019 when mining operations were halted due to economic reasons. A portion of the tailings in Springer Pit was dredged and deposited in the TSF from March 2018 to October 2019. From the restart of operations in June 2016 to October 2019, a total of about 20 million tonnes of tailings were deposited in the TSF. Construction of the TSF Corner 1 embankment was completed to elevation 968 m in 2018 (Golder 2019). Construction activities to raise the embankment to the permitted elevation of 970 m and deposition of tailings were restarted in July 2022.

As part of the restart of mining operations in 2022, Mount Polley Mining Corporation (MPMC) requested WSP Golder to advance studies to support the co-disposal of tailings excavated from Springer Pit in the Southeast Rock Disposal Site (SERDS) and to advance the design of a raise of the TSF embankment above elevation 970 m. Approximately 63 million tonnes of tailings are planned to be produced till the end of operations at Mount Polley mine (approximately 8.5 years of production at about 20,000 tonnes per day). This represents about 13 million tonnes more (about 18% more) than the life of mine plan considered at the time of preparation of the 2015 siting and deposition technology review.

The Health, Safety and Reclamation Code (HSRC) for mines in British Columbia (EMLI 2021) requires that an alternatives assessment for storage of tailings be submitted as part of the mine permit application. This technical memorandum has been prepared to update the alternatives assessment completed in 2015 and includes co-disposal of hydro-cyclone underflow in the SERDS as an alternative for tailings storage.

1.0 SITE AND TECHNOLOGY SELECTION OBJECTIVES

In selecting potential locations and technologies for the storage of tailings, the following objectives are to be met (BCMEM 2016):

- Provide secure and permanent storage facility
  - Physical stability
  - Chemically and biologically stable, or be designed to mitigate transport of contaminants into the receiving environment
- Minimize additional land disturbance (additional footprint of the facility)
- Maximize in-pit or underground backfill
- Minimize impacts to receiving environment
- Minimize social impact (e.g., negative public perceptions, disruption of traditional land use)
- Minimize cost, including the costs for investigation, design, procurement, construction, operation, and closure
- Incorporate post-closure land use objectives
- Limit the amount of free water within the impoundment

Typically, a single consolidated TSF is preferred over multiple smaller TSFs; however, there are cases where multiple TSFs may be the preferred option. Reasons to consider multiple TSFs include:

- Separation of tailings streams with different geochemical characteristics
- Using tailings as mine backfill (i.e., maximize in-pit or underground backfill)
- Location (e.g., relative to property boundaries, proximity to downstream receptors, ore body)

2.0 POTENTIAL SITES

The potential locations identified for tailings include surface disposal in the existing TSF or in a newly constructed TSF, co-disposal with waste rock (e.g., SERDS or TSF buttress), disposal in the underground mine workings, disposal in an open pit, or lake deposition. The following is a list of potential sites which can be considered for tailings deposition. The potential locations are shown in Figure 1.

- **Existing TSF**—Provide capacity by raising the facility to about elevation 987. The primary advantages of using the existing TSF are:
  - A relatively small additional footprint will be required.
  - The foundation conditions at the TSF have been thoroughly investigated and are well understood.
  - Limited additional infrastructure is needed.

- The primary disadvantages of using the existing TSF are:
  - Negative social perception due to raising the existing TSF.
  - Risk of failure due to internal erosion can be managed by constructing upstream drains, maintaining the pond away from the embankments, and limiting the amount of free water within the facility.
  - Some of the downstream infrastructure (i.e., seepage collection ponds, water treatment plant, powerlines, and access roads) may need to be relocated.
- **New TSF location**—Construct a new TSF at one of the identified potential locations shown in Figure 1. The size and configuration of a new TSF would be dependent on the tailings deposition technology; however, in general, the required area for any technology would be similar. Considering that about 49 million tonnes of tailings will require storage (assumes that about 14 million tonnes are deposited within the permitted elevation 970 m TSF), and that the achieved dry density will be in the range from about 1.35 t/m^3 for slurry deposition to 1.7 t/m^3 for filtered tailings, the volume of tailings to be stored would be in the range of 29 to 36 million m^3. Assuming an average tailings thickness of 20 m for an embankment height of about 30 m, the new TSF would require an area of about 150 to 180 ha. The primary advantages of developing a new TSF are:
  - Positive social perception due to not raising the existing TSF.
- The primary disadvantages of developing a new TSF are:
  - A large footprint would be required for the new TSF, in the order of 65 to 80% the size of the existing TSF.
  - Additional land disturbance will be required for the new borrow areas for dam construction materials, for access roads, for tailings and water conveyance corridors, and for seepage collection and water management ponds.
  - Increased catchment area and volume of water to be managed and treated.
  - A detailed site investigation will be required to characterize the foundation conditions at the new TSF location, which will likely also be partially underlain by glaciolacustrine soils.
  - Costs of construction and closure of a new facility and associated infrastructure (e.g., powerlines, access roads, tailings and water conveyance corridors, seepage collection and water management ponds).

Figure 1: Potential locations for a future tailings storage facility

- **Co-disposal with waste rock**—Disposal of tailings and waste rock in one facility or area. There are many different forms of co-disposal with varying degrees of mixing, physical arrangement, and mixture ratio of tailings to waste rock. Options include the paste rock blended concept, thickened tailings in cells in the waste rock dump, or cyclone underflow (coarse tailings) in the waste rock dump with the cyclone overflow (fine tailings) in a separate TSF.

As part of plans to restart mining operations, MPMC requested WSP Golder to advance studies to support the co-disposal of tailings from Springer Pit in the SERDS (Golder 2022). A similar concept could be considered for placement of the cyclone underflow within the SERDS or TSF buttress; however, the cyclone overflow would still require to be stored within an alternate location (e.g., existing TSF). The cyclone underflow to be co-disposed with waste rock could account for approximately 10% to 30% of the total tailings and will be dependent on the tailings gradation and the underflow gradation requirements. The advantages/disadvantages of co-disposal of tailings and waste rock depend on the tailings technology (e.g., hydro-cycloned tailings, filtered tailings) and are discussed in Sections 4.2 and 4.5.

- **Lake deposition**—Tailings deposition into an existing lake such that the tailings remain below the lake level. Nearby lakes include Polley Lake, Bootjack Lake and Quesnel Lake. This alternative results in a physically stable facility. Acid generation is prevented, which is not a concern for the Mount Polley tailings. The primary advantages of depositing the tailings in a lake are:
  - Minimal additional infrastructure required.

  The primary disadvantages of depositing the tailings in a lake are:
  - Increased footprint and loss of fish habitat.

- Impact on recreational area and negative social perception.
- Increased catchment area and volume of water to be managed and treated.
- a detailed site investigation will be needed to characterize the foundation conditions where retaining embankments will be required, which will likely also be partially underlain by glaciolacustrine soils.

- **Open pit deposition**—Deposition of tailings into an inactive, mined-out pit. The tailings are typically placed sub-aqueously (i.e., deposited under water). After deposition, the solids settle out and the supernatant water can be recycled for use within the mill or treated and discharged from the site. This is a favorable alternative providing a physically stable location without increasing the disturbed footprint.

  Three open pits exist at the Mount Polley mine site; however, Springer and Cariboo pits are part of the active mining operation and Wight Pit is used as part of the site-wide water management. Bullion Pit is a potential site for disposal of tailings from Mount Polley, which would allow to restore the pit to a more natural landform than the present condition. A dam would be required to form a closed perimeter around Bullion Pit. The primary advantages of depositing the tailings in an open pit are:

  - Uses footprint of previously mined area.

  The primary disadvantages of depositing the tailings in an open pit are:

  - Bullion pit is considered a heritage site and tourist attraction in the area.
  - Additional land disturbance will be required for the new borrow areas for dam construction materials, for tailings and water conveyance corridors, and for seepage collection and water management ponds.
  - Increased catchment area and volume of water to be managed and treated.
  - A detailed site investigation will be needed to characterize the foundation conditions where a retaining embankment will be required.
  - Costs of construction and closure of a new facility and associated infrastructure (e.g., powerlines, tailings and water conveyance corridors, seepage collection and water management ponds).

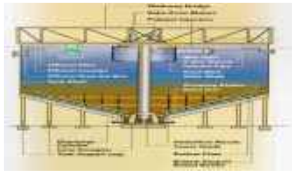
- **Underground disposal—**Tailings may be placed underground in mined-out areas as a means of tailings disposal only, or tailings may be incorporated in the mining process as a backfill material. The required strength of the backfill can vary from negligible (where the only objective is to fill voids) to several megapascals (where the backfill is required to provide structural support to allow for ongoing underground mining). In active mining environments, a maximum of about 50% of the tailings can be placed underground because of the higher porosity of the tailings relative to rock. The current Mount Polley mine plan does not include underground mining and the current underground at Wight Pit could only take a small proportion of the tailings generated. This alternative is not further assessed given the current plans at Mount Polley Mine.

3.0 TAILINGS MANAGEMENT TECHNOLOGIES

The available tailings management technologies are differentiated primarily by the water content of the tailings, which determines the transportation method and the deposition method. Mineral processing commonly results in tailings with solids contents in the range of 30% to 50%. Dewatering of the tailings can be carried out to increase the solids contents of the tailings. This may be done for water management reasons or for tailings management reasons. Similarly, tailings can be sorted into coarse and fines portions to reduce the volume of tailings to be stored in a tailings dam and potentially using the coarse fraction for construction. Examples of dewatering and sorting technologies are shown in Table 1. A summary of the difference between the technologies according to operational criteria is shown in Table 2.

Each technology is explained in more detail in the sub-sections below.

Table 1: Technology, Tailings Consistency, and Conveyance Technology



Dewatering/Sorting Technology	Tailings Consistency	Conveyance Technology
Conventional thickener 	Slurry 30% to 80% solids 	Gravity pipeline or launder, low pressure pipeline, with or without centrifugal pumps 
High-rate thickener 	High density slurry 55% to 65% solids 	Centrifugal pumps or piston diaphragm pumps 
Deep bed thickener, deep cone thickener 	Low density paste 60% to 70% solids 	Piston diaphragm pumps (high pressure) 
Filter 	High density paste 65% to 75% solids 	Dual positive displacement pumps with high-pressure steel pipelines 
Filter 	Filter cake >80% solids 	Truck or conveyor 
Hydro-cyclone 	Underflow: low to high density paste Overflow: slurry	Underflow: mechanically placed or positive displacement pumps. Can be diluted and conveyed in low pressure pipeline. Overflow: gravity pipeline, low pressure pipeline, with or without centrifugal pumps

Table 2: Comparison of Tailings Technologies According to Operational Criteria

Criteria	Conventional Slurry	Hydro-cycloned tailings (overflow ~70-90%)	Thickened Tailings	Paste	Filtered Tailings
Pumpability / Conveyance	Gravity flow or centrifugal pumps	Overflow: gravity flow or centrifugal pumps Underflow: mechanically placed or positive displacement pumps. Can be diluted and conveyed in low pressure pipeline.	Gravity flow or centrifugal pumps to piston diaphragm pumps	High pressure positive displacement pumps	Not pumpable, can be transported on trucks or conveyors
In-situ density after deposition	Tailings segregate during deposition resulting in areas with fine tailings and low density	Overflow: Deposition of slurry with low solids content and fine tailings results in low density Underflow: Can be mechanically compacted to achieve highest density	Possible to deposit tailings without segregation and achieve a more uniform deposit with higher density	Tailings can be deposited without segregation and achieve a uniform deposit with higher density	Can be mechanically compacted to achieve highest density
Supernatant water	Low solids content and tailings sedimentation, settlement, and consolidation releases highest volume of water during deposition	Hydro-cyclone does not recover water from the tailings. Highest volume of water remains in the overflow and is released during deposition.	Water recovered from the tailings in the thickener; thickened tailings release less water during deposition	More water recovered from the tailings in the thickener; paste tailings release less water during deposition	Highest amount of water recovered from the tailings in the filter plant; no water released from the tailings during deposition
ARD management	ARD management depends on the specific design of the facility				
Technology and conveyance costs	Lower	Low	Medium	High	Highest
Tailings beach slopes	Flatter 0.3% to 1.5%	Overflow: Flatter < 1% Underflow: can be mechanically placed and compacted at stable angles	Steeper 0.7% to 2%	Steeper 1% to 10%	Tailings mechanically placed and compacted at stable angles

Note: Green cells represent a favorable condition, while red cells represent a less favorable condition. The darker the shade of green or red, the more or less favorable the condition.
ARD = acid rock drainage.

3.1 Low Solids Content (Conventional) Slurry Deposition

Transport and deposition of tailings as a slurry (mixture of water and tailings solids) is commonly used in combination with wet ore mineral processing techniques. This method has been used at the Mount Polley Mine to deposit tailings into the TSF and Springer Pit.

The tailings are transported from the mill to the TSF in a pipeline or open launder chutes and deposited from a single point discharge or from multiple spigots. The deposition can be subaqueous or subaerial, but typically a subaerial beach is developed during the deposition sequence. The coarser fraction of tailings drops out near the discharge to form a beach and the finer fraction is carried to the supernatant pond. The tailings beach slopes typically range between 0.3% and 1.5%. At the Mount Polley TSF, the tailings beach slope has been surveyed to be in the order of 0.5% to 1.0%.

A supernatant pond is typically present within the facility, from which water is decanted by means of a floating barge or decant tower. The pond is maintained on the tailings and is necessary for sedimentation and settling. The size of the pond can be limited to that needed for operation of the water reclaim system. The process water requirements can be supplemented by an alternative source or by having an independent process water pond. Since the restart of operation at the Mount Polley TSF in 2016, the supernatant pond has been maintained on the northwest side of the facility, towards the natural ground and away from the embankments.

The consolidation process increases the density of the tailings, releasing water to the pond, internal drainage in the facility or to the foundation. The typical achieved settled average dry density is in the range of 1.3 to 1.7 t/m^3, depending on the tailings (e.g., mineralogy, grind, and clay content). At the Mount Polley TSF, the average density of the tailings deposited as a slurry is estimated to be about 1.35 t/m^3.

Containment dams can be constructed of earthfill, rockfill (potentially mine waste rock), or sand separated from the tailings using hydro-cyclones, with the design of the dams carried out to suit the characteristics of the site and the mining operation.

3.2 Hydro-cyclone Classified Tailings

Hydro-cyclones are used to separate the tailings into a fine (overflow) and coarse (underflow) fractions. The hydro-cyclones can be selected to produce a coarse fraction with a specified gradation (e.g., sand). The coarse fraction can be transported in pipelines and deposited from spigots or spreader bars and it can be compacted to achieve a dilative, non-liquefiable material. The sand can also be dewatered on screens and transported by truck or by conveyor belt. The fine fraction is typically transported by pipeline and deposited as a low solids content slurry in an impoundment.

The advantages of separating the coarse and fine fractions of the tailings include reducing the volume of tailings to be stored behind a tailings dam and potentially using the coarse fraction for construction of the dam. The disadvantages include flatter beach slopes, lower hydraulic conductivity and lower strength of the fine tailings deposited on the tailings dam. If hydro-cyclones are used at Mount Polley, the underflow would be disposed in the SERDS or TSF buttress and the overflow is deposited in the existing TSF.

The tailings beach slope in the TSF is expected to be flatter and the capacity to maintain a pond away from the embankments would be reduced and possibly eliminated. Assuming an average 0.5% tailings slope above and below water, it is estimated that:

- A maximum 100 m tailings beach could be maintained around a 1.5 Mm^3 TSF pond with a high level of deposition control.
- A pond with a size on the order of 2 Mm^3 would encroach onto the embankments.

The hydraulic conductivity of the fine tailings deposited in the TSF would be lower; therefore, the effectiveness of the upstream drain to control the water level and limit the hydraulic gradient across the embankments would be reduced and reliance on high-quality site-wide water management and tailings deposition would increase. It is estimated that the hydraulic conductivity of the fine fraction of the tailings could be 2 orders of magnitude lower (10^{-8} m/s) than the hydraulic conductivity of the tailings that have deposited near the embankment during deposition of the combined coarse and fine fractions of the tailings.

The change to hydro-cyclones would likely require a change to site water management practices. Based on challenges to manage site water in recent years, uncertainties on the actual tailings beach slope and capacity to maintain the pond away from the embankments, it is the opinion of the Mount Polley TSF EoR that alternative locations to manage site water outside of the TSF would be required if hydro-cycloning was implemented.

Dams constructed from cycloned sand include: the Gibraltar and Highland Valley Copper LL tailings dams in BC; Cerro Verde in Peru; and El Mauro, Las Tortolas, and Ovejeria dams in Chile. The Caserones Copper project in Chile places cyclone sand in a separate sand stack area and contains the cyclone overflow fines behind a rockfill dam.

3.3 Thickened (Non-Segregating) Tailings

Thickening of tailings involves placing slurry tailings in a tank, allowing the solids to settle to the bottom and be removed while water is removed from the top of the tank. Mechanical rakes and/or chemical additives are often required to increase the settling rate of the solids. The additives may be flocculants, coagulants, or a combination of both.

The tailings are typically deposited down a slope from several discharge points, with the tailings confined by a retaining dyke at the foot of the slope. Thickened tailings are generally non-segregating when deposited and form a homogenous mass.

Thickened tailings will bleed some water when deposited, but much of the process water is retained as part of the thickening process. Although a supernatant pond may not be formed, the TSF will still require surface water runoff and seepage management systems. A secondary facility for re-circulation of water may still be required.

The advantages of thickened tailings over conventional tailings typically include higher water recovery before transport and deposition and lower losses (relevant to sites with negative water balances, not surplus conditions as present at Mount Polley), increased storage capacity due to slightly higher settled density and steeper tailings slopes. The disadvantages include higher operational costs (processing and pumping). In areas with large earthquakes, structures to contain all the tailings may be required if liquefaction of the tailings can occur.

Examples of thickened tailings discharge include Kidd Creek Mine, Timmons, Ontario; Peak Mine, Australia; Century zinc mine, Australia; Osborne Mine, Australia; Falconbridge Strathcona mine, Sudbury, Ontario; Musselwhite mine, northwest Ontario; Essakane, Burkina Faso; and the Porgera Gold Mine, Papua New Guinea.

3.4 Paste

Paste tailings typically have solids contents of between 60% and 70% and are pumpable using high pressure pumps, are non-segregating, and typically do not release water. Paste tailings are achieved by a combination of mechanical devices (such as deep cone thickeners) and chemical additives including flocculants.

Paste tailings are frequently used for backfilling underground mine workings (often combined with cement and/or fly ash), but surface disposal of paste tailings is also possible.

Paste tailings can be transported using pressure pipelines to the storage area. Containment facilities are still required for the management of surface water from precipitation, although due to the increased density and increased slope of deposition of the tailings, the size and/or height of the facilities may be reduced compared to slurry type methods of disposal.

Paste tailings have typically been more considered for surface disposal in arid climates with limited water availability. Careful control of the thickener is required to obtain consistent rheology that will give consistent deposited slopes. Changes in the mineralogy, grind, and temperature can affect the rheology. Steeper deposition slopes can be achieved. These steeper slopes can produce inefficient filling for valley containment systems.

Examples of mines that use the paste technology for tailings deposition include Bulyanhulu, Tanzania; Myra Falls, BC; Esparanza, Chile; and Cobriza mine, Peru.

3.5 Filtered Tailings

Filtered tailings are produced using mechanical devices (e.g., high-capacity vacuum and pressure belt filters), often in combination with chemical additives. The tailings are usually dewatered in a high rate thickener to feed the filters. After filtration the tailings have about 80% to 85% solids and are too thick to pump. Instead, they are transported by truck or conveyor system and then stacked. Filtered tailings that are stacked are not dry, but rather have moisture contents at or near saturation.

Typically, filtered tailings are placed, spread, and compacted to form an unsaturated dense and stable stack. No additional containment structures, such as dams, are required to retain the tailings, though waste rock is typically used on the outer slopes to reduce erosion. These facilities may result in a smaller footprint area due to their increased density. Containment structures may be required to manage runoff and sediment from precipitation. If the stack is placed with bottom-up construction, concurrent reclamation of the tailings can be carried out.

The nature of the tailings produced, both the grain size and mineralogy, can play an important role in determining the effectiveness of filter processing. Tailings with a high percentage of clay-sized particles and with clay mineralogy reduce the efficiency of the filtering process and may result in high energy consumption.

The energy consumption and costs associated with filtration and transportation of filtered tailings are considerably higher than those related to slurry and thickened tailings disposal. Truck transport of the tailings increases the carbon footprint relative to methods using transport in pipelines. This method has mostly been utilized in specific conditions where water conservation is critical or only a small footprint is available.

Liners may be installed under the stack if groundwater contaminant could be a problem. Consolidation and downward drainage of the water in the tailings and climate conditions may result in saturated conditions at the base of the stack. Compaction is used to create a non-liquefiable material that will be stable in earthquakes.

Examples of dry stack tailings facilities are Greens Creek mine, Alaska; Raglan, Quebec; Mineral Hill, Montana; La Coipa, Chile; Pogo mine, Alaska; and Cerro Lindo, Peru. The Cerro Lindo tailings facility has a 30 m high water management dam located downstream of the tailings area.

4.0 ASSESSMENT OF TAILINGS MANAGEMENT ALTERNATIVES

The term BAT (best available technology) does not represent any one specific technology that can be applied to every situation. Rather, the technology must match the specific site conditions and the mining situation. The purpose of evaluating alternative technologies in this instance is to identify the preferred method of providing reliable containment of the tailings that will be produced from the remaining life of the Mount Polley Mine (approximately 8.5 years at about 20,000 tonnes per day). Chemical stability of the tailings is less of a concern due to the nature of the Mount Polley tailings. The conservation of water, which is a benefit of thickened and filtered tailings, is not an advantage at Mount Polley due to the net water surplus on the mine site that requires ongoing discharge of water from the site.

The open pits at the Mount Polley Mine are still being actively mined or used for water management and are, therefore, not available for tailings storage. The underground workings could only take a small proportion of the tailings and are used as part of the site water management.

The potential sites, and the potential technologies that could be applied to each site, are summarized in Table 3.

Table 3: Applicability of Tailings Technology to Potential Locations

Site	Conventional Slurry	Hydro-Cycloned Tailings	Thickened Tailings	Paste	Filtered Tailings
Existing TSF	●	●	●	●	●
New TSF	●	●	●	●	●
SERDS co-disposal		● (only underflow, after dewatering by screening)			●
Polley/Bootjack/Quesnel Lakes	●		●		
Bullion Pit	●	●	●	●	●

The options that could accommodate the required volume of tailings were evaluated against the following criteria:

- Environmental
  - Overall affected land footprint size of facility, including related infrastructure (e.g., borrow areas, access roads, power, tailings and water conveyance corridors, seepage collection and water management ponds)
  - Aquatic habitat
- Technical
  - Understanding of foundation conditions

- Socio-economic
  - Public perception as it relates to TSF failure in 2014
  - Maintenance of traditional lifestyle and land use (e.g., loss of access, loss of fishing area, recreation/tourism)
- Project economics
  - Life of mine cost, including construction, operation, and closure
  - Economic risks (e.g., time to start operation)

The five groups of sites have been evaluated based on the required objectives identified, as shown in Table 4.

Physical stability has not been included as a criterion because all potential alternatives can be designed to have a similarly low likelihood of failure. The consequence of failure is related to downstream receptors and the amount of water and eroded tailings that could be released in the event of a failure.

The advantage of paste or filtered tailings is to reduce the consequence of failure by eliminating the supernatant pond that forms when water is released from the tailings, and to increase the placed density of the tailings which reduces the mobility of the tailings in the event of a failure.

If conventional tailings are deposited within the existing TSF, the risk and consequence of failure can similarly be reduced. This can be achieved by implementing BAP (best applicable practices), and following the principles set out in the Independent Expert Engineering Investigation and Review Panel (IEERP) report of January 2015:

- Limit the amount of surface water to only that required for operation – The supernatant pond volume can be maintained within defined limits by having a water management plan, a secondary water storage facility for excess water if required, and water discharge through a spillway. These measures will reduce the risk of overtopping and limit the consequence if failure occurs.
- Promote unsaturated conditions in the tailings with drainage provisions – A minimum beach width is maintained between the embankment and the pond and an upstream drain can be constructed upstream of the embankment. This will result in a portion of the tailings being in an unsaturated condition. The upstream drain at the Corner 1 embankment has performed as intended allowing seepage and maintaining the tailings above the elevation of the drain in an unsaturated condition.
- Achieve dilatant conditions throughout the tailings deposit – The existing tailings within the TSF drained and consolidated after the TSF breach in 2014. Construct drainage through the embankment raise to allow seepage from the facility and promote consolidation of the tailings.

Based on the above, it is considered that tailings management with the goal to improve stability can be realized with tailings slurry deposition, as with alternative technologies such as thickened tailings, paste or filtered tailings. The tailings breach on 4 August 2014 was due to inadequate characterization of the foundation conditions. The foundation conditions and material strengths are now well understood. Implementation of the BAP and the ability to discharge water will limit the volume of water in the TSF.

Table 4: Evaluation of Tailings Storage and Disposal Alternatives

Location	Technology	Environmental Aspects (Additional Disturbed Footprint)	Technical Aspects (Understanding of Foundation Conditions)	Social Impact (Public perception and maintenance of traditional land use)	Economic Impact (Life of mine cost and time required for implementation)
Existing TSF	Low density slurry tailings	**Small footprint change (<50 ha)** Use of existing footprint	**Foundation conditions well understood** Considerable geological interpretation, investigation, and laboratory testing has been performed	**Negative perception** Use of the same facility and technology as prior to the breach	**Low cost** Limited additional infrastructure required Buttresses needed to achieve target levels of stability
	Thickened tailings			**Better perception** Use of the same facility but reducing surface water	**Increased capital and operating costs; longer time required for implementation** Procurement, construction, and operation of thickener Increased pumping cost Buttresses needed to achieve target levels of stability
	Filtered tailings	**Small footprint change (<100 ha)** Use of existing footprint but new water management pond required outside of TSF		**Better perception** Use of the same facility but reducing surface water	**Highest capital and operating cost; longest time required for implementation** Construction costs of new water management pond Procurement, construction, and operation of filter plants Trucks to haul tailings; dozers and graders to spread tailings Buttresses needed to achieve target levels of stability
Existing TSF and SERDS co-disposal	Hydro-cyclone underflow (SERDS/TSF buttress), overflow (TSF)	**Small footprint change (<100 ha)** Use of existing footprint but new water management pond required outside of TSF	**Foundation conditions well understood** Considerable geological interpretation, investigation, and laboratory testing has been performed at the existing TSF. Additional SERDS foundation investigation in progress.	**Negative perception** Reduction of tailings to be stored but uses the same facility	**Increased capital cost** Construction costs of new water management pond Buttresses needed to achieve target levels of stability Dozers to spread tailings
New TSF	Low density slurry tailings	**Large footprint increase (>200 to 300 ha)** Use of undisturbed area for new TSF, access roads, water management ponds, pipeline corridors, and surface water diversion ditches	**Limited information of foundation conditions** Foundation conditions likely to be geologically similar to those at existing TSF. Detailed investigation required to characterize foundation, in particular location and characteristics of glaciolacustrine soils.	**Positive perception** New facility; failed embankment not part of future TSF	**Increased capital cost** Construction, operation, and closure costs for new facility
	Hydro-cyclone overflow and underflow				
	Thickened tailings			**Positive perception** New facility and reduced surface water stored in the TSF	**Increased capital and operating costs; longer time required for implementation** Construction, operation, and closure costs for new facility Procurement, construction, and operation of thickener Increased pumping cost
	Filtered tailings				**Highest cost; longest time required for implementation** Time and cost for site investigation and design. Construction, operation, and closure costs for new facility Procurement, construction, and operation of filter plants Trucks to haul tailings; dozers and graders to spread tailings Construction costs of new water management pond

Table 4: Evaluation of Tailings Storage and Disposal Alternatives

Location	Technology	Environmental Aspects (Additional Disturbed Footprint)	Technical Aspects (Understanding of Foundation Conditions)	Social Impact (Public perception and maintenance of traditional land use)	Economic Impact (Life of mine cost and time required for implementation)
Bullion Pit	Low density slurry tailings	**Medium to large footprint increase** Use of an existing footprint disturbed by previous mining activities but new borrow areas, access roads, power, tailings and water conveyance corridors, surface water diversion ditches, seepage collection and water management ponds would be required	**Limited information of foundation conditions** Detailed investigation to characterize foundation where retaining embankments will be required; however, geological conditions are expected to be more favorable.	**Negative perception** Bullion pit considered a heritage site and tourist attraction for Likely	**Increased cost** Construction of new infrastructure, including tailings and water pumps and pipelines, high dam, seepage cutoff, and collection system to prevent water loss to Quesnel River
Quesnel, Bootjack or Polley Lake	Low density slurry tailings	**Large footprint increase and loss of aquatic habitat** Use of undisturbed or partially undisturbed aquatic habitat.	**Limited information of foundation conditions** Foundation conditions likely to be geologically similar to those at existing TSF. Detailed investigation to characterize foundation where retaining embankments will be required, in particular location and characteristics of glaciolacustrine soils.	**Negative perception** Loss of fish habitat; loss of recreational area	**Low cost** Minimal additional infrastructure required
SERDS co-disposal	Filtered tailings	**Minimal footprint change** Potential footprint increase of waste dump.	**Foundation conditions reasonably well understood** Additional SERDS foundation investigation and characterization in progress. Investigation of footprint expansion required.	**Positive perception** New facility and technology that reduces surface water.	**Highest cost; longest time required for implementation** Procurement, construction, and operation of filter plants Trucks to haul tailings; dozers and graders to spread tailings

5.0 FINDINGS

The following observations have been made regarding the range of options considered:

- The best available option is to store the tailings to be produced in the remaining life of mine within the existing TSF as conventional slurry.
  - The existing TSF has the best-studied foundation conditions of any of the potential TSF locations.
  - Conventional tailings can be operated in a manner that reduces both the likelihood (conservative assessment of soil strength and adoption of conservative design criteria resulting in wide buttresses along the embankments) and consequence of failure (wide beaches, relatively dense tailings, and a small pond volume) provided that accumulation of water does not occur.
- Separating the tailings into fine (overflow) and coarse (underflow) fractions with hydro-cyclones could reduce the amount of tailings to be stored in the TSF by 10 to 30% (i.e., in the order of 2 to 6 m embankment height) if the coarse fraction is placed in the SERDS or TSF buttress; however, a separate water management pond with a storage capacity of about 4 Mm^3 to manage the 1-in-200-year freshet volume would be required (e.g., facility with a dam height in the range of 20 m). A separate water management pond would require significant investigation (foundation conditions would be required to be characterized to a sufficient level to enable appropriate design), add to the disturbed area of the mine, and require more closure work at the completion of mining.
- Thickened tailings offer limited advantages over conventional tailings. The mine site has an overall positive water balance, and freshet water management would be carried out using the TSF, similar to the conventional tailings option. The maximum pond size is controlled by run-off during freshet and not by the needs of the mine operation (i.e., saving water at the mill by thickening does not offer an advantage).
- The high capital cost of a filter plant may not be economic given the relatively short remaining life of the mine. A separate water management pond with a storage capacity of about 4 Mm^3 to manage the 1-in-200-year freshet volume would also be required (e.g., facility with a dam height in the range of 20 m).
- A new land-based TSF footprint is unlikely to offer advantages over the existing TSF footprint. The failure that occurred in the existing TSF was caused by a combination of inadequate understanding of the foundation conditions, inappropriate analysis of the range of loading conditions, and the construction of steep fill slopes. The foundation conditions of the existing TSF can accommodate additional dam construction, providing that the slopes of the dams are matched to the foundation strengths. Each of these issues can therefore be addressed by appropriate design at the existing TSF site. Using a different land-based site would require significant investigation (foundation conditions would be required to be characterized to a sufficient level to enable appropriate design), add to the disturbed area of the mine, and require more closure work at the completion of mining.
- The only advantage to using the Bullion Pit is that an area with significant historical mining disturbance could be restored to a landscape similar to the pre-mining condition. The delay to the mine operation related to the investigation and design of the containment structures and the seepage control system to minimize water loss to the Quesnel River, coupled with the increased costs for transporting the tailings to the Bullion Pit and water from the Bullion Pit to the mine and the need for an environmental impact assessment, make this alternative unattractive, and, likely would prevent continuation of operations.
- Deposition of tailings in lakes provides numerous advantages in terms of the physical stability of tailings. Deposition of tailings in lakes is an appropriate option for some situations; however, the permitting of such facilities is difficult, particularly when the lakes provide habitat for fish. This is the case for all of the potential

lakes that could be considered. Polley Lake is judged to be more likely to be considered for tailings deposition than other lakes in the area but given the trout population in Polley Lake it is considered to be a less favorable site than an on-land site.

6.0 RECOMMENDATIONS

It is recommended that the tailings produced in the remaining life of the Mount Polley mine be transported as conventional (slurry) tailings to the existing TSF and be managed using BAPs. These would include the following:

- Routine and sustained discharge of mine water such that the volume of water stored in the TSF is maintained low
- Managing the pond in the TSF such that beaches are maintained against the containing embankments throughout the operational life of the TSF
- Providing drainage to promote the desaturation and densification of the tailings.

Glaciolacustrine (Main Embankment) and low plasticity silty clay (South Embankment)		20	0.2	Peak: $T = 0.22\ \sigma_v' \ OCR^{0.71}$, where σ_p' = 1,200 kPa
Glaciolacustrine (Main Embankment - approx. El. 922 m Stn. 2+400 and 2+750)		20	0.2	Peak: $T = 0.22\ \sigma_v' \ OCR^{0.71}$, where σ_p' = 850 kPa
Upstream Fill		20	-	Mohr-Coulomb: φ = 32°; *c* = 0 kPa
Till Core		20.5	-	Mohr-Coulomb: φ = 33°; *c* = 0 kPa
Filter		20	-	Mohr-Coulomb: φ = 30°; *c* = 0 kPa
Transition		20	-	Shear-Normal Function: $T = 1.726\ \sigma'^{0.899}_n$
Rockfill		21.5	-	Shear-Normal Function: $T = 1.726\ \sigma'^{0.899}_n$
Tailings		17	-	Mohr-Coulomb: φ = 25°; *c* = 0 kPa Undrained: $\tau / \sigma'_v = 0.1$

REFERENCES/NOTES

1. B-bar values were assigned to the till, glaciofluvial and glaciolacustrine for the short-term static case to account for excess pore water pressures that may be generated during construction.
2. For pseudo-static loading condition, GLU shear strength reduced to 80%.

STRESS-DEFORMATION ANALYSES OF THE ELEVATION 974 M TAILINGS STORAGE FACILITY AT MOUNT POLLEY MINE

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) has retained WSP Canada Inc. (WSP) to complete a detailed design to raise of the tailings storage facility (TSF) at the Mount Polley Mine. The design to support raising the TSF from its currently permitted elevation of 970 m to a crest elevation of 974 m is presented in WSP (2024). The design crest elevation 974 m is an interim design to enable the TSF to be raised whilst design efforts for a potential raise of the TSF to contain the life of mine tailings is advanced.

This report summarizes the results of stress-deformation analyses carried out on two (2) sections of the TSF to support the detailed design for the raise of the TSF to elevation 974 m. The analyses were based on two-dimensional finite difference models developed using the commercially available computer code FLAC Version 8.1 (Cundall 2012). The objectives of the analyses are:

- Assess the stability of the embankments at the end of construction up to elevation 974 m.
- Evaluate the seismic stability, and potential level and pattern of deformation under the 2,475-year earthquake load.

The analyses were carried out for two (2) design earthquake motions selected from eleven (11) acceleration-time histories from crustal and subduction interface earthquake events and matched to the 2,475-year ground motion spectrum. The design earthquake ground motions generated are presented in WSP (2023a).

This document includes the analysis procedure, characterization of the foundation and embankment materials, and the static and seismic deformation analyses results. This report should be read in conjunction with the detailed design report (WSP 2024) and the most recent TSF site characterization report (WSP 2023a).

2.0 BACKGROUND

The Mount Polley Mine is a copper and gold mine operated by MPMC, a subsidiary of Imperial Metals Corporation. The site is located approximately 56 km northeast of Williams Lake, British Columbia, between Polley Lake and Bootjack Lake. The TSF is located about 3 km southeast of the mill and includes one embankment that is approximately 4.8 km in length. The embankment is subdivided into three sections:

the Main Embankment, Perimeter Embankment, and South Embankment. The embankment has incorporated a staged expansion design utilizing modified centerline and centerline construction methods. The general zoning of the TSF embankment includes the following:

- upstream fill comprising select fill or tailings sand
- low-permeability till core
- filter zone
- transition zone

Rockfill forms the downstream wedge of the embankments and the downstream buttress along the Perimeter and Main embankments.

The Mount Polley Mine began production in 1997 and operated until October 2001 when operations were suspended for economic reasons. In March 2005, the mine restarted and was in operation up to the time of the TSF breach in August 2014. The embankment crest was near elevation 968 m at the time.

In 2015, the Freshet Embankment was constructed to elevation 950 m through the breach area to allow the capture and temporary storage of the 2015 and 2016 freshet flows. The construction of buttresses along the Perimeter and Main embankments was completed in October 2016 (Golder 2015a, 2017).

The 23 June 2016 amendment of the Mines Act Permit M-200 authorized the return to full operations at the mine, including construction of the TSF design to elevation 970 m (Golder 2015b) and deposition of tailings. Construction to raise the Freshet Embankment at Corner 1 to elevation 970 m started in June 2016. By September 2018, construction of the Perimeter Embankment at Corner 1 had been completed to elevation 968 m (Golder 2019). The raise of the Freshet Embankment is referred to as the Perimeter Embankment at Corner 1.

Mining operations at the Mount Polley mine were halted between May 2019 and Q4 2021 for economic reasons. In June 2022, the mill restarted operations and tailings deposition into the TSF resumed. Construction to raise the South, Main and Perimeter embankments to elevation 970 m was restarted in July 2022 and was completed in 2023. The maximum height of the Main Embankment is about 57 m; the Perimeter Embankment about 42 m and the south embankment about 32 m.

Results of limit equilibrium analyses carried out for the TSF detailed design to elevation 974 m (WSP 2024) indicated that all sections analysed had a factor of safety (FoS) above 1.5 for static conditions and a FoS above 1.0 for pseudo-static conditions and met the design criteria. In this study, stress-deformation analyses were carried out to further confirm the static and seismic stability of the embankments including the potential for strain weakening of glaciolacustrine units.

3.0 PROCEDURE

In general, the stress-deformation analyses included the following:

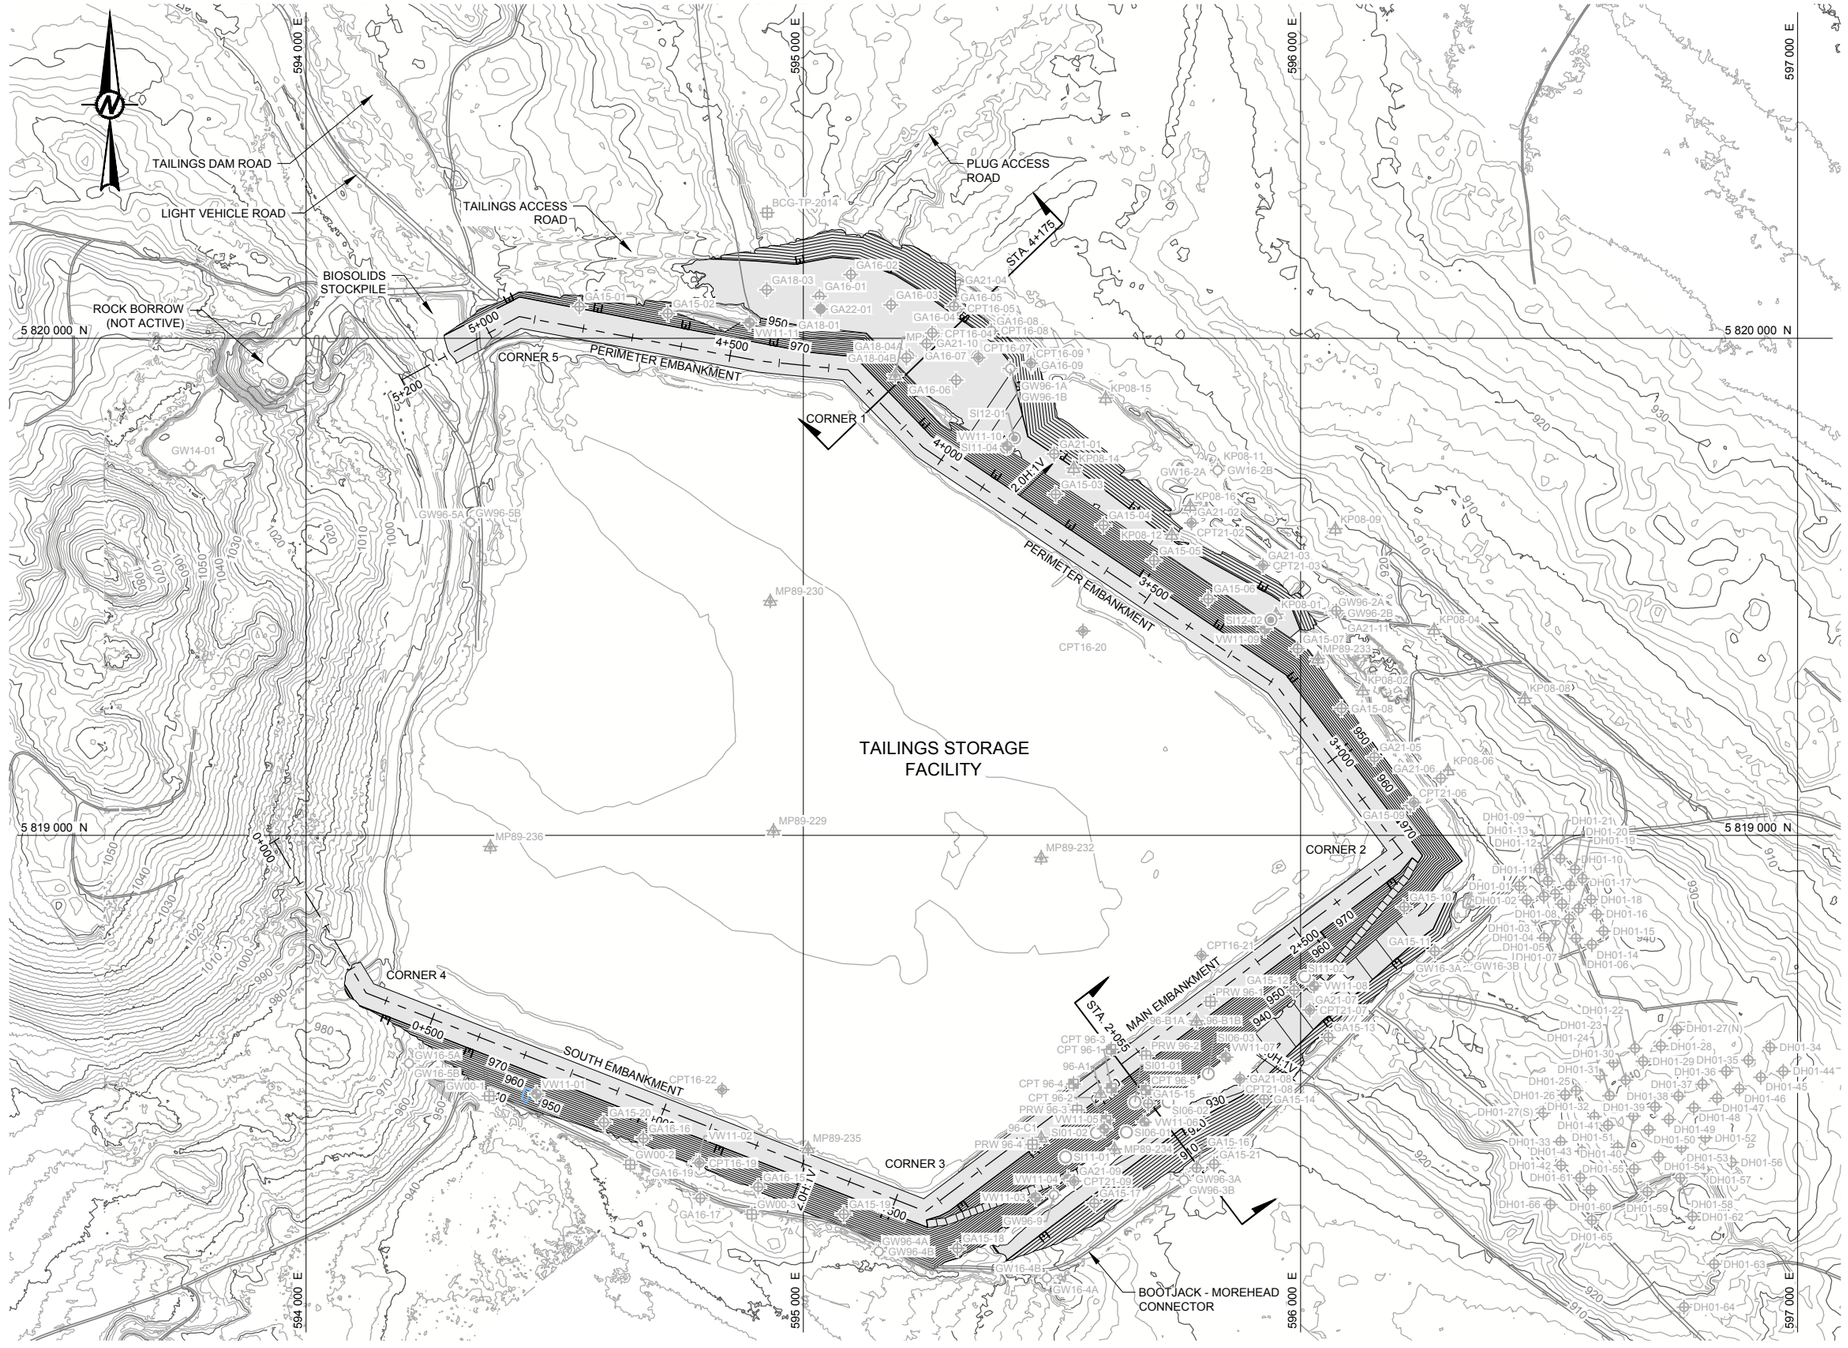
- Selection of the sections of the TSF to be analyzed.
- Characterization of the materials behaviour under static and seismic conditions.
- Selection of constitutive models to reproduce the characteristic behaviour of the materials.
- Development of finite difference models for the selected sections of the TSF.
- Simulation of the staged construction of the embankments up to elevation 974 m.
- Calculation of the factor of safety at the end of construction at elevation 974 m.
- Simulation of the design earthquake motion.
- Evaluation of the seismic stability of the embankments.

Each aspect of the procedure is described in the following sections of the report.

4.0 EMBANKMENT SECTIONS

Glaciolacustrine deposits have been identified along the Main and Perimeter embankments.

The overconsolidated glaciolacustrine deposits at the Perimeter Embankment at Corner 1 are identified as semi-continuous and have the lowest preconsolidation stress in the area of the TSF (WSP 2023). Along the rest of the Perimeter Embankment foundation, overconsolidated glaciolacustrine deposits are not continuous and have been characterized having a higher preconsolidation stress.



A semi-continuous layer of glaciolacustrine soil is present along the length of the Main Embankment foundation. The glaciolacustrine deposit at the Main Embankment has been characterized having the higher preconsolidation stress in the area of the TSF.

A layer of low plasticity silty clay interpreted to have deposited in a glaciolacustrine environment was identified directly above bedrock near Stn. 1+100 at the South Embankment; however, the geotechnical testing completed on the material showed that it is not representative of the intermediate or high plasticity glaciolacustrine units found at the Main and Perimeter embankments, including at Corner 1.

The stress-deformation analyses were carried out on section 2+055 at the Main Embankment and section 4+175 at the Perimeter Embankment at Corner 1. The section at the Main Embankment represents the tallest section of the facility and includes the semi-continuous layer of glaciolacustrine soil in the foundation. The section at the Perimeter Embankment includes the portion of the foundation that failed in 2014 and that has the glaciolacustrine deposit with lower preconsolidation stress. These sections also correspond to those controlling the design of the buttress at each embankment based on limit equilibrium analyses (LEA). The layout of the TSF and the location of the sections is presented in Figure 1, the geometry of the sections is shown in Figure 2; and the approximate construction sequence and groundwater conditions are presented in Table 1 and Attachment 1. The sections geometry and the construction sequence are based on construction record reports for the Main Embankment

(AMEC 2014, Golder 2017a) and the Perimeter Embankment at Corner 1 (Golder 2015a, 2017b, 2018, 2019); and the detailed design report of the TSF for elevation 974 m (WSP 2024).

The response of piezometers installed within the glaciolacustrine unit at the Perimeter Embankment at Corner 1 indicate that excess pore water pressure generated during construction of the Freshet Embankment dissipated after about one (1) year (WSP 2023a). Based on this, it was assumed in the model that if less than a year passed between construction stages then full dissipation of excess pore water pressure in the glaciolacustrine unit had not occurred (see Table 1).

Note:

(1) Maximum elevation of the buttress.

(2) Water table elevation immediately upstream of the till core. A 100 m long tailings beach was assumed between the embankment and the TSF pond.

(3) Full dissipation of excess pore water pressure not expected before the beginning of the following construction stage.

5.0 MATERIAL CHARACTERIZATION

This section summarizes the geotechnical characterization of the materials for numerical modelling purposes. The TSF site characterization report (WSP 2023a) presents in detail the results of geotechnical testing and interpretation of geotechnical parameters.

The stratigraphic sequence identified in the area of the TSF can be generalized in order of increasing depth as follows:

- embankment materials and tailings
- till
  - glaciolacustrine sub-units
  - glaciofluvial sub-units
- bedrock

At the Perimeter Embankment at Corner 1, two distinct glaciolacustrine units have been identified and characterized separately. The location of the units is shown in Figure 2.

5.1 Foundation Characterization

5.1.1 Bedrock

Generally weathered volcaniclastic conglomerate, volcanic debris or completely weathered bedrock. Results of a downhole seismic test carried out in borehole BH15-10 indicate that the time-averaged shear-wave velocity in the upper 30 m (V_{s30}) of bedrock is about 850 m/s (WSP 2023b). The small strain shear stiffness (G_{max}) of the bedrock was estimated as:

$$G_{max} = \rho_b \cdot (V_s)^2 \qquad \textbf{Equation 1}$$

Where ρ_b is the bulk density and V_s the shear wave velocity, considered equal to the V_{s30}. The static and dynamic shear modulus were calculated as $0.95G_{max}$.

5.1.2 Foundation Till

The foundation till is generally a mixture of gravel, sand and low plasticity fines ranging from silt to silty clay, with consistency ranging from firm to hard. Collected samples showed an average fines content of 50% and an average plasticity index of 11 (WSP 2023a). Effective friction angles were estimated from triaxial tests performed on undisturbed samples at about 34 degrees (BCMEM 2015). Results from pressuremeter testing indicate that the friction angle from the upper till at Corner 1 ranges between 36 and 48 degrees, with an average of about 40 degrees.

The average shear wave velocity measured in downhole seismic tests is about 500 m/s (WSP 2022). The small strain shear stiffness (G_{max}) was calculated using Equation 1 and the static shear modulus was estimated as $0.5G_{max}$.

The shear stress-strain behaviour of the foundation till was characterized using the shear modulus reduction curves presented by Vuccetic and Dobry (1991) for a plasticity index (PI) of 15.

5.1.3 Glaciofluvial Unit

The glaciofluvial unit is generally gravelly sandy silt to silty sand with trace gravel, and an estimated compactness ranging from compact to very dense. Samples tested showed an average fines content of 63% and the fines were generally non-plastic to low plasticity. Shear strength results indicate a peak friction angle of about 35 degrees (WSP 2023a). The shear stress-strain behaviour of the glaciofluvial unit was assumed to be equal to that of the foundation till.

5.1.4 Glaciolacustrine Units

Glaciolacustrine units were identified along the Main and Perimeter embankments. Two distinct glaciolacustrine deposits have been identified at Corner 1 and are referred to as UGLU and LGLU. The UGLU was identified as the soil layer through which the 2014 undrained failure developed and was the focus of subsequent forensic investigations (IEEIRP 2015; KCB 2015a,b). The shear strength of the glaciolacustrine units, except for the UGLU that sheared during the failure in 2014, were characterized based on their preconsolidation stress.

The glaciolacustrine unit at the Main Embankment is generally low to intermediate plasticity clay, with trace to some sand, and consistency ranging from very stiff to hard. GLU samples collected from the Main Embankment showed an average plasticity index of 17.

The UGLU at Corner 1 generally consists of intermediate to high plasticity clay, with trace to some sand, and consistency ranging from firm to stiff. UGLU samples showed an average plasticity index of 27.

The LGLU at Corner 1 generally consists of low to intermediate silty clay to clay, with trace to some sand. LGLU samples showed an average plasticity index of 15.

Results from laboratory and field testing showed different degrees of overconsolidation of the glaciolacustrine units. Table 2 summarizes the vertical effective preconsolidation stress estimated for each unit (WSP 2023a).

Table 2: Vertical Effective Preconsolidation Stress of Glaciolacustrine Units from the Main Embankment and Perimeter Embankment at Corner 1

Location	Unit	Vertical Effective Preconsolidation Stress (kPa)
Main Embankment	Glaciolacustrine Unit (GLU)	1200
Perimeter Embankment at Corner 1	Upper Glaciolacustrine Unit (UGLU)	400
	Lower Glaciolacustrine Unit (LGLU)	700

The overconsolidation ratio (OCR) of the glaciolacustrine units was calculated as follows:

$$OCR = \frac{\sigma'_{vp}}{\sigma'_{vc}}$$ **Equation 2**

Where σ'_{vp} equals the vertical effective preconsolidation stress and σ'_{vc} is the current vertical effective vertical stress.

The peak undrained shear strength ($S_{u\text{-}peak}$) of the glaciolacustrine units was characterized using the SHANSEP (Stress History and Normalized Soil Engineering Properties) method proposed by Ladd and Foot (1974). Results of simple shear tests carried out on undisturbed GLU samples from the Main and Perimeter embankments yielded the following expression for estimating the peak undrained strength ratio ($S_{u\text{-}peak}/\sigma'_{vc}$) (WSP 2023a):

$$\frac{S_{u-peak}}{\sigma'_{vc}} = 0.22 \cdot OCR^{0.71} \qquad \textbf{Equation 3}$$

Undisturbed UGLU specimens from the Corner 1 exhibited a propensity for strain-weakening on shearing during simple shear tests, with an estimated sensitivity of 2 to 3 (KCB 2015a,b). A post-peak reduction in undrained shear strength was observed at shear strains in excess of 5%, and full weakening was attained at shear strains in excess of 60% (Zabolotnii 2020). Figure 3 shows the characteristic strain-weakening function considered for the glaciolacustrine units. Plastic shear strains refer to shear strains accumulated once the peak undrained shear strength is fully mobilized.

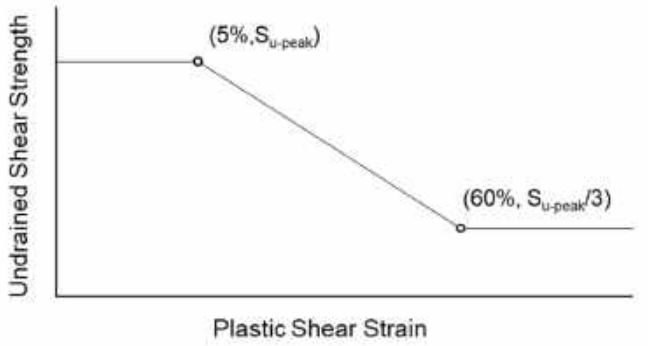

Figure 3: Glaciolacustrine Units Strain-Weakening Function

The UGLU drained peak friction angle was determined as 22 degrees (KCB 2015a,b). Drained shear strength parameters were considered for the portions of the GLU with overconsolidation ratios greater than 3.

The undrained shear strength of the UGLU that sheared during the failure in 2014was modelled constant and equal to 22 kPa, which corresponds to the average minus one standard deviation of the measured remoulded undrained shear strength values from field vane tests and CPTs as part of the forensic investigation in 2014 (WSP 2023a). Since then, the embankment was repaired and constructed to elevation 970 m (approx. 42 m high) over the area of UGLU that sheared. Potential strength gains from reconsolidation of the UGLU that sheared in 2014 have not been included in the characterization.

Shear wave velocity, V_s, of the UGLU and LGLU at Corner 1 was measured during geotechnical investigations with SCPT (BCMEM 2015). Measured V_s ranged between 120 m/s and 350 m/s. A characteristic shear wave velocity of 230 m/s was considered for the glaciolacustrine units. The small strain shear stiffness (G_{max}) was calculated using Equation 1 and the static shear modulus was assumed to be $G_{max}/8$.

Cyclic direct simple shear tests were carried out on undisturbed glaciolacustrine samples from the Main Embankment and Perimeter Embankment at Corner 1 (WSP 2023a). A preliminary assessment indicates factors of safety against cyclic softening generally greater than 1.5 under the 2,475-year earthquake load.

The shear stress-strain behaviour of the glaciolacustrine units was characterized using the shear modulus reduction curves presented by Vuccetic and Dobry (1991) for the average plasticity index (PI) of 15.

5.2 Embankment Materials and Tailings Characterization

Embankment materials were characterized based on the available data from construction monitoring (Golder 2015a; AMEC 2014) and from typical values published in literature.

Shear strength of the rockfill and transition materials was characterized by the average peak friction angle presented by Leps (1970). The peak friction angle, ϕ, of the rockfill and transition is given by:

$$\boldsymbol{\phi = 45.7 - 2.8 \cdot ln\left(\frac{\sigma'_h}{P_a}\right) < 55\ degrees} \qquad \textbf{Equation 4}$$

Where σ'_h is the horizontal effective stress and P_a is the atmospheric pressure.

The shear strength of the till core was measured on the triaxial apparatus on reconstituted specimens of till (KP 1995; BCMEM 2015). The friction angle considered for the till core was 33 degrees.

The friction angles adopted for the filter, upstream fill, and tailings were 30, 32 and 25 degrees, respectively. These values are consistent with the friction angle values used in the limit equilibrium analysis carried out for the elevation 970 and 974 m detailed TSF designs (Golder 2015b, WSP 2024).

The small strain shear stiffness (G_{max}) and static shear modulus (G_{stat}) of the embankment materials and tailings were estimated based on the compaction effort or expected density, from the Mount Polley Mine TSF construction record reports and from typical values obtained from literature (Byrne et al. 1987).

The average elastic modulus (E_0) of the cut-off wall material, estimated from the mix design (Golder 2016), was used to estimate the small strain shear stiffness of the cut-off wall at Corner 1 using:

$$\boldsymbol{G_{max} = \frac{E_0}{(2(1+\nu))}} \qquad \textbf{Equation 5}$$

Where ν is the Poisson ratio, assumed for the cut-off wall equal to 0.25.

6.0 CONSTITUTIVE MODELS

For the simulation of the staged construction of the embankments the elastic-perfectly plastic Mohr-Coulomb model was used to simulate the nonlinear behaviour of the tailings, embankment soils, and the foundation soils non-susceptible to strain-weakening (i.e., GLU with OCR greater than 3, UGLU that sheared in 2014, till and glaciofluvial soils). The strain-softening constitutive model was used to simulate the behaviour of the GLU with overconsolidation ratios less or equal to 3 (OCR≤3). The strain-softening constitutive model is based on the elastic-perfectly plastic Mohr-Coulomb model and allows the definition of the strength parameters (e.g. cohesion) as piecewise-linear functions of a softening parameter measuring the plastic shear strain. The elastic-perfectly plastic Mohr-Coulomb model was used to simulate the nonlinear behaviour of the UGLU that sheared during the failure in 2014 and GLU with overconsolidation ratios greater than 3 (OCR>3). The behaviour of the bedrock and cut-off wall was simulated with the linear elastic model. Table 3 presents the summary of the constitutive models and parameters used for the simulation of the staged construction of the embankments.

The dynamic mechanical response of both the bedrock and the cut-off wall was simulated as linear elastic (see Table 4). The dynamic behaviour of the GLU that sheared during the failure in 2014 and the GLU with overconsolidation ratio greater than 3 was modelled by complementing the linear elastic-perfectly plastic constitutive model with a hysteretic damping model. The seismic response of the GLU with overconsolidation ratios less or equal to 3 was numerically simulated by complementing the strain softening model with a hysteretic damping model. A sigmoidal fitting function was used to represent the characteristic shear stress-strain behaviour of the materials. Table 5 shows a summary of the model parameters used for these materials.

The dynamic response of the foundation till, glaciofluvial and till core was numerically modelled as non-linear, Mohr-Coulomb materials using the constitutive model UBC Hysteretic. In this model, the non-linear response is obtained by modifying the initial tangent shear moduli, that equals the small strain shear modulus ($G_{t\text{-}ini}=G_{max}$), in accordance with a hyperbolic law that depends on the shear strain level. Under cyclic loading, damping is estimated by the hysteretic loops formed by the stress-strain curves. The model input parameters are summarized in Table 6.

The dynamic response of the rockfill, filter, transition, upstream fill, and tailings was numerically modelled using the constitutive model UBCSAND developed to simulate earthquake loading and liquefaction. UBCSAND is an elasto-plastic effective stress model with the mechanical behaviour of the soil skeleton and pore water fully coupled. In UBCSAND, plastic shear induces a change in the soil skeleton volume and, if the pores are filled with water, a change in pore water pressure and effective stress occurs. Details of UBC Hysteretic and UBCSAND models can be found in Naesgaard (2011). The model input parameters are summarized in Table 7.

Table 3: Summary of the Constitutive Models and Parameters Used in the Simulation of the Staged Construction of the Embankments

Description	Constitutive Model	ρ_b (t/m^3)	Shear Strength Parameters		Elastic Parameters (1)			
			c (kPa)	ϕ (°)	$k_{G\text{-}stat}$	n	$k_{B\text{-}stat}$	m
Embankment Materials and Tailings								
Rockfill	Mohr-Coulomb	2.2	0	Equation 4	120	0.4	$8/3k_{G\text{-}stat}$	0.4
Transition		2.0						
Upstream Fill		2.0		32				
Filter		2.0		30				
Till Core		2.1		33	131	0.5		0.5
Tailings		1.7		25	94			
Cut-off Wall	Elastic	2.2	-		$G_{stat}=1.3x10^6$		$B_{stat}=5/3G_{stat}$	
Foundation Materials								
GLU (OCR≤3) (2)	Strain-softening	2.0 (3)	S_u (4)	0	$G_{stat}=1.3x10^4$		$B_{stat}=8/3G_{stat}$	
GLU (OCR>3) (2)	Mohr-Coulomb		0	22				
UGLU that sheared in 2014		1.8	22	0				
Till / Glaciofluvial		2.2	0	34	$G_{stat}=2.8x10^5$		$B_{stat}=8/3G_{stat}$	
Bedrock	Elastic	2.3	-		$G_{stat}=1.6x10^6$		$B_{stat}=8/3G_{stat}$	

Note:

(1) The static elastic shear modulus (G_{stat}) and the static elastic bulk modulus (B_{stat}) were calculated using the corresponding number (k) and exponent (n or m), mean effective stress, p'=(σ'$_1$+σ'$_2$+σ'$_3$)/3; and atmospheric pressure, P_a=100 kPa; for example: $G_{stat} = k_{G-stat} \cdot P_a \cdot \left(\frac{p'}{P_a}\right)^n$.

(2) GLU refers to GLU from the Main Embankment, and UGLU and LGLU from the Perimeter Embankment at Corner 1.

(3) Except for the UGLU from the Perimeter Embankment at Corner 1 where 1.8 t/m^3 was used. (4) S_u was calculated using Equation 2, Equation 3 and the strain-weakening function (see Figure 5).

Nomenclature: bulk density (ρ_b), cohesion (c), angle of internal friction (ϕ), static shear modulus number ($k_{G\text{-}stat}$), static shear modulus exponent (n), static bulk modulus number ($k_{B\text{-}stat}$) and static bulk modulus exponent (m).

Table 4: Parameters of the Linear Elastic Constitutive Model for the Seismic Analysis

Description	G_{dyn} (kPa)	B_{dyn} (kPa)
Bedrock	$1.6x10^6$	G_{dyn}
Cut-off Wall	$1.3x10^6$	G_{dyn}

Nomenclature: dynamic shear modulus (G_{dyn}) and dynamic bulk modulus (B_{dyn}).

Table 5: Parameters of the Mohr-Coulomb and Strain-softening Model for the Seismic Analysis

Description	Constitutive Model	G_{max} (kPa)	B_{max} (kPa)	c (kPa)	ϕ (°)	a	b	x_0
GLU (OCR≤3)	Strain-softening	$1.1x10^5$	G_{max}	S_u (1)	0	1.015	-0.52	-1.2
GLU (OCR>3)	Mohr-Coulomb		(2)	0	22			
UGLU that sheared in 2014				22	0			

Note:

(1) Su calculated using Equation 2, Equation 3 and the strain-weakening function (see Figure 5).

(2) Bmax was calculated as Bmax=2Gmax(1+ν)/(3(1- ν)), where ν is the Poisson ratio equal to 0.49.

Nomenclature: small strain shear stiffness (G_{max}), small strain bulk stiffness (B_{max}), cohesion (c), angle of internal friction (ϕ), and hysteretic parameters (a, b and x_0; Cundall 2012).

Table 6: Parameters of the UBC Hysteretic Model for the Seismic Analysis

Description	hgmax (kPa)	hbulk (kPa)	hfric (°)	hn	hrf	hdfac	hrm	hmodf1
Till / Glaciofluvial	$5.5x10^5$	hgmax	34	2	0.75	1	1.5	0.8
Till Core	(1)	hgmax	33	2	1	1	1	0.8

Note:

(1) hgmax was calculated as $\mathrm{hgmax} = k_g \cdot P_a \cdot \left(\frac{p\prime}{P_a}\right)^{n_g}$, where kg=977, ng=0.5, Pa=100 and p'=(σ'1+σ'2+σ'3)/3.

Nomenclature: maximum shear modulus (hgmax), maximum bulk modulus (hbulk), cohesion (hcoh), angle of internal friction (hfric), and hysteretic parameters (hn, hrf, hdfac, hrm, hmodf1).

Table 7: Parameters of the UBCSAND Model for the Seismic Analysis

Description	K_{ge}	K_b	n_e	m_e	K_{gp}	n_p	ϕ_{pt} (°)	ϕ (°)	R_f

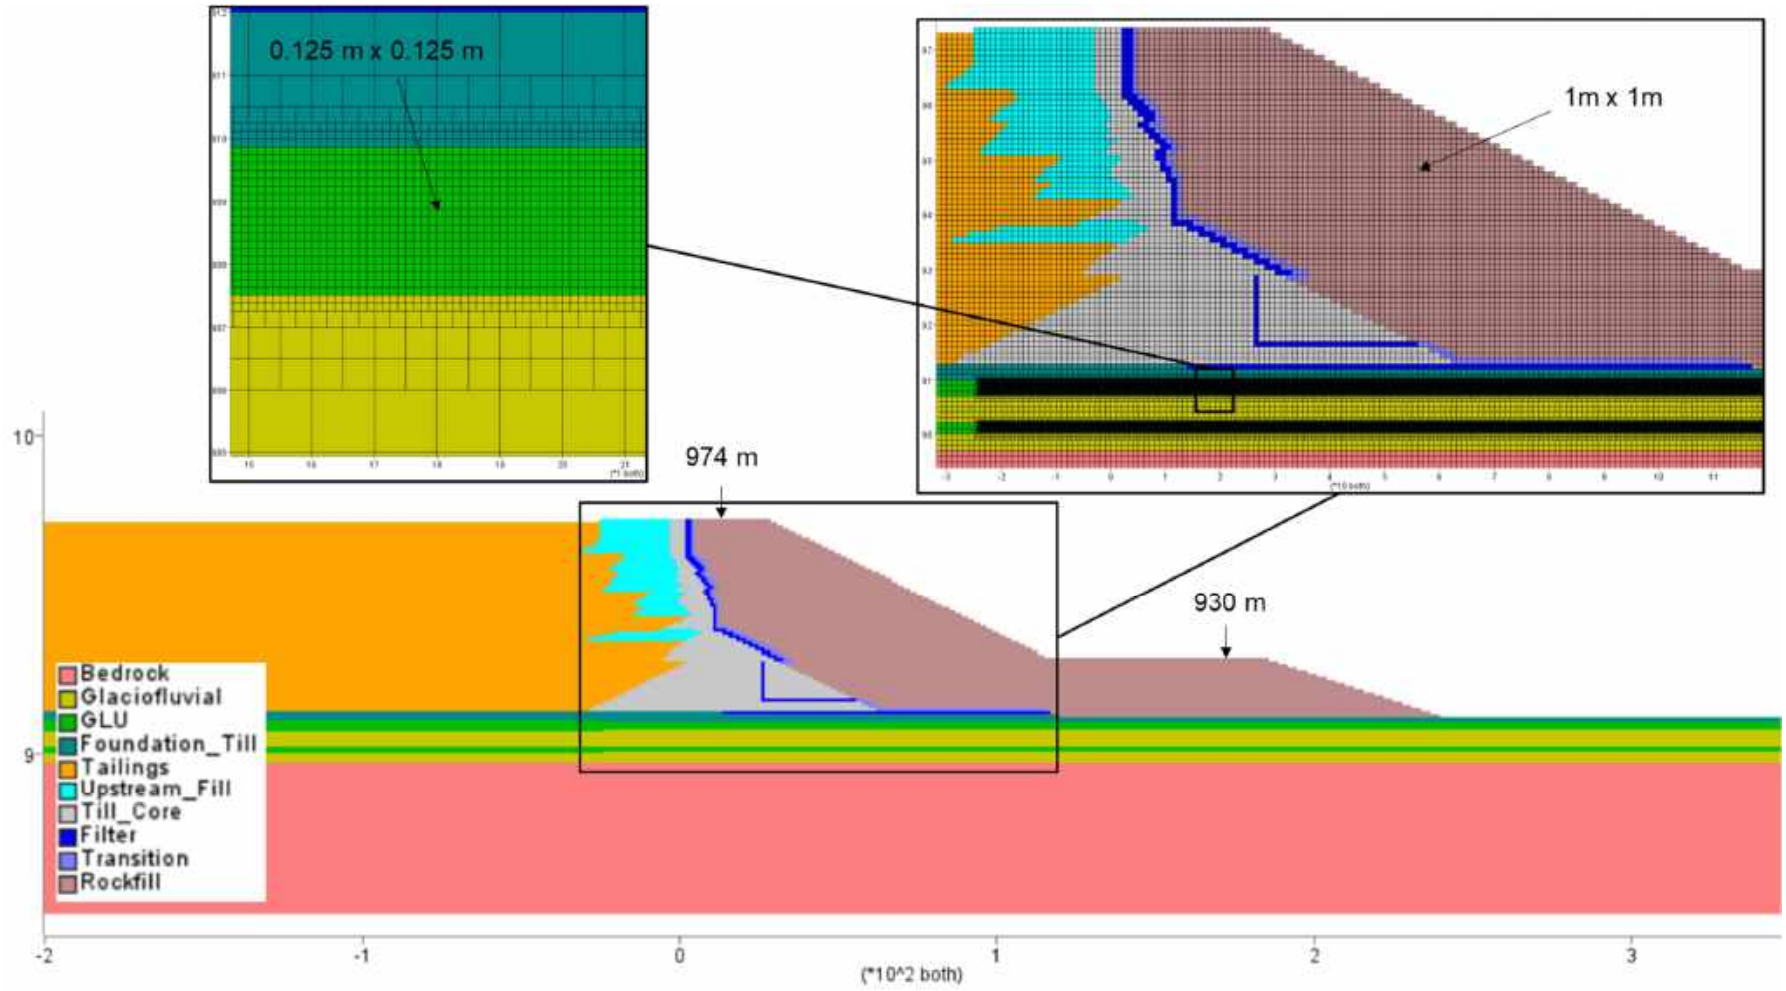
Nomenclature: elastic shear modulus number (K_{ge}), elastic bulk modulus number (K_b), elastic shear modulus exponent (n_e), elastic bulk modulus exponent (m_e), plastic shear modulus number (K_{gp}), plastic shear modulus exponent (n_p), peak friction angle (ϕ), friction angle at phase transformation (ϕ_{cv}) and constant that modifies the hyperbola (R_f).

7.0 STATIC ANALYSIS

The static analysis was carried out to further confirm the stability of the embankments at the end of construction to elevation 974 m. The following sections describe the finite difference models simulation of the staged construction of the embankments and the analysis results.

7.1 Finite Difference Models

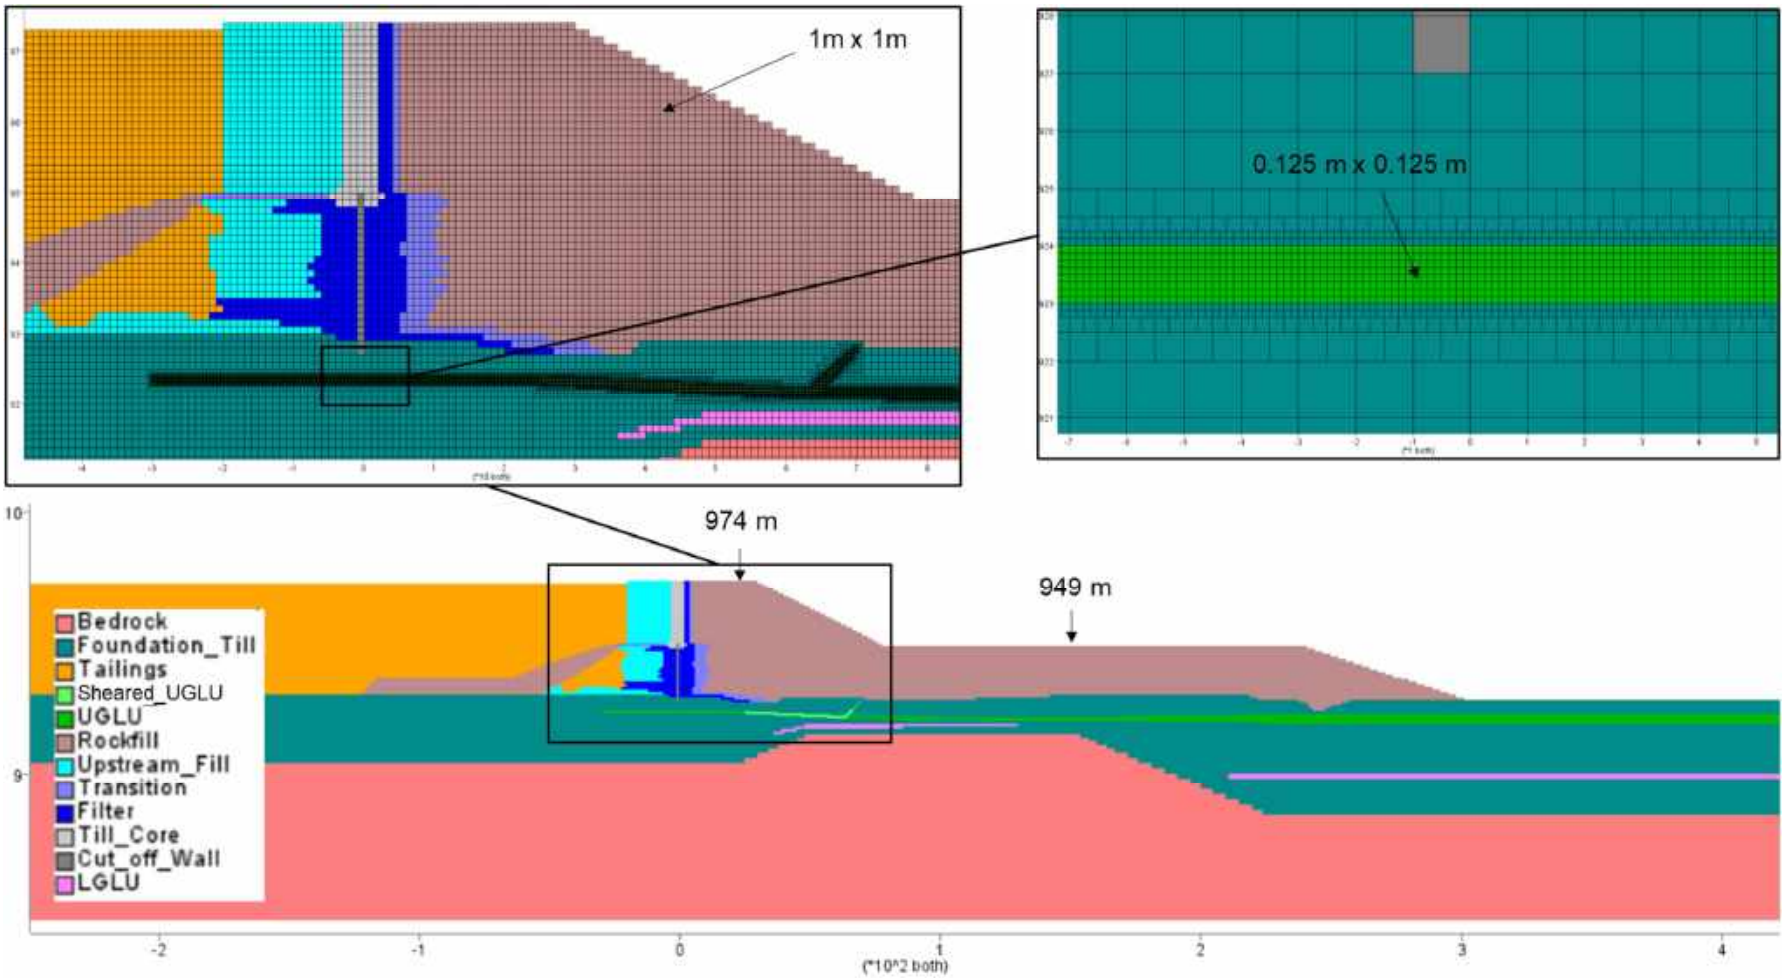
Two-dimensional (2D) finite difference models were developed for the selected sections of the TSF using the commercially available computer code FLAC Version 8.1 (Cundall 2012).



The finite difference mesh developed for section 2+055 at the Main Embankment and section 4+175 at the Perimeter Embankment at Corner 1 are shown in Figure 4 and Figure 5, respectively. The meshes extend vertically from about elevation 845 m to the embankments crest design elevation of 974 m. Horizontally, the meshes extend far enough from the embankments to avoid boundary effects. The mesh size is 1 m by 1 m at the centre of the model, increasing to about 4 m by 4 m to the far ends. Numerical models with strongly nonlinear behaviour, such as the strain-weakening behaviour exhibited by the glaciolacustrine units, are particularly sensitive to mesh sizing. Furthermore, results of three-dimensional deformation analyses of the Perimeter Embankment performed by Zabolotnii (2020) suggest that strain localization in a shear band with a thickness not exceeding 12 to 13 cm was requisite for the initiation of the breach at the Mount Polley TSF in 2014. Hence, the mesh size in the GLU at the Main Embankment and the UGLU at the Perimeter Embankment was refined to 0.125 m by 0.125 m.

7.2 Simulation of the Staged Construction of the Embankments

The staged construction of the embankments was simulated by sequentially activating horizontal layers of materials, each 1 m thick, following the construction sequence presented in Table 1. After activating each layer, the model was run to equilibrium and material properties updated according to the new stress state. If a tailings layer was activated, the pond level was raised to maintain a 100 m beach upstream of the embankment, and the pore pressures updated. Hydrostatic conditions were assumed below the water table.



The consolidation-induced hardening of the GLU was modelled by adjusting the undrained strength of the GLU based on the existing stress state. This adjustment was only applied at the end of construction stages where complete dissipation of excess pore water pressure was expected before the beginning of the following stage (see Table 1). Plastic shear strains accumulated in previous construction stages were carried over to the following stages (i.e., GLU was assumed to not heal once the peak undrained shear strength was fully mobilized).

For the simulation of the staged construction of the embankments, the bottom boundary of the 2D numerical models was considered fixed in both vertical and horizontal directions, while the lateral boundaries were considered fixed only in the horizontal directions (i.e., on vertical rollers).

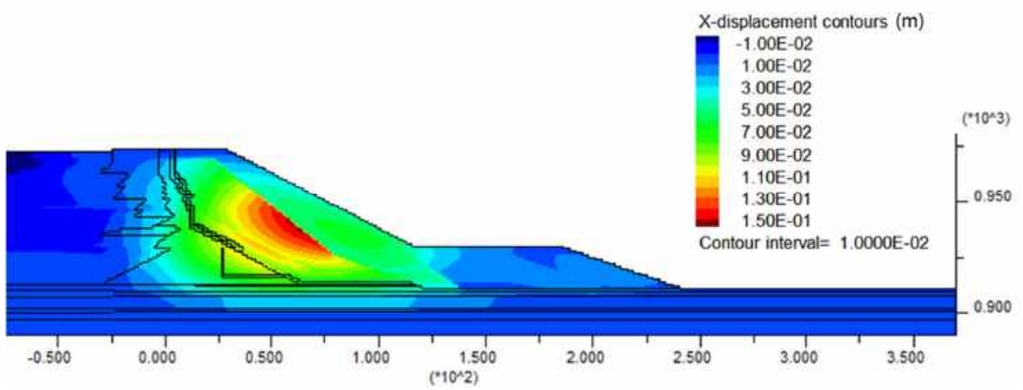
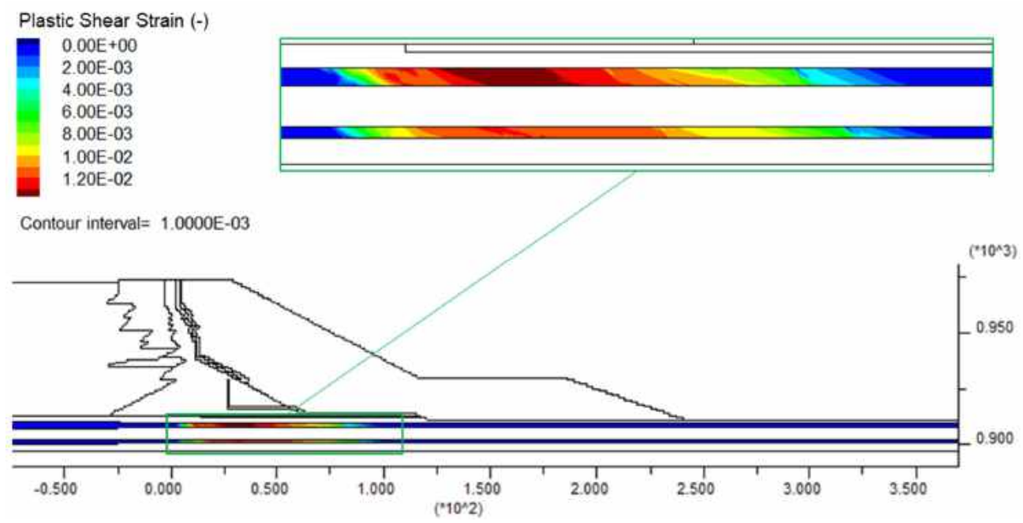
7.3 Analysis Results

This section presents the results of the static analysis carried out on section 4+175 of the Main Embankment (see Figure 6) and section 2+055 of the Perimeter Embankment (see Figure 7). Contours of horizontal displacements are presented to evaluate potential deformation mechanisms. Contours of accumulated plastic shear strains at the end of construction are presented to evaluate the potential for strain-weakening in the GLU. Plastic shear strains greater than zero but less than 5% indicate that the peak undrained shear strength was fully mobilized. Plastic shear strains greater than 5% indicate post-peak conditions and initiation of weakening. Plastic shear strains greater than 60% indicate that full weakening was attained (see Figure 3). For clarity, plastic shear strains accumulated in the UGLU that sheared in 2014 are not presented in Figure 7. The UGLU that sheared in 2014 was modelled as fully weakened. The factor of safety of the embankments was computed at the end of construction using the strength reduction method.



7.3.1 Main Embankment – Section 2+055

Contours of predicted horizontal displacement in the Main Embankment (see Figure 6a) show a limited, block type downstream movement of the embankment associated with shear strains accumulated in the GLU during construction. Predicted plastic shear strains accumulated in the GLU below the downstream slope of the Main Embankment are less than 1.5% (see Figure 6b), indicating that the peak undrained shear strength is fully mobilized but the weakening process is not initiated. The factor of safety (FoS) computed for section 2+055 of the Main Embankment is about 1.6 and corresponds to a block-type slip surface through the glaciolacustrine unit, as shown in Figure 6c. These results indicate that section 2+055 of the Main Embankment meets the long-term factor of safety design criteria under the analysed conditions.



7.3.2 Perimeter Embankment at Corner 1 – Section 4+175

Contours of predicted horizontal displacement in the Perimeter Embankment at Corner 1 (see Figure 7a) show a limited, block type downstream movement of the embankment associated with shear strains accumulated in the UGLU, including the UGLU that sheared during the failure in 2014, during construction. A relatively small shear band (about 3 m long) with a maximum plastic shear strain of about 10% is predicted to develop immediately downstream of the UGLU zone that sheared in 2014. However, the predicted level of strain-weakening is relatively low (less than 6% strength reduction in a 3 m long shear band). The predicted plastic shear strains in the rest of the UGLU are generally less than 5%. The factor of safety (FoS) computed for section 4+175 is about 1.7 and corresponds to a block-type slip surface through the UGLU, as shown in Figure 7c. The static analysis results indicate that this section of the Perimeter Embankment at Corner 1 meets the long-term factor of safety design criteria under the analysed conditions.

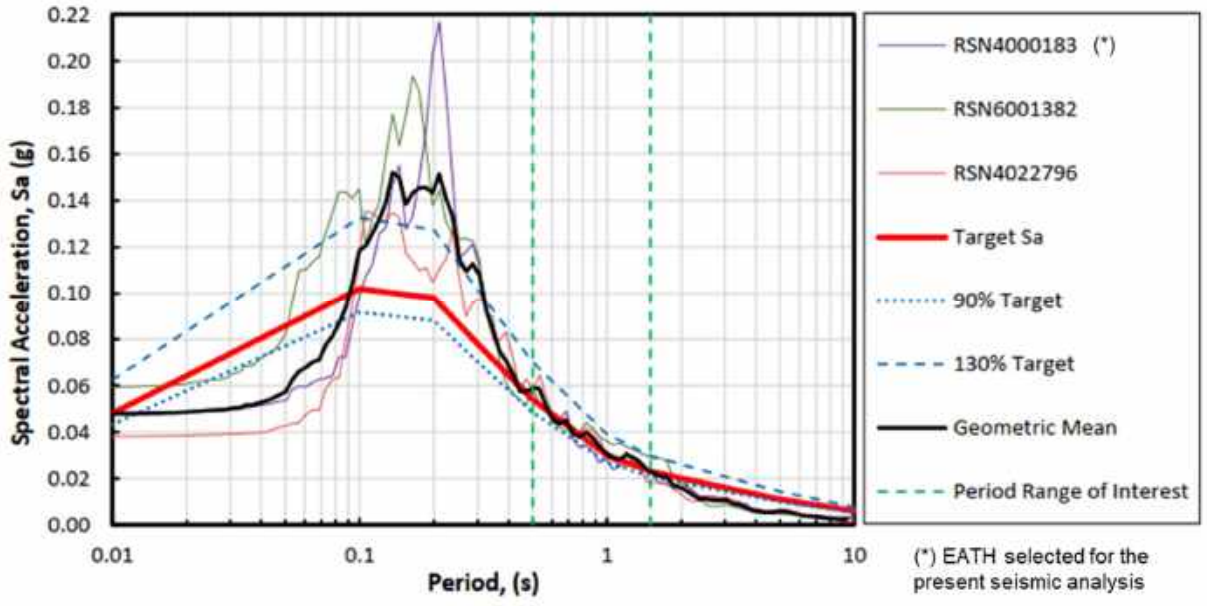
8.0 EARTHQUAKE GROUND MOTIONS

WSP (2023b) carried out a site-specific probabilistic seismic hazard analysis (PSHA) for the Mount Polley TSF site. In this section, only a summary of the results is presented.



Earthquake ground motions were reported as 5%-damped, mean uniform hazard acceleration response spectra at annual exceedance probabilities (AEPs) of 1/1,000, 1/2,475, 1/5,000 and 1/10,000 for the site-specific average shear wave velocity in the 30 m below ground surface (V_{s30}) of 849 m/s. Deaggregations results show that both, near-field, moderate-magnitude earthquakes, and far-field subduction interface earthquakes contribute to the site seismic hazard. The shallow crustal earthquakes sources are dominated by moderate-magnitude earthquakes (**M**6.0 to **M**6.5) close to the site (i.e. <60 km) at all AEPs. The contribution to hazard at the site from Cascadia subduction zone sources is from large earthquakes (**M**8+) at 450 to 550 km from these at all AEPs and spectral periods of interest. Eleven two-horizontal-component earthquake acceleration time histories (EATHs; 22 records) were developed using amplitude scaling to the site-specific 1/2,475 AEP uniform hazard acceleration response spectrum within the period range of interest of 0.5 to 1.5 seconds. These 22 EATHs were developed with eight two-component (16) records from crustal earthquakes and three two-component (6) subduction interface earthquake records. Figure 8 and Figure 9 show the response spectra of one component of the individual scaled EATHs compared with the target spectrum for both crustal and subduction interface motion, respectively.

Following the design criteria (WSP 2024), earthquake ground motions with a return period of 2,475 years were selected for seismic analysis of the Mount Polley Mine TSF site. One crustal motion (RSN4478N) and one subduction interface motion (RSN4000183EW) were selected from the 22 EATHs developed, corresponding to those with the maximum Arias intensity for each seismic source.

9.0 SEISMIC ANALYSIS

The seismic analysis was carried out to further confirm the stability of the embankments under the 2,475-year earthquake loading. The following sections describe the finite difference models, simulation of the design earthquake and the analysis results.

9.1 Finite Difference Models

The size of the elements used in the finite difference model have an impact on the solution time of the seismic analysis. The smaller the elements, the greater the solution time due to the increased number of elements and the reduced timestep. The finite difference models developed for the static analysis considered 0.125 m by 0.125 m elements for the GLU at the foundation of the Main Embankment and the UGLU at Corner 1. The utilization of such element size for the seismic analysis leads to impractical solution times. Hence, the element size in the GLU was increased to 0.5 m by 0.5 m to perform the seismic analysis. The rationale behind this modification is presented in the following paragraphs.

The selection of the elements size used for the GLU in the static analysis is based on the results of the three-dimensional deformation analyses that suggest that strain localization in a shear band with a thickness not exceeding 12 to 13 cm was requisite for the initiation of the breach at the Mount Polley TSF in 2014 (Zabolotnii 2020). A level of conservatism is introduced in a two-dimensional deformation analysis when adopting the same element size for the GLU since the three-dimensional stability effects in the slope are not included.

The finite difference model developed for the Perimeter Embankment at Corner 1 in Section 7.1 was modified to evaluate the mesh size sensitivity and the degree of conservatism incorporated when using different element sizes for the UGLU. The model was adjusted to represent the geometry, groundwater conditions and construction

sequence of the embankment up to when it failed in 2014 at an approximate crest elevation of 969 m. The staged construction was simulated using different element sizes for the UGLU from 0.125 m to 1 m. Figure 10 shows a summary of the results of the analyses. An element size of 0.5 m still adds a degree of conservatism to the solution while allowing for reasonable solutions times for the seismic analysis.

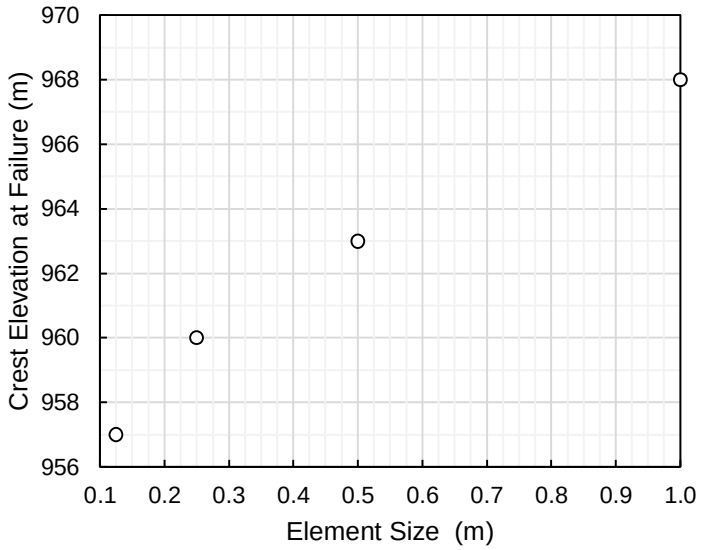

Figure 10: Mesh Sensitivity of the Modified Perimeter Embankment at Corner 1 Finite Difference Model

9.2 Conditions Prior to Application of Seismic Loading

The pre-seismic stress conditions in the embankments and foundation were estimated by simulating the staged construction of the embankments up to elevation 974 m, using 0.5 m by 0.5 m elements in the GLU. The assumed groundwater conditions include a 100 m tailings beach upstream of the embankment, as shown in Figure 11 and Figure 12. Hydrostatic conditions were assumed below the water table.

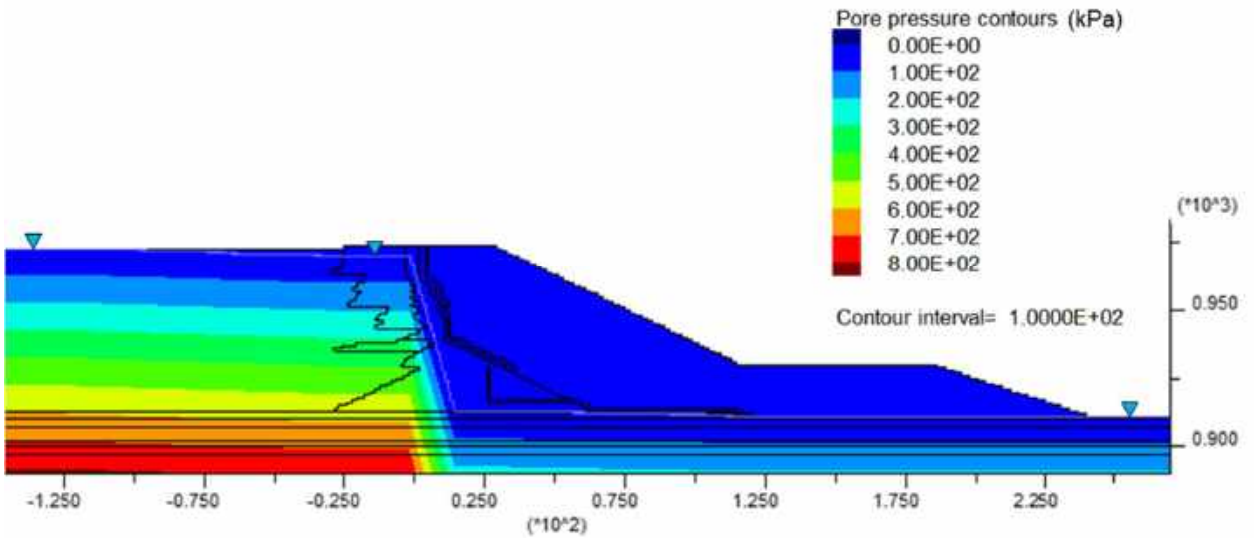

Figure 11: Assumed Pre-Seismic Groundwater Conditions, Section 2+055 – Main Embankment

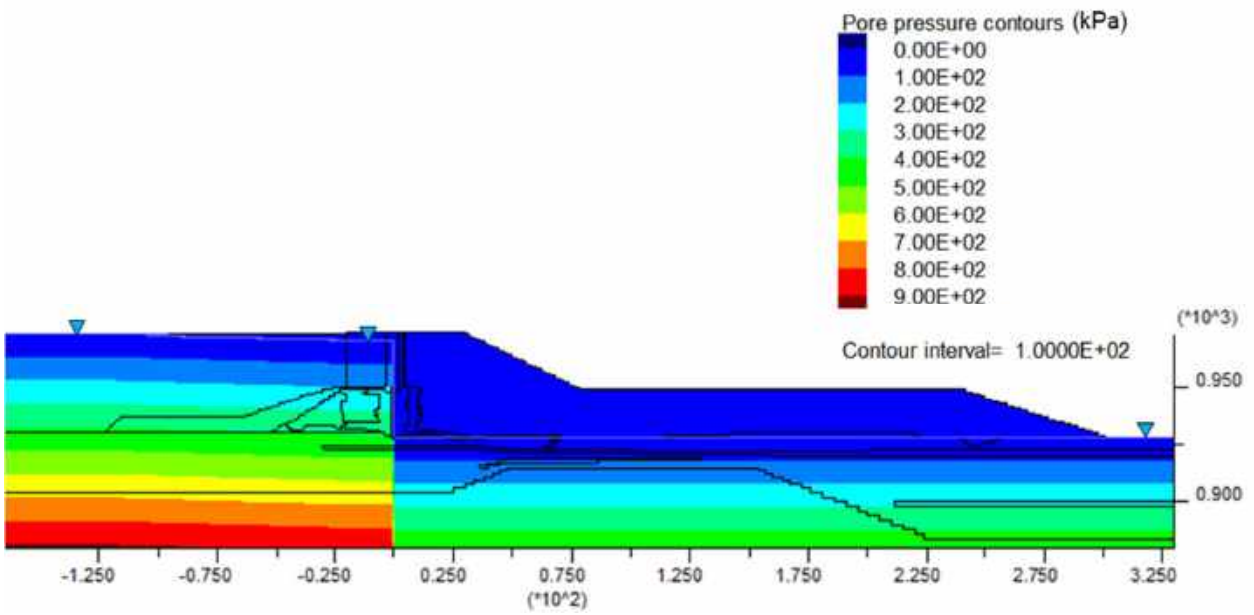

Figure 12: Assumed Pre-Seismic Groundwater Conditions, Section 4+175 – Perimeter Embankment at Corner 1

9.3 Simulation of the Design Earthquake

The response of the embankments to the design earthquake was simulated by using selected earthquake acceleration time histories (EATHs) developed in the seismic hazard assessment as input ground motions at the base of the models. One crustal motion (RSN4478N) and one subduction interface motion (RSN4000183EW) were selected from the 22 EATHs developed, corresponding to those with the maximum Arias intensity for each seismic source (see Section 8.0). The polarity (sign) of each input ground motion was inverted and the analysis repeated to assess the effect of earthquake directionality on the embankments seismic response. Direct polarity (DP) refers to the earthquake acting in one direction and reverse polarity (RP) to the opposite direction.

For the simulation of the design earthquake loading, the bottom boundaries of the model were assigned as quiet (flexible base) and the lateral boundaries as free-field.

9.4 Analysis Results

The following sections present the results of the seismic analysis carried out on section 2+055 of the Main Embankment Figure 13 to Figure 15) and section 4+175 of the Perimeter Embankment at Corner 1 (Figure 16 to Figure 18). For ease of presentation, contours plots are presented only for EATHs applied with direct polarity. Attachment 2 presents the results obtained with the selected EATHs with both polarities.

Contours of predicted horizontal and vertical seismic displacements at the end of earthquake shaking are presented to evaluate potential deformation mechanisms. Predicted displacement-time histories at selected points of the embankment are presented to assess the stability of the embankment at the end of earthquake shaking. Contours of accumulated plastic shear strains during seismic loading are presented to evaluate the potential for strain-weakening in the GLU. Contours of excess pore water pressure ratio are presented to identify where liquefaction was predicted. The excess porewater pressure ratio, $r_u=\Delta u/\sigma'_{v0}$, is defined as the ratio between the excess pore water pressure (Δu) developed during cyclic loading and the initial vertical effective stress (σ'_{v0}).

Full liquefaction occurs when the excess pore water pressure developed during cyclic loading is equal to the initial vertical effective stress (r_u=100%) However, r_u values greater than about 70% are typically high enough to induce significant soil softening and weakening. Zones where r_u exceeds 70% are referred herein as liquefied even though full liquefaction was not reached.

9.4.1 Predicted Main and Perimeter Embankment Deformations

The displacement-time histories show that the movement of both sections analysed stop at the end of earthquake shaking, indicating that the embankment in both analysed sections is stable at the end of the earthquake design ground motions (see Figure 13 and Figure 16). The maximum permanent horizontal displacement in the downstream direction predicted in the embankments and buttresses is less than 5 cm.

Results obtained using the subduction interface motion indicate that a deformation mechanism, with limited upstream movement and settlement of the upstream fill (up to 0.5 m), is initiated upstream of the embankments due to liquefaction of the tailings and upstream fill during earthquake shaking. These displacements could potentially affect the serviceability of the upstream drains at elevation 970 m. This deformation mechanism is not observed during the crustal motion because liquefaction is not triggered in the tailings and upstream fill.

The maximum permanent horizontal and vertical displacements predicted at the centreline of the embankments (i.e., at the crest of the till core) are less than 4 cm. The serviceability of the till core is not expected to be affected by this level of displacements.

9.4.2 GLU Plastic Shear Strains and Potential Strength Weakening

Main Embankment – Section 2+055

Predicted plastic shear strains accumulated during earthquake shaking are less than 0.5% in the GLU at the Main Embankment. Plastic shear strains predicted in the GLU at the end of the construction of the Main Embankment up to elevation 974 m were less than 1.5% (see Figure 6b). The predicted total plastic shear strains (static plus seismic) are still less than 2%. Hence, the weakening process is not expected to be initiated in the GLU at the Main Embankment during the earthquake design ground motions.

Perimeter Embankment at Corner 1 – Section 4+175

Predicted plastic shear strains during earthquake shaking are less than 1% in the UGLU below the downstream slope of the Perimeter Embankment at Corner 1. The static analysis predicted a limited shear band at that location with plastic shear strains of about 10% (see Figure 7b), indicating that the weakening process was initiated during construction of the embankment up to elevation 974 m. The predicted level of strain-weakening is relatively low (less than 1.5% strength reduction) and does not have a significant impact on the seismic stability of the embankment at Corner 1.

Predicted plastic shear strains during earthquake shaking is about 2% in the UGLU below the downstream slope of the buttress at the Perimeter Embankment at Corner 1. The static analysis did not predict development of plastic shear strains at that location during construction of the embankment up to elevation 974 m. Hence, initiation of the weakening process is not expected in the UGLU at that location during the earthquake design ground motions.

10.0 CONCLUSIONS

Stress-deformation analyses were carried out on section 2+055 of the Main Embankment and section 4+175 of the Perimeter Embankment at Corner 1 to support the detailed design for the raise of the TSF from elevation 970 to 974 m. The analyses were performed to further confirm the stability of the embankments at the end of construction up to elevation 974 m (static analysis) and under the 2,475-year earthquake load (seismic analysis). One crustal motion and one subduction interface motion were used as input ground motions in the seismic analysis. The conclusions of the analyses are presented in the following sections.

10.1 Static Analysis

- Section 2+055 of the Main Embankment and section 4+175 of the Perimeter Embankment at Corner 1 are predicted to be stable at the end of construction up to elevation 974 m under the analysed conditions.
- The factor of safety computed at the end of construction is about 1.6 for section 2+055 of the Main Embankment and about 1.7 for section 4+175 of the Perimeter Embankment at Corner 1.
- Strain-weakening is not predicted in the GLU at section 2+055 of the Main Embankment during construction up to elevation 974 m.
- Assuming a constant 22 kPa undrained shear strength for the UGLU that sheared during the failure in 2014 (i.e., no inclusion of potential strength gains from reconsolidation), a shear band about 3 m long with a maximum plastic shear strain of about 10% is predicted to develop below the downstream slope of the Perimeter Embankment at Corner 1 at section 4+1475. However, the predicted degree of strain-weakening is relatively low (about 6% strength reduction in a 3 m long shear band) and does not have a significant impact on the stability of the elevation 974 m embankment.

10.2 Seismic Analysis

- Section 2+055 of the Main Embankment and section 4+175 of the Perimeter Embankment at Corner 1 are predicted to be stable under the action of the 2,475-year earthquake ground motion.
- The maximum permanent horizontal displacement in the downstream direction is less than 5 cm in the embankments and buttresses of both analysed sections under the action of the 2,475-year earthquake ground motion.
- The maximum permanent horizontal and vertical displacements predicted at the centreline of the embankments in both analysed sections are less than 4 cm at the end of the 2,475-year earthquake ground motion. The serviceability of the till core is not expected to be affected by this level of displacements.
- Strain-weakening is not predicted in the GLU at section 2+055 of the Main Embankment under the action of the 2,475-year earthquake ground motion.
- Assuming a constant 22 kPa undrained shear strength for the UGLU that sheared during the failure in 2014 (i.e., no inclusion of potential strength gains from reconsolidation), a relatively low level of strain-weakening (less than 1.5% strength reduction) is predicted in the UGLU under the downstream slope of the Perimeter Embankment at section 4+175, during the 2,475-year earthquake ground motion. This degree of weakening is relatively low (less than 1.5% strength reduction) and does not have a significant impact on the seismic stability of the embankment.

- A deformation mechanism, with limited upstream movement and settlement of the upstream fill (up to 0.5 m) may develop if the phreatic surface upstream of the till core is relatively shallow and the seismic loading is enough to trigger liquefaction in the tailings and upstream fill. This deformation mechanism was predicted in both analysed sections and only under the action of the subduction interface motion. The displacements associated with this deformation mechanism could potentially affect the serviceability of the upstream drain at elevation 970 m. The seismic loading from the crustal motion was not sufficient to trigger liquefaction in the tailings and upstream fill.

11.0 CLOSING

We trust the above meets your present requirements. If you have any questions or comments, please contact the undersigned.

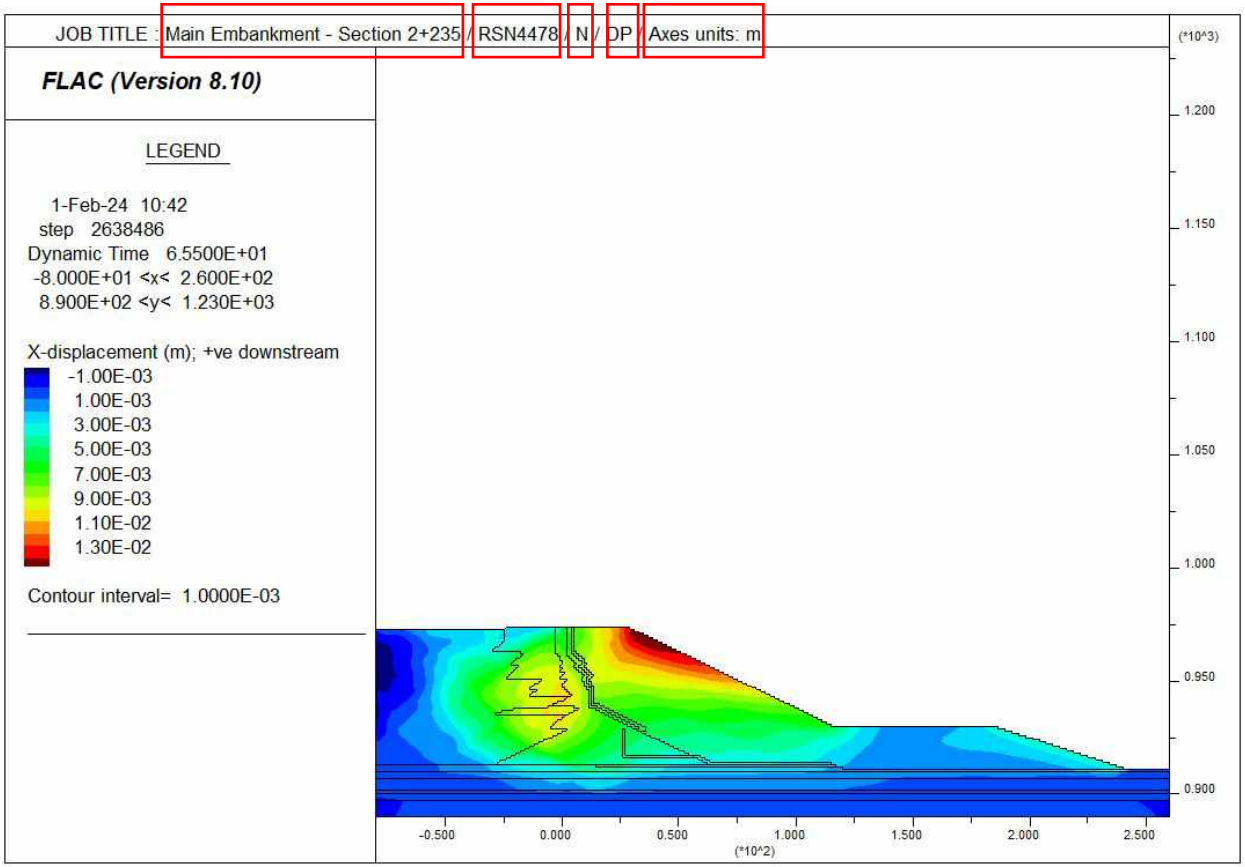
ATTACHMENT 2



Seismic Analyses Results

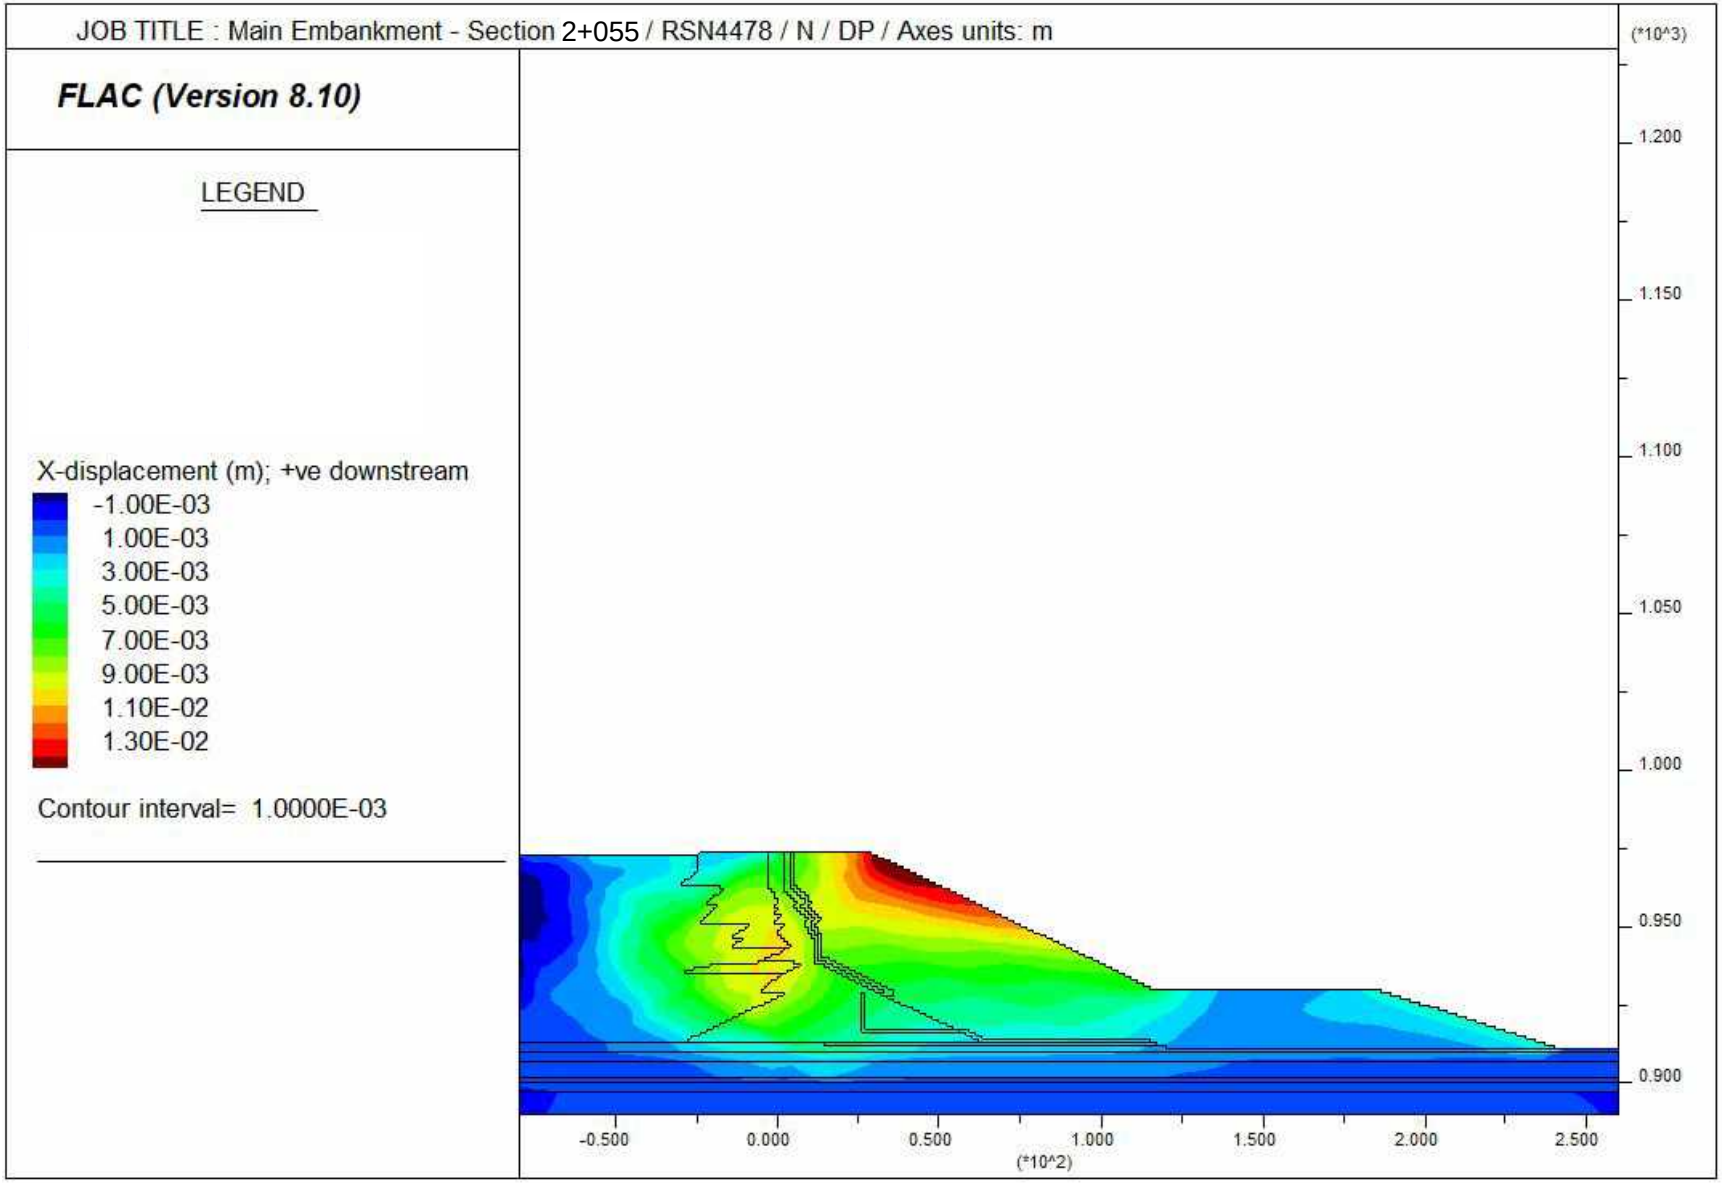


Table of Contents

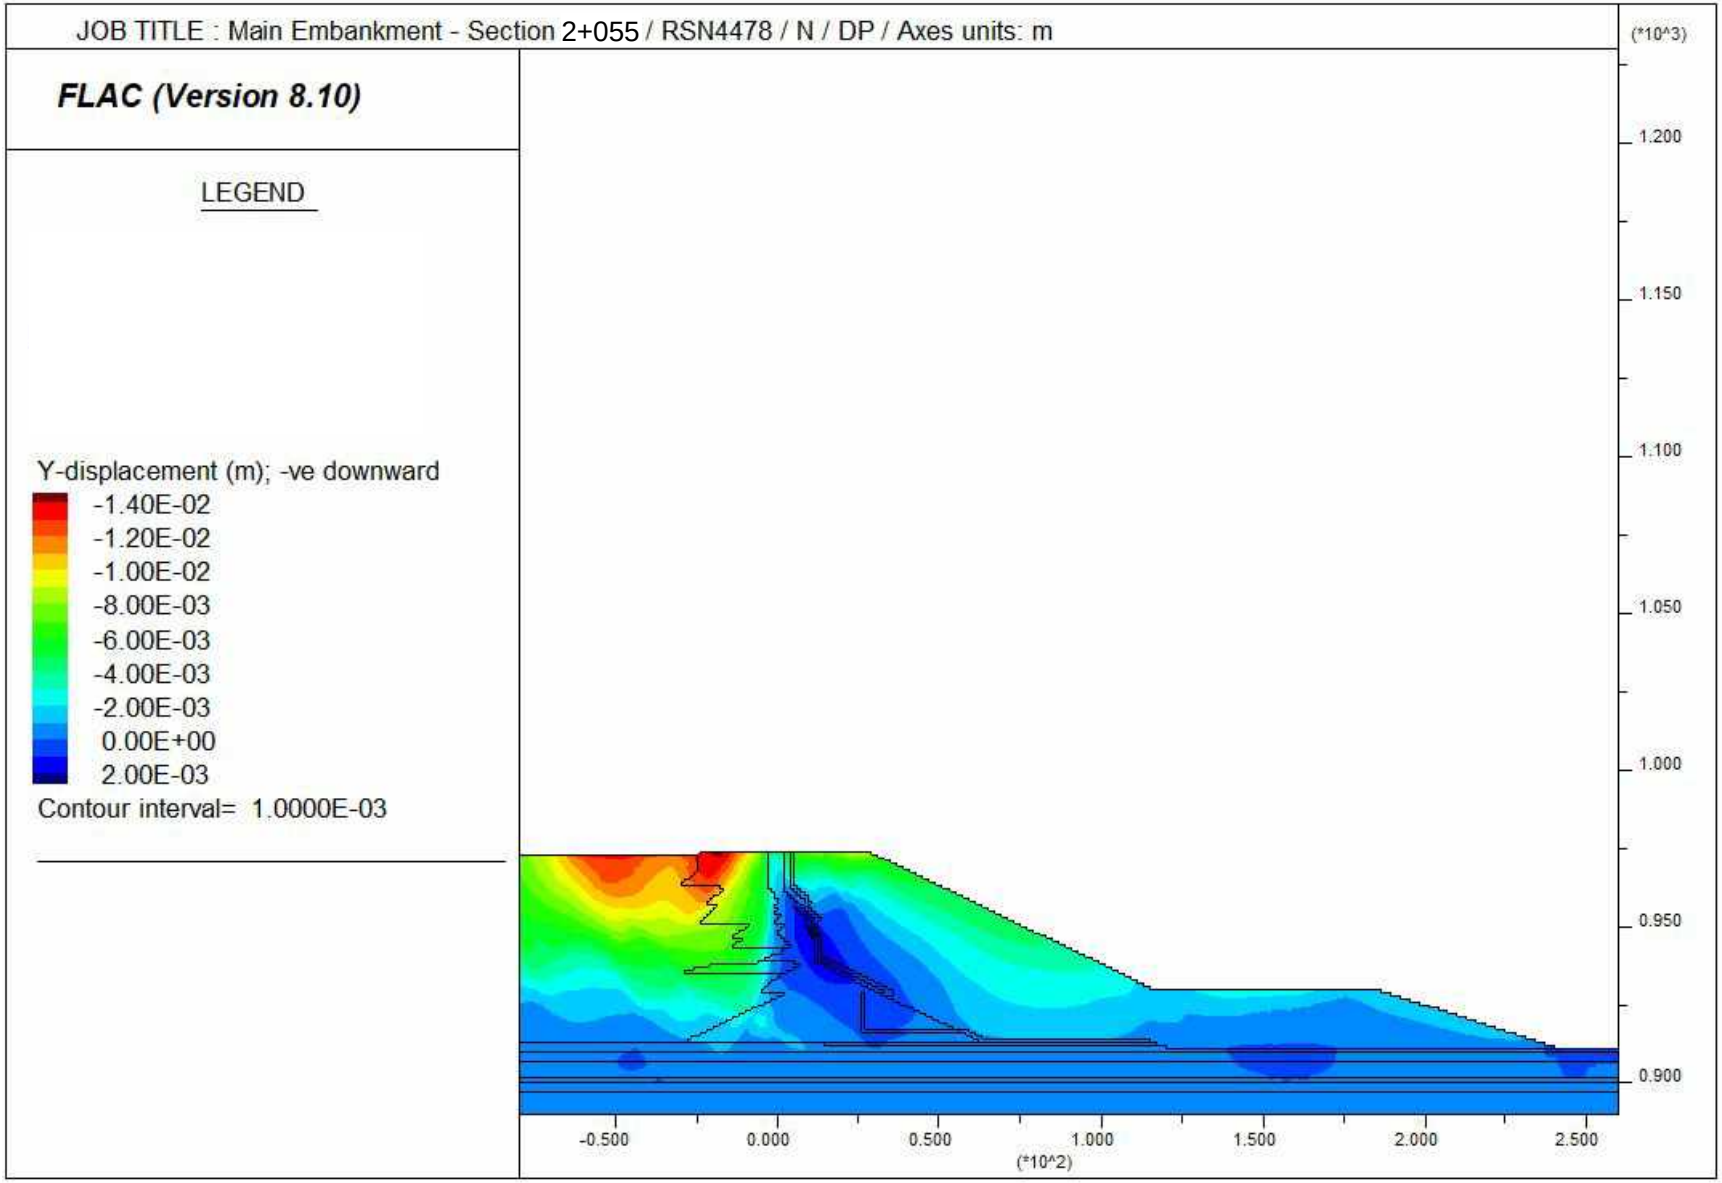
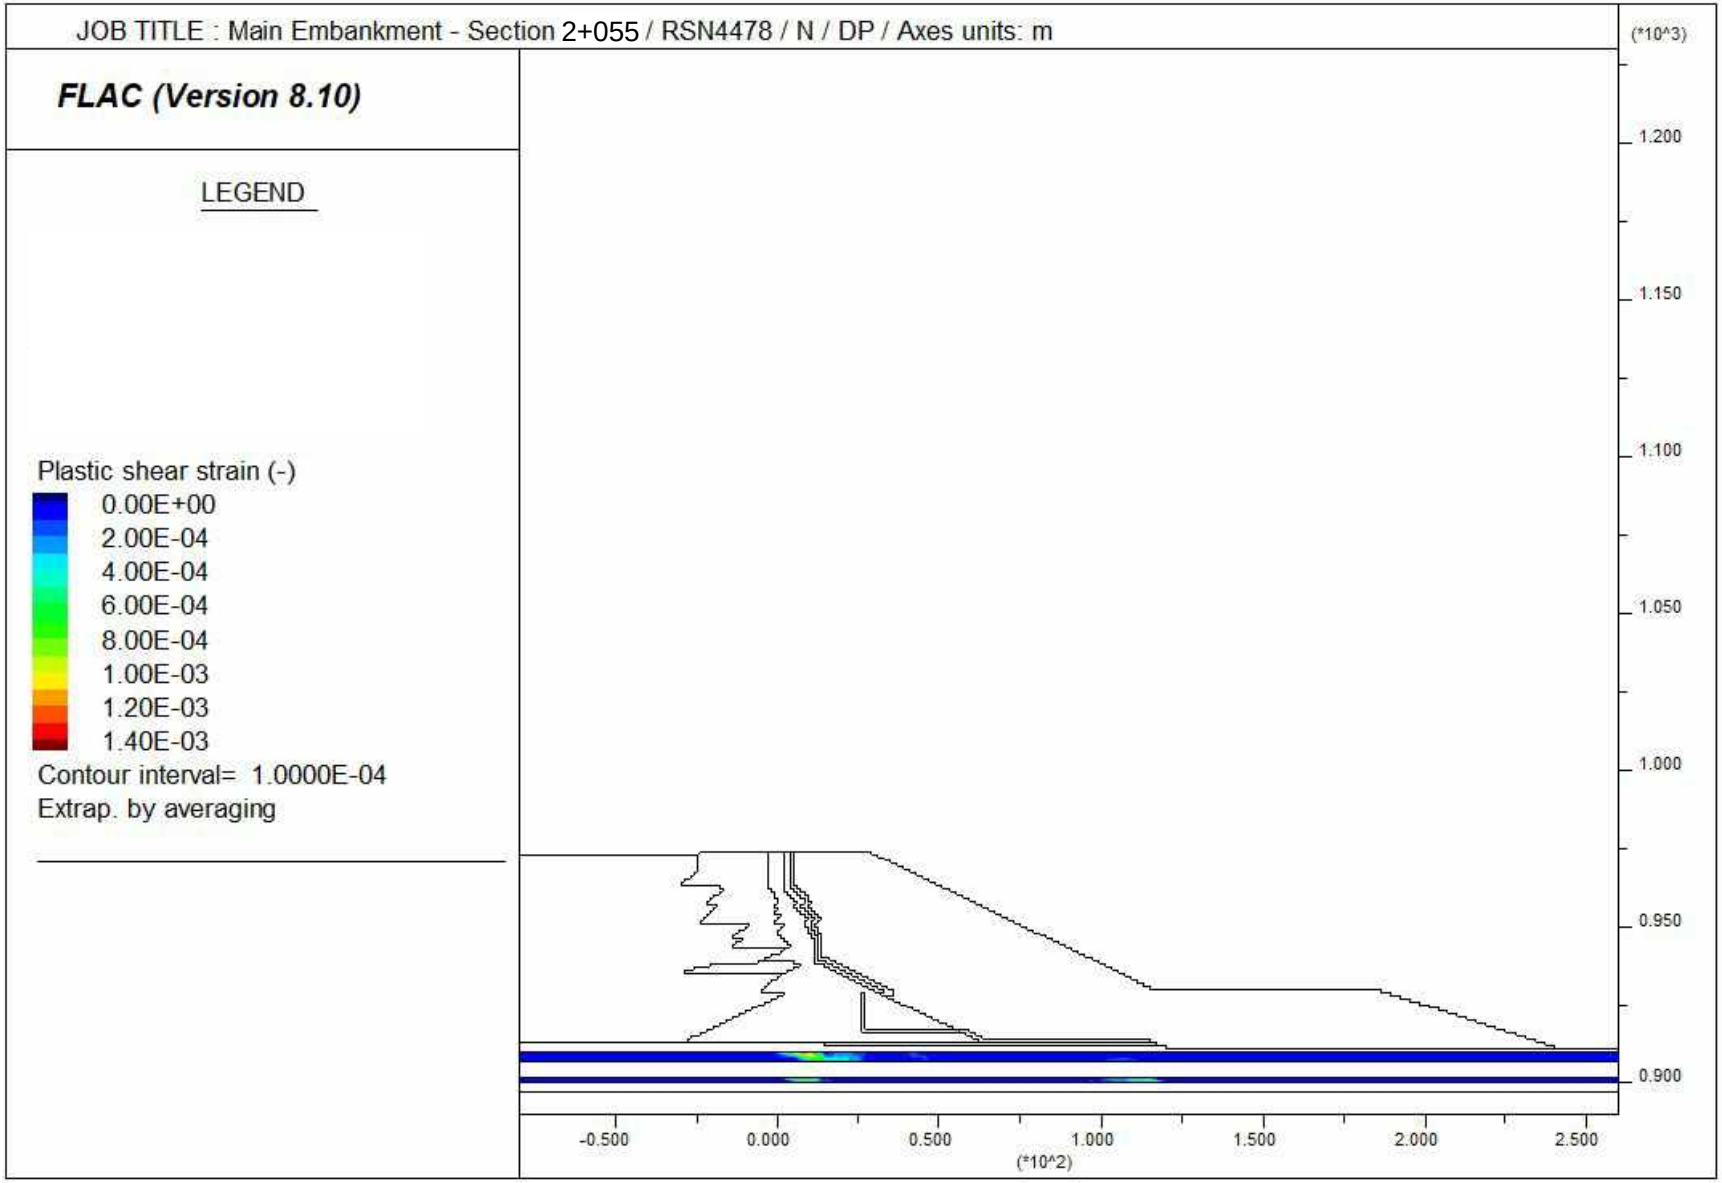
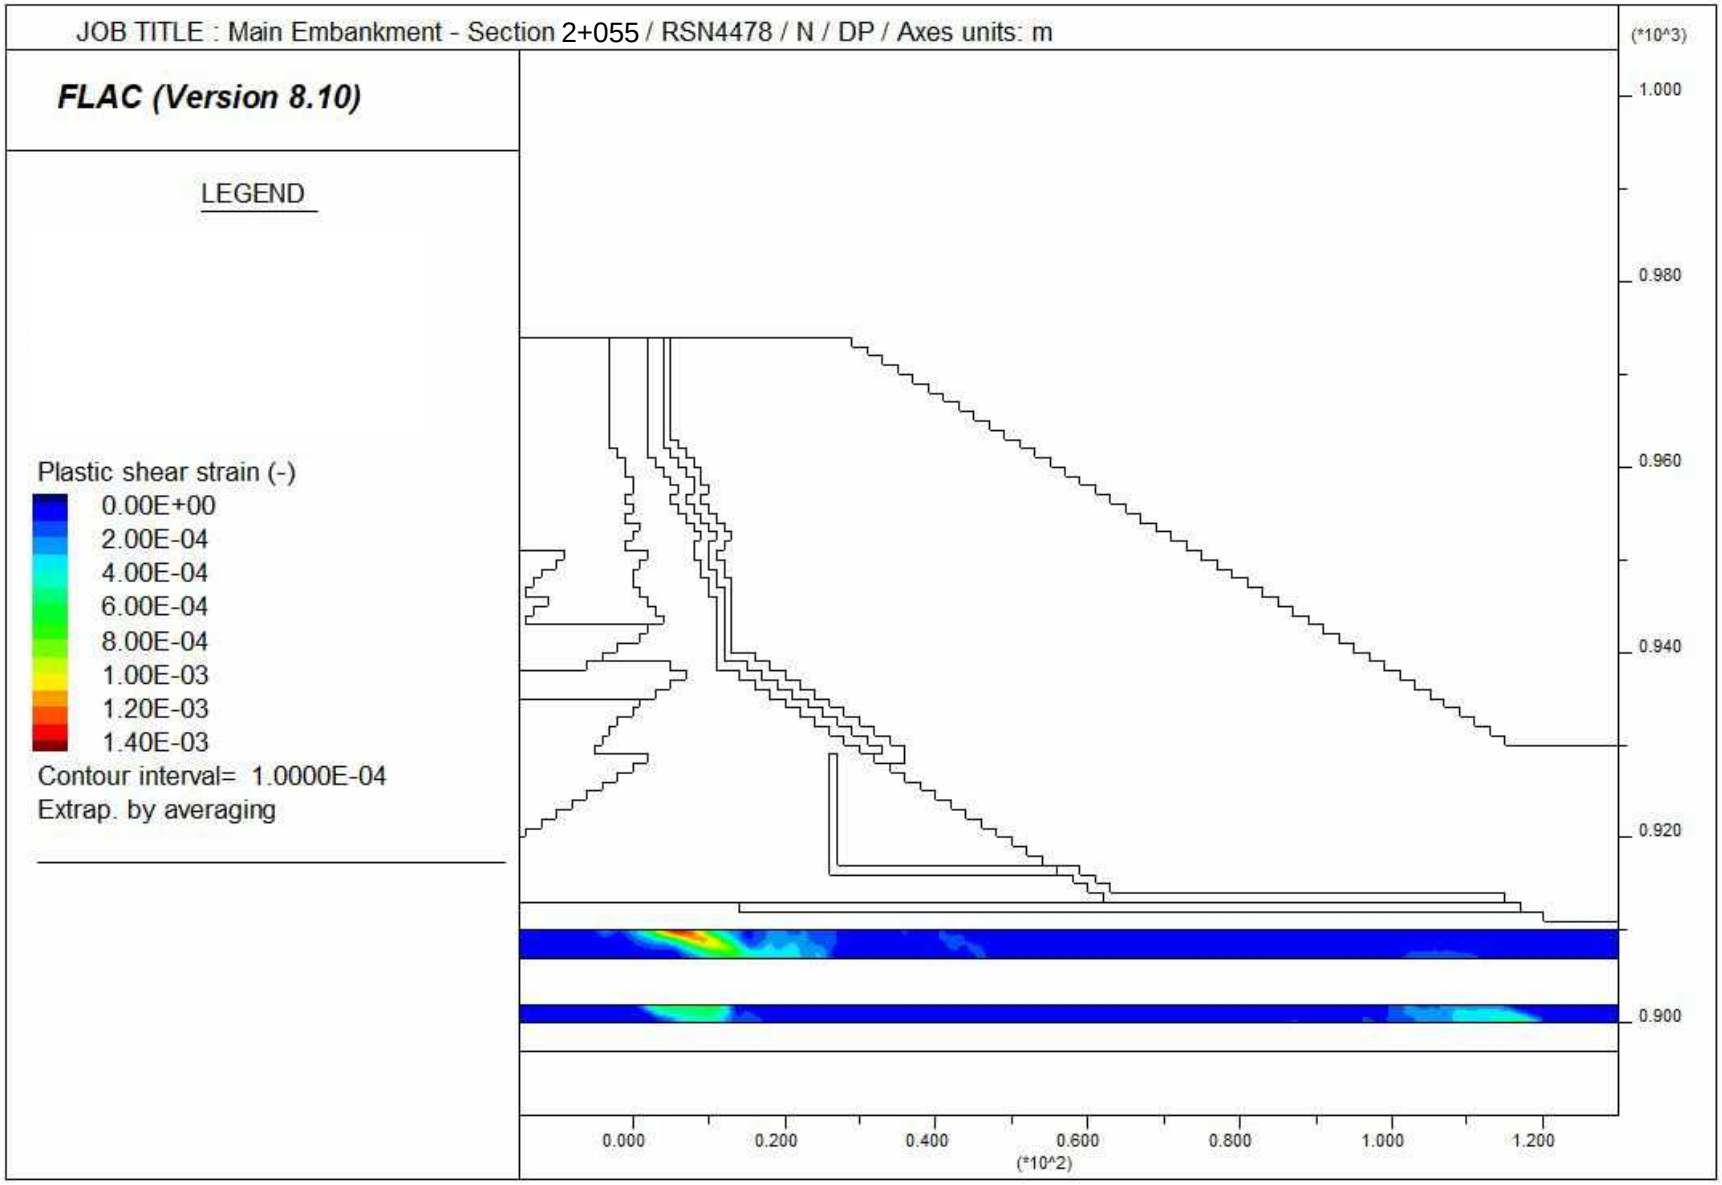


Name	Page number
Attachment Structure	**2**
Main Embankment – Section 2+055	
▪ RSN4478, Crustal Motion	
• Direct Polarity (DP)	3
• Reverse Polarity (RP)	8
▪ RSN4000183, Subduction interface motion	
• Direct Polarity (DP)	13
• Reverse Polarity (RP)	18
Perimeter Embankment at Corner 1 – Section 4+175	
▪ RSN4478, Crustal Motion	
• Direct Polarity (DP)	23
• Reverse Polarity (RP)	29
▪ RSN4000183, Subduction interface motion	
• Direct Polarity (DP)	35
• Reverse Polarity (RP)	41



1. Embankment – Section:
   - Main Embankment
   - Perimeter Embankment at Corner 1
2. Record Sequence Number:
   - RSN4478N, Crustal Motion
   - RSN4000183EW, Subduction interface motion
3. Component earthquake motion:
   - North (N)
   - East/West (EW)
4. Polarity:
   - Direct Polarity (DP)
   - Reverse Polarity (RP)
5. Axes units: metres



Example:

APPENDIX I

Water Management Design

TECHNICAL MEMORANDUM

DATE April 9, 2024 **Reference No.** CA0020527.4505-015-TM-Rev0-31151

TO Matt O'Leary
Mount Polley Mining Corporation

CC Lee Nikl, Jesse Maddaloni, Germán Pizarro and Andrew McIntosh

FROM Daniel Mullen, Nasim Hossein, and Don Kidd **EMAIL daniel.mullen@wsp.com; nasim.hosseini@wsp.com; donald.kidd@wsp.com**

TAILINGS STORAGE FACILITY RAISE TO ELEVATION 974 M DESIGN – FREEBOARD AND WATER LEVEL ANALYSIS – MOUNT POLLEY MINE

1.0 INTRODUCTION

Mount Polley Mine is a copper and gold mine operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. The mine is located approximately 56 km northeast of Williams Lake, British Columbia, between Polley Lake and Bootjack Lake. The total surface area of the site is 17.8 square kilometres (km^2). The tailings storage facility (TSF) is located about 3 km southeast of the mill and includes one embankment that is approximately 4.8 km in length.

This technical memorandum has been prepared by WSP Canada Inc. (WSP) to provide the hydrologic input for the design of the TSF spillway to support raising the existing TSF from its currently permitted elevation of 970 m to 974 m. The purpose of this technical memorandum is as follows:

- Assess a minimum freeboard that needs to be maintained at all times to prevent overtopping of the TSF by wave action.
- An emergency spillway (spillway) design that will maintain the required minimum freeboard during the design event.
- Estimate inflow volumes generated by the design events.
- Determine the water level at which pumping of site water to the TSF must cease.

2.0 BACKGROUND

During normal operations, the TSF will be managed by maintaining the pond volume within the operating range for reclaim water and make-up water. Deposition of tailings will be planned to maintain the pond away from the embankment and against the natural ground on the western perimeter.

The inflows that directly contribute to the TSF are from precipitation on the direct footprint of the TSF and runoff from the catchment directly above the TSF. The major contribution to TSF supernatant volume is site contact water pumped from facilities including the Central Collection Sump and Perimeter Embankment Till Borrow Pond.

Temporary detention of water in the TSF is necessary to manage large site runoff volumes that can be generated during freshet; however, a fundamental basis of the water management plan is to not accumulate water on site year over year within the TSF by treating and discharging water.

A site-wide water balance model has been developed (WSP 2023b) to support water management planning and to predict water volume/level in the TSF throughout future operations. The water balance model shows that the maximum TSF pond volume during the operational phase remains within the normal operating range during average conditions (50th percentile) and increases to approximately 3.5 million m^3, which represents the 99.5th percentile volume.

A spillway will be included in the design of the TSF Raise to Elevation 974 m as an emergency control measure to prevent potential overtopping of the facility.

3.0 DESIGN CRITERIA AND INPUTS

The design criteria for the TSF spillway during operation are described in the technical design basis memorandum document for TSF Raise to Elevation 974 m (WSP 2023a); inputs to the TSF freeboard and water level assessment are summarized in Table 1.

Table 1: Tailings Storage Facility Freeboard and Water Level Assessment Spillway Design Inputs Summary

Item No.	Item Description	Design Basis	Reference/Rationale
Background			
1	Horizontal and vertical datum	Horizontal datum is UTM Zone 10 NAD83 CSRS and vertical datum is relative to local tailings grid.	2023 LiDAR contours with 0.1 m resolution provided by MPMC (Fullerton 2024)
Climate and Hydrology			
2	24-hour 1:200-year precipitation depth	69 mm	Section 3.3
3	72-hour probable maximum precipitation (PMP)	339 mm	Section 3.3
4	24-hour snowmelt depth component of the environmental design flood (EDF)	16 mm	24-hour snowmelt using 24-hour 1:200-year precipitation and mean April temperature Section 3.4
5	72-hour snowmelt depth component of the inflow design flood (IDF)	54 mm	72-hour snowmelt using 72-hour PMP and mean April temperature Section 3.4

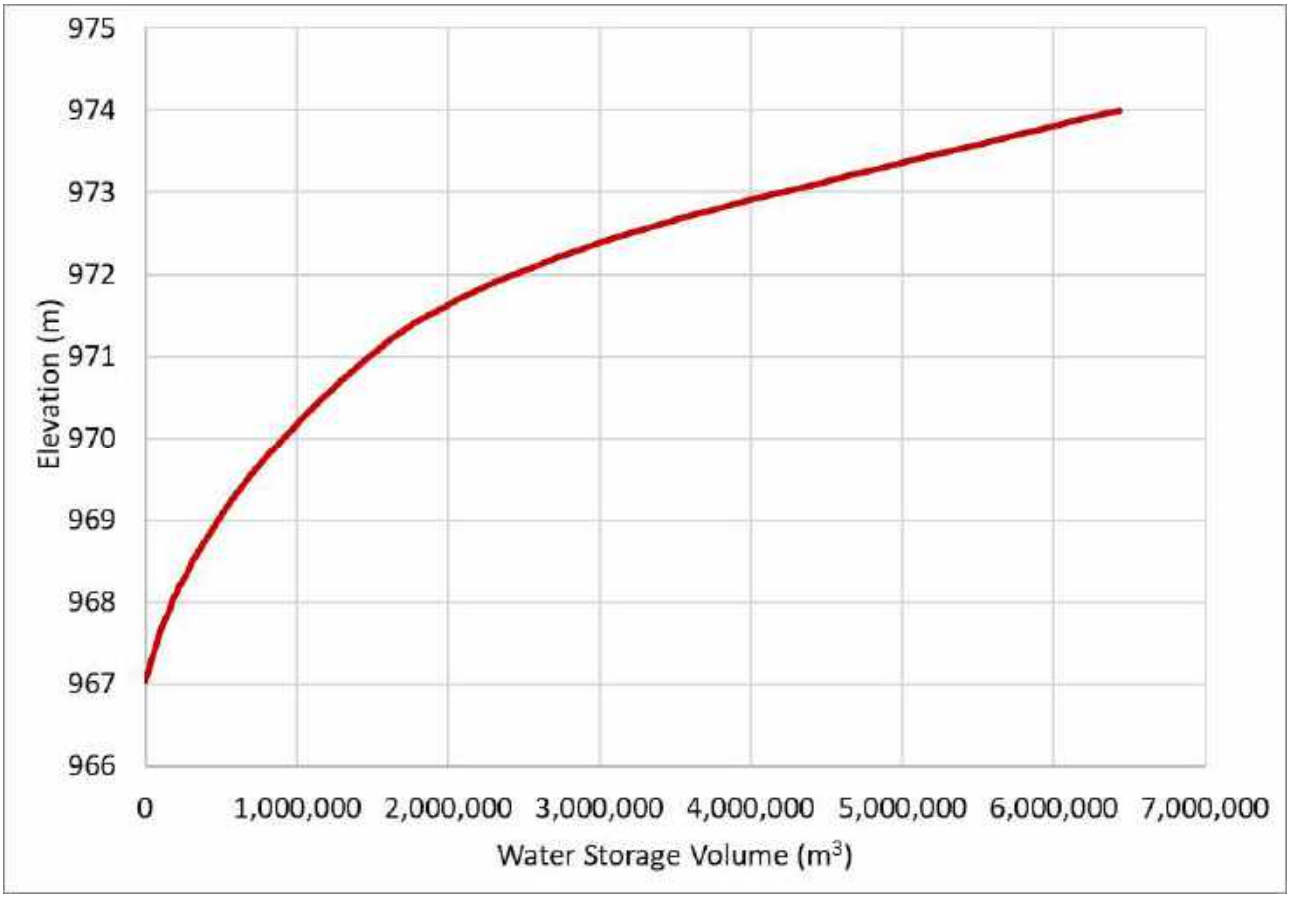

Table 1: Tailings Storage Facility Freeboard and Water Level Assessment Spillway Design Inputs Summary

Item No.	Item Description	Design Basis	Reference/Rationale
6	Snowmelt distribution	Evenly distributed over 12 hours centred on the storm peak intensity for each day	Adopted

No. = number; TSF = tailings storage facility; MPMC = Mount Polley Mining Corporation; IDF = inflow design flood; PMP = probable maximum precipitation; EDF = environmental design flood; UTM = Universal Transverse Mercator; NAD83 = North American Datum of 1983; CSRS = Canadian Spatial Reference System.

3.1 Tailings Storage Facility Storage Curve

The TSF storage curve applied in the analysis was generated from a tailings deposition model with a dam crest height of 974 m and tailings freeboard (defined as the height between the crest of the TSF and the maximum elevation of tailings) of 0.9 m and by considering a 0.5% sub-aerial and 2% sub-aqueous tailings beach slope (Figure 1) (WSP 2024).

m = metre; m^3 = cubic metre.

Figure 1: Tailings Storage Facility Stage Storage Curve

3.2 Catchment Characteristics

Catchment areas directly contributing to the TSF are provided in Table 2. This catchment delineation is the basis for the TSF spillway design. The water inflows to the TSF that are not pumped and therefore not in the direct control of the operator are as follows:

- precipitation on the direct footprint of the TSF
- runoff from the catchment directly above the TSF (TSF upstream catchment B and C)
- potential runoff from the upstream catchment (catchment A); depending on the updates to the tailings pipeline ditch

Table 2: Tailings Storage Facility Catchment Areas

Catchment	Watershed Area (km^2)
TSF upstream contact A[(a)]	0.43
TSF upstream contact B	0.24
TSF upstream contact C[(b)]	0.52
TSF	2.38

(a) The catchment area is to be refined per update to the tailings pipeline ditch.
(b) Potentially diverted via a diversion channel.
TSF = tailings storage facility; km^2 = square kilometres.

Each catchment was assigned a US Department of Agriculture (USDA) Soil Conservation Service (SCS) curve number (USDA 2009) value (Table 3) based on the land type to predict direct runoff. The wet antecedent moisture condition III was considered in the modelling.

The time of concentration was estimated using the SCS TR-55 method (USDA 2009), which divides the longest flow path into sheet flow, shallow concentrated flow, and open channel flow, and considers a minimum time of concentration of 6 minutes. The lag time was estimated as 60% of the time of concentration. Catchment areas and corresponding lag time values are provided in Table 3.

Table 3: Summary of Catchment Area Parameters

Catchment Area	Lag Time (min)	CN Value (AMC III)	Description
TSF direct	3.6[(a)]	95	TSF area
TSF upstream contact A	14.5	78	undisturbed area and disturbed area with some compacted haul road portions draining directly to TSF
TSF upstream contact B	8.6		
TSF upstream contact C	12	74	undisturbed area with some disturbed portions draining to TSF

(a) A minimum time of concentration of 6 minutes.
TSF = tailings storage facility; CN = curve number; AMC = antecedent moisture condition; min = minute.

3.3 Extreme Precipitation Events

Precipitation depths used to estimate inflows to the TSF for various return periods are presented in Table 4 and the 24-, 48-, and 72-hour probable maximum precipitation (PMP) depths are presented in Table 5.

Table 4: 24-hour Precipitation Depths for Mount Polley Mine, 1974 to 2021

Return Period (year)	24-hour Rainfall Depth (mm)[(a)]
2	33
10	47
25	54
100	64
200	69
1,000	80

(a) Log Pearson III distribution (WSP 2022).

Table 5: Probable Maximum Precipitation Depths

Duration	Depth (mm)[(b)]
24-hour	224[(a)]
48-hour	278
72-hour	339[(a)]

(a) Source: WSP 2022.
(b) Values rounded to the nearest mm.

3.4 Snowmelt

The snowmelt was determined using an energy balance method based on net longwave radiation, net shortwave radiation, and sensible and latent heat fluxes (Dunne and Leopold 1978), noting that the snowmelt is assumed to occur under cloudy skies. Consistent with runoff patterns observed on site during freshet, the snowmelt is expected to occur between March and May with a relatively greater proportion of melting happening in April.

The method is set out in Equation 1:

$$M_{R-t} = 1.42T_a + 2.5 + \frac{R_t T_a C_W}{L} + 0.0059 T_a u_2 \quad \textbf{(Equation 1)}$$

where:

$M_{R\text{-}t}$ = snowmelt in mm/day snow water equivalent for return period event duration t
R_t = rainfall depth in mm for return period event duration t, averaged over the duration of the storm
T_a = average air temperature over the return period event duration in °C
C_W = specific heat of water (equal to 1 calorie per gram per Celsius [cal/g/°C])
L = latent heat of fusion of ice equal to 80 cal/g
u_2 = wind speed in km/d

The input parameter values for Equation 1 are summarized in Table 6 and the estimated snowmelt depths are summarized in Table 7.

Table 6: Snowmelt Parameter Input Values

Parameter	Value	Rationale
R_t	See Table 4 and Table 5	Snowmelt generated by rainfall events
T_a	3.7°C	Average April air temperature (assumed snowmelt period); Climate Baseline Update (WSP 2022)
u_2	225 km/day (2.6 m/s)	Average April wind speed; tailings storage facility inflow design flood technical memorandum (Golder 2017)
C_W	1 cal/g/°C	Assumed
L	80 cal/g	Assumed

T_a = average air temperature over the return period event duration in °C; u_2 = wind speed in km/d; C_w = specific heat of water; L = latent heat of fusion of ice; cal/g/°C = calorie per gram per Celsius; cal/g = calorie per gram.

Table 7: Snowmelt Depth

Duration	Depth (mm)
24-hour 1:200-year	16
24-hour PMP	23
48-hour PMP	38
72-hour PMP	54

PMP = probable maximum precipitation; mm = millimetre.

3.5 Freeboard

The freeboard for a water-retaining structure can be defined as the minimum vertical distance between the still pool reservoir level and the crest of the retaining structure (CDA 2013, 2019). This distance needs to be maintained at all times to prevent overtopping of the containing structure by waves resulting from wind and wave set-up and run-up. The Canadian Dam Association provides the following definitions to calculate the freeboard (CDA 2013):

- *Normal freeboard* is the difference in elevation between the dam crest and the maximum operating water level of the facility. The normal freeboard is required to protect the structure from overtopping by 95% of waves caused by wind with an annual exceedance probability of 1:1,000-year event with the reservoir at maximum normal elevation.
- *Minimum freeboard* is the difference in elevation between the dam crest and the maximum water level that would result from the peak design inflow. The minimum freeboard is required to protect the structure from overtopping by 95% of waves caused by the most critical wind when the reservoir is at its maximum level during the inflow design flood (IDF). The wind for the significant consequence dam has an annual exceedance probability of a 1:10-year event.

The freeboard calculations follow the procedures and equations discussed in CDA (2013, 2019). Wind speeds, pond depth, and dam slope geometry were considered to determine the greatest wave uprush value for the normal and minimum freeboard scenarios.

Hourly wind speed and direction data for the study site are only available from 1997 to 2003, and daily wind speed data are available from 2019 to 2021. Thus, hourly data from the Environment and Climate Change Canada Williams Lake A climate station from 1961 through 2023 (ECCC 2023) were used as the basis for the frequency analysis to estimate extreme hourly wind speed for an annual exceedance probability ranging from 1:2 to 1:1,000-year. The results are provided in Table 8. No directional component was considered in this study and the wind was assumed to follow the longest fetch length of the TSF for conservatism.

Table 8: Hourly Maximum Wind Speed at the Williams Lake Station A

Annual Exceedance Probability (years)	Maximum Hourly Wind Speed (m/s)
2	23.0
10	26.3
20	27.3
50	28.6
100	29.5
200	30.3
500	31.4
1,000	32.1

m/s = metre per second.

Wave run-up was calculated using the random wave run-up height on gentle slope method by Mase (1989). A contingency of 0.3 m was selected to account for uncertainty due to settlement, crest irregularities, and construction tolerances for crest and spillway invert elevation (ANCOLD 2012). The freeboard calculation inputs and the corresponding normal and minimum freeboard are shown in Table 9. The minimum freeboard of 0.7 m is recommended when passing the IDF through the spillway.

Table 9: Tailings Storage Facility Required Freeboard Values

Description	Unit	Minimum	Normal
Design wind speed	m/s	26 (1:10-year)	32 (1:1,000-year)
Dam crest elevation	m	974	974
Maximum water elevation at IDF	m	973.3	973.3
Fetch length	km	2.0	2.0
Average water depth	m	2.3-3.8	2.3-3.8
Beach Slope	m/m	0.01[(a)]	0.01[(a)]
Wave height	m	0.76	0.97
Wind setup	m	0.08	0.11
Wave run-up[(b)]	m	0.31	0.39
Wave uprush (setup and run-up)	m	0.4	0.5
Contingency	m	0.3	0.3
Freeboard (wave uprush plus contingency)	m	0.7	0.8

(a) The beach slope is less than the minimum slope recommended by Mase (1989). The lowest recommended slope of 1/30 was used in the wave run-up estimation.

(b) Calculated using the method by Mase (1989).

IDF = inflow design flood; m = metre; m/s = metre per second; m/m = metre per metre; km = kilometre.

4.0 HYDROLOGIC AND HYDRAULIC MODELLING

4.1 Inflow Design Flood

Based on the *Health, Safety and Reclamation Code for Mines in British Columbia* (BCMEM 2022; EMLI 2022), the TSF is ranked as a significant consequence of failure facility (CDA 2013 and WSP 2023a). For a significant consequence dam, BCMEM (2022) recommends an IDF with an annual exceedance probability of one third of the way between the 1:975-year event and the probable maximum flood (PMF). For conservatism and consistency with WSP's best practice, the IDF for the TSF was selected as the PMF. The PMF for the TSF was estimated using the 72-hour PMP event plus snowmelt (snowmelt calculated using mean April temperature and the PMP rainfall). The 72-hour annual PMP of 339 mm was chosen over the spring PMP of 272 mm (WSP 2023a) to be conservative due to the inherent uncertainty in estimating the PMF. Rainfall, snowmelt depths used to estimate inflows to the TSF for the IDF event are presented in Table 10.

The rainfall depth component of the IDF was distributed using the USDA SCS Type II method for a three-day period, with a 24-hour distribution applied for each day.

The 72-hour PMP rainfall was distributed for each day of the event as follows:

a) **Day 1**—The 24-hour PMP was used.

b) **Day 2**—The rainfall depth was calculated as the difference between the 24-hour PMP and 48-hour PMP.

c) **Day 3**—The rainfall depth was calculated as the difference between the 48-hour PMP and 72-hour PMP.

The snowmelt depth component of the IDF was distributed evenly over a 12-hour period each day centred on the peak rainfall intensity of the rainfall events. Similar to the rainfall distribution for day two and day three of the events (i.e., 48-hour and 72-hour events), the snowmelt for each 12-hour period was equal to the incremental snowmelt depth from 24-hour and 48-hour snowmelt, and 48-hour and 72-hour snowmelt.

Table 10: Summary of Inflow Design Flood Parameters

Duration	Mean April Temperature (°C)	Depth[b] (mm)		
		PMP Rainfall	Total Snowmelt	Total Rainfall Plus Snowmelt
24-hour	3.7	224[a]	23	247
48-hour		278	38	316
72-hour		339[a]	54	393

(a) Source: WSP 2022.

(b) Values rounded to the nearest millimetre.

PMP = probable maximum precipitation; °C = degrees Celsius; mm = millimetre.

4.2 Environmental Design Flood

The environmental design flood (EDF) is the most severe flood that is to be managed without release of untreated water to the environment and is necessary in situations where water must be retained with no discharge to the environment or with controlled discharge through a treatment system (CDA 2019). According to CDA (2019), the selection of return period and duration of the EDF depends on factors such as the water quality that is being stored and could be released, regulatory requirements, frequency of overflow events, the rate and duration of the overflows, the environmental sensitivity of the receiving environment, downstream flow in the receiver, downstream mixing characteristics, and public perception on the matter. The following factors have been considered in the selection of EDF:

- The site-wide water balance model demonstrates that the TSF has sufficient capacity to retain the site runoff volumes during the 99.5th percentile storm event (WSP 2023b).
- Under normal conditions, the history of toxicity testing of the TSF supernatant has demonstrated that it is non-toxic.
- The water quality model predictions report (WSP 2023c) demonstrated that the measured concentrations at the TSF supernatant pond are generally below permit limits, with the exceptions for total copper and total phosphorous, total arsenic, total zinc, and dissolved aluminum. The source of the increased concentrations in the monitoring data for these parameters is thought to be due to the discharge of leachate to the TSF from the onsite test heap leach facility (Golder 2022), which has since been decommissioned. These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process. Water quality is anticipated to undergo greater dilution during a freshet due to increased flows, which naturally dilute substances in the water. Under non-flood conditions, TSF supernatant is collected and treated.
- Snowpack is regularly monitored on site to predict water flow patterns resulting from snowmelt and to effectively manage reservoir storage.
- The immediate mixing would primarily take place within Bootjack Creek, with expected limitations on dilution. During flood events, it is common for fish to be displaced downstream, reducing their exposure to undiluted runoff.
- MPMC is required to contain and treat up to a 1-in-10-year storm flow (EMA Permit 11678).

Based on these factors, the EDF for the TSF was estimated using the 24-hour 1-in-200-year rainfall plus snowmelt. Rainfall and snowmelt depths used to estimate inflows to the TSF for the EDF event are presented in Table 11.

Table 11: Summary of Environmental Design Flood Estimation

Duration	Mean April Temperature (°C)	Depth[b] (mm)		
		1:200-year Rainfall	Total Snowmelt	Total Rainfall Plus Snowmelt
24-hour	3.7	69[a]	16	85

(a) Source: WSP 2022.

(b) Values rounded to the nearest millimetre.

°C = degrees Celsius; mm = millimetre.

4.3 Methodology

A hydrologic model was developed using United States Army Corps of Engineers Hydrologic Engineering Center Hydrologic Modeling System (HEC-HMS) Model Version 4.11 (USACE 2023) to estimate inflow volumes to the TSF during the EDF and IDF events and peak flows over the proposed spillway channel during the IDF event. Inputs to the HEC-HMS model are discussed in Section 3.0 and the IDF parameters are discussed in Section 4.1.

The spillway inlet was modelled in the HEC-HMS model using the broad-crested weir equation (Brater and King 1976) to define the capacity of the weir. The spillway inlet structure will be trapezoidal with 7H:1V side slopes to allow a trafficable surface. For the trapezoidal channel composed of both triangular and rectangular sections, the discharge coefficient was determined by considering the combined effect of these two geometries on the flow characteristics of the channel. Rectangular weir coefficients of 1.4-1. and triangular weir coefficients of 1.0-1.3 were adopted depending on the hydraulic configuration of the spillway channel and crest (Smith 1995).

Design Storage Volume and Elevations

The TSF will be managed by maintaining the pond volume within the operating range for reclaim water and make-up water. The normal operating water volume of the TSF pond has been set as a range of 1.5 to 1.7 million m^3.

For operation, a trigger level to cease pumping of site water to the TSF is introduced. The trigger water level is set at 0.2 m below the spillway invert to allow time for operations to stop pumping water into the TSF in preparation for potential passage of the IDF through the spillway.

The spillway invert elevation for the TSF was determined through an iterative process using the HEC-HMS model to estimate the required minimum freeboard between the water surface passing through the spillway during the IDF and the dam crest. For modelling purposes, it was conservatively assumed that the water level within the TSF is at the invert elevation of the spillway at the beginning of the IDF event. The invert elevation of the spillway was set at elevation 972.9 m to provide the required minimum freeboard of 0.7 m (Section 3.5). The spillway was designed to convey peak discharge from the TSF during the IDF event while maintaining the required freeboard. The spillway invert was designed with a base width of 6 m with a slope of 0.3% across the dam crest.

As previously discussed, the TSF will temporarily retain site runoff volumes that can be generated during freshet and storm events. The site-wide water balance model demonstrates that the TSF has sufficient capacity to retain the site runoff volumes during the 99.5th percentile storm event (3.5 million m^3; WSP 2023b), with the EDF inflow volumes fitting comfortably within that range.

The water level and inflow volume model results for the TSF are provided in Table 12.

Table 12: Tailings Storage Facility with Spillway Water Level and Inflow Volume Results for Dam Crest Elevation 974 m

Parameters	Values
Dam crest elevation (m)	974.0
IDF inflow volume (million m^3)	1.3
Spillway invert elevation (m)	972.9
Maximum water level over spillway (during passage of IDF) (m)	973.3
Environmental design flood (million m^3)	0.2
Trigger water level to stop pumping site water to the TSF (m)	972.7

Table 12: Tailings Storage Facility with Spillway Water Level and Inflow Volume Results for Dam Crest Elevation 974 m

Parameters	Values
Normal operational pond volume range (million m^3)	1.5-1.7

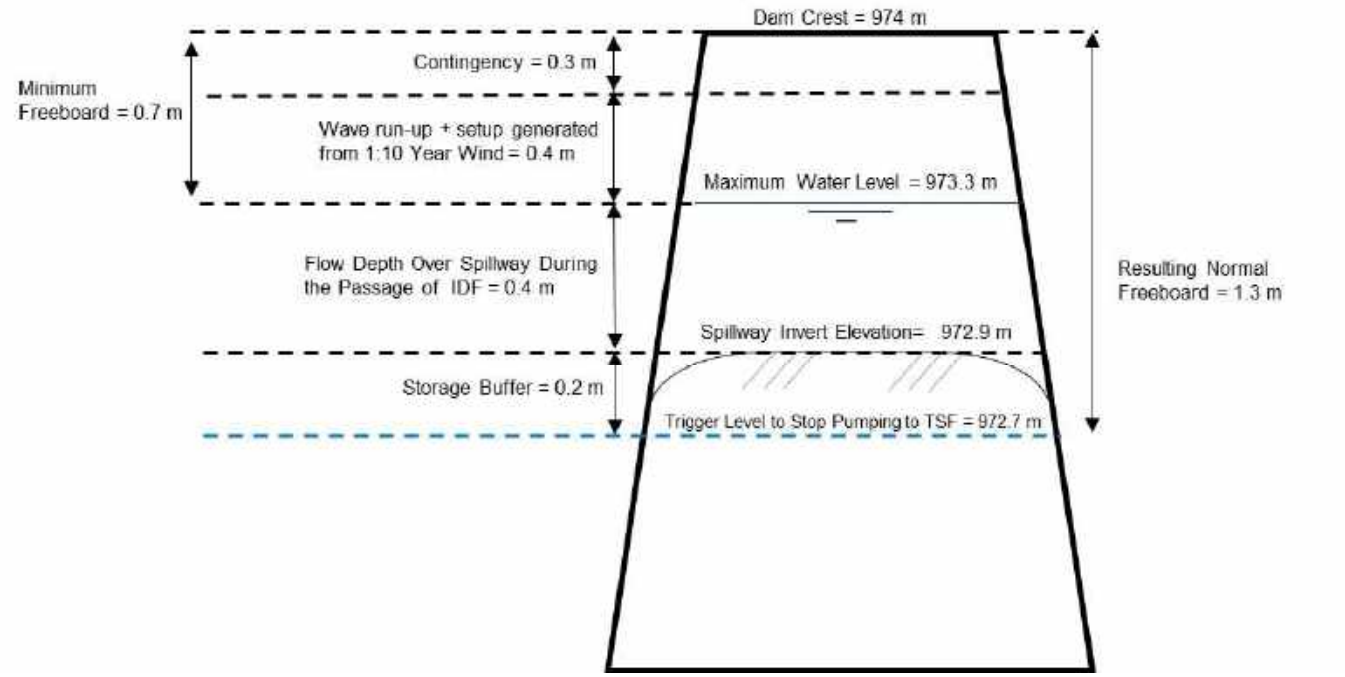
IDF = inflow design flood; TSF = tailings storage facility; m = metre; m^3 = cubic metre.

The required elevation of the spillway invert will depend on the actual constructed embankment elevation. The emergency spillway design elevations relative to the dam crest elevation are provided in Table 13. The TSF storage curve applied in the analysis was deemed representative of the TSF storage curve for dam crest elevations between 970 and 974 m.

Table 13: Emergency Spillway Design Elevations

Description	Depth Below Dam Crest (m)
Trigger water level to stop pumping site water to the TSF	1.3 m
Spillway invert elevation	1.1 m
Maximum water level over spillway (during passage of IDF)	0.7 m

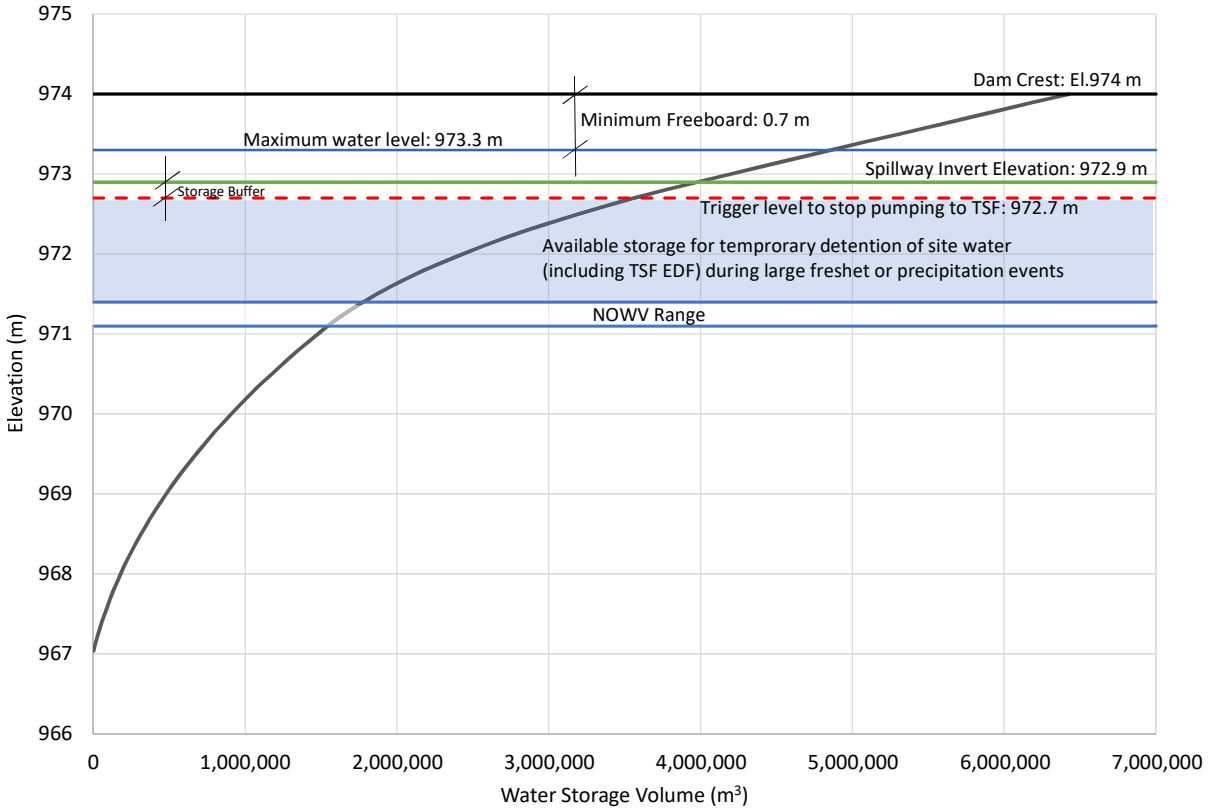
TSF = tailings storage facility; IDF = inflow design flood; m = metre.



The proposed spillway dimensions and the key results from the HEC-HMS model for the spillway are provided in Table 14, and a schematic of the results is provided in Figure 2 and Figure 3.

Table 14: Summary of the Spillway Arrangement and Flood Routing Results for Inflow Design Flood

Dam Crest Elevation (m)	Spillway Invert Elevation (m)	Spillway Base Width (m)	TSF Peak Discharge During the Passage of IDF (m^3/s)	Maximum Water Level Elevation During the Passage of IDF (m)	Minimum Freeboard (m)	Resulting Normal Freeboard[(a)] (m)
974.0	972.9	6.0	2.8	973.3	0.7	>1.3



(a) The normal freeboard required is 0.8 m and presented in Section 3.5. The resulting normal freeboard is the difference in elevation between the dam crest and the maximum operating water level of the facility from the Trigger water level.

TSF = tailings storage facility; IDF = inflow design flood; m = metre; m^3/s = cubic metres per second.

IDF = inflow design flood; TSF = tailings storage facility; m = metre.

Figure 2: Design Events in Relation to Tailings Storage Facility Embankment with Spillway

TSF = tailings storage facility; EDF = environmental design flood; NOWV = normal operating water volume; m = metre; m^3 = cubic metre.

Figure 3: Design Events in Relation to the Tailings Storage Facility Storage Curve for Crest Elevation 974 m

5.0 SUMMARY

Inflow volumes to the TSF were estimated using the United States Department of Agriculture Soil Conservation Service (SCS) method. Rainfall-runoff models were developed using the SCS method implemented with HEC-HMS software (version 4.11) (USACE 2023).

The freeboard calculations follow the procedures and equations discussed in CDA (2013, 2019). A minimum freeboard of 0.7 m was recommended while passing the IDF (Section 3.5).

The IDF for the TSF was estimated using the 72-hour PMP of 339 mm plus 54 mm snowmelt. The runoff volume generated by the IDF was 1.3 million m^3.

The spillway inlet elevation was proposed at 1.1 m below the dam crest to convey the peak discharge while providing the minimum freeboard required during the design event. The spillway invert was designed to have a base width of 6 m and 7H:1V side slopes to allow a trafficable surface with a slope of 0.3% across the dam crest.

A trigger water level was set at 0.2 m below the spillway invert to allow time for operations to stop pumping site water to the TSF.

6.0 CLOSURE

We trust that the information presented herein meets the current MPMC requirements. Please do not hesitate to contact the undersigned with any questions or concerns.

Checklist And Signoff for An Independent Review of High-Risk Professional Activities or Work

RE: Mount Polley Mine Tailings Storage Facility
Detailed Design to Elevation 974 m

Mount Polley Mine
British Columbia, Canada

PROFESSIONAL OF RECORD

German Pizarro-Sala, P.Eng.

WSP Canada, Inc
840 Howe Street, Vancouver, BC

Item	Reviewed Initials	Remarks
Criteria for carrying out Professional Activities or Work	PSW	Project design basis and design criteria established and documented.
Applicable codes, standards, and other requirements (laws, regulations, design requirements, etc.)	PSW	Applicable regulations and guidelines stated and used to develop criteria and guidance for design.
Geographical and/or environmental conditions and requirements	PSW	Site geotechnical and hydrotechnical conditions are documented. Site visit carried out. Foundation site investigations were carried out, documented and results used in design. Available data on tailings reviewed, an estimated tailings lower bound strength for tailings strength was used in design as stated in the report.
Assumptions for Professional Activities or Work	PSW	Integrated with the Design Criteria, Design Basis sections.
Concept for Professional Activities or Work	PSW	This work is detailed design for construction. Concept was completed as part of previous stages of work. Report includes Siting and Technology review.
Test and analysis procedures and results	PSW	Report includes details on site investigation, material property testing, stability, and seepage analysis.
Quality control and quality analysis procedures	PSW	Quality assurance and control are included as part of the Technical Specifications document. attached as an appendix.

Item	Reviewed Initials	Remarks
Calculations or analysis of representative elements	PSW	Verification of calculation and analysis reviews were completed through 3rd party verifications of the work. Evidence that reviews of the data and modelling were provided as Review Confirmations, Stability: Stability_974 (Static, PS, and post-EQ)_06DEC2023_YJ (1).xlsx; Seepage: Regular Drain Seepage Analyses (QAQC)_16FEB2024_YJ.xlsx; Filter: Gradation Envelope Comparison_29JAN2024_ED.xlsx. This satisfies that these reviews were completed by qualified personal. I did not review the specific modelling or calculation work.
Review of representative details	PSW	Detailed review of the Design Report was completed, comments/questions/recommendations made and presented to the EoR and Deputy EoR, and responses and actions taken were appropriate.
Integration of third-party components and artifacts	PSW	Work by external parties (pipe design, hydrology) are integrated with design basis criteria and final design and analysis.
Representation of output (e.g., drawings, reports, spreadsheets, models)	PSW	Drawings and cross sections were reviewed and were clear and appropriate for use.
Hazards (current and future) identified in the Risk Assessment	PSW	Risk assessment was provided as a Failure Modes and Effects Assessment, together with a Technical Memo dated March 6, 2024, providing additional details to these failure modes. This was adequate for use.
Adequacy and implementation of mitigation measures	PSW	Mitigations within the design were appropriate to the client's risk tolerance and applicable guidance.
Concerns discussed with the Professional of Record	PSW	Concerns were discussed and resolved.
For global, repetitive, or iterative design, recommendation for intervals of Independent Review	PSW	N/A

Study Limitations

WSP Canada Inc. (WSP) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by WSP for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents WSP's professional judgement based on the knowledge and information available at the time of completion. WSP is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to WSP by MPMC, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by WSP are considered its professional work product and shall remain the copyright property of WSP. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

1.0 INTRODUCTION

The Mount Polley Mine is a copper and gold mine operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. The mine site is located approximately 56 km northeast of Williams Lake, British Columbia, near the town of Likely. The mine is situated between Polley Lake and Bootjack Lake, and key components include open pits; waste rock dump sites; crusher, process plant, and administrative buildings; water management systems; and the tailings storage facility (TSF). The mine began production in 1997 and tailings generated at the process plant have been deposited as a low solids content slurry in the TSF located approximately 3 km southeast of the process plant.

The 23 June 2016 amendment of the *Mines Act* Permit M-200 authorized construction and operation of the TSF to elevation 970 m (Golder 2015g); however, mining operations were suspended in May 2019 when the TSF embankment crest elevation was about 968 m.

As part of the restart of mining operations, MPMC requested WSP Canada Inc. (WSP) to advance the design of a raise of the TSF embankment above elevation 970 m. Approximately 63 million tonnes of tailings are planned to be produced and deposited in the TSF until the end of operations at the Mount Polley Mine (approximately 8.5 years of production at about 20,000 tonnes per day). Deposition of tailings generated at the process plant into the TSF resumed in June 2022 and construction to raise the TSF embankment crest to elevation 970 m restarted in July 2022.

This report presents a site characterization for the embankment foundation of the Mount Polley TSF. Site conditions are summarized with respect to climate, geology, seismicity, geotechnical conditions, hydrogeology, and geochemical conditions. Investigations of the TSF foundation site are listed for reference. A discussion of site conditions and features with the potential to impact the TSF is presented with the TSF design approach.

The Engineers and Geoscientists British Columbia (formerly The Association of Professional Engineers and Geoscientists of British Columbia, APEGBC) site characterization for dam foundation guidelines (APEGBC 2016) were followed during the preparation of this report. It is intended that this report be updated with data from future site investigations and with observations and data from construction and operation of the facility over the life of the TSF. Should the understanding and interpretation of site conditions change with time, then required changes will be documented in future revisions of this report.

This report is to be read with the Study Limitations section, which forms an integral part of this document.

MPMC defined and uses the coordinate system tailings grid for the TSF. All coordinates and elevations are presented in tailings grid.

2.0 TAILINGS STORAGE FACILITY DESCRIPTION

The TSF includes one embankment that is approximately 4.6 km in length and has a maximum height of about 55 m as of the end of 2022. The embankment is subdivided into three sections, referred to as the Main Embankment, Perimeter Embankment, and South Embankment. The general layout of the TSF embankment is shown in Figure 1 and Figure 2. The embankment has incorporated a staged expansion design utilizing modified centreline and centreline construction methods. The general zoning of the TSF embankment includes the following:

- upstream fill comprising selected fill or tailings sand
- low permeability till core
- filter zone
- transition zone
- rockfill forming the downstream zone of the embankment and the downstream buttress along the Perimeter and Main Embankments.

The TSF Clean Water Ditch is located upstream of the TSF between Corner 4 and Corner 5 and diverts runoff into a small wetland downstream of the South Embankment.

Refer to the TSF elevation 970 m detailed design and the TSF life of mine feasibility design reports for additional information (Golder 2015g,h).

3.0 FOUNDATION INVESTIGATIONS AND STUDIES

The foundation investigations and studies considered for the TSF foundation characterization are listed below. Details of report contents and scope of investigations are summarized in APPENDIX A.

A layout of the TSF with the locations of the site investigations are shown in Figure 1 and Figure 2.

Geotechnical Investigations

- *Report on Geotechnical Investigations and Design of Open Pit, Waste Dumps and Tailings Storage Facility* (KP 1990)
- *Report on 1995 Geotechnical Investigations for Mill Site and Tailings Storage Facility* (KP 1995a)
- *Stage 2A Tailings Facility Construction Selected Excerpts from Reference Information* (KP 1997d)
- *Mount Polley Mine Project: Tailings Storage Facility 2011 Geotechnical Site Investigation* (AMEC 2012)
- *Mount Polley Dam Failure – Site Investigation Progress Report No. 2* (KCB 2015c)
- *Report on Mount Polley Tailings Storage Facility Breach* (IEEIRP 2015)
- *Mount Polley Dam Failure – Advanced Laboratory Testing Program Progress Report No. 4* (KCB 2015b)

TSF Construction Record Reports

- *Mount Polley Mine Tailings Storage Facility Report on 1998 Construction and Annual Inspection* (KP 1999)
- *Mount Polley Mine Tailings Storage Facility Report on 1999 Construction* (KP 2000)
- *Mount Polley Mine Tailings Storage Facility Report on Stage 3 Construction* (KP 2001)
- *Mount Polley Mine Tailings Storage Facility Report on Stage 4 Construction* (KP 2007a)
- *Mount Polley Mine Tailings Storage Facility Report on Stage 6A Construction* (KP 2009)
- *2015 Freshet Management Embankment As-Built Construction* (Golder 2015f)

4.0 CLIMATE

The five-year update of the climate baseline for the site is presented in WSP Golder (2022a) and includes precipitation, air temperature, relative humidity, solar radiation, evaporation, snow depths, and wind speed and direction. Updated climate change projections for the site are also provided.

The 1974 to 1993 climate records from the nearby Environment and Climate Change Canada Likely climate station and 1995 to 2021 climate records from the local MPMC climate stations served as the basis for developing statistics for describing precipitation and temperature conditions for the site. Records from local, regional, and MPMC climate stations were reviewed to assist in characterizing climate parameters.

The site experiences high summer precipitation due to summer storms, and the lowest monthly precipitation occurs in February. Precipitation typically occurs as snowfall starting in November and accumulating until March. Average annual precipitation at the site is estimated to be 612 mm with a standard deviation of 118 mm based on precipitation records for the site from 1974 to 2021. Typically, the increase of temperatures over 0°C starts in March, leading to freshet until June.

A summary of the updated baseline climate parameters is provided in Table 4-1. An evaluation of future climate change projections indicates future climate at the site will likely be warmer and wetter, with larger variations throughout the months.

Table 4-1: Summary of Key Climate Parameters for the Mount Polley Mine

Parameter	Value
Mean annual total precipitation (mm)	612
1:2-year 24-hour rainfall (mm)	33
1:10-year 24-hour rainfall (mm)	47
1:200-year 24-hour rainfall (mm)	69
Projected annual total precipitation anomaly from baseline for 2050s (%)	+5
Projected annual total precipitation anomaly from baseline for 2080s (%)	+8
Mean annual temperature (°C)	3.9
Average winter season (sub-zero mean monthly temperatures)	November to March
Mean snow water equivalent for the month of March (mm)	185
Projected annual air temperature anomaly from baseline for 2050s (°C)	+1.8
Projected annual air temperature anomaly from baseline for 2080s (°C)	+2.7
Mean annual shallow lake evaporation (mm)	673
Mean annual potential evapotranspiration (mm)	863

Note: Statistics are based on reviewed historical records from multiple climate stations and measured and derived data (where applicable).

5.0 QUATERNARY GEOLOGY

This section provides an overview of the Quaternary geology of the TSF embankment area, including geomorphological setting, regional and local geology, stratigraphic interpretation of subsurface investigation data, and interpreted depositional environment and Quaternary history of the area.

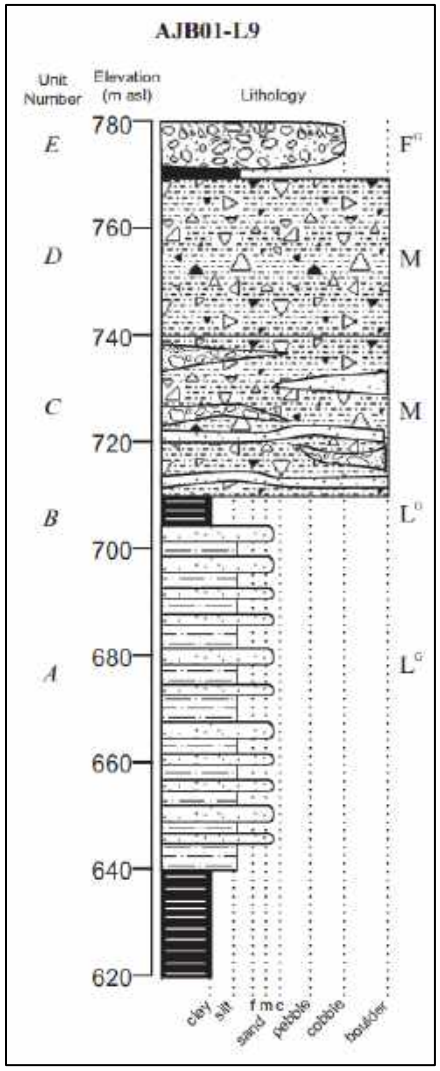
5.1 Regional Geomorphological Setting

The region is located on the eastern edge of the Interior Plateau, at the boundary between the Quesnel Highlands and the Fraser Plateau (Holland 1976; Bichler and Bobrowsky 2003). Terrain and geomorphology of the region comprises flat and gently rolling topography with hummocky bedrock exposures, dissected by a network of streams and lakes (Holland 1976; McAndless and Taylor 2006). Surface drainage patterns are influenced by bedrock topography; most of the stream valleys in the region have a northwest orientation and drain southward toward the lowland area north of the western arm of Quesnel Lake (Bichler and Bobrowsky 2003).

During the late Pleistocene, the area of the TSF was covered by the Cordilleran Ice Sheet (Clague 1987, 1988). The gently undulating topography and surface expression of the lowland area at the head of the west arm of Quesnel Lake is the result of glacial erosion and deposition of Quaternary sediments in an environment that evolved initially as a result of glacial advance followed by glacial retreat and inundation by meltwater, creating a glacial lake (glaciolacustrine) environment (Golder 2015c). Glacial landforms within the region include streamlined landforms associated with ground moraine, such as flutings, drumlins, drumlinoid ridges, and craig and tail features (Bichler and Bobrowsky 2003). These landforms indicate a predominantly northwesterly ice flow direction for the Cordilleran Ice Sheet in the Quesnel region (Clague 1988; Bichler and Bobrowsky 2003; Hashmi et al. 2015).

5.2 Regional Surficial Geology

The regional surficial geology is predominantly the result of erosion and deposition associated with the late Pleistocene (Wisconsinan) glacial episode referred to as the Fraser Glaciation (Clague 1987, 1988).



The regional surficial geology is dominated by till, glaciofluvial, and glaciolacustrine sediments of the Fraser Glaciation (Bichler and Bobrowsky 2003; McAndless and Taylor 2006). The glacial stratigraphy locally contains colluvial deposits derived from landslides initiating on valley walls during the late Pleistocene and Holocene (Clague 1988; Bichler and Bobrowsky 2003). Holocene fluvial deposits overlie the glacial deposits in areas local to watercourses and waterbodies throughout the region (Bichler and Bobrowsky 2003).

Bichler and Bobrowsky (2003) identified an “advance glaciolacustrine unit” (Illustration 5-1, Units A and B) that is overlain by a sequence consisting of basal till with intercalated glaciofluvial and glaciolacustrine sediments (Units C and D). This stratigraphic sequence is evident in available subsurface investigation data from the TSF area (Section 5.4). Basal till within the region is typically matrix-supported diamicton massive to weakly stratified, with faceted striated cobbles and boulders (Clague 1988) and is interpreted to be deposited during net glacial advance (Bichler and Bobrowsky 2003).

Glaciolacustrine sediments are present within most of the basal till in the major valleys (Illustration 5-1, Units A and B). These deposits are typically characterized by sub-horizontal, rhythmically bedded sand, silt, and clay in a coarsening upwards sequence. The unit is capped by fine-grained sediment, either rhythmically bedded or massive clay or silt, with local dropstones (Bichler and Bobrowsky 2003).

Glaciofluvial deposits are common within the major valleys, deposited in a succession of well-defined terraces (Clague 1988; Bichler and Bobrowsky 2003). Glaciofluvial sediments typically comprise moderately sorted, weakly to moderately compacted cobble or boulder gravel with a sand matrix (Illustration 5-1, Unit E). Gravel is also present locally in the form of hummocky blankets at higher elevations. Glaciofluvial fan deposits occur within valleys, with a similar composition to that of the glaciofluvial sediments, but typically with a greater sand content (Bichler and Bobrowsky 2003).

Morainal (ablation) till deposits more than 1 m thick are widespread and typically comprise poorly sorted, moderately to well-compacted silty clay diamicton. In the area of the TSF, these deposits are interpreted as ablation till (Illustration 5-1, Units C and D), deposited during net glacial recession (Clague 1988; Bichler and Bobrowsky 2003).

Source: Bichler and Bobrowsky 2003.

asl = above sea level; F^G = glaciofluvial deposits; M = basal till; L^G = glaciolacustrine deposits.

Illustration 5-1: Stratigraphic Column

5.3 Local Surficial Geology

A number of geotechnical subsurface investigations have been carried out in the TSF area (Section 3.0). The local surficial geology comprises Quaternary glacial sediments overlain by fill / anthropogenic deposits. A generalized stratigraphic sequence for the Quaternary sediments in the TSF area is presented in Illustration 5-2. The generalized stratigraphy reflects interpretations of the subsurface geology from geotechnical investigations conducted in the area of the TSF.

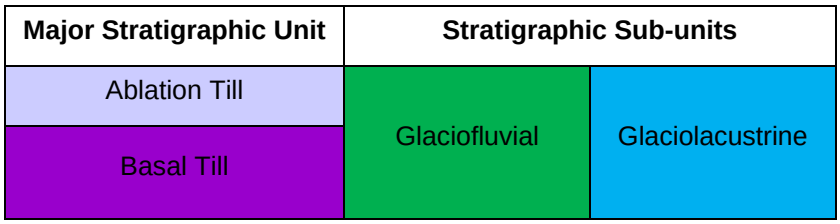


Illustration 5-2: Generalized Stratigraphic Column for Quaternary Sediments of the Tailings Storage Facility Embankment Area

This stratigraphic sequence is generally applicable to the mine area and TSF, with local variations associated with the depositional and erosional history of a particular area. The surficial geological units of the TSF embankment area are interpreted to represent two main stages of the Fraser Glaciation: the advance stage and recessional stage (Bichler and Bobrowsky 2003). Basal till is punctuated by glaciofluvial and glaciolacustrine deposits that typify the early stages of deposition (the advance stage), represented in the TSF area by basal till and associated sub-units. The ablation till and some layers of the glaciofluvial and glaciolacustrine sub-units were likely deposited during the recession stage of glaciation (Section 5.5).

Available mapping indicates the TSF area is underlain by altered, deformed, and brecciated volcanic and intrusive igneous rocks of the Late Triassic Nicola Group, with local sandstone and conglomerate of the Kamloops Group, Dragon Mountain Formation and some unnamed sediment groups (Logan et al. 2007).

5.4 Stratigraphic Interpretation

5.4.1 Methods

Stratigraphic correlations developed from the borehole data from the TSF area are presented as a series of interpretive geological cross-sections (Figure 3 to Figure 9). The stratigraphic interpretation conducted as part of this TSF foundation characterization study expands on the methods and geological interpretation and correlation completed by Golder in 2015, with updates to the previous work based on recent, detailed geological data from boreholes located close to the cross-section profile lines. General procedures used in development of the updated cross-sections and stratigraphic correlations are summarized as follows:

- **Lateral offset, priority and inferred boundaries**—Preference was given to incorporating geological data from boreholes located close to the cross-section lines and to boreholes that had the most detailed geological descriptions of the subsurface conditions encountered. Boreholes that were farther from cross-section lines were reviewed for geological correlation criteria, including information on the specific stratigraphic sequence and elevations of contacts between the different geological units. Boreholes with significant lateral offset from the lines of cross-section were generally omitted given the high degree of uncertainty in projection of the data.

- **Contact type**—Borehole logs with detailed geological descriptive information were used to determine the typical contact type between units (i.e., sharp or gradational).
- **Characteristics**—Geotechnical laboratory testing results were used to assist with distinguishing between geological units where available.

The geological criteria used to develop key stratigraphic correlations between different units are detailed in subsequent sections, with specific criteria for the glaciolacustrine deposits presented in Table 5-1. The criteria were applied to the geological descriptions in each of the boreholes used in the data compilation and review, and stratigraphic correlations identified.

Table 5-1: Stratigraphic Criteria for the Glaciolacustrine Sub-units

Geological Property	Typical Description
Unified Soil Classification System (USCS)[(a)]	CL, Cl, CH, or ML
Structure	Laminated, varved, or massive
Particle size distribution	Less than 5% gravel and 20% sand
Atterberg limits – plasticity index	10 to 25 (typically correlated to intermediate or high plasticity descriptions)
Typical stratigraphic location	Overlying or interbedded with glaciofluvial units

a) From the USCS Group Symbols: CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay, CH = high-plastic clay, ML = inorganic silt with slight or low plasticity.

Interpretation of borehole data is necessarily subjective due to the different terminology used and the consistency with which it is applied. For example, lamination, varving, and bedding were apparently used interchangeably in some of the descriptions of surficial deposits in the different borehole records both among the various consultant data sets, as well as within data obtained from individual consultants.

The scope of each previous investigation determined the level of detail included on the borehole logs in terms of stratigraphic unit descriptions, and whether geotechnical testing was completed. For example, the WSP Golder 2022 geotechnical investigation focused on identifying the glaciolacustrine unit, and therefore the borehole logs segregate units at a detailed scale accompanied by extensive geotechnical testing. In contrast, in the Knight Piésold Ltd. (KP) 1989 report, borehole records provide much less detail in terms of stratigraphic segregation of units and geotechnical testing. Not all borehole logs reviewed had plasticity ratings for stratigraphic units, nor did the associated investigation include Atterberg limits for every layer of the glaciolacustrine unit. In some factual reports, borehole records were not updated to reflect the geotechnical testing results of various surficial units. Therefore, review of both data sets was important to provide accurate stratigraphic interpretation. The Unified Soil Classification System was not used to describe surficial sediment textures in all factual reports, with some instead referring to the Wentworth Scale.

For presentation purposes on the interpretive geological cross-sections (Figure 3 to Figure 9), units of glacial sediment typically less than 0.5 m thick, as described in borehole records, were not shown on the cross-sections due to the scale of the section. This was specifically the case for thinner layers of the glaciofluvial and glaciolacustrine sub-units that were incorporated into adjacent units for cross-section presentation purposes. Similarly, small-scale interbedding, particularly among the glaciofluvial and glaciolacustrine sub-units, has not been shown on some sections.

In some areas of the TSF, the geological contact between glacial sediments and bedrock was difficult to identify accurately given the intensity of bedrock weathering. Therefore, the position of the surficial sediment-bedrock contact should be considered approximate in many parts of the TSF area.

5.4.2 Glacial Environments and Depositional Processes

Depositional environments associated with glacial sediments are inherently complex, particularly in ice-front or ablation zone settings, which are typically associated with glaciofluvial and glaciolacustrine deposits and sedimentation processes.

Glacial lakes disrupt the flow of meltwater and intercept glacial sediment being generated by processes such as ablation (ice removal) (Tweed and Carrivick 2015). Variability in the types of flow processes and meltwater velocities can complicate stratigraphic interpretation of glacial lake deposits. Sediment deposition and distribution in glaciolacustrine environments can be associated with gravity, turbidity, and density flows or currents (Carrivick and Tweed 2013). These flows can lead to structures and stratified deposits that may be interpreted as a mix of glaciofluvial and glaciolacustrine materials, particularly near the edges of a glacial lake where streams enter and exit an otherwise stagnant body of water. Sediment deposition in proximal zones of ice-marginal lakes can also be influenced by proglacial (ice front) activity.

Hillslope processes and valley tributaries entering the ablation zone following glacial retreat can also impact glaciolacustrine depositional environments (Carrivick and Tweed 2013). Ice contact deltas and the up-ice side of grounded fans can have similar characteristics to diamictic-textured till materials (Carrivick and Tweed 2013). Mass movement of valley hillslopes via processes such as slumps, debris slides, and debris flows can cause material to enter the subaqueous or water-free environment (depending on timing) and mix with existing sediments. Valley tributary systems entering the glaciofluvial and glaciolacustrine environments may also result in flow overlap and inter-fingering deposits. These mixing environments can lead to discontinuous and complex textures and structures. These processes and conditions were taken into consideration in the course of carrying out stratigraphic correlations for the TSF area.

5.5 Depositional Environment and Quaternary History of the Tailings Storage Facility Embankment Foundation Area

The stratigraphic interpretation of the TSF area generally correlates with that described by Bichler and Bobrowsky (2003), and the Golder (2015c) interpretation.

Two main stages of glacial activity can be interpreted from the surface and subsurface geological record in the TSF embankment area:

1) advance stage

2) recessional stage

5.5.1 Advance Stage

Depositional environments that developed during the late Pleistocene (Wisconsinan) Fraser Glaciation were dominated in the early stages by glacial advance of the Cordilleran ice sheet over much of central British Columbia (Clague 1987, 1988). Basal till and moraine punctuated by glaciofluvial and glaciolacustrine deposits typify the early stages of deposition, represented in the TSF area by basal till and associated sub-units.

These deposits are present across the TSF area, except in the South Embankment where bedrock is at a relatively high elevation, and the basal till unit is not interpreted to be present. The total maximum thickness of the advance glacial deposits is approximately 40 m (Figure 3 to Figure 9).

The basal till unit typically comprises a mixture of silt/clay with sand and gravel, punctuated by interbedded layers of glaciofluvial and glaciolacustrine sub-units. The relative consistency of the basal till is typically stiff to hard as a result of deposition under or in contact with glacial ice. Sediment comprising the glaciofluvial and glaciolacustrine units was transported from the area of the glacial ice sheet by meltwater streams and accumulated in lakes and stream channels in a pro-glacial (ice marginal) environment in front of the glacier. These sub-units are interpreted to represent hiatuses and/or minor localized glacial retreat, with some glaciofluvial deposits likely representing ice-frontal meltwater channel deposits. The glaciolacustrine and glaciofluvial materials were subsequently overridden and compacted by the glacial ice.

5.5.2 Recessional Stage

Ablation till and some layers of the glaciofluvial and glaciolacustrine sub-units were likely deposited during the recessional stage of glaciation, when ice stagnation, retreat and melting were the dominant processes.

The ablation till unit typically comprises firm to stiff silt and silty clay, with secondary components of gravel and sand. Fines were typically non-plastic or of low plasticity, and locally mottled. Pockets of organic material, mottled fines and iron oxide staining were encountered towards the top of the unit. These characteristics are typical of subaerially exposed sediments, allowing for weathering and development and/or deposition of organic materials.

Glaciofluvial deposits were observed locally at various levels within the ablation till unit. These discontinuous silty sand layers may represent late-stage, short-lived advance during the early-stage net glacial recession, marked by isolated glaciofluvial environments.

The glaciolacustrine sub-unit encountered near the base of the ablation till is interpreted to have formed during early-stage net glacial recession, in areas of localized ponding of glacial meltwater. These glaciolacustrine deposits likely represent the approximate upper boundary of the pro-glacial basal till and associated sub-units.

The Klohn Crippen Berger Ltd. (KCB 2015a) summary report presents an alternative interpretation for the Quaternary history of the TSF area, instead suggesting two separate glaciations: the penultimate glaciation and the Fraser Glaciation. The key difference between the KCB (2015a) interpretation of the Quaternary history of the TSF area and the interpretation presented in this report is that of the ablation till unit, which was interpreted by KCB to represent basal till deposited during advance of a second glaciation rather than ablation till deposited during retreat of the Fraser Glaciation:

- The basal till unit was interpreted by KCB (2015a) to be deposited during net advance of the penultimate glaciation.
- The ablation till unit was interpreted to be basal in origin, deposited during net advance of glaciers in the Fraser Glaciation. Interfingering of the glaciofluvial and glaciolacustrine deposits within the till unit was interpreted to represent multiple periods of glacial advance and retreat during the Fraser Glaciation.
- The diamicton within the ablation till unit was determined to be due to the presence of subglacial landforms mapped in the vicinity of the TSF area.
- Layers of the glaciolacustrine and glaciofluvial sub-units were interpreted to be deposited during glacial retreat of the penultimate glacial period, and during advance of the Fraser Glaciation.

5.5.3 Geological Units of the Tailings Storage Facility Embankment Foundation Area

5.5.3.1 Ablation Till Unit

The ablation till unit in the TSF area is interpreted as till derived from sediment entrained within the glacial ice and deposited directly by melting ice (ablation), typically in the terminus portion of the glacier. It commonly overlies basal till since it is deposited in the latest stages of glaciation. In the TSF area, these deposits are interpreted to be associated with glacial recession.

The main variables used to identify the ablation till unit were elevation, stratigraphic position, and typical unit thickness. The general elevation range of the base of the unit was estimated from borehole data to be between 925 and 940 m but may be as low as 910 m (e.g., Main Embankment).

The ablation till unit typically comprises firm to stiff silt and silty clay, with components of gravel and sand. Pockets of organic material, mottled fines, and iron oxide staining have been described towards the top of the unit. Fines are typically non-plastic or of low plasticity and are occasionally mottled.

Contacts between the ablation till unit and the overlying anthropogenic materials are sharp. The contact between the ablation till unit and underlying basal till unit is typically gradational, except where separated by the glaciolacustrine or glaciofluvial sub-units.

5.5.3.2 Basal Till Unit

Basal till is formed by the subglacial deposition of sediment carried within or below the glacier. In the TSF area, the basal till is interpreted to have been deposited during net glacial advance (Clague 1988).

The basal till unit underlies the ablation till unit and occurs at elevations between approximately 875 and 930 m, with the top contact of the unit typically between 895 and 915 m. The basal till unit is typically stiff to hard, and is composed of a mixture of silt, clay, sand, and gravel with occasional cobbles. The basal till unit differs from the ablation till unit in terms of elevation, sequence of deposition, gradation, and colour. Both the basal and ablation till units are grey to brown; however, mottling associated with oxidation and iron staining, and local pockets of organic material have been observed in the ablation till.

5.5.3.3 Glaciolacustrine Sub-unit

Glaciolacustrine deposits result from settlement of suspended sediment within lakes or sub-glacial meltwater, typically creating layers of silt and clay with laminated or varved (seasonal layering) structures (Tweed and Carrivick 2015).

Stratigraphic criteria for identifying glaciolacustrine deposits are presented in Table 5-1. The key controlling variables were structure, texture, and plasticity, where available. The glaciolacustrine sub-unit typically comprises silt, silty clay, or clay with lesser fine sand, with a varved or laminated structure. Locally, this unit may be more massive and lack a layered structure. Plasticity of this unit is typically medium to high. Trace gravel has been noted locally within the glaciolacustrine sub-unit and may represent dropstones; sand and clay lenses are recorded within some layers of this unit.

The glaciolacustrine sub-unit is interpreted to include all stratigraphic horizons with a layered structure and descriptions indicating deposition in a glacial lake or subglacial setting. This differs slightly from the geotechnical interpretation of the unit, which also applies geotechnical parameters to classify the unit (Table 5-1). As such, there are some locations where the glaciolacustrine sub-unit shown in the geological cross-section has been identified based on geological interpretation only. For example, at approximate Station 0+450 in the South

Embankment, the glaciolacustrine sub-unit has been identified at the base of the ablation till based on descriptions in borehole logs and interpreted depositional setting (Figure 3). At this location (boreholes VW11-02 and GA16-19), a layer of non-plastic to low plasticity silt with some clay and sandy to trace sand was described as bedded with occasional dropstones. This layer is interpreted to have been deposited in a glaciolacustrine environment, but it has geotechnical characteristics that differ from the intermediate and high plasticity glaciolacustrine units identified at the Main and Perimeter embankments (Section 7.3.4).

The glaciolacustrine sub-unit was typically observed near the base of the ablation till unit. It typically overlies or is interbedded with the glaciofluvial sub-unit throughout the basal till at elevations between approximately 900 and 920 m, with some layers locally occurring as low as 887 m (Perimeter Embankment). Reported thicknesses of glaciolacustrine deposits in the TSF area vary from approximately 0.3 to 15 m.

The glaciolacustrine sub-unit encountered near the base of the ablation till is interpreted to have formed during early-stage net glacial recession, in areas of localized ponding of glacial meltwater.

5.5.3.4 Glaciofluvial Sub-unit

Glaciofluvial deposits, sometimes referred to as outwash deposits, comprise sediments and landforms produced by glacial meltwater streams. The outwash sediment typically comprises cobbles, gravel and sand, with minor silt and silty clay. Glaciofluvial deposits may show a lateral decrease in grain size due to relatively rapid downstream movement of sediment. A depositional pattern known as braiding is also typical due to a lack of distinct channelling of sediment and high sediment load.

The key controlling variables for identifying glaciofluvial deposits are texture (sand and gravel dominated), grading, and sorting (where available).

A discontinuous silty and fine to coarse sand unit with trace fine gravel was identified locally within the ablation till unit between approximately 920 and 936 m elevation (Main Embankment). This may represent late-stage, short-lived advance activity during the early-stage net glacial recession, marked by isolated glaciofluvial environments.

The glaciofluvial sub-unit encountered within the basal till is typically interbedded with the glaciolacustrine sub-unit and is sub-divided into sand-dominated and gravel-dominated units. The sand-dominated glaciofluvial sub-unit typically comprises fine- to coarse-grained sand with trace silt, or silty sand with trace gravel noted locally. This sub-unit was recorded extensively throughout the basal till unit from approximately 882 to 924 m (Perimeter Embankment). Recorded thicknesses of the sand-dominated glaciofluvial layers within the TSF area range from approximately 0.15 to 12 m.

The gravel-dominated glaciofluvial sub-unit was identified locally within the Main Embankment and Perimeter Embankment only. The sub-unit typically comprises fine- to coarse-grained gravel with some sand, silt, and cobbles and was typically deposited in sequence with the sand-dominated glaciofluvial sub-unit. The gravel-dominated unit occurs between approximately 886 m (Main Embankment) and 924 m (Perimeter Embankment) elevation, with recorded thicknesses ranging from approximately 0.3 to 3 m.

Glaciofluvial sub-unit layer thicknesses were noted to vary spatially within the same layer, which is typical of stream deposition. Bifurcation (branching) and interfingering with adjacent units are also common stratigraphic characteristics of the glaciofluvial sub-unit. However, as previously noted, such detailed stratigraphic correlations were only possible where boreholes were located close to the line of the cross-section. As such, it is likely that these features are more common within the TSF area than is currently presented on the cross-sections.

Contacts between the glaciofluvial sub-unit and the glaciolacustrine sub-unit are typically sharp, and contacts with the basal till unit are commonly gradational.

The glaciofluvial sub-unit within the basal till is inferred to correlate with sand lenses described in the regional surficial stratigraphy by Bichler and Bobrowsky (2003), interpreted to represent ice-frontal meltwater channel deposits.

5.5.3.5 Bedrock

Weathered bedrock was encountered across the TSF area between approximately 873 and 968 m elevation. Bedrock described in boreholes typically comprised sand and gravel with some fines, recorded as weathered volcaniclastic conglomerate, volcanic debris or completely weathered bedrock. Locating the contact between the bedrock and overlying till was inherently difficult at many borehole locations given the highly weathered nature of the upper part of the bedrock. As such, the weathered bedrock can be difficult to distinguish from the overlying surficial deposits (Panteleyev et al. 1996; Golder 2015c).

6.0 SEISMIC HAZARD

The Mount Polley TSF site is located within the Canadian Cordillera, part of the North American Cordillera that was formed by convergent tectonic processes and the successive accretion of a number of allochthonous terranes to the ancient western margin of the North American plate, likely beginning sometime in the Late Triassic to Early Jurassic (approximately 180 to 200 million years ago) (Monger and Price 1979; Price 1994, 2000; Ricketts 2008; Monger 1989).

The present-day tectonics of western Canada are strongly influenced by the effects of relative motions of the Pacific and North America plates and remnants of the former Farallon plate that was largely subducted. The modern Explorer, Juan de Fuca, and Gorda plates are the remains of the much larger Farallon plate.

The Cascadia subduction zone (CSZ) marks the boundary where the Juan de Fuca, Explorer, and Gorda plates are being subducted beneath western North America. The 1,200 km long CSZ extends from northern California to British Columbia and is approximately 460 km west of the Mount Polley Mine at its closest approach. The present-day convergence (subduction) velocity ranges from about 43 mm/yr for the Juan de Fuca plate that decreases to the northwest to about 20 mm/yr for the Explorer plate (North America fixed). The CSZ has produced repeated great earthquakes (i.e., above moment magnitude (**M**)8) throughout the Holocene Epoch. The most recent CSZ great earthquake was an estimated **M**9.0 in January of 1700. The Cascadia subduction interface is currently locked and accumulating strain toward a future large or great earthquake (e.g., Dragert et al. 1994; Hyndman and Wang 1995; Mazzotti et al. 2003).

The southern Canadian Cordillera, where the Mount Polley Mine is located, has relatively low rates of historical seismicity relative to the CSZ. However, intermediate-to-large magnitude earthquakes have been recorded. For example, a **M**6.0 earthquake in 1918 had an epicentre approximately 220 km east of the site and a **M**5.5 earthquake occurred in 1986 with an epicentre approximately 200 km north of the site. Both earthquakes occurred in the “Rocky Mountain Trench” that marks the boundary between the western Foreland Fold and Thrust Belt and the Quesnel terrane and other terranes. The 1986 earthquake had a thrust fault mechanism, which is consistent with the general structural trends mapped in the area (e.g., Rogers et al. 1990).

WSP developed a site-specific seismic hazard model for the Mount Polley site based on source models developed for the 6th Generation Canadian National Seismic Hazard Model (Canada SHM6) and a review of geological and paleoseismological features (APPENDIX B). Both near-field, moderate-magnitude crustal earthquakes and far-field subduction interface earthquakes contribute to the site seismic hazard. The shallow crustal earthquake sources are dominated by moderate-magnitude earthquakes (**M**6.0 to **M**6.5) close to the site (i.e., less than 60 km away) at all annual exceedance probabilities. The contribution to hazard at the site from CSZ sources is from large earthquakes (**M**8+) at 450 to 550 km from the site at all annual exceedance probabilities and spectral periods of interest.

Probabilistic analysis results from the site-specific hazard model are listed in Table 6-1.

Table 6-1: Site-Specific Accelerations (5%-damped) for Selected Annual Exceedance Probabilities and Spectral Periods at the Mount Polley Tailings Storage Facility Site (V_{S30} = 849 m/s)

Performance Level – Annual Exceedance Probability	Spectral Period (s)	Acceleration[a] (g)					
		Mean	Fractile

	1.5	0.041	0.032	0.034	0.039	0.047	0.048

a) 5%-damped, mean, geometric-mean, peak horizontal acceleration.

PGA = peak ground acceleration.

7.0 GEOTECHNICAL CONDITIONS

This section presents a summary of results of geotechnical testing and interpreted geotechnical parameters.

A summary of available geotechnical data collected during subsurface investigations in the area of the TSF embankment is provided in APPENDIX C (Tables C1 to C5). This includes information related to boreholes, test pits, cone penetration tests (CPTs), monitoring wells and other instrumentation, and laboratory index testing results. The subsurface investigation locations are shown relative to the TSF embankment in Figure 1 and Figure 2. Surficial geological cross-sections were developed for the encountered foundation conditions which are shown in Figure 3 to Figure 9.

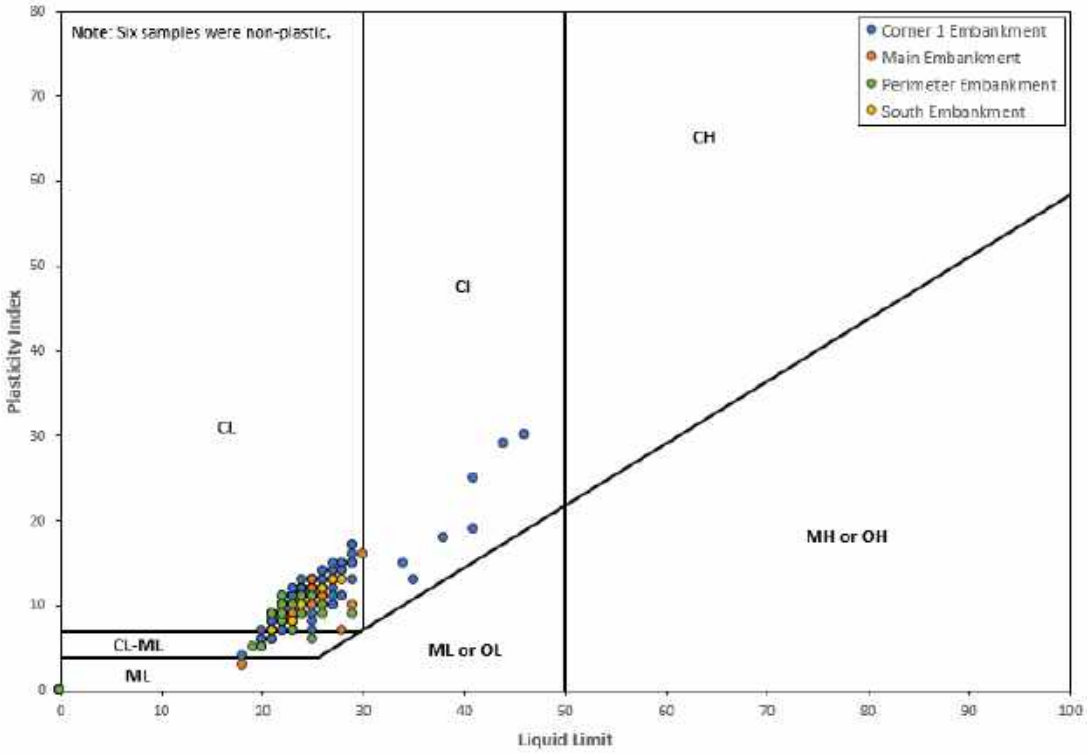
A borehole was drilled downstream of the Corner 1 Embankment after completion of the investigation program carried out in 2021 and 2022 (referred to as borehole GA22-01). The record of borehole and other relevant information is provided in APPENDIX D.

The following stratigraphic units were identified in the foundation of the TSF embankment.

- **Till**—The till is generally a mixture of gravel, sand, and low plastic fines ranging from silt to silty clay. The material is generally cohesive with a consistency from firm to hard. The average water content is approximately 12% (ranges from 2% to 33%). Results of geotechnical testing are presented in Section 7.1.
- **Glaciofluvial units**—The glaciofluvial units are generally gravelly sandy silt to silty sand with trace gravel. The fines content ranges from about 4% to 100% and are generally non-plastic. The material is generally non-cohesive with a compactness ranging from compact to very dense. The average water content is approximately 17% (ranges from 2% to 34%). Results of geotechnical testing are presented in Section 7.2.
- **Glaciolacustrine units**—The glaciolacustrine units are generally silty clay to clay with trace to some sand. The fines are generally intermediate to high plasticity. The material is generally cohesive with a consistency ranging from firm to very stiff. The average water contents and clay contents of the glaciolacustrine units vary based on location. Results of geotechnical testing are presented in Section 7.3.
- **Highly weathered bedrock**—Generally weathered volcaniclastic conglomerate, volcanic debris or completely weathered bedrock.

7.1 Till

Till has been encountered during many previous subsurface investigations carried out near the foundation of the TSF. Representative samples were collected throughout the investigations with selected samples chosen for subsequent laboratory testing. The laboratory testing programs generally included a range of index and/or advanced laboratory tests dependent on the specific objective at the time. A summary of the index properties for the samples of till is presented in Table 7-1.



The Atterberg limit results for each embankment are shown graphically in Illustration 7-1. The fines are generally non-plastic or low plasticity and range from silt to silty clay (ML to CL, respectively). Thirteen test results were outside of this general range and had an intermediate plasticity. The samples with an intermediate plasticity were all collected from the Corner 1 Embankment.

The natural water content results were plotted against elevation, which is shown in Illustration 7-2. The average water content of the till was approximately 12% and ranged from 2% to 33%.

Table 7-1: Summary of Index Properties of Till

Index Property		Average	Minimum	Maximum	Number of Tests
Gradation	Gravel (%)	15	0	45	218
	Sand (%)	35	3	61	
	Fines (%)	50	16	97	
Liquid limit[a]		25	18	46	169
Plastic limit[a]		14	11	22	
Plasticity index[a]		11	3	30	
Water content (%)		11.8	2.0	33.1	1,645
Specific gravity of solids		2.76	2.73	2.78	6

a) Atterberg limits exclude six non-plastic results.

CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay; CH = high-plastic clay; CL-ML = low-plastic silty clay to clayey silt; ML = inorganic silt with slight or low plasticity; MH = high-plastic silt, generally classified as clayey silt; OL = low-plastic organic silt; OH = high-plastic organic silt.

Illustration 7-1: Plasticity Chart of Till Samples

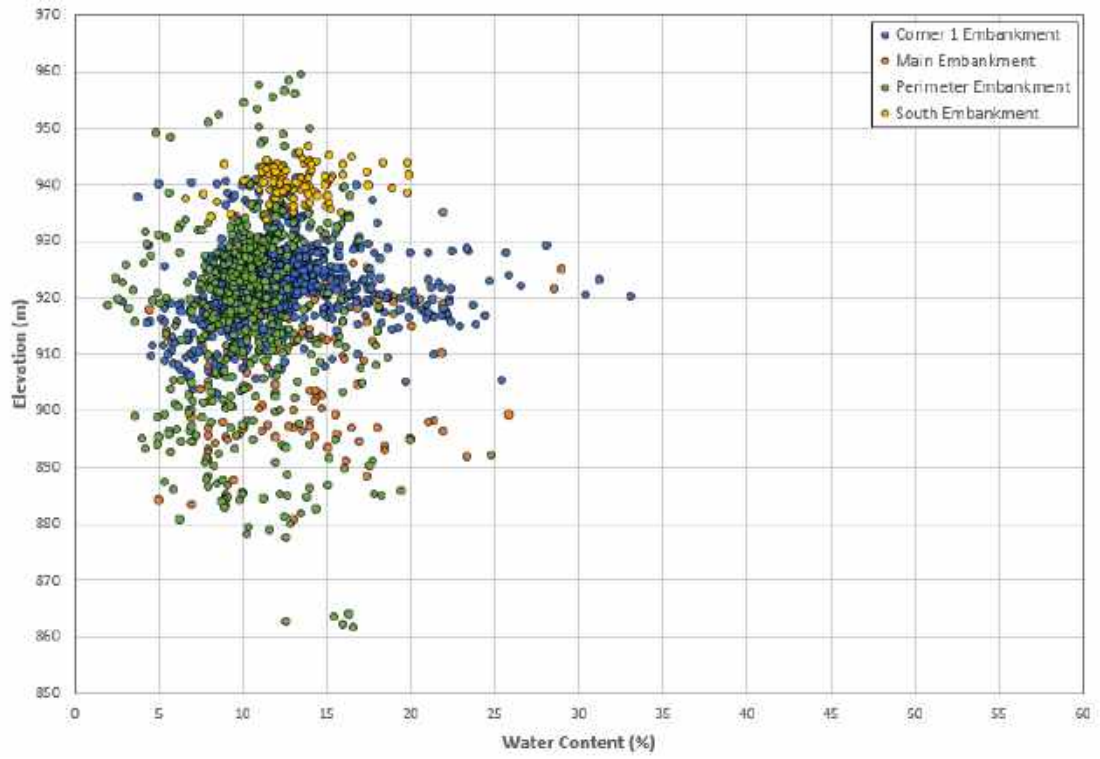


Illustration 7-2: Water Content against Elevation of Till Samples

A summary of the shear strength test results from till samples is presented in Table 7-2. The peak friction angle ranged from 30 to 41 degrees with a cohesion of 0 kPa.

Pressuremeter test results indicate the friction angle of the till at the Corner 1 Embankment ranges between 36 and 48 degrees, with an average of about 40 degrees (IEEIRP 2015).

Table 7-2: Shear Strength Test Results of Till

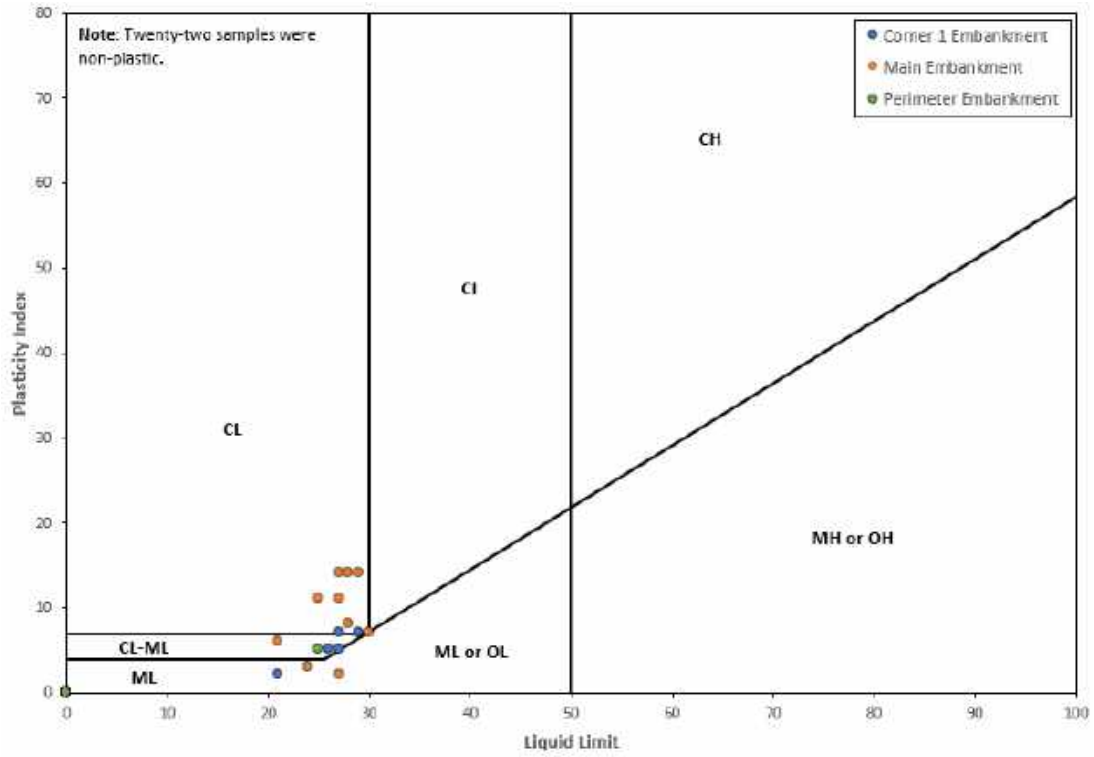
Borehole / Test Pit No.	Sample No.	Sample Type	Elevation (m)	Peak Shear Strength Parameter		Source
				Friction Angle (degrees)	Cohesion (kPa)	
TP95-27	n/a	Grab	926.2	35	0	KP (1995a)
TP95-37	n/a	Grab	937.0	35	0	
MR14-105	4B	Thin-walled tube	927.8	34	0	IEEIRP (2015)
MR14-106	2	Thin-walled tube	924.6	34	0	
MR14-111	5A	Thin-walled tube	922.9	35	0	
MR14-113	1C	Thin-walled tube	928.0	33	0	
SH14-10A	12	Sonic core	922.4	41	0	KCB (2015b)
	10	Sonic core	921.6	30	0	
	14	Sonic core	918.7	37	0	
TP14-01	BS-01	Block	n/a	34	0	
	BS-01	Block	n/a	33	0	

n/a = not applicable, not available

The median shear wave velocity measured in the till foundation ranged from about 320 to 400 m/s at the Corner 1 Embankment (Golder 2016a).

7.2 Glaciofluvial Unit

A summary of the index properties for the glaciofluvial samples collected from the foundation of the TSF embankment is presented in Table 7-3.



A total of 38 Atterberg limit test results were available for samples of glaciofluvial. Atterberg limit tests were generally only carried out on samples described as exhibiting some plastic behaviour. The fines are generally a non-plastic to low plastic material and range from silt to silty clay (ML to CL, respectively). Twenty-two of the 38 test results were non-plastic. The material is generally non-cohesive with a compactness ranging from compact to very dense. The Atterberg limit results for each embankment are shown graphically in Illustration 7-3.

The natural water content results were plotted against elevation, which is shown in Illustration 7-4. The average water content of the glaciofluvial was approximately 17% and ranged from 2% to 34%.

Table 7-3: Summary of Index Properties of Glaciofluvial Unit

Index Property		Average	Minimum	Maximum	Number of Tests
Gradation	Gravel (%)	6	0	47	43
	Sand (%)	32	0	85	
	Fines (%)	63	4	100	
Liquid limit[a]		26	21	30	16
Plastic limit[a]		19	13	25	
Plasticity index[a]		8	2	14	
Water content (%)		16.9	2.2	33.9	393
Specific gravity of solids		2.78	2.78	2.78	1

a) Atterberg limits exclude 22 non-plastic results.

CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay; CH = high-plastic clay; CL-ML = low-plastic silty clay to clayey silt; ML = inorganic silt with slight or low plasticity; MH = high-plastic silt, generally classified as clayey silt; OL = low-plastic organic silt; OH = high-plastic organic silt.

Illustration 7-3: Plasticity Chart of Glaciofluvial Samples

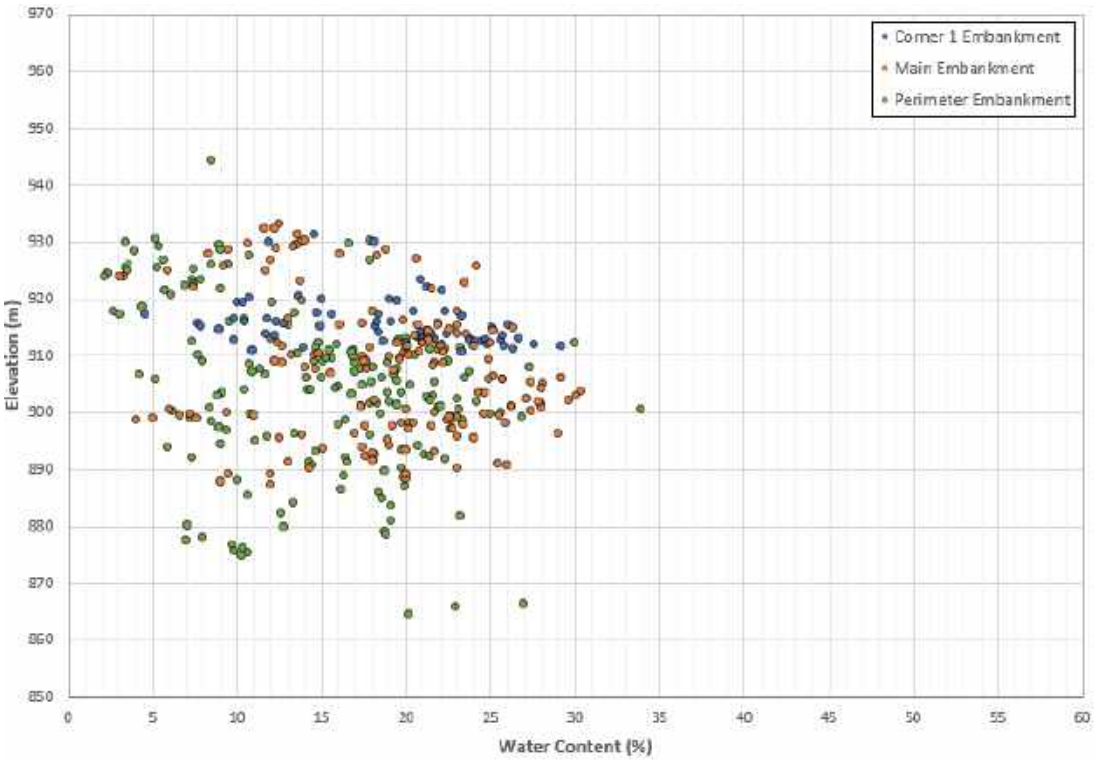


Illustration 7-4: Water Content against Elevation of Glaciofluvial Samples

A summary of the shear strength test results from glaciofluvial samples is presented in Table 7-4. The peak friction angles were 35 and 36 degrees with a cohesion of 0 kPa.

Table 7-4: Shear Strength Test Results of Glaciofluvial Unit

Borehole / Test Pit No.	Sample No.	Sample Type	Elevation (m)	Peak Shear Strength Parameter		Source
				Friction Angle (degrees)	Cohesion (kPa)	
Central Collection Sump	n/a	Thin-walled tube	n/a	36	0	Golder (2015d)
GA15-21	9 (C|U)	Thin-walled tube	902.5	35	0	

n/a = not applicable, not available

7.3 Glaciolacustrine Unit

Glaciolacustrine deposits were identified along the Main, Perimeter, and Corner 1 embankments:

- **Main Embankment**—A semi-continuous layer of glaciolacustrine soil is present at an elevation of approximately 900 to 910 m and extends along the length of the Main Embankment. A shallower layer of glaciolacustrine soil near elevation 920 m was identified near Station 2+400 and 2+750. Results of geotechnical testing completed on samples of glaciolacustrine soils from the Main Embankment are presented in Section 7.3.1.
- **Perimeter Embankment**—The glaciolacustrine soil deposits are not continuous and their elevations generally range between about 885 and 935 m. Results of geotechnical testing completed on samples of glaciolacustrine soils from the Perimeter Embankment are presented in Section 7.3.2.
- **Corner 1 Embankment**—Upper and lower glaciolacustrine soil deposits are present at this location. The upper glaciolacustrine deposit is a semi-continuous layer between approximate elevation 918 and 925 m from approximate Station 20+000 to 20+300. The lower glaciolacustrine deposit is also a semi-continuous layer between approximate elevation 900 and 918 m. Results of geotechnical testing completed on samples of glaciolacustrine soils from the Corner 1 Embankment are presented in Section 7.3.3.

A layer of low plasticity silty clay interpreted to have deposited in a glaciolacustrine environment was encountered directly above bedrock near Station 1+100 at the South Embankment; however, the geotechnical testing completed on the material showed it not to be representative of the intermediate or high plasticity glaciolacustrine units found within the footprint of the Corner 1, Main, and Perimeter embankments (Golder 2017). The results of the geotechnical testing are presented in Section 7.3.4.

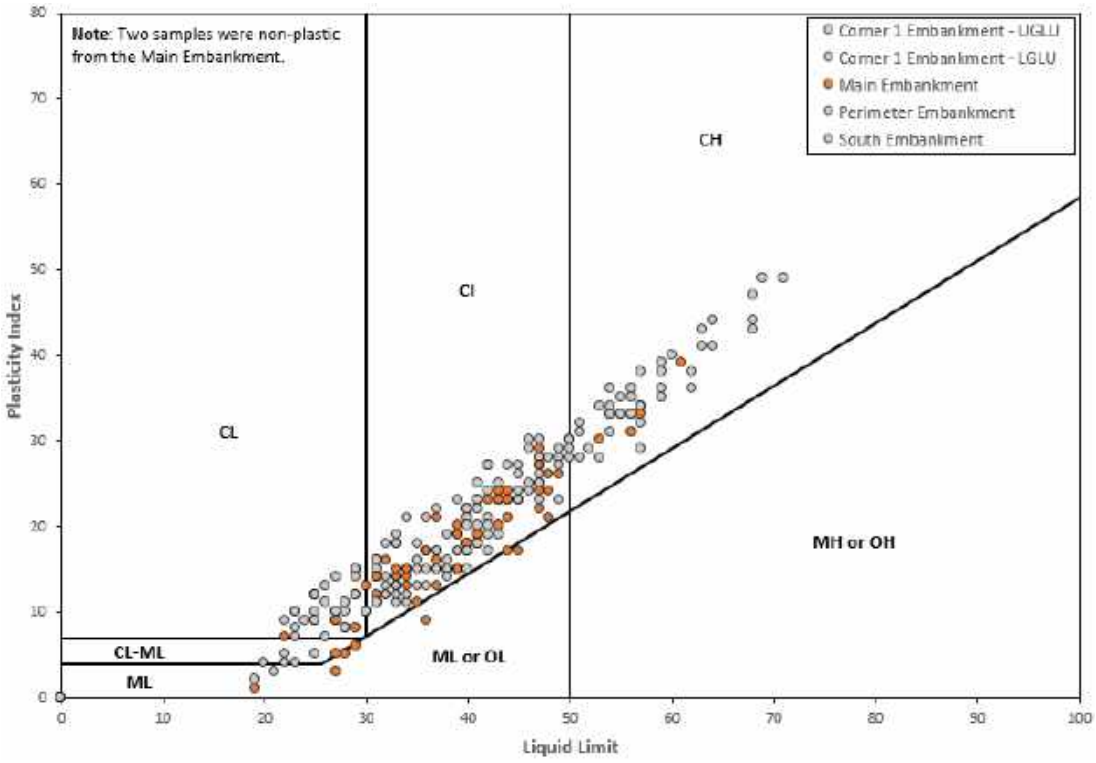
7.3.1 Main Embankment

A summary of the index properties for samples of glaciolacustrine material collected from the foundation of the Main Embankment is presented in Table 7-5.

The Atterberg limit results are shown graphically in Illustration 7-5. The fines are generally a low to intermediate plastic material and range from silt to silty clay (ML to CI, respectively). Six results were outside of this general range and were either non-plastic or had a high plasticity.

The natural water content results were plotted against elevation, which is shown in Illustration 7-6. The average water content of the glaciolacustrine samples from the Main Embankment was approximately 26% and ranged from 6% to 42%.

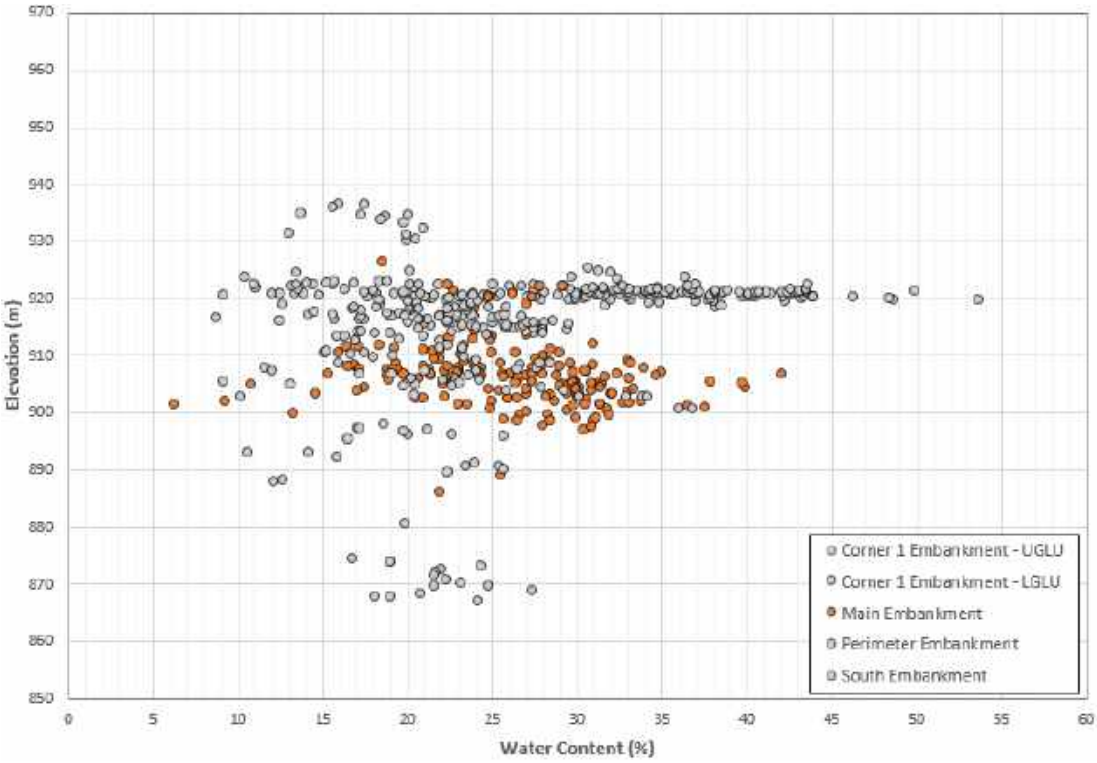
The natural water content results were also plotted against clay content as shown in Illustration 7-7. A total of 44 hydrometer test results were available for glaciolacustrine samples from the Main Embankment foundation. The average clay content (defined as particles smaller than 0.002 mm) of the glaciolacustrine samples was approximately 30% and ranged from 7% to 49%. A general trend of increasing water content with increasing clay content can be seen in the illustration.



All available test results for glaciolacustrine samples collected from the foundation of the other embankments were incorporated into the illustrations for comparison.

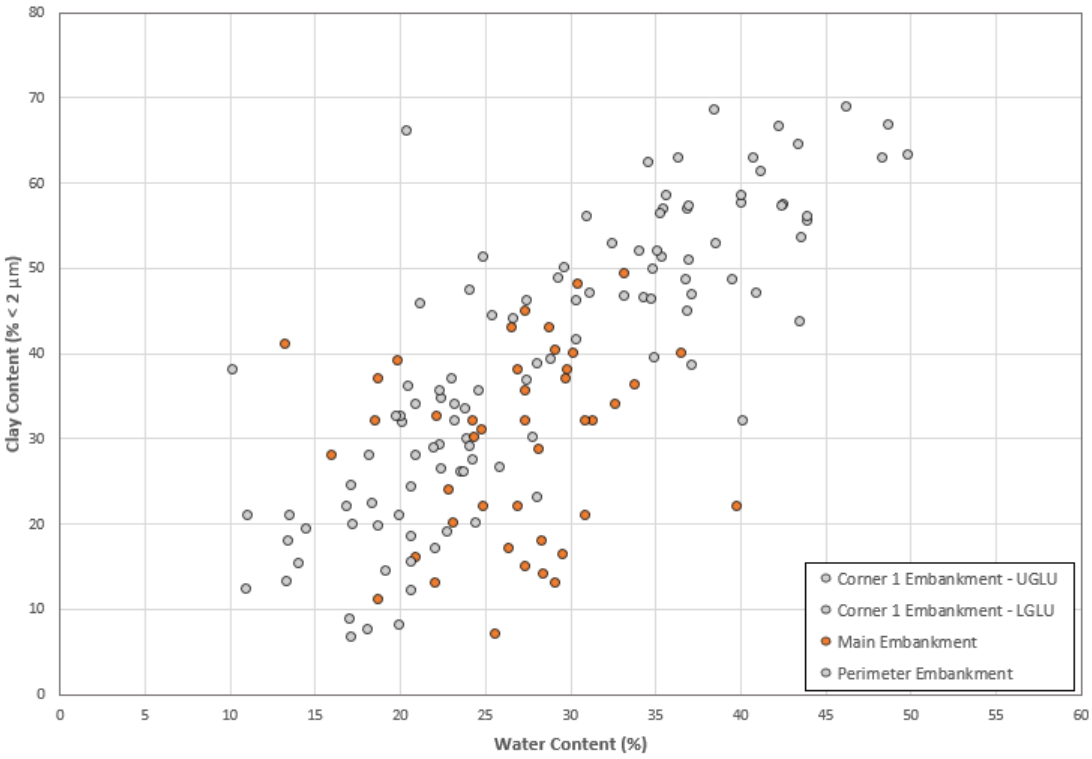
Table 7-5: Summary of Index Properties of Glaciolacustrine at the Main Embankment

Index Property		Average	Minimum	Maximum	Number of Tests
Gradation	Gravel (%)	0	0	5	52
	Sand (%)	6	0	40	
	Fines (%)	94	60	100	
	Silt (%)	65	44	92	44
	Clay[a] (%)	30	7	49	
Liquid limit[b]		39	19	61	62
Plastic limit[b]		21	15	28	
Plasticity index[b]		17	1	39	
Water content (%)		26.1	6.3	42.1	179
Specific gravity of solids		2.75	2.65	2.80	8



a) Clay is defined as particles smaller than 0.002 mm.

b) Atterberg limits exclude two non-plastic results from the Main Embankment.

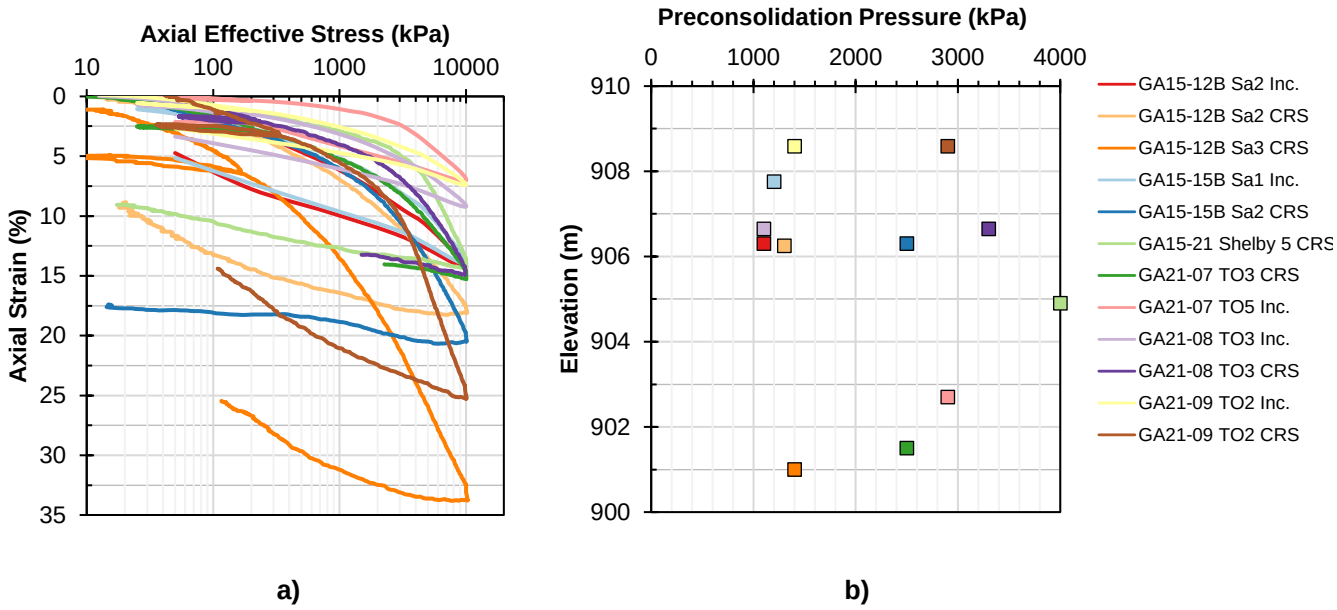


CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay; CH = high-plastic clay; CL-ML = low-plastic silty clay to clayey silt; ML = inorganic silt with slight or low plasticity; MH = high-plastic silt, generally classified as clayey silt; OL = low-plastic organic silt; OH = high-plastic organic silt.

Illustration 7-5: Plasticity Chart of Glaciolacustrine Samples from the Main Embankment

LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-6: Water Content against Elevation of Glaciolacustrine Samples from the Main Embankment



LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-7: Water Content against Clay Content of Glaciolacustrine Samples from the Main Embankment

The results of consolidation tests carried out on sonic drilling and thin-walled tube samples of glaciolacustrine material from the Main Embankment are shown in Table 7-6 and Illustration 7-8a. Illustration 7-8b presents the preconsolidation pressures estimated using the Casagrande method.

Table 7-6: Consolidation Test Results of Glaciolacustrine Samples at the Main Embankment

Borehole No.	Sample No.	Sample Type	Elevation (m)	Estimated Preconsolidation Pressure (kPa)		Source
				Casagrande	Strain Energy	
GA15-12B	2	Sonic core	906.3	1,100	1,200	Golder (2015d)
GA15-12B	2	Sonic core	906.3	1,300	1,500	
GA15-12B	3	Sonic core	901.0	1,400	1,200	
GA15-15B	1	Thin-walled tube	907.8	1,200	1,400	
GA15-15B	2	Thin-walled tube	906.3	2,500	2,700	
GA15-21	5	Thin-walled tube	904.9	4,000	4,000	
GA21-07	TO3	Thin-walled tube	902.7	2,900	3,000	WSP Golder (2022b)
GA21-07	TO5	Thin-walled tube	901.5	2,500	2,600	
GA21-08	TO3	Thin-walled tube	906.6	1,100	1,100	
GA21-08	TO3	Thin-walled tube	906.6	3,300	3,400	
GA21-09	TO2	Thin-walled tube	908.6	1,400	1,300	
GA21-09	TO2	Thin-walled tube	908.6	2,900	2,800	

CRS = constant rate of strain; Inc. = incremental load.

Illustration 7-8: a) Consolidation Test Results on Glaciolacustrine Samples at the Main Embankment and b) Inferred Preconsolidation Pressure from Laboratory and Cone Penetration Test Data

The quality of the samples was assessed using two different methods. Lunne et al. (1997) use the $\Delta e/e_0$ value to evaluate the sample quality, where Δe is the change in sample void ratio caused by reapplying the in situ effective stress (σ_{v0}'), and e_0 is the initial void ratio of the soil. Karlsrud and Hernandez-Martinez (2013) use the M_0/M_L value for sample quality evaluation, where M_0 is the maximum constrained modulus in the overconsolidated stress range and M_L is the minimum constrained modulus after the preconsolidation pressure. Table 7-7 shows the sample quality assessment based on values of $\Delta e/e_0$ and M_0/M_L and Table 7-8 presents the results of the assessment.

Table 7-7: Sample Quality Assessment Criteria

Sample Quality	Lunne et al. (1997)		Karlsrud and Hernandez-Martinez (2013)
	$\Delta e/e_0$ for OCR = 1-2	$\Delta e/e_0$ for OCR = 2-4	
1 – Very good to excellent	<0.04	<0.03	>2.0
2 – Good to fair	0.04–0.07	0.03–0.05	1.5–2.0
3 – Poor	0.07–0.14	0.05–0.10	1.0–1.5
4 – Very poor	>0.14	>0.10	<1.0

e_0 = initial void ratio; Δe = change in sample void ratio caused by reapplying σ_{v0}'; σ_{v0}' = in situ effective stress; OCR = overconsolidation ratio.

Table 7-8: Quality Assessment of Glaciolacustrine Samples from the Main Embankment

Borehole No.	Sample No.	Sample Type	Consolidation Test	Lunne et al. (1997)	Karlsrud and Hernandez-Martinez (2013)
GA15-12B	2	Sonic core	Incremental load	Poor	Very poor
GA15-12B	2	Sonic core	CRS	Very poor	Poor
GA15-12B	3	Sonic core	CRS	Very poor	Very poor
GA15-15B	1	Thin-walled tube	Incremental load	Poor	Very poor
GA15-15B	2	Thin-walled tube	CRS	Good to fair	Poor
GA15-21	5	Thin-walled tube	CRS	Very good to excellent	Good to fair
GA21-07	TO3	Thin-walled tube	CRS	Poor	Poor
GA21-07	TO5	Thin-walled tube	Incremental load	Very good to excellent	Poor
GA21-08	TO3	Thin-walled tube	Incremental load	Good to fair	Very poor
GA21-08	TO3	Thin-walled tube	CRS	Poor	Poor
GA21-09	TO2	Thin-walled tube	Incremental load	Good to fair	Very poor
GA21-09	TO2	Thin-walled tube	CRS	Poor	Good to fair

CRS = constant rate of strain.

The results of the laboratory consolidation tests were compared with the interpreted preconsolidation pressure from CPTs carried out along the Main Embankment. The preconsolidation pressure (σ'_p) from the CPT data was estimated as $\sigma'_p = 0.33 (q_t - \sigma_{vo})$ (Mayne 2001). The comparison is shown in Illustration 7-9. Tests corresponding to very poor quality samples, using either of the two methods, are excluded from the comparison. The CPT data are seen to correlate reasonably well with the laboratory consolidation tests and provide a degree of confidence in the CPT interpreted preconsolidation pressure.

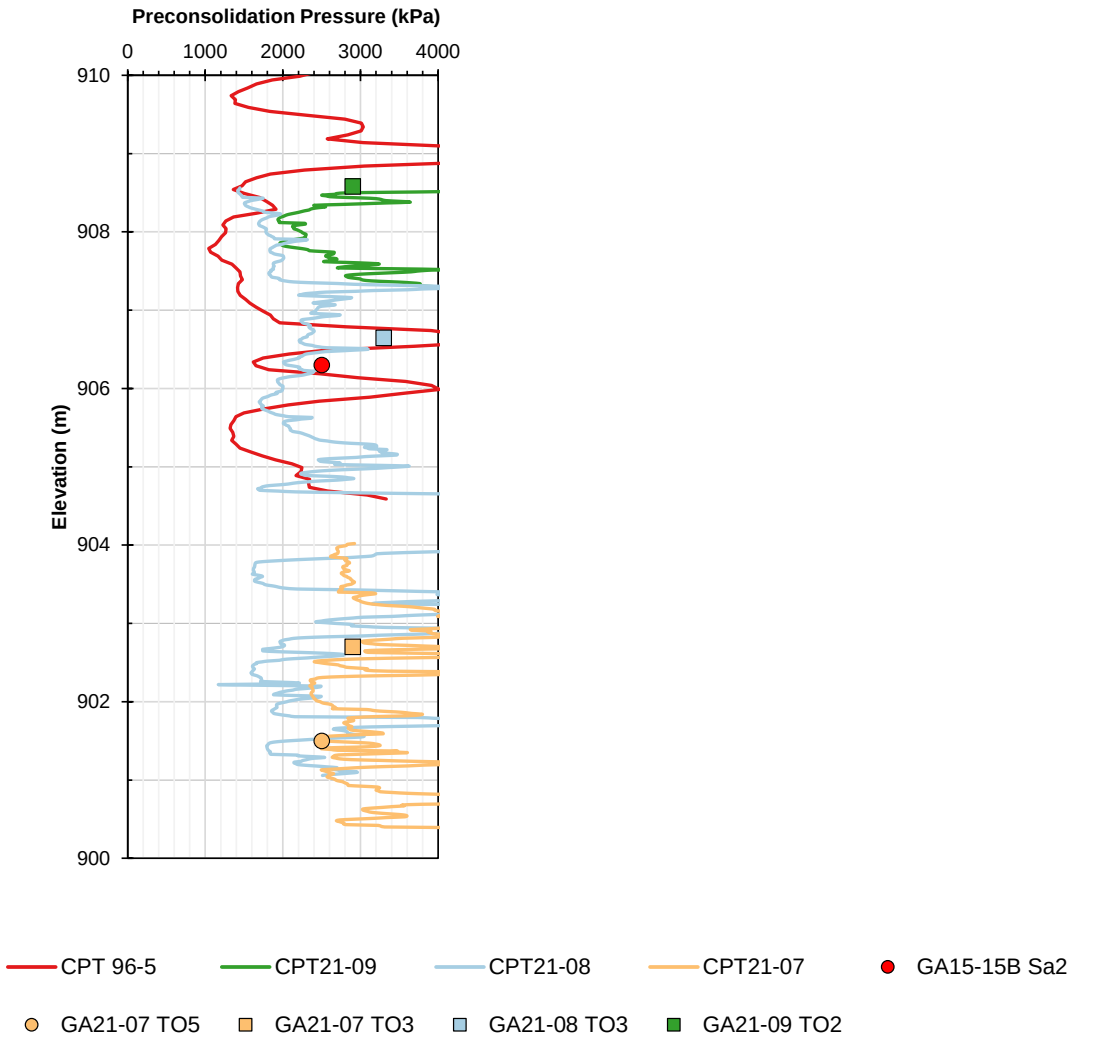


Illustration 7-9: Preconsolidation Pressure Comparison between Laboratory and Cone Penetration Test Data

The interpretations of CPTs from 1996 are presented in Golder (2015e). The interpretations of CPTs from 2021 are presented in APPENDIX E. Illustration 7-10a presents the preconsolidation pressure interpreted from all CPT data obtained at the elevation of the semi-continuous layer of glaciolacustrine soil (typically between approximate elevation 900 and 910 m). The interpreted preconsolidation pressure is generally greater than 1,200 kPa. A few points have a preconsolidation pressure between 1,000 and 1,200 kPa, as can be seen at an elevation of about 917 m for sounding PRW96-1, just below elevation 915 m for CPT96-1, and just below elevation 908 m for CPT96-5.

As shown in Illustration 7-10b, the preconsolidation pressure interpreted from CPT21-07 data near elevation 922 m (higher elevation glaciolacustrine deposit present between approximate Station 2+400 and 2+750) is greater than 850 kPa.

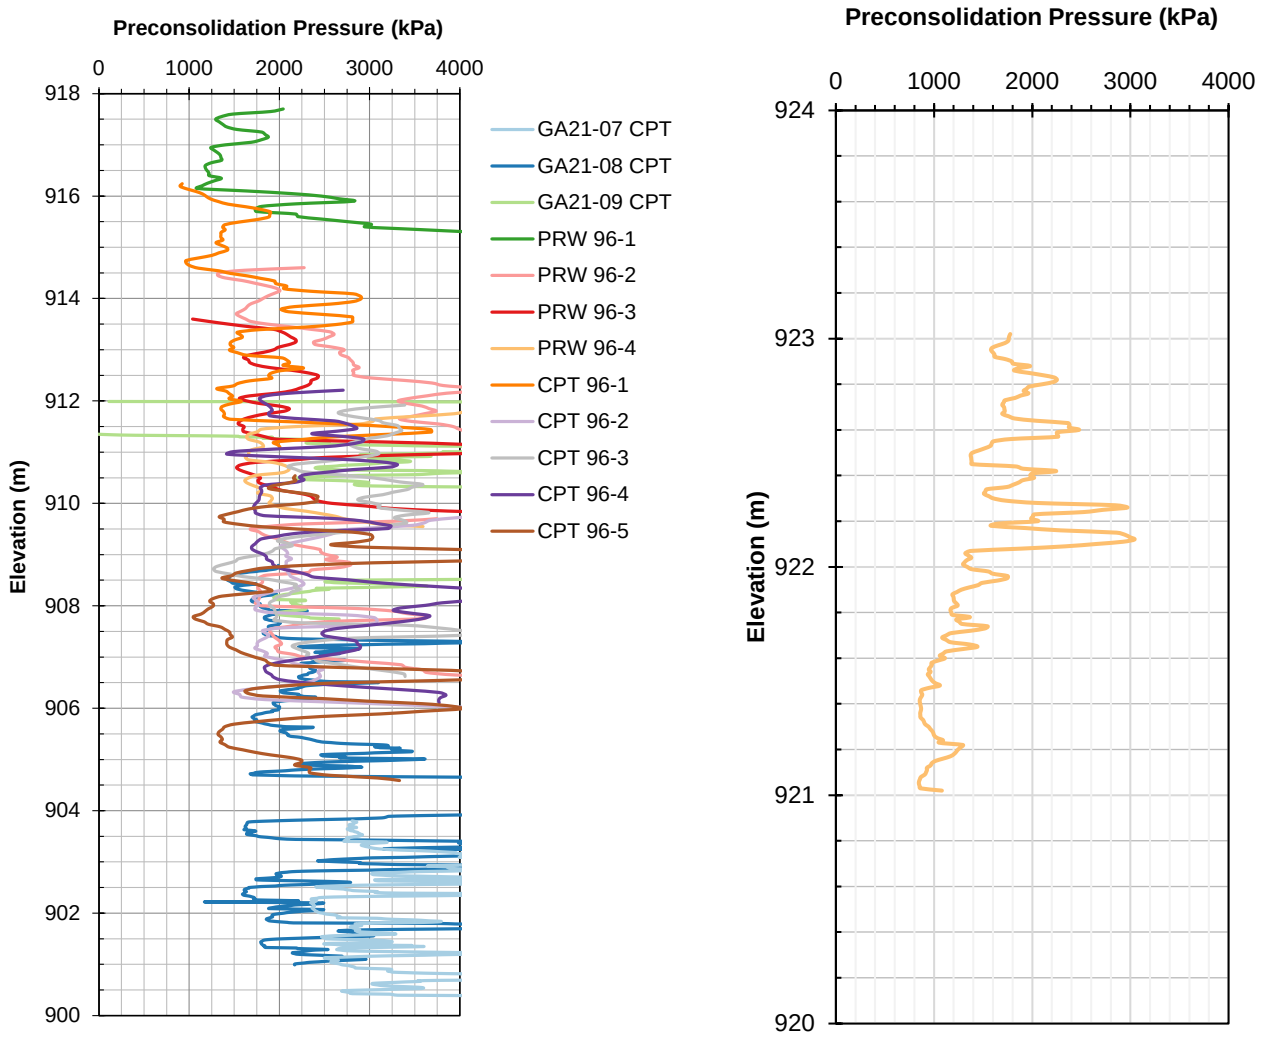

Illustration 7-10: a) Inferred Preconsolidation pressure from Main Embankment Cone Penetration Test Data between Elev. 900 and 918 m and b) Inferred Preconsolidation pressure from Main Embankment CPT21-07 Data between Elev. 921 and 923 m.

The undrained shear strength was measured in the laboratory with simple shear tests on glaciolacustrine soil samples from the Main Embankment (Golder 2015d; WSP Golder 2022b). A summary of the simple shear test results is presented in Table 7-9. The overconsolidation ratio (OCR) is presented for samples consolidated in the laboratory beyond the estimated preconsolidation pressure of the sample prior to shearing.

Table 7-9: Simple Shear Test Results of Glaciolacustrine Samples at the Main Embankment

Borehole No.	Sample No.	Sample Type	Initial Water Content (%)	Plasticity Index	Initial Vertical Effective Stress (kPa)	OCR	Maximum Undrained Shear Strength Ratio	Undrained Shear Strength Ratio at 20% Strain

	TO5	Thin-walled tube	26.7	21	300	8.0	0.74	0.63

n/a = not applicable, not available

OCR = overconsolidation ratio.

Illustration 7-11a presents the undrained shear strength ratio function obtained following the SHANSEP (Stress History and Normalized Soil Engineering Properties) method (Ladd and Foot 1974). The results of the tests completed on samples collected from the Perimeter Embankment (Table 7-13 in Section 7.3.2) are also included in the illustration. The samples used to determine the SHANSEP parameters were reconsolidated to a vertical effective stress of 2,400 kPa and then the stresses were reduced to achieve the desired OCR before shearing them. Illustration 7-11b shows the undrained shear strength ratio function corresponding to a preconsolidation pressure of 1,200 kPa and compares it with results of simple shear tests carried out on specimens that were directly reconsolidated to different effective vertical stresses.

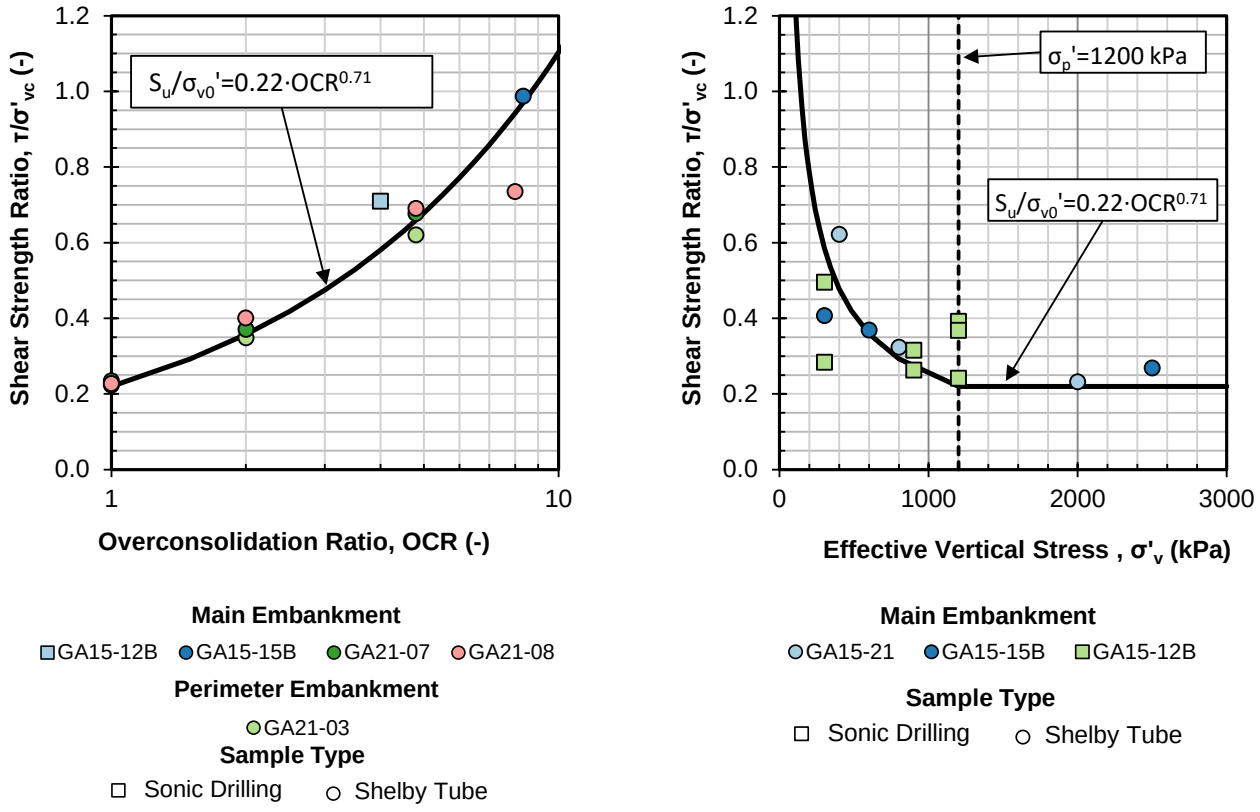

Illustration 7-11: Simple Shear Test Results on Glaciolacustrine Material at the Main Embankment and Perimeter Embankment a) Undrained Shear Strength Ratio Function Estimated Following the SHANSEP Method and b) Undrained Shear Strength Ratio Function for a Preconsolidation Pressure of 1,200 kPa

Undrained shear strength profiles were inferred using the data from CPTs carried out in 1996 and 2021 assuming an average N_{kt} factor of 15. The interpretations of CPTs from 1996 are presented in Golder (2015e). The interpretation of CPTs carried out in 2021 is presented in APPENDIX E. The undrained shear strength profiles show a strength greater than that calculated using the SHANSEP model with a preconsolidation value of 1,200 kPa. The sensitivity interpreted from the CPT data generally ranges between 2 and 3.

The effective friction angle of undisturbed glaciolacustrine samples from the Main Embankment was measured in direct shear tests and triaxial tests.

Direct shear tests were conducted on a sample collected downstream of the Main Embankment, adjacent to the Seepage Collection Pond, at a depth of 2.5 to 3.0 m (KP 2007b). No index properties were available for this sample. The peak friction angle was 26 degrees, and the residual friction angle was 23 degrees (with zero cohesion).

Triaxial tests were conducted on a reconstituted sample from the foundation of the Main Embankment (KP 1995a). The sample had a water content of 28.5% and contained 40% sand and 46% silt size particles. The peak friction angle was 33 degrees, assuming zero cohesion.

The undrained cyclic strength of undisturbed glaciolacustrine samples from the Main Embankment were measured in cyclic direct simple shear tests (WSP Golder 2022b). Illustration 7-12 shows the test results in terms of the cyclic strength ratio (CSR) required to generate single-amplitude shear strains of 3% during uniform cyclic loading.

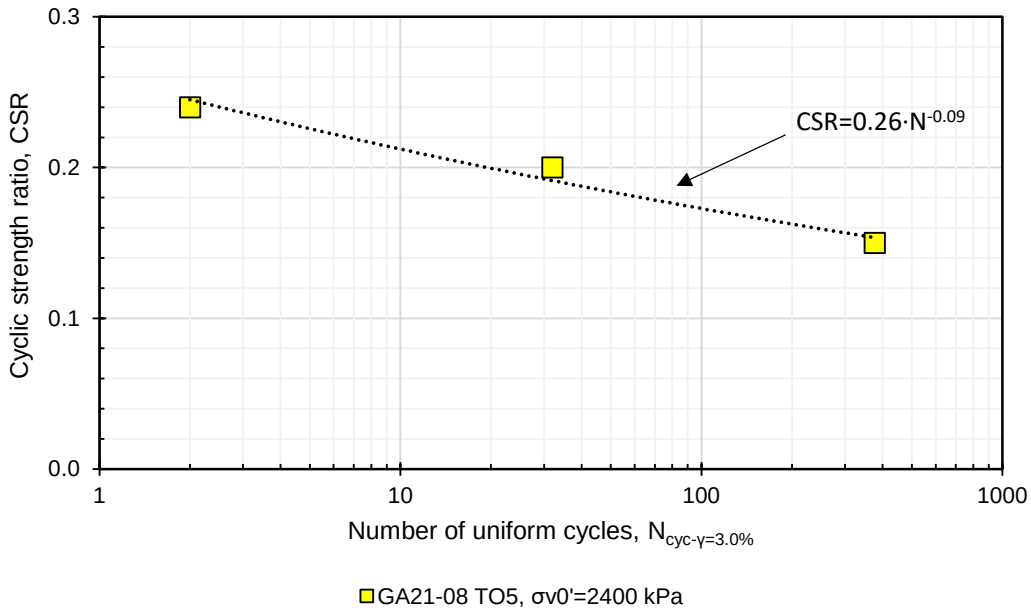

Illustration 7-12: Cyclic Strength Ratio Required to Cause Cyclic Failure (3% Strain) Versus the Number of Uniform Loading Cycles for the Glaciolacustrine at the Main Embankment.

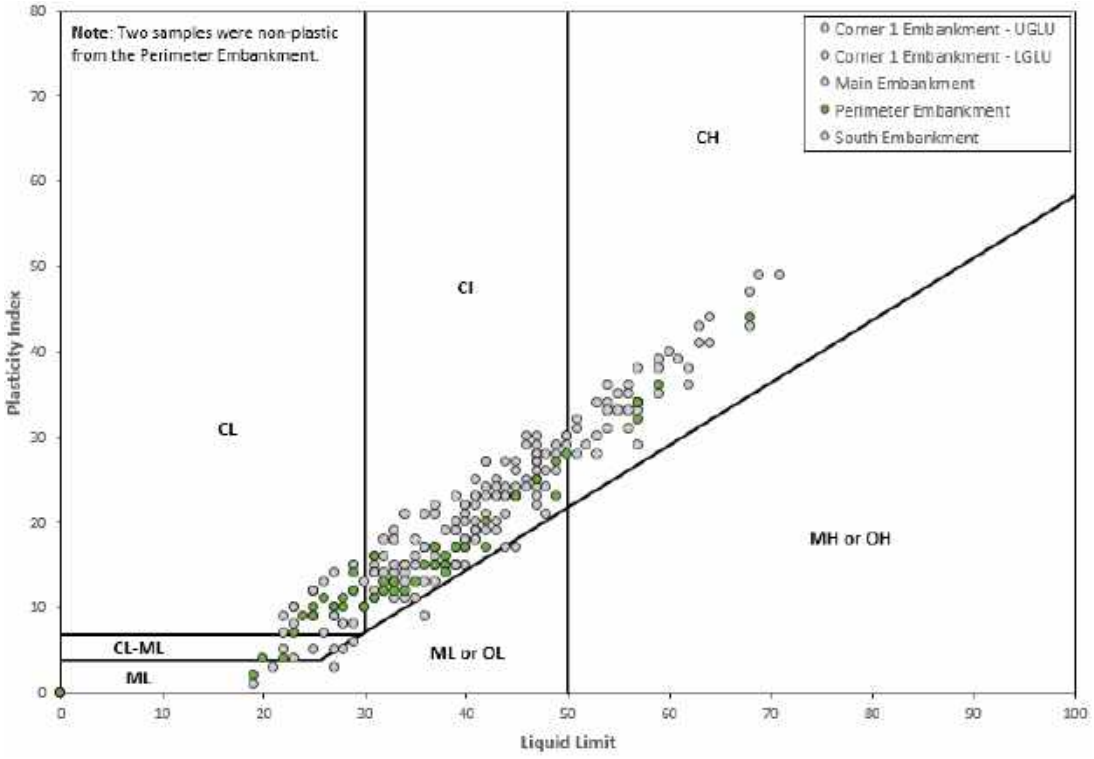
7.3.2 Perimeter Embankment

A summary of the index properties for samples of glaciolacustrine material collected from the foundation of the Perimeter Embankment is presented in Table 7-10.

The Atterberg limit results are shown graphically in Illustration 7-13. The fines are generally a low to intermediate plastic material and range from silt to silty clay (ML to CI, respectively). Six results were outside of this general range and were either a non-plastic silt (ML) or a high plastic clay (CH).

The natural water content results were plotted against elevation, which is shown in Illustration 7-14. The average water content of the glaciolacustrine samples from the Perimeter Embankment was approximately 21% and ranged from 9% to 37%.

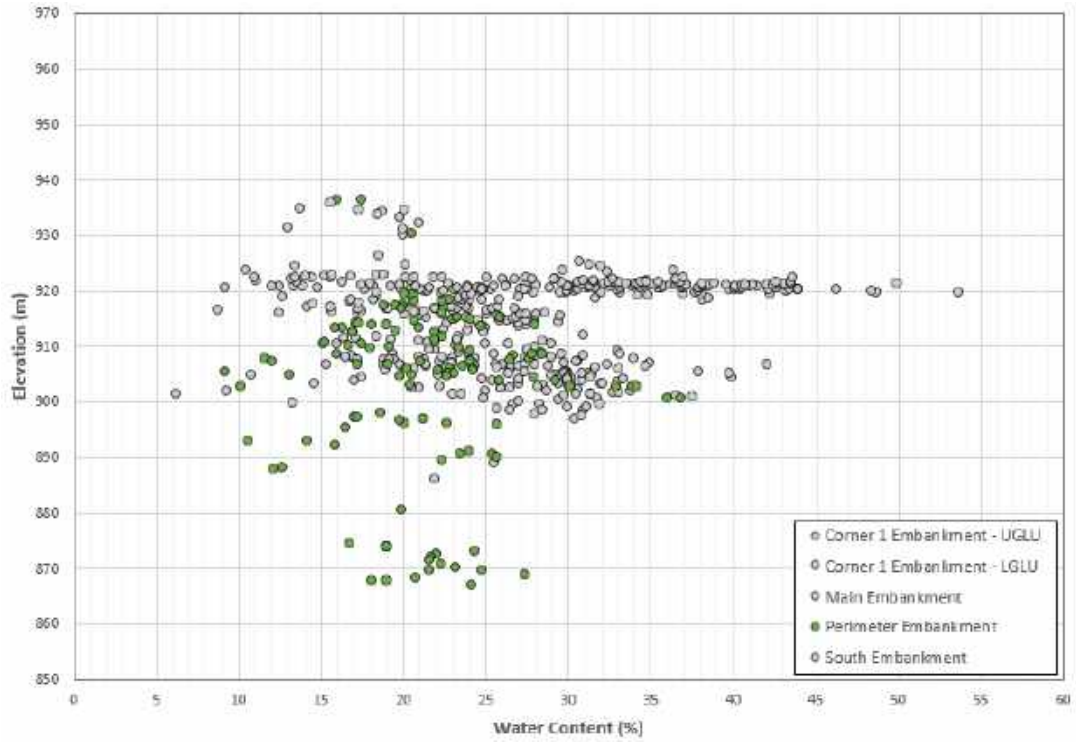
The natural water content results were also plotted against clay content as shown in Illustration 7-15. A total of 22 hydrometer test results were available for glaciolacustrine samples from the Perimeter Embankment foundation. The average clay content of the glaciolacustrine samples was approximately 29% and ranged from 7% to 71%. A general trend of increasing water content with increasing clay content can be seen in the illustration.



All available test results for glaciolacustrine samples collected from the foundation of the other embankments were incorporated into the illustrations for a comparison.

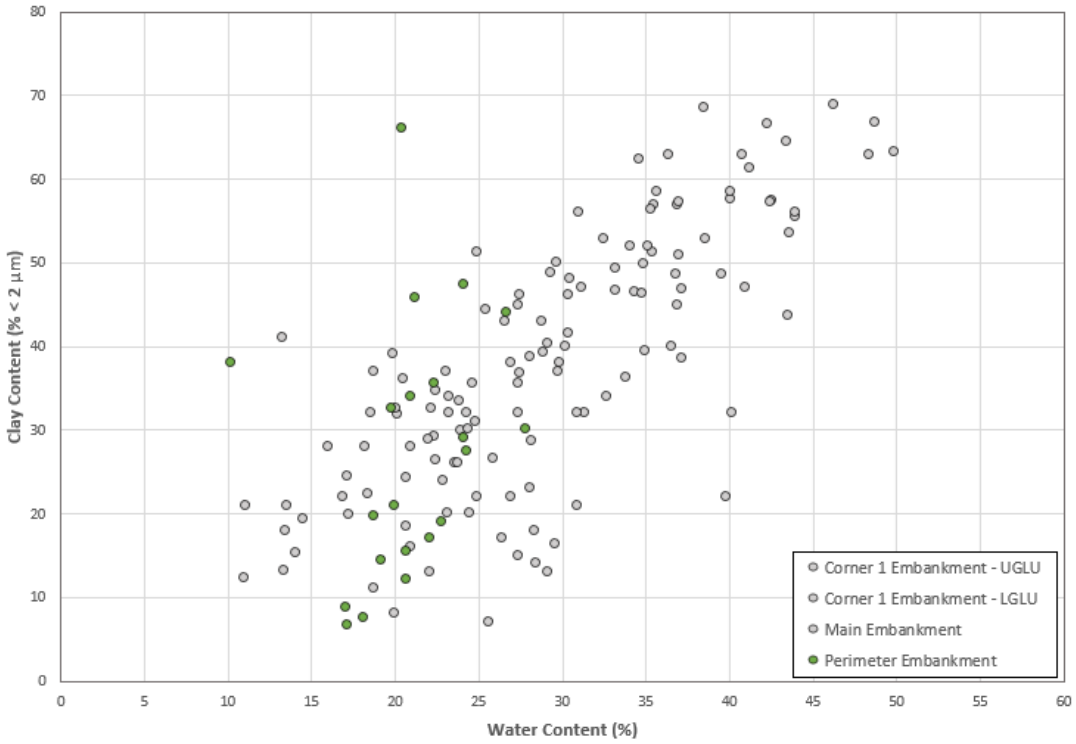
Table 7-10: Summary of Index Properties of Glaciolacustrine at the Perimeter Embankment

Index Property		Average	Minimum	Maximum	Number of Tests
Gradation	Gravel (%)	1	0	7	37
	Sand (%)	9	0	36	
	Fines (%)	90	60	100	
	Silt (%)	63	29	81	22
	Clay[a] (%)	29	7	71	
Liquid limit[b]		36	19	68	43
Plastic limit[b]		20	15	26	
Plasticity index[b]		16	2	44	
Water content (%)		21.4	9.2	36.8	113



a) Clay is defined as particles smaller than 0.002 mm.

b) Atterberg limits exclude two non-plastic samples from the Perimeter Embankment.



CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay; CH = high-plastic clay; CL-ML = low-plastic silty clay to clayey silt; ML = inorganic silt with slight or low plasticity; MH = high-plastic silt, generally classified as clayey silt; OL = low-plastic organic silt; OH = high-plastic organic silt.

LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-15: Water Content against Clay Content of Glaciolacustrine Samples from the Perimeter Embankment

Table 7-11 and Illustration 7-16a show the results of consolidation tests carried out on sonic drilling and thin walled-tube samples of glaciolacustrine soil from the Perimeter Embankment. Illustration 7-16b presents the preconsolidation pressures estimated using the Casagrande method and compares them with the interpreted preconsolidation pressure from CPT21-03 carried out in the Perimeter Embankment. The preconsolidation pressure (σ'_p) from the CPT data was estimated as $\sigma'_p = 0.33 (q_t - \sigma_{vo})$ (Mayne 2001) and is generally greater than 1,500 kPa after the initial push of the cone. The interpretations of CPTs carried out in 2021 are presented in APPENDIX E.

Table 7-11: Consolidation Test Results of Glaciolacustrine Samples at the Perimeter Embankment

Borehole No.	Sample No.	Sample Type	Elevation (m)	Estimated Preconsolidation Pressure (kPa)		Source
				Casagrande	Strain Energy	
GA15-06	Run 11a	Sonic core	908.4	1,500	1,500	Golder (2015d)
GA15-06	Run 11b	Sonic core	908.3	1,500	1,500

GLU = glaciolacustrine unit.

Illustration 7-16: a) Consolidation Test Results on Glaciolacustrine Samples at the Perimeter Embankment and b) Inferred Preconsolidation Pressure from Laboratory and Cone Penetration Test Data

The quality of the samples was assessed using the methods proposed by Lunne et al. (1997) and Karlsrud and Hernandez-Martinez (2013). A description of both methods is presented in Section 7.3.1. The results of the assessment are summarized in Table 7-12.

Table 7-12: Quality Assessment of Glaciolacustrine Samples from the Perimeter Embankment

Borehole No.	Sample No.	Sample Type	Consolidation Test	Lunne et al. (1997)	Karlsrud and Hernandez-Martinez (2013)
GA15-06	Run 11a	Sonic core	Incremental	Poor	Poor
GA15-06	Run 11b	Sonic core	Incremental	Very poor	Poor
GA15-06	Run 11c	Sonic core	Incremental	Very poor	Very poor
GA21-03	TO2	Thin-walled tube	CRS	Poor	Good to fair
GA21-03	TO3	Thin-walled tube	Incremental	Good to fair	Very poor
GA21-03	TO4	Thin-walled tube	CRS	Very poor	Poor
GA21-03	TO5	Thin-walled tube	CRS	Good to fair	Poor
GA21-03	TO5	Thin-walled tube	Incremental	Very good to excellent	Poor
GA21-11	TO2	Thin-walled tube	CRS	Very good to excellent	Very good to excellent

CRS = constant rate of strain.

The peak undrained shear strength was measured in the laboratory with simple shear tests on glaciolacustrine soil samples from the Main Embankment and Perimeter Embankment (Golder 2015d; WSP Golder 2022b). A single undrained shear strength ratio function was obtained following the SHANSEP method, as shown in Illustration 7-11. A summary of the simple shear test results from the Perimeter Embankment is presented in Table 7-13.

Table 7-13: Simple Shear Test Results of Glaciolacustrine Samples at the Perimeter Embankment

Borehole No.	Sample No.	Sample Type	Initial Water Content (%)	Plasticity Index	Initial Vertical Effective Stress (kPa)	OCR	Maximum Undrained Shear Strength Ratio	Undrained Shear Strength Ratio at 20% Strain
GA21-03	TO4	Thin-walled tube	21.3	15	500	4.8	0.62	0.56
			19.8	n/a	1,200	2.0	0.35	0.34
GA21-03	TO5	Thin-walled tube	23.3	28	2,400	1.0	0.22	0.19

OCR = overconsolidation ratio.

7.3.3 Corner 1 Embankment

Upper and lower glaciolacustrine soil deposits are present at the Corner 1 Embankment. The upper glaciolacustrine unit (UGLU) was identified as the soil layer through which the 2014 undrained failure developed and was the focus of the subsequent forensic investigations (IEEIRP 2015; KCB 2015b,c). As such, the characterization of the UGLU is presented in more detail than for the other soil units.

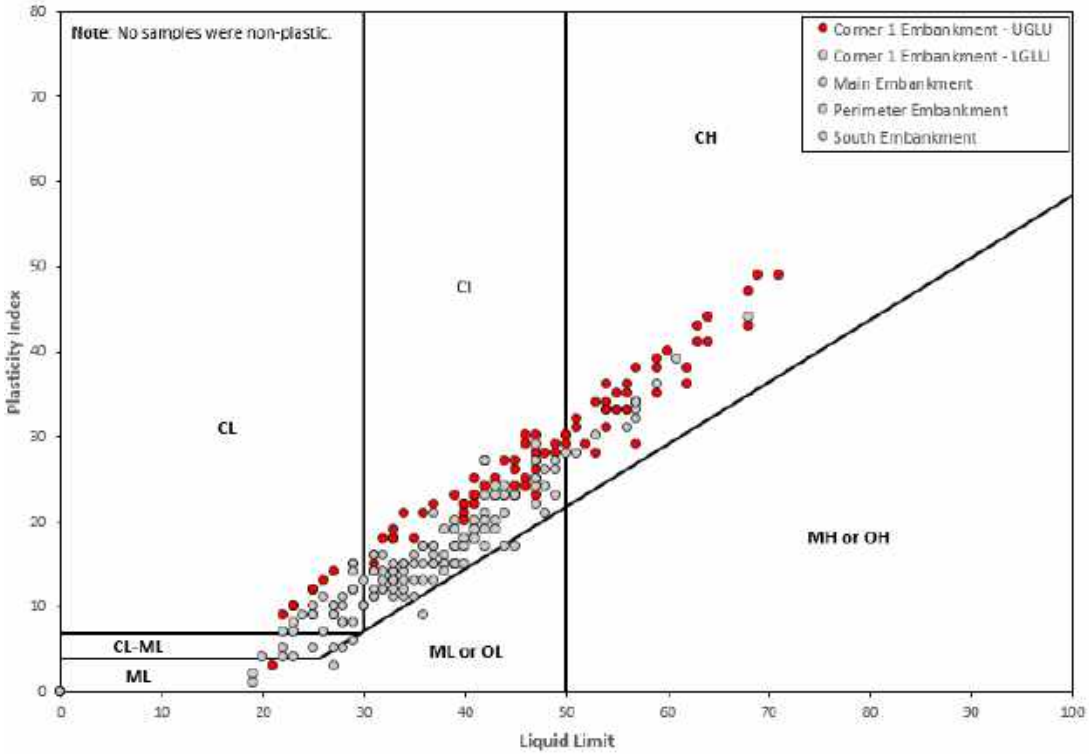
7.3.3.1 Upper Glaciolacustrine Unit

The UGLU generally consists of intermediate silty clay to high plasticity clay with trace to some sand and is firm to stiff. The UGLU deposit is a semi-continuous layer between about elevation 918 and 925 m from approximately Station 20+000 to 20+300. The maximum thickness of the UGLU within the breach area at Corner 1 is about 3 m as indicated from the forensic investigation carried out by the Independent Expert Engineering Investigation and Review Panel (IEEIRP 2015). The foundation investigation completed in 2016 also confirmed that the UGLU extended downstream of the breach area (Golder 2017). A summary of the index properties for samples of the UGLU collected from the Corner 1 Embankment is presented in Table 7-14.

The Atterberg limit results are shown graphically in Illustration 7-17. The fines are generally an intermediate to high plasticity material and range from silty clay to clay (CI to CH, respectively). Six results were outside of this general range and were either a low plasticity silt (ML) or a low plasticity silty clay (CL).

The natural water content results were plotted against elevation, which is shown in Illustration 7-18. The average water content of the UGLU is approximately 31% and ranges from 9% to 54%. The water content of the UGLU is generally much greater compared to the glaciolacustrine material encountered at the other embankments as shown in the illustration. The illustration also shows a relatively consistent layer of UGLU material from approximate elevation 918 to 925 m.

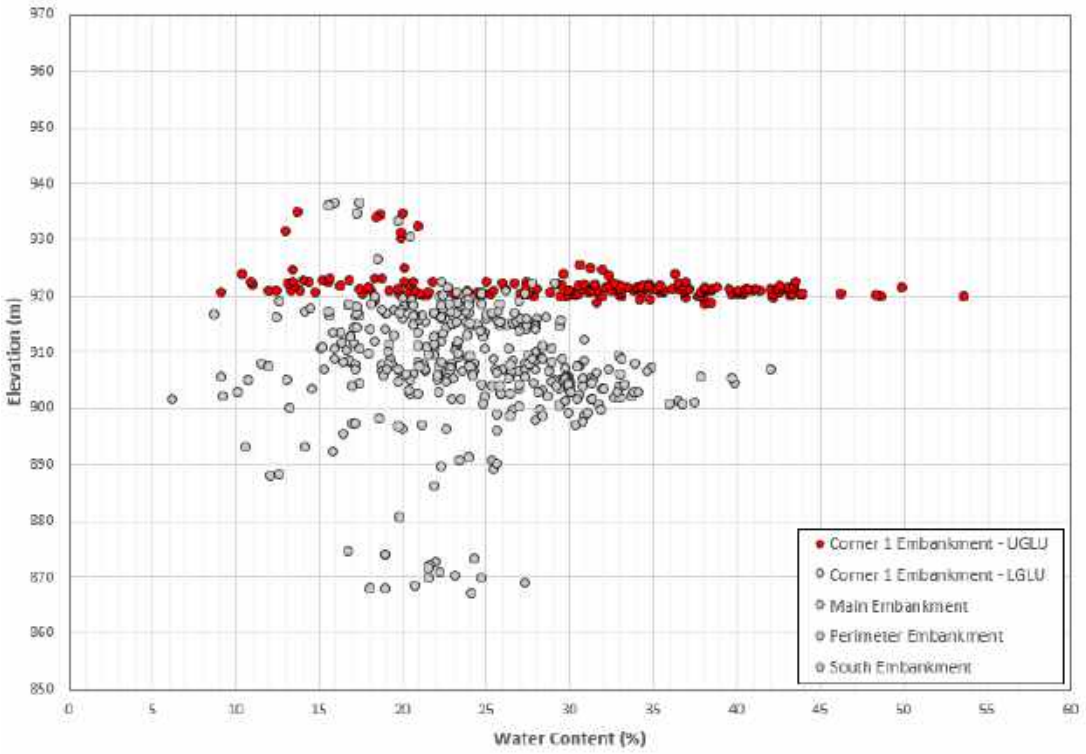
The natural water content results were also plotted against clay content as shown in Illustration 7-19. A total of 70 hydrometer test results were available for the UGLU sampled from the foundation of the Corner 1 Embankment. The average clay content of the UGLU is approximately 46% and ranges from 8% to 69%.



The clay content of the UGLU is generally much greater compared to the glaciolacustrine material encountered at the other embankments as shown in the illustration. A general trend of increasing water content with increasing clay content can also be seen in the illustration.

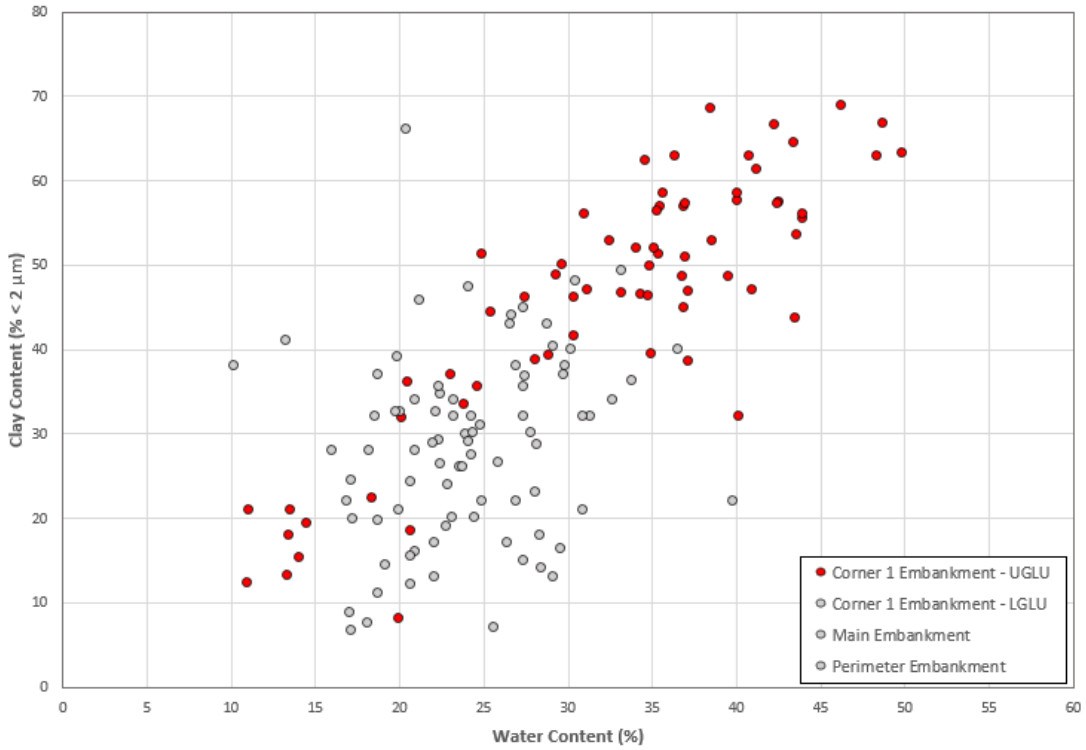
All available test results for glaciolacustrine samples collected from the foundation of the other embankments were incorporated into the illustrations for a comparison.

Table 7-14: Summary of Index Properties of Upper Glaciolacustrine Unit



Index Property		Average	Minimum	Maximum	Number of Tests
Gradation	Gravel (%)	3	0	32	72
	Sand (%)	9	0	35	
	Fines (%)	88	43	100	
	Silt (%)	42	20	72	70
	Clay[(a)] (%)	46	8	69	
Liquid limit		46	21	71	96
Plastic limit		19	13	28	
Plasticity index		27	3	49	
Water content (%)		30.5	9.2	53.7	189
Specific gravity of solids		2.80	2.75	2.87	12

a) Clay is defined as particles smaller than 0.002 mm.



CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay; CH = high-plastic clay; CL-ML = low-plastic silty clay to clayey silt; ML = inorganic silt with slight or low plasticity; MH = high-plastic silt, generally classified as clayey silt; OL = low-plastic organic silt; OH = high-plastic organic silt.

LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-18: Water Content against Elevation of Upper Glaciolacustrine Unit Samples from the Corner 1 Embankment

LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-19: Water Content against Clay Content of Upper Glaciolacustrine Unit Samples from the Corner 1 Embankment

Table 7-15 and Illustration 7-20 show the results of consolidation tests carried out on the UGLU samples. The results show that the UGLU has a preconsolidation pressure, σ'_p, of about 400 kPa. Estimated hydraulic conductivity from consolidation tests was about 5×10^{-10} m/s for stresses between 100 and 800 kPa, and a coefficient of consolidation (c_v) of about 5×10^{-7} m^2/s. The coefficient of consolidation estimated from pore pressure response in the field following rockfill placement (using piezometer VST14-03) was 6×10^{-7} m^2/s.

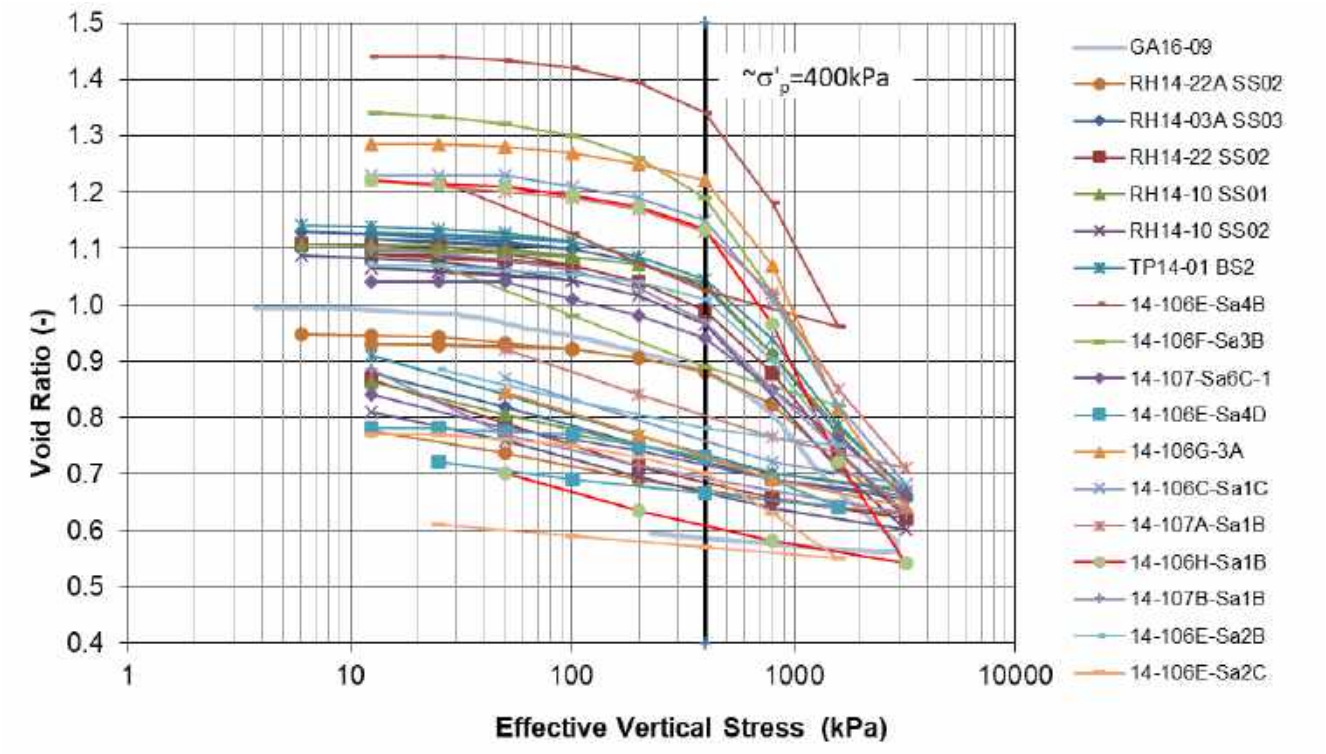

Table 7-15: Consolidation Test Results of Upper Glaciolacustrine Unit Samples

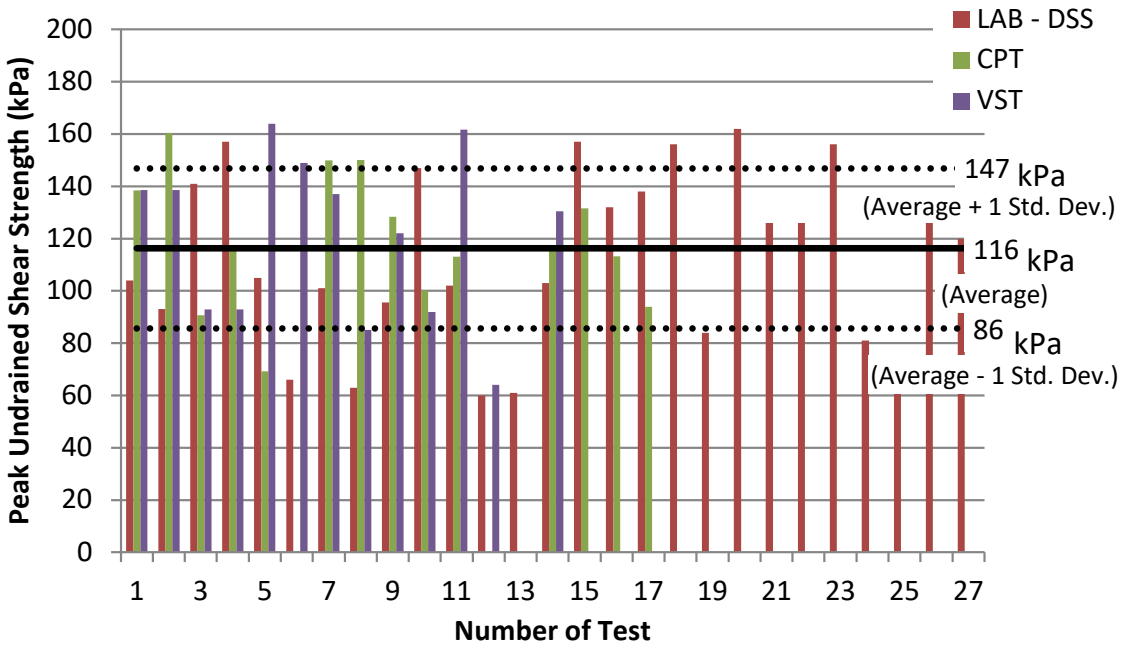
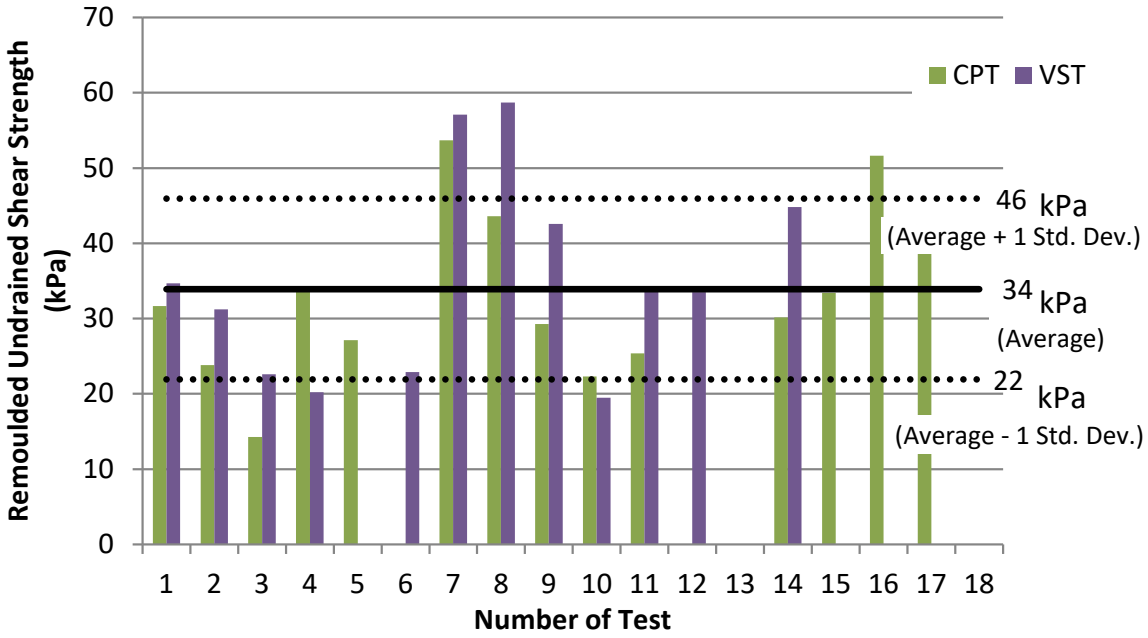
n/a = not available, not applicable.



OCR = overconsolidation ratio.

The peak undrained shear strength and remoulded (residual) undrained shear strength were measured with an electronic field vane during the forensic investigations (IEEIRP 2015; KCB 2015c). The peak and remolded undrained shear strengths were also estimated from CPT data collected during the forensic investigations. The sensitivity of the UGLU was inferred to be about 2 to 3 based on average CPT tip resistance within and outside of the breach area (IEEIRP 2015). The undrained shear strength, s_u, was estimated using the cone tip resistance, q_t, total overburden stress, σ'_{v0}, and bearing factor, N_{kt}, as follows:

$$s_u = \frac{q_t - \sigma_{v0}}{N_{kt}}$$

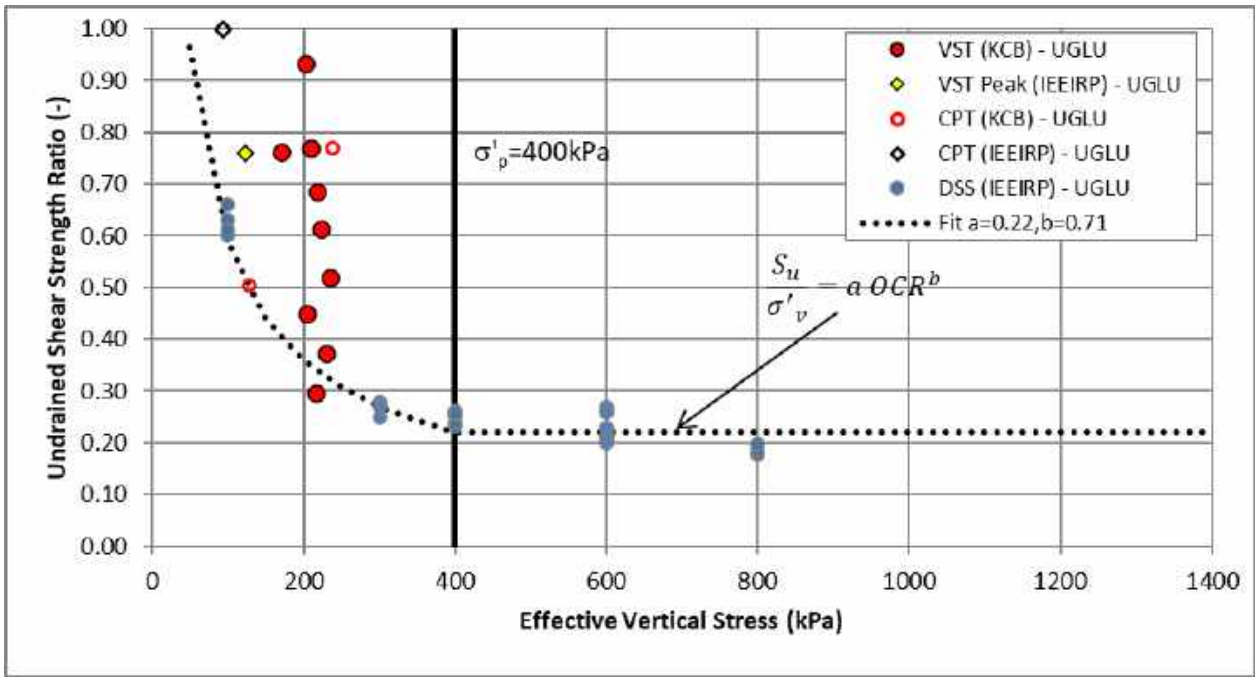


A value N_{kt} of 15 was used. The remoulded shear strength, s_{u_r}, was estimated directly from the sleeve friction resistance, f_s.

Illustration 7-21 and Illustration 7-22 show the average values and standard deviation for the peak and remoulded undrained shear strengths, respectively, estimated for the UGLU. The peak shear strength includes values estimated from the field vane test, CPTs, and simple shear tests. The remoulded undrained shear strength includes values from the field vane tests and CPTs.

LAB - DSS = direct simple shear; CPT = cone penetration test; VST = vane shear test.

Illustration 7-21: Peak Undrained Shear Strength Estimated for the Upper Glaciolacustrine Unit

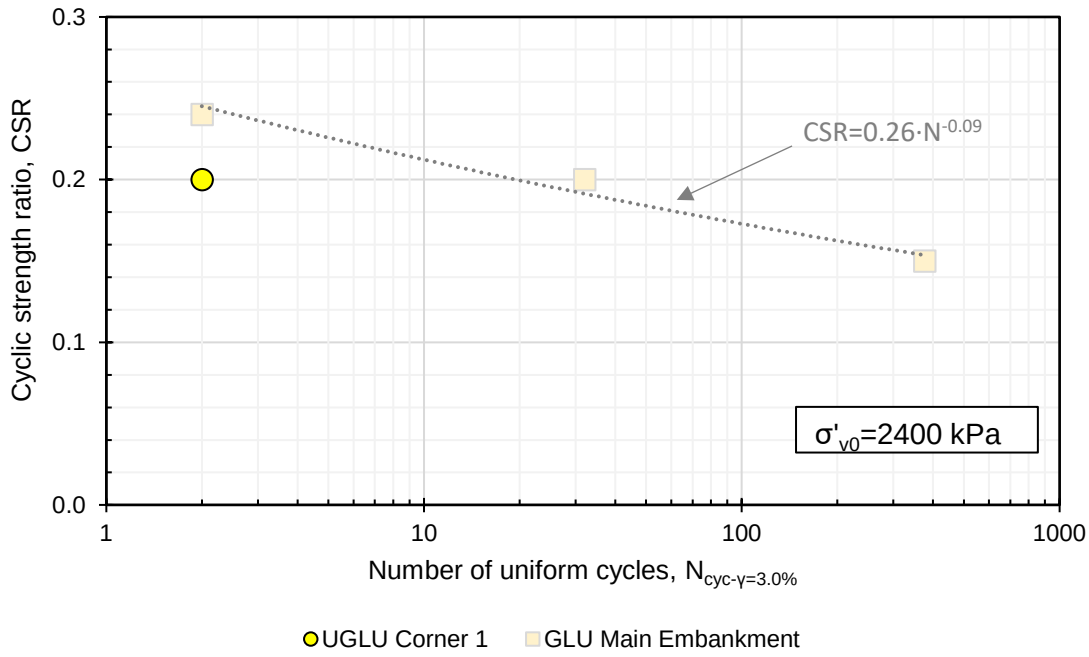


CPT = cone penetration test; VST = vane shear test.

Illustration 7-22: Remoulded Undrained Shear Strength Estimated for the Upper Glaciolacustrine Unit

The peak and remolded undrained shear strengths were also estimated using CPT data collected during the foundation investigation in 2016 downstream of the zone of the breach (Golder 2017). The estimated peak and remolded undrained shear strengths were typically greater than the averages estimated at the zone of the breach.

Illustration 7-23 shows the shear strength ratio estimated from simple shear tests at various effective vertical stress levels. Data obtained from the field vane and CPT is also included in the illustration. The undrained shear strength ratio function based on the SHANSEP method is included in Illustration 7-23. The undrained shear strength ratio (s_u/σ'_v) of the UGLU decreases with increasing effective vertical stress level. For stresses higher than the estimated preconsolidation pressure, the undrained shear strength ratio is constant at $s_u/\sigma'_v = 0.22$.



CPT = cone penetration test; OCR = overconsolidation ratio; s_u = undrained shear strength; σ'_p = preconsolidation pressure; σ'_v = effective vertical stress; SS = simple shear; UGLU = upper glaciolacustrine unit; VST = vane shear test.

Illustration 7-23: Peak Undrained Shear Strength Ratio Estimated for the Upper Glaciolacustrine Unit

The IEEIRP report presents stability analyses using a range of strength ratios from 0.22 to 0.27, with the IEEIRP "favouring a result above the average, say 0.25." The deformation analyses carried out by the IEEIRP using PLAXIS indicated collapse occurring at an undrained strength ratio of 0.29.

The peak and residual effective friction angles of the UGLU were measured on undisturbed samples in direct shear tests. The peak effective friction angle was also measured in a triaxial test, with the specimen rotated to allow failure along the GLU. The peak effective friction angle ranged from 19 to 31 degrees, and the residual effective friction angle ranged from 11 to 28 degrees, assuming zero cohesion and for normal stresses up to 800 kPa.

The undrained cyclic strength of the UGLU was measured on a single thin-walled tube sample in a cyclic direct simple shear test. Illustration 7-24 shows the test result in terms of the CSR required to generate peak (single-amplitude) shear strains of 3% during uniform cyclic loading. The test result is compared with other results obtained on glaciolacustrine samples from the Main Embankment.

σ_v'= effective vertical stress; GLU = glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

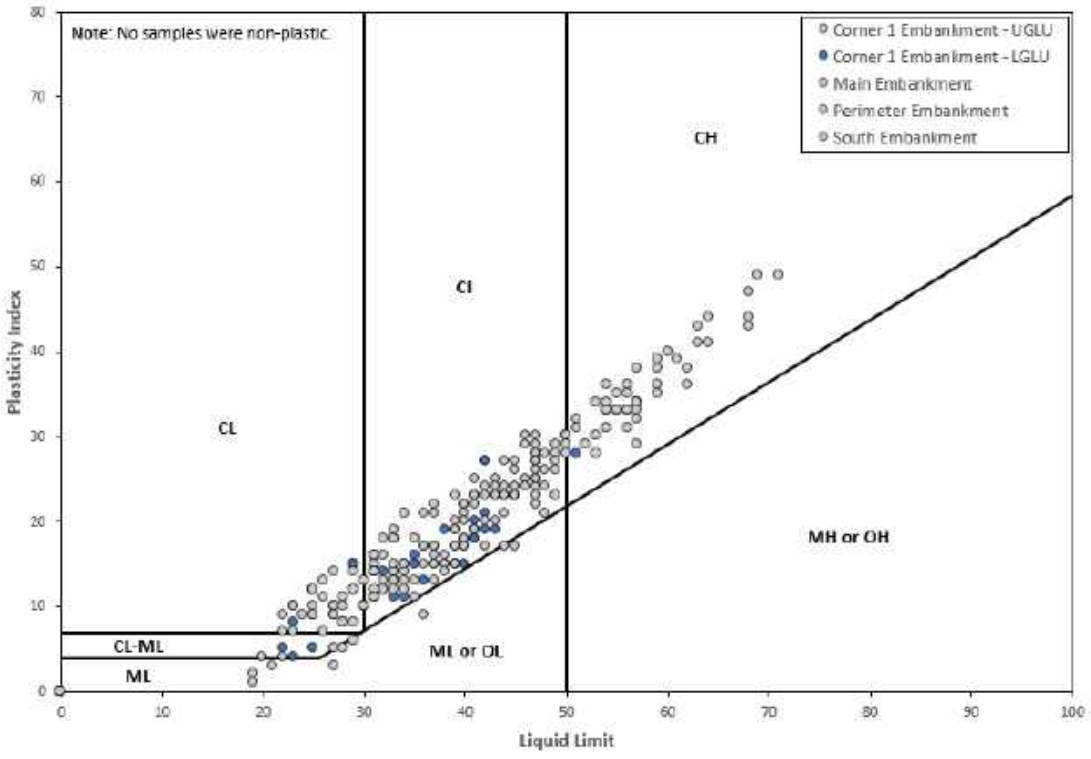
Illustration 7-24: Cyclic Strength Ratio Required to Cause Cyclic Failure (3% strain) versus the Number of Uniform Loading Cycles for the Upper Glaciolacustrine Unit

7.3.3.2 Lower Glaciolacustrine Unit

The lower glaciolacustrine unit (LGLU) deposit is a semi-continuous layer between approximate elevation 900 and 918 m. The maximum thickness of the LGLU within the breach area at Corner 1 is approximately 5 m. The foundation investigation completed in 2016 also confirmed that the LGLU extended downstream of the breach area (Golder 2017). A summary of the index properties for samples of the LGLU collected from the Corner 1 Embankment is presented in Table 7-18.

The Atterberg limit results are shown graphically in Illustration 7-25. The fines are generally a low to intermediate plastic material and range from silty clay – clayey silt to silty clay (CL-ML to CI, respectively). One test was outside of this general range, resulting in a high plasticity clay (CH).

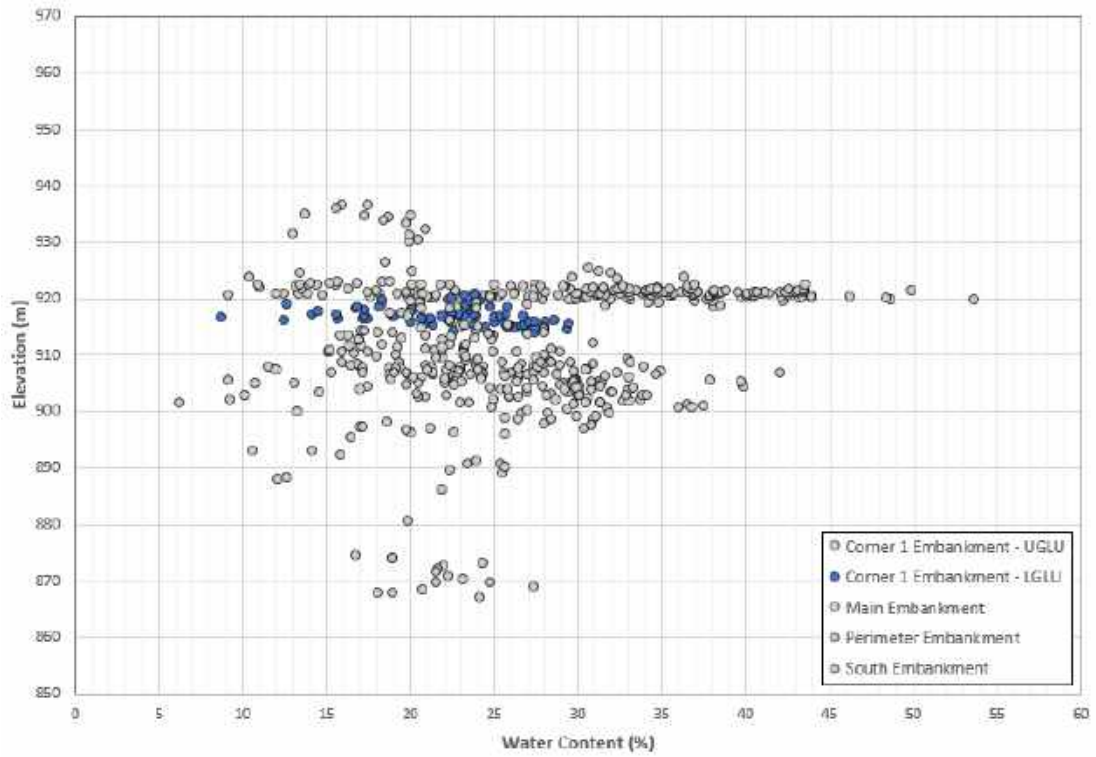
The natural water content results were plotted against elevation, which is shown in Illustration 7-26. The average water content of the LGLU is approximately 22% and ranges from 9% to 30%. The water content of the LGLU is generally much lower compared to the UGLU also encountered at the Corner 1 Embankment.



The natural water content results were also plotted against clay content as shown in Illustration 7-27. A total of 20 hydrometer test results were available for the LGLU sampled from the foundation of the Corner 1 Embankment. The average clay content of the LGLU is approximately 28% and ranges from 20% to 37%. The clay content of the LGLU is generally much lower compared to the UGLU.

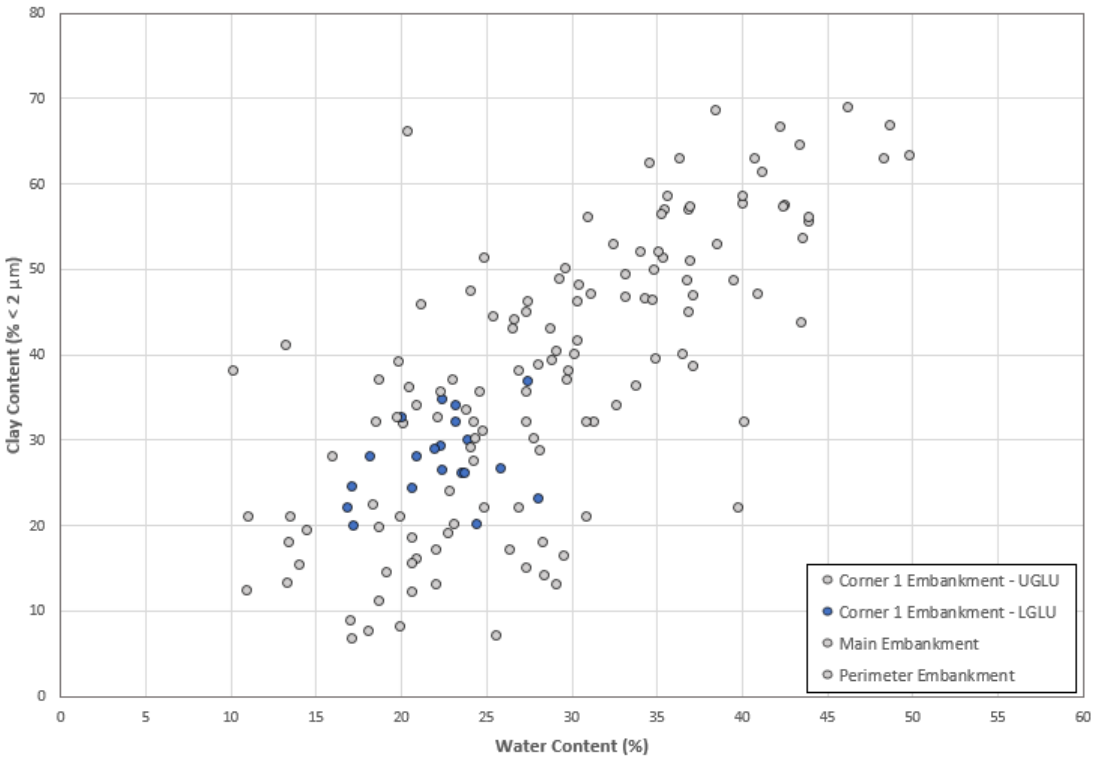
All available test results for glaciolacustrine samples collected from the foundation of the other embankments were incorporated into the illustrations for comparison.

Table 7-18: Summary of Index Properties of Lower Glaciolacustrine Unit



Index Property		Average	Minimum	Maximum	Number of Tests
Gradation	Gravel (%)	1	0	9	20
	Sand (%)	5	0	18	
	Fines (%)	94	80	100	
	Silt (%)	66	54	74	20
	Clay[a] (%)	28	20	37	
Liquid limit		35	22	51	29
Plastic limit		20	14	25	
Plasticity index		15	4	28	
Water content (%)		22.3	8.8	29.5	79
Specific gravity of solids		2.75	2.75	2.75	1

a) Clay is defined as particles smaller than 0.002 mm.



CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay; CH = high-plastic clay; CL-ML = low-plastic silty clay to clayey silt; ML = inorganic silt with slight or low plasticity; MH = high-plastic silt, generally classified as clayey silt; OL = low-plastic organic silt; OH = high-plastic organic silt.

Illustration 7-25: Plasticity Chart of Lower Glaciolacustrine Unit Samples from the Corner 1 Embankment

LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-26: Water Content against Elevation of Lower Glaciolacustrine Unit Samples from the Corner 1 Embankment

LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-27: Water Content against Clay Content of Lower Glaciolacustrine Unit Samples from the Corner 1 Embankment

Table 7-19 and Illustration 7-28 show the results of consolidation tests carried out on the LGLU samples. The results show that the LGLU has a preconsolidation pressure, σ'_p, between about 700 and 1,200 kPa.

Table 7-19: Consolidation Test Results of Lower Glaciolacustrine Unit Samples

Borehole No.	Sample No.	Sample Type	Elevation (m)	Estimated Preconsolidation Pressure (kPa)	Source

	4-bottom	25.8	17	1,200	n/a	n/a	0.23	0.17

n/a = not available, not applicable.

OCR = overconsolidation ratio.

Illustration 7-29 presents the undrained shear strength ratio function from the SHANSEP method using a preconsolidation pressure of 700 kPa. For stresses higher than the estimated preconsolidation pressure, the undrained shear strength ratio is constant at $s_u/\sigma'_v = 0.22$.

σ'_p = preconsolidation pressure; σ'_v = effective vertical stress; s_u = undrained shear strength; LGLU = lower glaciolacustrine unit; OCR = overconsolidation ratio; SS = simple shear.

Illustration 7-29: Peak Undrained Shear Strength Ratio Estimated for the Lower Glaciolacustrine Unit

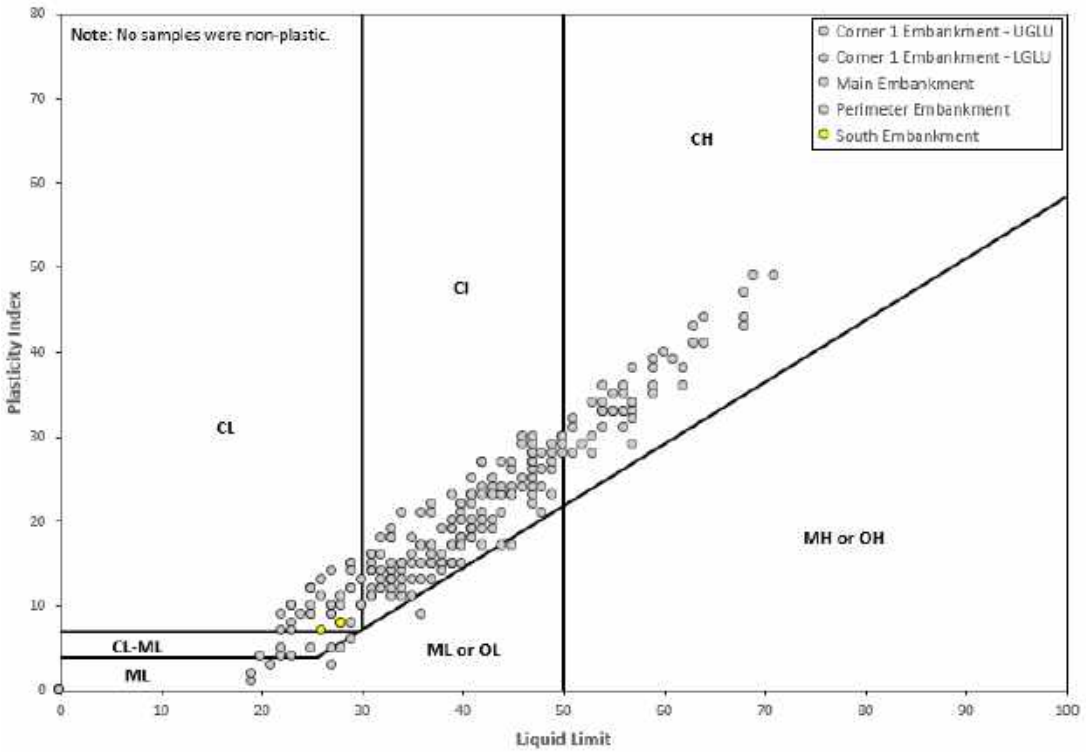
A peak effective friction angle of 33 degrees and a residual effective friction angle of 25 degrees were measured on a single undisturbed sample of LGLU in a direct shear test (KCB 2015b).

7.3.4 South Embankment

One of the objectives of the 2016 foundation investigation was to confirm the characteristics of the soil previously identified as of glaciolacustrine origin in borehole VW11-02 (AMEC 2012) and to provide limits on the areal extent of this material along the South Embankment.

The material previously identified as of glaciolacustrine origin was encountered in boreholes DH98-BL-03 and VW11-02, which were drilled near a small tributary of Edney Creek (near Station 1+100). Boreholes GA16-17 and GA16-19 drilled within the area also encountered a bedded, silty soil. The area is estimated to extend about 100 m along the alignment of the South Embankment.

The description of the material intersected in borehole DH98-BL-03 is “Silt, glaciolacustrine, glaciofluvial. Rel. low permeability.” (KP 1999). The description of the material intersected in borehole VW11-02 is “SILT, some clay to clayey, trace sand, low plasticity to non-plastic, hard, […], varved”. The plastic and liquid limits were reported as 20% and 28%, respectively, and the natural water content was reported as 17% (AMEC 2012). Borehole GA16-19 was drilled within 5 m of VW11-02 and intersected material described as “sandy, clayey SILT, trace gravel.” Bedding was observed in the material intersected in GA16-19 but was not described as varved. The plastic and liquid limits were reported as 19% and 26%, respectively, and the natural water content was reported as 16% (Golder 2017). The material intersected in borehole GA16-17 (downstream of GA16-19) is described as “sandy SILT to SILTY SAND, trace gravel; brown; non-cohesive” with a measured water content of 20% (Golder 2017). The thickness of the material encountered in the four boreholes ranges from 0.5 to 1.5 m. In these four boreholes, the silty layer directly overlies bedrock.



A summary of the index properties for the samples of the low plasticity silty clay collected from the foundation of the South Embankment (near Station 1+100) is presented in Table 7-22.

The Atterberg limits and natural water content results against elevation are shown graphically in Illustration 7-30 and Illustration 7-31, respectively. All available test results for glaciolacustrine samples collected from the foundation of the other embankments were incorporated into the illustrations for a comparison. The fines are a low plastic silty clay with a natural water content ranging from 15% to 20%.

The low plasticity and relatively low water content of the silty clay layer encountered at these locations are not representative of the intermediate or high plasticity glaciolacustrine units found within the footprint of the Corner 1 Embankment. Also, CPT16-19 refused at the depth of the low plasticity silty clay layer, with a tip resistance (greater than 20 MPa) and sleeve friction (greater than 500 kPa) greater than the typical values obtained in glaciolacustrine units at the Corner 1 and Main embankments.

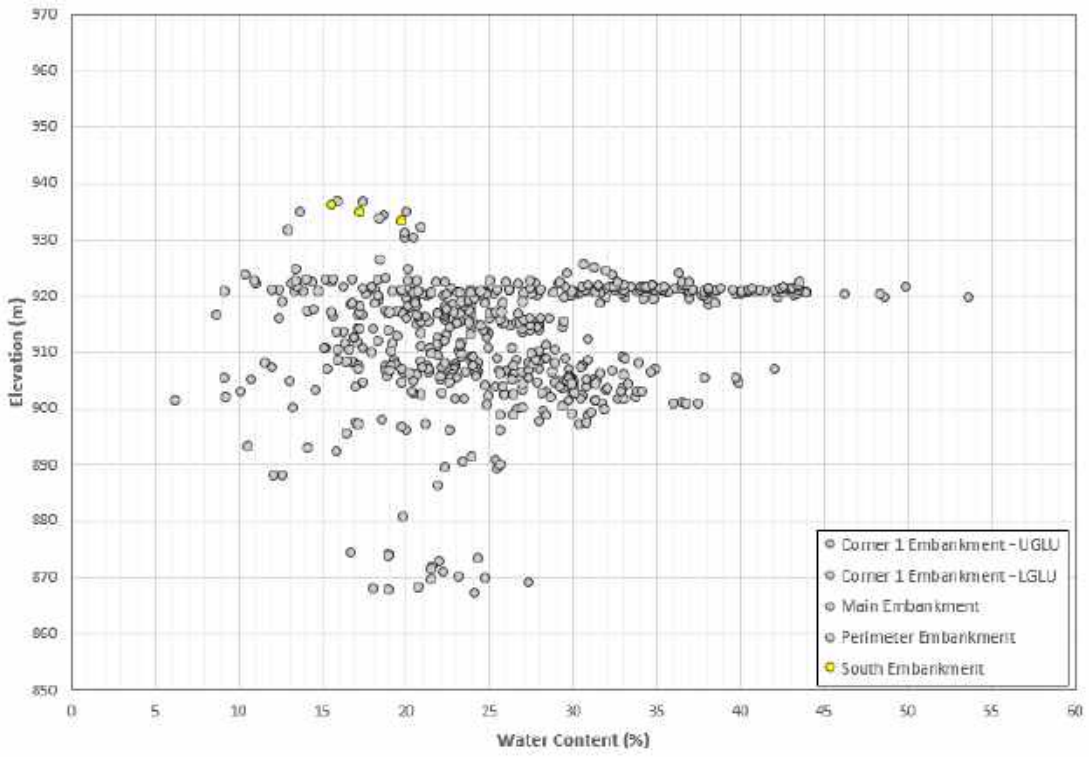


Table 7-22: Summary of Index Properties of Low Plasticity Silty Clay at the South Embankment

Index Property	Average	Minimum	Maximum	Number of Tests
Liquid limit	27	26	28	2
Plastic limit	20	19	20	
Plasticity index	8	7	8	
Water content (%)	17.6	15.6	19.8	3

CL = low-plastic clay, generally classified as silty clay; CI = intermediate-plastic clay, generally classified as silty clay; CH = high-plastic clay; CL-ML = low-plastic silty clay to clayey silt; ML = inorganic silt with slight or low plasticity; MH = high-plastic silt, generally classified as clayey silt; OL = low-plastic organic silt; OH = high-plastic organic silt.

Illustration 7-30: Plasticity Chart of Low Plasticity Silty Clay Samples from the South Embankment

LGLU = lower glaciolacustrine unit; UGLU = upper glaciolacustrine unit.

Illustration 7-31: Water Content against Elevation of Low Plasticity Silty Clay Samples from the South Embankment

7.4 Material Parameters for Stability Analyses

The material parameters for stability analyses are presented in Table 7-23.

Till and glaciofluvial materials vary in gradation depending on location, elevation, and depositional history; however, the results of the laboratory testing show a relatively consistent high strength. The shear strength parameters selected for the foundation till and glaciofluvial layers represent an average for the materials. The strength parameters are consistent with the parameters used in previous design analyses, testing results and analyses of the Corner 1 Perimeter Embankment breach carried out by the IEEIRP (2015), and the results of laboratory testing completed by KCB (2015b,c).

Glaciolacustrine soils have been analyzed using total stress (undrained) strength parameters. The total stress approach uses the SHANSEP model that accounts for preconsolidation of the soil. The preconsolidation pressure that has been selected for modelling the strength of each of the glaciolacustrine soil layers is based on the data collected for the specific layer and soils in the immediate area. The data used include the results of the laboratory strength testing, CPT profiles, the response of the soils during in situ testing and sampling (e.g., not being able to push a shear vane into the soil layer and bending of Shelby tubes during sampling) and correlation with index testing. Along the Perimeter and Main embankments, the preconsolidation pressure values selected for the analyses are at or below the lower bound of the values calculated from the laboratory consolidation tests and estimated from the CPT profiles.

Table 7-23: Foundation Material Parameters for Stability Analyses

Material	Unit Weight (kN/m^3)	Shear Strength	Pore Pressure Coefficient B-bar[(a)]	Notes
Foundation till	22	ϕ' = 34° c = 0 kPa	0.2	Triaxial testing of samples of till by IEEIRP (2015) and KCB (2015b)
Glaciofluvial	22	ϕ' = 34° c = 0 kPa	0.2	Triaxial testing of undisturbed glaciofluvial samples by Golder (2015d)
UGLU (Corner 1 Embankment)	18	Peak: $T = 0.22\ \sigma_v' \ OCR^{0.71}$ Where σ'_p = 400 kPa Remoulded: S_{ur} = 22 kPa	0.46 (peak)	Field and laboratory test programs by IEEIRP (2015) and KCB (2015b,c) including vane shear tests, CPT, and direct simple shear, direct shear, and triaxial testing Remoulded undrained shear strength selected as the average minus one standard deviation of the measured undrained shear strength values
LGLU (Corner 1 Embankment)	20	$T = 0.22\ \sigma_v' \ OCR^{0.71}$ Where σ'_p = 700 kPa	0.2	Field and laboratory test programs by IEEIRP (2015), KCB (2015b,c) and Golder (2017, 2019) including vane shear tests, CPT, and direct simple shear, direct shear, and triaxial testing
GLU (Perimeter Embankment)	20	$T = 0.22\ \sigma_v' \ OCR^{0.71}$ Where σ'_p = 900 kPa	0.2	Consolidation testing by Golder on samples from boreholes GA15-06, GA21-03, and GA21-11 at Perimeter Embankment indicate preconsolidation pressure from 900 to 3,600 kPa (excluding the samples assessed to be of very poor quality). σ'_p = 900 kPa selected as the design basis

Table 7-23: Foundation Material Parameters for Stability Analyses

Material	Unit Weight (kN/m^3)	Shear Strength	Pore Pressure Coefficient B-bar[(a)]	Notes
GLU (Main Embankment)	20	$T = 0.22\ \sigma_v'\ OCR^{0.71}$ Where $\sigma'_p = 1{,}200$ kPa	0.2	Field and laboratory test programs by KP (2007b), AMEC (2012), Golder (2015d), and WSP Golder (2022b) including vane shear tests, CPT, direct simple shear, direct shear, and triaxial testing Consolidation tests indicate a range of preconsolidation pressure from 2,500 kPa to 4,000 kPa (excluding the samples assessed to be of very poor quality) and CPT data indicate a minimum preconsolidation pressure of about 1,200 kPa. $\sigma'_p = 1{,}200$ kPa selected as the design basis
		$T = 0.22\ \sigma_v'\ OCR^{0.71}$ Where $\sigma'_p = 850$ kPa (GLU at approx. elev. 922 Station 2+400 and 2+750)		Field and laboratory test programs by AMEC (2012), Golder (2015d) and WSP Golder (2022b) CPT21-07 data indicate a minimum preconsolidation pressure of about 850 kPa. $\sigma'_p = 850$ kPa selected as the design basis
Low plasticity silty clay (Sta. 1+100 South Embankment)	20	$T = 0.22\ \sigma_v'\ OCR^{0.71}$ Where $\sigma'_p = 1{,}200$ kPa	0.2	Index laboratory testing by Golder (2017)

a) Refer to Section 7.4.1 for explanation of selected B-bar values.

T = shear strength; σ_v'= effective vertical stress; ϕ_p' = peak friction angle; c = cohesion; CPT = cone penetration test; GLU = glaciolacustrine unit; LGLU = lower glaciolacustrine unit; OCR = overconsolidation ratio; σ'_p = preconsolidation pressure; UGLU = upper glaciolacustrine unit.

7.4.1 Pore Pressure Response within the Foundation Soils

Excess pore pressures are generated within soils when a load is applied at a rate faster than water can drain from the pore spaces in the soil. The amount of excess pore pressure depends directly on the magnitude of the applied load, the permeability of the soil, and the rate of application. The pore pressure response within the soil units can be interpreted by means of the pore pressure coefficient B-bar, defined as the change in pore pressure over the change in confining stress (Skempton 1954).

Pore pressure response was measured within the glaciolacustrine, till, and glaciofluvial layers within the Corner 1 area by vibrating wire piezometers (VWPs) monitored during construction of the 2015 Freshet Management Embankment, and at a single location along the Perimeter Embankment during the buttress construction.

Pore pressure response in the UGLU (Corner 1 Embankment) was measured with VWP VST14-03, located beneath the zone of compacted rockfill for the 2015 Freshet Management Embankment construction. The maximum B-bar measured was 0.46 at an intermediate stage of construction, and at the end of fill placement (Golder 2015b). It was determined that the glaciolacustrine soils will take approximately one year to dissipate excess pore water pressures based on the rate of consolidation measured in the laboratory and the field.

Pore pressure responses in the till and glaciofluvial layers were measured with VWP SH14-07, located adjacent to the zone of upstream fill placement. The maximum B-bar measured was 0.23 at the initial piezometer readings following fill placement. The B-bar values decreased to maximums of 0.19 and 0.15 with further fill placement (Golder 2015b). The decrease in the pore pressure and hence B-bar is due to drainage from the soil occurring at a rate faster than the rate of load application.

Only the VWPs installed in borehole GA15-06 at Station 3+400 (Perimeter Embankment) showed a pore pressure response to the approximately 5 m high buttress rockfill constructed along the Perimeter Embankment in 2015. All other VWPs installed along the foundation of the Perimeter Embankment buttress did not record a response to the construction of the buttress. The maximum B-bar measured was 0.16 (Golder 2015e).

VWPs B6, B7, B11, and B12 installed in till and glaciolacustrine layers in the foundation of the Main Embankment buttress recorded excess pore water pressure when rockfill was stockpiled for embankment construction in 2022. The maximum B-bar values measured in till and glaciolacustrine soil were 0.12 and 0.13, respectively.

8.0 HYDROGEOLOGY

Much of the factual and conceptual understanding of groundwater conditions near the TSF was obtained from Golder (2016b,c), Golder (2021), and MPMC (2021).

8.1 Hydrogeological Units and their Properties

The hydrostratigraphy at the TSF includes mine waste materials (tailings), fill materials associated with engineered structures (TSF embankment), soil deposits, bedrock formations, and bedrock structures. The key native hydrogeological units which form the foundation of the TSF are depicted in the cross-sections in Figure 3 to Figure 9 and are listed in Table 8-1, along with a summary of hydraulic conductivity estimates associated with these units.

The locations of the boreholes and monitoring wells listed in Table 8-1 are shown in Figure 1 and Figure 2. Completion details related to the boreholes, test pits, cone penetration tests (CPTs), and the monitoring wells are provided in APPENDIX C (Tables C1 to C5). Single-well response test analyses that were completed in 2022 to obtain in situ hydraulic conductivity estimates are provided in APPENDIX F. Analyses regarding the hydraulic conductivity estimates based on grain size using HydrogeoSieveXL™ (an Excel-based tool to estimate hydraulic conductivity from grain-size analyses) are provided in APPENDIX G. Details on the hydraulic conductivity estimates for the glaciolacustrine unit from the analysis of CPT dissipation tests are provided in APPENDIX E. All other hydraulic conductivity estimates outlined in Table 8-1 are from historical reports referenced in the table.

Table 8-1: Hydrogeological Units and Hydraulic Conductivity (K) Test Results

Hydrostratigraphic Unit	Borehole / Monitoring Well	Source / Consultant	Method	Estimated Hydraulic Conductivity (m/s)	Material Description (as summarized from original log)
Ablation till	MP89-231	IMC (1990)	Packer test	6.4×10^{-8}	Silty till 9–12 m depth

CPT = cone penetration test.

8.1.1 Surficial Native Deposits

The surficial deposits underlying the TSF consist of glacial deposits, predominantly till (ablation till and basal till) with interbeds of glaciofluvial and glaciolacustrine sediments. The relative distribution of the till, glaciofluvial, and glaciolacustrine sediments varies by location according to the depositional and erosional history of the area as shown on the cross-sections (Figure 3 to Figure 9). The combined thickness of the glacial deposits range from approximately 5 m along a bedrock knoll near the South Embankment to approximately 60 m along portions of the Main Embankment. During foundation preparation at the North Abutment of the TSF in 2022, the thickness of the glacial deposits was observed to be on the order of 2 m. Additional test pits need to be excavated when construction resumes in 2023 to confirm the glacial deposit thickness.

The TSF till core has been keyed into the foundation till. Where the natural surficial till along and upstream of the till core alignment was observed to be less than 2 m thick, and was underlain by glaciofluvial/glaciolacustrine sediments, a low permeability till liner was constructed with a nominal thickness of at least 2 m (KP 1997a, 2011 Section 2.2; Golder 2016b, Section 3.3.1.7).

Based on the information outlined in Table 8-1 above, the hydraulic conductivity of the foundation till (ablation till and basal till) is highly variable, ranging from 1×10^{-5} m/s to 2×10^{-8} m/s. The hydraulic conductivity of the till liner was estimated by KP (2005) to be on the order of 1×10^{-8} m/s. The range in hydraulic conductivity for the glaciofluvial units, 8×10^{-4} m/s to 2×10^{-6} m/s, confirms that these units are more permeable and may act as preferential pathways for seepage from the TSF. Conversely, the range in hydraulic conductivity for the glaciolacustrine deposits, 7×10^{-8} m/s to 2×10^{-10} m/s, confirms that these units have a low permeability and may act as barriers for seepage migration and/or as confining units where they occur directly above glaciofluvial units, and could potentially cause artesian pressures in the underlying glaciofluvial units.

A previous hydrogeological assessment by Golder (2016c), which involved development of a numerical groundwater flow model for the TSF area, estimated the bulk horizontal and vertical hydraulic conductivity of the foundation soils to be on the order of 5×10^{-7} m/s and 5×10^{-8} m/s respectively (i.e., an anisotropy of 10:1), based on the results of model calibration to observed hydraulic heads and seepage flow rates at the facility. Therefore, these calibrated values are considered representative of the composite foundation overall.

8.1.2 Bedrock

The upper portion of the bedrock beneath the TSF is weathered and/or fractured and consists predominantly of volcanic conglomerate based on drilling observations in the TSF footprint prior to mining (IMC 1990).
The thickness of this weathered bedrock zone is highly variable and is inferred to range from 2 to 40 m based on borehole logs for the 1996 series monitoring wells (KP 1997b) and the 2015 series boreholes (Golder 2015d).
The underlying competent bedrock consists of Nicola Group volcanics that, according to the local geology map (Logan et al. 2007), likely consist of undivided mafic volcanic and volcanoclastic rocks and/or intrusive rocks (pseudoleucite syenite).

Based on the information outlined in Table 8-1, the hydraulic conductivity of weathered bedrock is highly variable, ranging from 5×10^{-6} m/s to 1×10^{-10} m/s in the vicinity of the TSF. Competent bedrock had a similar range in hydraulic conductivity as that of weathered bedrock (5×10^{-6} m/s to 9×10^{-10} m/s). The calculated geometric mean of the individual tests for weathered and competent bedrock is approximately 9×10^{-8} m/s and 3×10^{-8} m/s respectively. Based on the results of packer testing at two boreholes, the hydraulic conductivity of competent bedrock is expected to generally decrease with depth (as seen at MP89-236), except where bedrock fractures are encountered (as seen at MP89-235).

8.2 Groundwater Recharge/Discharge and Tailings Storage Facility Seepage

The central area of the mine site is a topographic high consisting of Polley Mountain, which reaches an elevation of approximately 1,255 m. The TSF is located about 3 km southeast of this location in a topographically low area with an original ground surface elevation of approximately 920 to 940 m. Topographic high areas are typically areas where groundwater recharge occurs, whereas topographic low areas are typically areas where groundwater discharge occurs.

8.2.1 Recharge Areas

Groundwater recharge from precipitation near the TSF is expected to occur primarily along topographic highs, such as upgradient of the western boundary of the TSF, between the TSF and Bootjack Lake. The recharge rate in this area was estimated to be approximately 20% of average annual precipitation based on the results of numerical model calibration for a groundwater flow model of the TSF area (Golder 2016c).

Prior to construction of the TSF, groundwater discharge to ground surface was reported to occur within the footprint of the TSF, as indicated by the presence of a small pond and two swampy marsh-like areas within this footprint. This is supported by the observation of a near-surface water table, artesian pressures measured below the west side of the TSF footprint, and upward groundwater flow gradients measured along the Main and Perimeter embankments, as described in Section 8.4.1). However, the construction of the TSF and the presence of the TSF Pond changed the groundwater conditions such that the TSF Pond is now a source of groundwater recharge (i.e., contributes to seepage through the foundation). The TSF Pond level rose from approximately 938 to 962 m between 2016 and 2018 (Section 8.3), and then remained relatively stable thereafter, at an elevation of approximately 962 to 963 m. The TSF Pond elevation is inferred to control the amount of seepage that reports to the TSF seepage collection systems, as described in Section 8.2.2.

8.2.2 Tailings Storage Facility Seepage

Seepage through the TSF embankment is collected at the downstream seepage collection ponds and ditches. The seepage collection ponds and ditches are unlined and are reportedly installed within till. Limited recharge is expected to occur from the seepage collection systems to the groundwater system.

The primary systems that report to the seepage collection ponds and ditches are:

- foundation drains that underlie the downstream shell of the dam
- upstream toe drains within the South, Main, and Perimeter Embankments
- four passive pressure relief wells (PRW96-1 to PRW96-4) and trenches installed below the Main Embankment

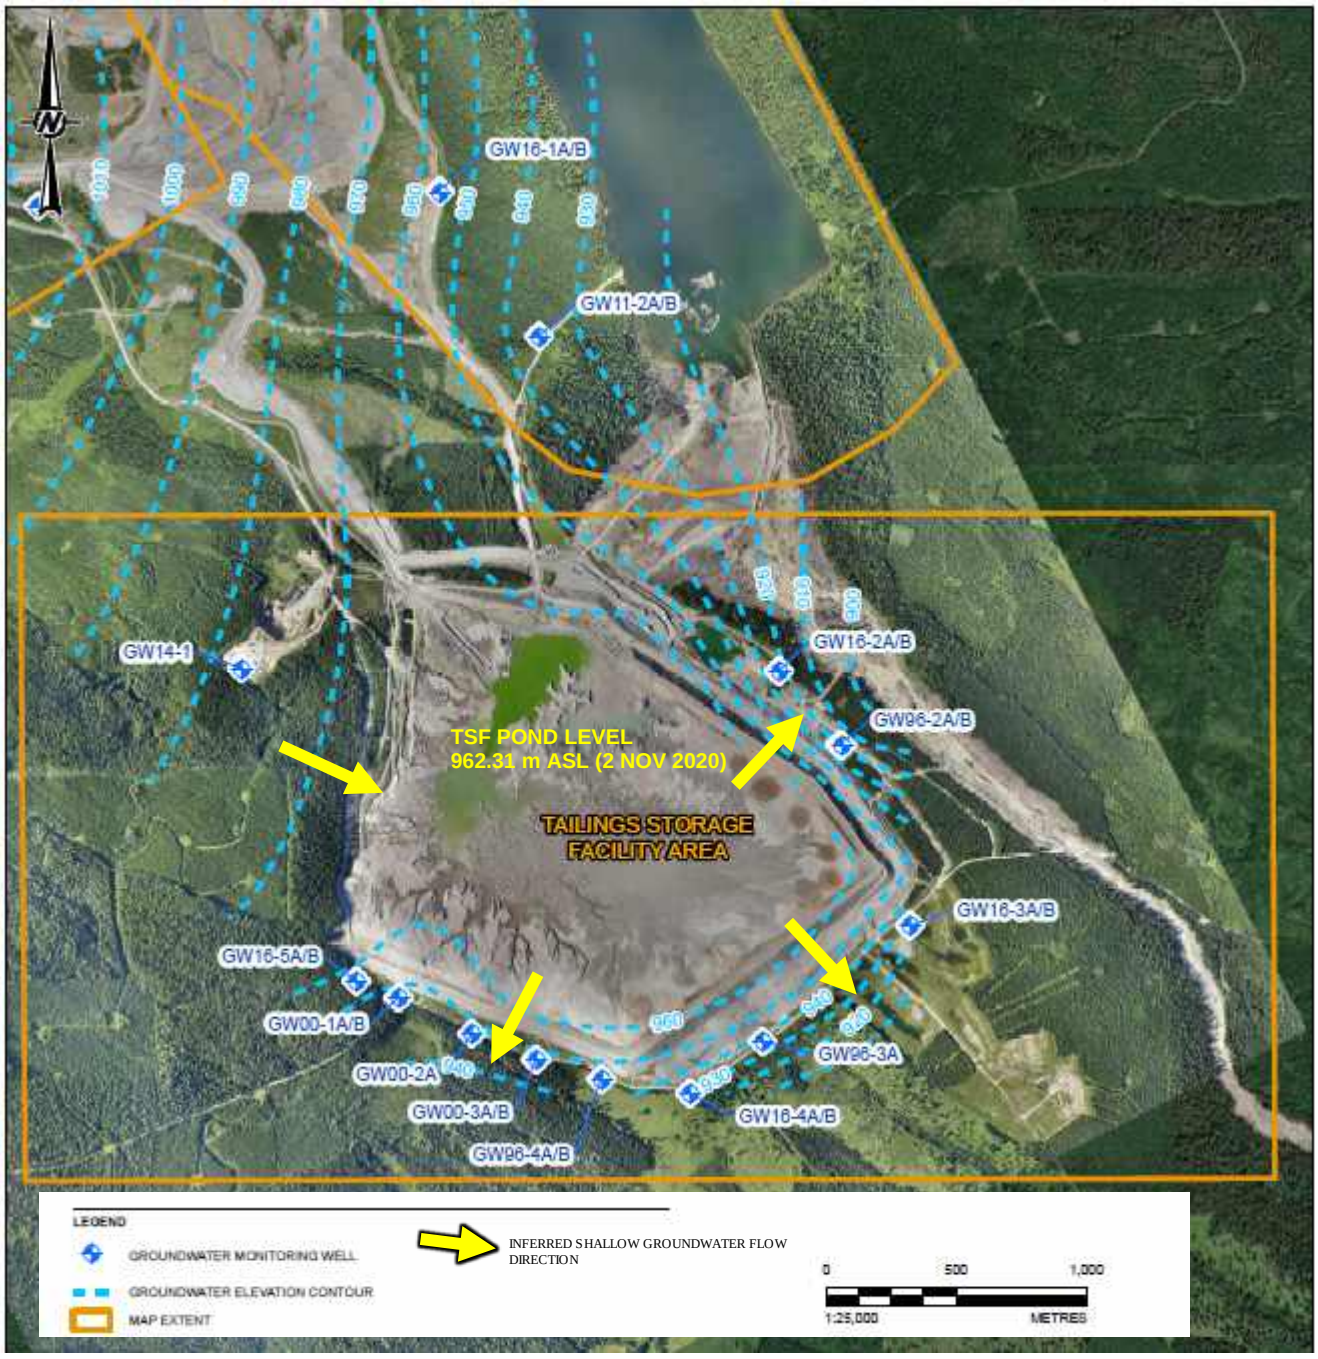
Measured flows reporting to the TSF seepage collection systems ranged between about 2,500 and 6,200 m^3/d (29 and 72 L/s) in 2021 (Golder 2022a). Most of the seepage (70% to 80%) is from the upstream drain at Corner 1 (21 to 45 L/s), with the remaining (20% to 30%) being a combination of flow from upstream drains, seepage through the embankments, flow from passive pressure relief wells and runoff (8 to 27 L/s). Golder (2015g) previously reported measured flows from the foundation drains to be on the order of 80 L/s in 2014 prior to the breach. Although not explicitly stated in the Golder (2015g) report, the foundation drains are considered to be connected to the upstream drains, and flow measurements through the embankment and from the pressure relief wells without the contribution from the upstream drains is not available.

Seepage losses through the foundation on the order of 35 to 294 m^3/d (0.4 to 3.4 L/s, about 2.2 L/s on average) were estimated to bypass the downstream seepage collection ditches and ponds based on estimates in previous design reports which considered TSF embankment elevations of 960 m (KP 1995b) and 965 m (KP 2005). More recent estimates of the seepage losses are not available.

8.2.3 Discharge Areas

The primary groundwater discharge areas downgradient of the TSF footprint include Edney Creek, Edney Creek tributaries, and Hazeltine Creek.

Within the TSF embankment foundation, there are four passive pressure relief wells and connecting trenches that were installed within native soils in 1996 (KP 1997c, Section 5.2.2). These wells act to reduce the artesian pressures along the foundation of the Main Embankment and constitute a discharge area for groundwater. The pressure relief wells are situated directly below the Main Embankment between approximately Station 1+800 and 2+300 (see Figure 1) and consist of auger holes drilled to a depth of between 10 and 22 m and backfilled with filter sand. The pressure relief trenches were excavated and backfilled with gravelly sand. Because these wells are buried below the embankment, direct flow measurement from the wells is not possible. As indicated in Section 8.2.2, flows from these wells are routed to the TSF Main Embankment Seepage Collection Pond.



8.3 Hydraulic Heads and Vertical Hydraulic Gradients

The most recent groundwater level data is reported in the *2021 Annual Groundwater Monitoring Report* (Golder 2022b). The following information is based on that report.

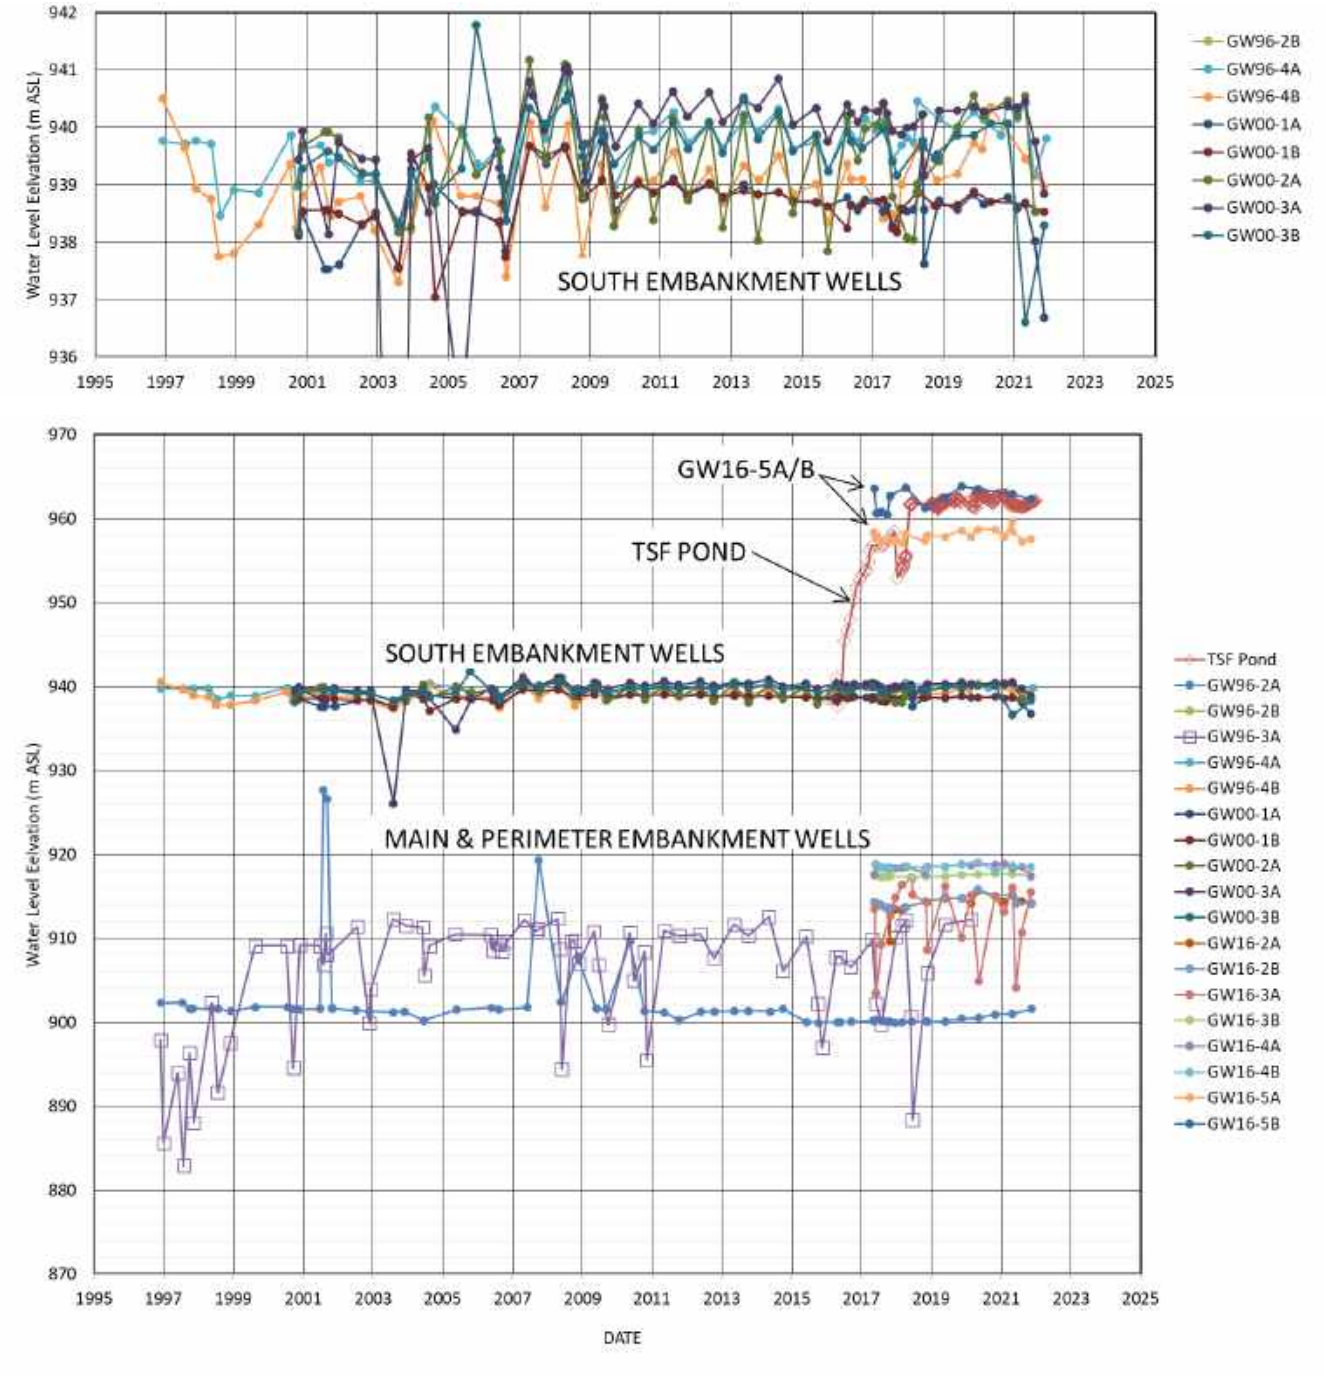
Hydraulic Heads

Groundwater monitoring has been ongoing at the mine site since 1995 with the objectives to monitor direction, quantity, and quality of groundwater flow near all mine facilities. As part of this program, eight monitoring well pairs (each with one deeper well and one shallow well, and typically one bedrock and one overburden well per pair) and three single monitoring wells, all situated next to the outer perimeter of the TSF, are monitored monthly to annually, depending on location. The well locations are shown on the plan in Illustration 8-1, and also shown on the cross-sections in Figure 3 to Figure 9. Completion details for the wells are provided in APPENDIX C (Table C4). The monitoring well locations include the following, listed from west to east:

- Northwest Side: GW14-1
- South Embankment: GW16-5A/B, GW00-1A/B, GW00-2A, GW00-3A/B, GW96-4A/B
- Main Embankment: GW16-4A/B, GW96-3A, GW16-3A/B
- Perimeter Embankment: GW96-2A/B, GW16-2A/B

Source: Golder (2021) modified Figure 6.

Illustration 8-1: Shallow Hydraulic Head Contours for November 2020



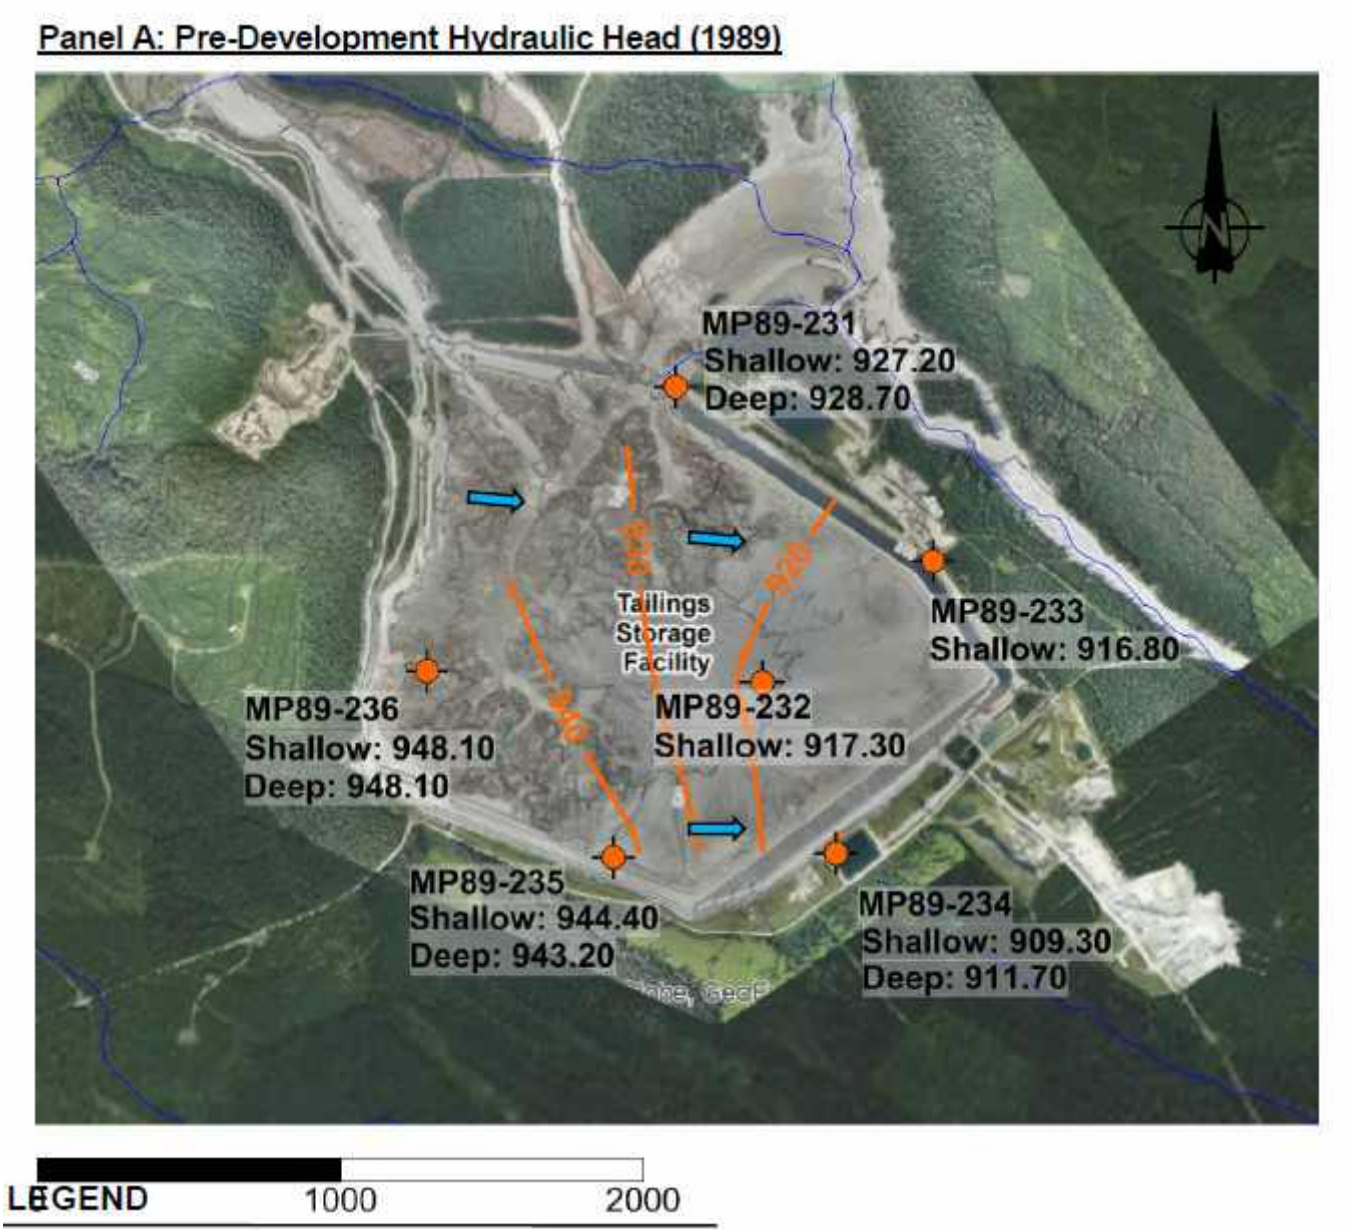
Hydraulic heads around the TSF ranged from a high of 963 m (at GW16-5B) on the northwest side of the facility to a low of 915 m (at GW96-2B) on the northeast side in 2021. As shown on the time-series water level plot in Illustration 8-2, the hydraulic heads have remained fairly constant over time since approximately 2003, excluding seasonal water level fluctuations of approximately 2 to 3 m at most locations (the small seasonal variation relative to the total head change across the facility suggests that these seasonal variations are unlikely to affect overall interpretation of groundwater flow directions near the TSF). Conversely, the TSF Pond level rose from approximately 938 m to approximately 962 m between 2016 and 2018, and then remained relatively stable thereafter at an elevation between 961 and 963 m. Currently, the monitoring well nest located at the west end of the South Embankment (GW16-5A/B) has hydraulic heads that are relatively close to the TSF Pond level, whereas hydraulic heads along the remaining perimeter of the facility are significantly lower. Although not shown in Illustration 8-1, the surface water level in Bootjack Lake, situated approximately 2 km northwest of the TSF, was approximately 987 m in 2021 (approximately 24 m higher than the current TSF Pond level), and the groundwater level within the bedrock knoll in between the TSF and Bootjack Lake was inferred to be higher relative to the lake level based on measured groundwater levels to the northwest of the TSF and closer to Polley Mountain (GW96-7; approximately 1,017 m). The distribution in hydraulic heads indicates that the groundwater flow direction is radially outward from the TSF towards the southwest, southeast, and northeast, with some groundwater inflow into the facility from the northwest. Groundwater flow direction is discussed in more detail in Section 8.4.

Next to the Perimeter Embankment, the hydraulic head observed in the deep well screen at GW96-2A completed in weathered bedrock (901.61 m on 25 November 2021) is significantly lower than would be expected based on nearby surface water elevations in Edney Creek and Hazeltine Creek, with surface water level elevations being about 10 m higher. The high hydraulic conductivity results for GW96-2A at an elevation of 878 m (3×10^{-6} m/s, see Table 8-1) indicates a possible zone of enhanced permeability at this location. According to Golder (2016c), the low water level measurement in GW96-2A suggests the well could be connected locally, through this enhanced permeability zone, to farther down-gradient and downstream areas of Hazeltine Creek. Based on the groundwater quality results for the TSF described in Section 9.5 and considering the groundwater quality trends for this well from pre-mining to present shown in Figure 10, this well does not appear to be influenced by seepage from the TSF. This suggests that the inferred enhanced permeability zone at GW96-2A is not hydraulically connected to the TSF.

Vertical Hydraulic Gradients

Data from the multi-level wells from 2019 onwards indicated mostly downward (shallow to deep) vertical hydraulic gradients around the TSF perimeter with the following exceptions:

- A consistently upward hydraulic gradient, observed from November 2019 to November 2021 next to the South Embankment close to the southwest corner of the facility (at GW96-4A/B and GW00-3A/B).
- Periodic flowing artesian conditions since approximately 2003 observed or inferred (water levels recorded at the top of the well collar on some occasions; however, the static water level height above the well collar has not been measured) at bedrock well GW96-3A situated southeast of the Main Embankment. This well location is situated downgradient of the four passive pressure relief wells described in Section 8.2.3 and next to the Main Embankment Seepage Collection Pond.



TSF = tailings storage facility.

Illustration 8-2: Tailings Storage Facility Pond Level and Surrounding Groundwater Levels over Time

8.4 Groundwater Flow Direction

8.4.1 Pre-development Groundwater Flow Direction

Prior to the TSF construction, hydraulic head measurements were collected by KP (1990) at 10 monitoring wells and piezometers. The inferred groundwater flow directions based on these data are presented in Illustration 8-3 below.

Source: KP 1990; modified from Figure 4 in Golder 2016c.

Illustration 8-3: Pre-development Hydraulic Heads and Groundwater Flow Direction

Based on the measured hydraulic heads, the groundwater flow direction prior to the development of the TSF was inferred to be from the west and northwest towards the east and southeast. The water table was observed to be near ground surface, with artesian pressures measured within the TSF basin at MP89-236 and upward groundwater flow gradients measured along the Main and Corner 1 embankments (MP89-234 and MP89-231). The observed upward gradients and artesian flow conditions are consistent with reported observations of two swampy areas and a small pond within the footprint of the TSF prior to development. A downward hydraulic gradient was observed at MP89-235, which is located near a bedrock ridge (topographic high) adjacent to and beneath the South Embankment.

8.4.2 Current Groundwater Flow Direction

The current groundwater flow direction in the area of the TSF is inferred to be partly dependent on the TSF Pond level. Provided that surface water level elevations within the TSF are above the surrounding shallow groundwater level, groundwater flow will be radial from the TSF towards the southwest, southeast, and northeast. However, when the TSF Pond level falls below the shallow groundwater levels on the west side of the TSF, then the TSF area becomes a flow-through environment, similar to pre-development conditions described above, with groundwater flow directed across the TSF from the west and northwest towards the east and southeast.

The plan in Illustration 8-1 shows the November 2020 hydraulic head contours and groundwater flow directions around the perimeter of the TSF. In 2020 and 2021, groundwater flow towards the TSF was from the upgradient, northwest side of the facility (i.e., area of GW14-1 and GW16-5A/B), originating from the area of Bootjack Lake and Polley Mountain. With the TSF Pond level at approximately 962 m, groundwater within the TSF footprint was inferred to flow radially outward towards the southwest (towards Edney Creek and its tributaries), southeast, and northeast (towards Hazeltine Creek).

8.5 Groundwater Use Downgradient of the Mine

A search in the Ministry of Environment's online database (iMapBC) in December 2022 indicated that there are no mapped aquifers within a radius of 10 km from the mine. The closest mapped aquifer, Fraser Plateau Lave Aquifer No. 124 IIIB (11), is a laterally extensive bedrock unit that was classified as having low demand and moderate vulnerability. The northern limit of this aquifer is situated more than 15 km south of the mine and is not considered to be hydraulically connected to groundwater from the mine area and the Hazeltine Channel corridor. This database search also indicated that water supply wells are not present in the immediate vicinity of the mine. The closest wells are approximately 6 km east, on the opposite (eastern) shore of Quesnel Lake. The database also contains information on water wells that are located northwest from the mine (near Little Lake) and southwest from the mine (near Gavin Lake) at a distance of at least 7 km. Considering these distances and the fact that several surface water features are between these wells and the mine, it is unlikely that seepage from the mine facilities could reach these wells or the closest mapped aquifer. A map showing the results of the water well search and the nearest mapped aquifer is included in APPENDIX F.

9.0 GEOCHEMICAL CONDITIONS

9.1 Monitoring Program

As stated previously, groundwater monitoring by MPMC has been ongoing at the mine site since 1995 with the objectives to monitor direction, quantity, and quality of groundwater flow near all mine facilities. The monitoring wells used to monitor groundwater levels around the perimeter of the TSF (listed in Section 8.3) are also used to monitor groundwater quality. The monitoring well network is shown in Illustration 8-1.

Groundwater samples from the monitoring wells are collected quarterly or semi-annually, depending on location, and are analyzed for field parameters, anions, nutrients, and dissolved metals and are reported annually. The analyses are focused on nine parameters of interest which included hardness, sulphate, nitrate, and the following dissolved metals: aluminum, arsenic, cadmium, molybdenum, and selenium.

The most recent groundwater quality data for the TSF area is reported in the *2021 Annual Groundwater Monitoring Report* (Golder 2022b). Water quality trend plots from this report are provided in Figure 10.

9.2 Baseline Groundwater Quality

The plots in Figure 10 provide information on baseline and early operations groundwater quality conditions, from 1996 to approximately 1999, at a few monitoring wells that were installed prior to or at the start of TSF operations in 1998 and continue to be monitored today. Based on these plots, baseline groundwater quality conditions are generally characterized by low concentrations of dissolved metals, sulphate, and nitrate and low to moderate hardness, with the exception of one monitoring well (GW96-3A) where concentrations of many parameters fluctuated substantially. The erratic results at GW96-3A suggest that non-natural factors (e.g., possible well contamination or well design flaws such as bentonite seal within the screened interval) were affecting the water quality results from this well. It should be noted that periodically flowing artesian conditions have been observed or inferred at this well and that it is situated next to the unlined Main Embankment Seepage Collection Pond (Section 8.3).

9.3 Tailings Storage Facility Tailings

The following information on metal leaching and acid rock drainage geochemistry is from the SRK *Derivation of Geochemical Source Terms, Mount Polley Mine* (Appendix C in Golder 2016b) and from Kennedy and Anglin (2016).

The Mount Polley copper-gold porphyry deposit is classified as an alkalic porphyry copper gold deposit. The mined mineralized zones are enriched in copper and selenium relative to global norms. Processing of the ore yields a copper sulphide concentrate. The tailings are lower in sulphide mineral content compared to the ore because most of the copper sulphides were removed through ore processing. In addition, mill process reagents, with the exception of lime, are not expected to be present within tailings. Furthermore, processing changes over time were minimal and not expected to affect the geochemical reactivity of the tailings; therefore, tailings geochemistry can be considered generally consistent over time.

Mount Polley tailings are classified as non-acid generating based on operational monitoring and testing of tailings spilled into Hazeltine Creek in August 2014. Compared to crustal normal concentrations, copper and selenium were present in the tailings sampled from Hazeltine Creek following the tailings release at order of magnitude higher concentrations, indicating tailings enriched in copper and selenium. However, average selenium concentrations in the operational tailings from within the TSF were lower than the spilled tailings in the creek and were similar to background levels (i.e., similar to average selenium concentrations in stream sediment samples from the region surrounding Mount Polley [Kennedy and Anglin 2016, Section 5.2.2]).

Humidity cell tests and column tests that ran for about 52 weeks and 35 weeks, respectively, using selected samples which had typical characteristics of tailings in the impoundment, were used to assess potential tailings leachate quality. The leachate quality from these tests is described below:

- pH typically between 8.0 and 8.2
- sulphate concentrations initially on the order of 1,000 mg/L, with decreasing concentrations over time that reached lower stabilized values
- highest copper concentration of 0.15 mg/L in one test, but with typical maximum concentrations of 0.02 mg/L in humidity cell test leachates and 0.05 mg/L in column test leachates
- highest selenium concentrations were 0.01 mg/L in humidity cell test leachates and 0.06 mg/L in column test leachates
- molybdenum concentrations initially between 2 and 3 mg/L in column leachates

9.4 Tailings Storage Facility Pond Water Quality

The quality of the TSF Pond water is monitored several times per year at monitoring location E1a as part of the Mount Polley Mine's Comprehensive Environmental Monitoring Plan under the *Environmental Management Act* Permit 11678 and *Mines Act* Permit M-200. The following water quality characteristics with respect to selected parameters of interest for this contact water (i.e., mine-affected water) from E1a were obtained from MPMC (2021, Section 4.10.1). Note that the mine was in care and maintenance in 2020 so values for the period between 2012 and 2014 are also included below.

- Annual mean hardness of 450 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 438 mg/L.
- Annual mean chloride concentration of 8.9 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 24.3 mg/L.
- Annual mean sulphate concentration of 438 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 542 mg/L.
- Annual mean nitrate concentration of 1.9 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 6.4 mg/L.
- Annual mean total iron concentration of 0.188 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 0.272 mg/L.
- Annual mean total copper concentration of 0.357 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 0.010 mg/L.
- Annual mean total selenium concentration of 0.0292 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 0.0260 mg/L.
- Annual mean total molybdenum concentration of 0.158 mg/L in 2020. For comparison, the pre-breach (2012 to 2014) mean was 0.184 mg/L.

MPMC (2021) reports that, of the parameters of interest, total molybdenum and possibly chloride have shown a general increasing trend after post-breach deposition of tailings commenced. Total copper concentrations have increased in recent years due to seepage with high copper concentration from the heap leach trial area in the waste dump.

9.5 Current Groundwater Quality

Based on the inferred groundwater flow direction described in Section 8.4, the upgradient and downgradient wells relative to the TSF are as follows:

- upgradient wells:
  - west: GW14-1 (no water quality data available for this location)
  - southwest (Corner 4): GW16-5A/B (potentially side-gradient)
- downgradient wells:
  - South Embankment: GW00-1A/B, GW00-2A, GW00-3A/B, GW96-4A/B
  - Main Embankment: GW16-4A/B, GW96-3A, GW16-3A/B
  - Perimeter Embankment: GW96-2A/B, GW16-2A/B

The following summary on groundwater quality is based on information from the *2021 Annual Groundwater Monitoring Report* (Golder 2022b). This summary provides an overview of the 2021 groundwater quality results and the groundwater quality trends for monitoring wells located around the TSF (as shown in Figure 10).

Over the last decade or so, although there were increasing parameter of interest concentration trends at some locations, significant changes to groundwater quality at the perimeter of the TSF had not been identified except with respect to sulphate. Sulphate concentrations in the shallow groundwater downgradient of the TSF approached or reached levels observed in the TSF Pond water next to the Perimeter Embankment at GW16-2B and GW96-2B and next to the South Embankment at GW96-4B. The highest sulphate concentrations were observed at GW96-2B in November 2021 (543 mg/L). These wells are known or inferred to be completed in glaciofluvial units based on soil descriptions and the relatively high hydraulic conductivity results (Table 8-1). The remaining wells indicated relatively stable or slightly decreasing sulphate concentration trends.

Groundwater quality results for the upgradient well nest location, GW16-5A/B, indicated no significant trends since the installation of the wells in 2016. Furthermore, the water quality at this location appears to be similar to baseline or pre-development water quality (described in Section 9.2).

The 2021 groundwater quality results were compared to the British Columbia (BC) Ministry of Environment and Climate Change Strategy Contaminated Sites Regulation (BC ENV 1997) standards for protection of freshwater aquatic life and the BC Approved Water Quality Guidelines for protection of aquatic life (BCWQG AW; BC ENV 2021). An analysis of the results indicated no exceedances of the Contaminated Sites Regulation standards for protection of freshwater aquatic life and no exceedances of the BCWQG AW guidelines with the following exceptions concerning the BCWQG AW criteria only:

- pH above the guideline range (6.5 to 9.0) at one downgradient well location (GW00-3A, pH = 11), with two locations only slightly above the guidelines (GW00-1A, GW16-2A)
- sulphate concentrations above the chronic guideline (128 to 429 mg/L, hardness dependent) at several downgradient well locations (GW96-2B in November 2021 [543 mg/L] but not in May 2021: GW96-4B [471 to 507 mg/L]; GW00-1A [226 mg/L]; GW16-2B [475 to 518 µg/L])
- dissolved iron above the acute guideline (350 ug/L) at one downgradient well location (GW96-4B, 785 to 877 µg/L); elevated dissolved iron concentrations were observed at the two upgradient well locations (GW14-1 in February to August 2021 [1,120 to 1,300 µg/L] but non-detectable in November 2021 [<30 µg/L], and GW16-5A [675 to 716 µg/L]).

10.0 DISCUSSION

This section presents a discussion of potential dam safety issues related to site conditions, along with the TSF design approach to mitigate each issue.

A general embankment description is included in Section 2.0. With a 970 m crest elevation, the embankment is approximately 4.8 km in length and has a maximum height of 58 m. The embankment has incorporated a staged expansion design utilizing modified centreline and centreline construction methods. The zoning of the embankment includes a low permeability till core, filter, and transition zones and rockfill zones forming the downstream shell of the embankment and the downstream buttress.

The elevation 970 m TSF design description is presented in Golder (2015g). The design to raise to facility to 987 m follows the same philosophy and is presented in WSP Golder (2022c).

10.1 Stability

Strength of Foundation Materials

Potential stability issues related to the strength of foundation materials include:

- insufficient strength in the foundation (i.e., glaciolacustrine layers) to resist the loads applied by the dam
- strain weakening of glaciolacustrine soils
- unidentified foundation conditions (e.g., unidentified glaciolacustrine deposits)

Multiple field investigations have been completed along the foundation of the embankment and buttress to delineate the extent and characterize the different foundation materials.

The weaker layers in the foundation of the embankment and buttress are the glaciolacustrine deposits. Extensive field and laboratory investigations have been completed to characterize the strength of the glaciolacustrine deposits.

The design approach is to analyze embankment stability and deformation considering the interpreted foundation conditions and includes:

- limit equilibrium analyses of downstream failure modes under static and pseudo-static conditions for the range of foundation conditions along the embankment
- limit equilibrium analyses with a range of glaciolacustrine deposits strength to assess sensitivity to potential variability
- stress-deformation analysis (2D FLAC model) to predict patterns of deformation and potential redistribution of stresses due to strain weakening of glaciolacustrine deposits

The design approach also follows the principles set out in the IEEIRP report of January 2015:

- Limit the amount of surface water to only that required for operation.
- Promote unsaturated conditions in the tailings with drainage provisions (i.e., minimum beach width and upstream drain).
- Achieve dilatant conditions throughout the tailings deposit (i.e., the existing tailings within the TSF drained and consolidated after the TSF breach in 2014 and the upstream drain promotes consolidation of new tailings).

Loading of Foundation Materials

The potential stability issue related to raising the TSF is the development of excess pore water pressure in the foundation materials during construction.

Extensive field and laboratory investigations have been completed to characterize the glaciolacustrine deposits.

The pore pressure response has been monitored within the glaciolacustrine deposits, till, and glaciofluvial layers during construction of the Corner 1 Embankment and Perimeter and Main embankment buttresses.

The design approach is to analyze embankment stability including the generation of excess pore water pressure due to loading of the foundation at key stages of construction.

Groundwater Conditions

The potential stability issue related to groundwater conditions is the failure of the Main Embankment vertical drain wells and the development of artesian pressures in the foundation.

The pore water pressure has been monitored within the glaciofluvial, till, and glaciolacustrine layers in the foundation of the Main Embankment. The readings show that the Main Embankment's vertical passive pressure relief wells continue to work and artesian pressures have not developed.

The design approach is to analyze embankment stability assuming that artesian pressures redevelop to the levels measured prior to the installation of the Main Embankment vertical drain wells.

10.2 Seepage

The potential seepage issue related to site conditions is the development of preferential flow pathways in the foundation soils (e.g., glaciofluvial layers) or bedrock, leading to increased seepage and potential groundwater quality issues.

- The design approach is to include suitable foundation preparation, placement of a filter blanket downstream of the till core and confirmation that a minimum thickness of competent till is present on surface along and upstream of the till core alignment. Where the thickness of competent till is adequate, the till core is keyed into the foundation till. Where the thickness of competent till is less than the minimum required, a till blank is constructed upstream of the till core and the till core is keyed into competent till or bedrock to cut-off through layers of higher hydraulic conductivity soils (e.g., glaciofluvial) or bedrock (e.g., fractured bedrock).
- For raises of the TSF, the thickness of competent till is confirmed during construction of the South and North abutments.

Monitoring data collected since 1996 shows that groundwater quality downgradient of the TSF is being affected by seepage from the TSF. The concentration of sulphate in groundwater downgradient of the TSF approached or reached levels observed in the TSF Pond water; however, it does not exceed the BC ENV (1997) Contaminated Sites Regulation water quality standards for protection of freshwater aquatic life. Additional groundwater monitoring downgradient of the TSF between monitoring wells showing elevated sulphate concentrations and surface water receptors should be planned.

11.0 CLOSURE

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this report.

We trust the above meets your present requirements. If you have any questions, please contact the undersigned.

THIS FIGURE IS INTENDED FOR CLIENT'S ONE TIME USE ONLY AND IT IS NOT INTENDED OR REPRESENTED BY WSP TO BE SUITABLE FOR REUSE BY ANY PARTY, INCLUDING, BUT NOT LIMITED TO, THE CLIENT, ITS EMPLOYEES, AGENTS, SUBCONTRACTORS OR SUBSEQUENT OWNERS ON ANY EXTENSION OF A SPECIFIC PROJECT OR FUTURE PROJECTS, WHETHER CLIENT'S OR OTHERWISE, WITHOUT WSP'S PRIOR WRITTEN PERMISSION. ANY MANIPULATION, ADAPTATION, MODIFICATION, ALTERATION, MISUSE OR REUSE UNAUTHORIZED BY WSP WILL BE AT CLIENT'S SOLE RISK. WSP EXPRESSLY DISCLAIMS ALL LIABILITY AGAINST ALL THIRD PARTIES RELYING, USING OR MAKING DECISIONS ON THIS FIGURE. THIRD PARTIES DO SO AT THEIR OWN RISK. EXCEPT WHERE WRITTEN AGREEMENT STATES OTHERWISE, THIS FIGURE IS THE PROPERTY OF WSP CANADA INC.

NOTES

1. ALL UNITS ARE IN METRES UNLESS NOTED OTHERWISE.
2. COORDINATES AND ELEVATIONS SHOWN ARE REFERENCED TO TAILINGS GRID.
3. THE FORENSIC INVESTIGATION BOREHOLES NEAR CORNER 1 (FROM 2014) ARE NOT SHOWN ON THE FIGURE FOR CLARITY, REFER TO FIGURE 02.
4. THE FOLLOWING DRILLING INVESTIGATIONS ARE NOT SHOWN ON THE FIGURE FOR CLARITY: DH97-BA (KP 1997c), DH97-BA2 (IEERP 2015), DH98-BA2 (IEERP 2015), DH98-BA4 (IEERP 2015), DH98-BL (KP 1999), PRW98 (KP 1999), BH99 (KP 1999), AND DH99 (KP 2000).
5. TEST PIT INVESTIGATIONS ARE NOT SHOWN ON THE FIGURE FOR CLARITY.

TEST HOLE LEGEND

BH19-02
o/s -88.59

DENOTES TEST HOLE TYPE, INVESTIGATION YEAR AND ID NUMBER
DENOTES PERPENDICULAR DISTANCE FROM TEST HOLE TO SECTION LINE IN METRES
GROUNDWATER LEVEL / PIEZOMETRIC HEAD IN NOVEMBER / DECEMBER 2021
EXISTING VIBRATING WIRE PIEZOMETER
MONITORING WELL SCREEN
TEST HOLE RECORD SHOWING SOIL CONDITIONS (FOR DETAILED GEOTECHNICAL INFORMATION REFER TO RECORD OF BOREHOLE)

NOT USED FOR THE GEOLOGICAL PROFILE BOUNDARIES SYMBOLS SUMMARY

*	REVIEWED BOREHOLE LOG DATA ONLY. BOREHOLE LOG NOT USED FOR CREATING STRATIGRAPHIC BOUNDARIES.
**	BOREHOLE LOG DID NOT PROVIDE SUFFICIENT GEOLOGICAL DETAIL FOR INCLUSION IN STRATIGRAPHIC INTERPRETATION.

SOIL LITHOLOGY

FILL, PT - PEAT, OL - ORGANIC SILT, OH - ORGANIC SILT, CL - SILTY CLAY, TOPSOIL, CI - SILTY CLAY, CH - CLAY, MH - CLAYEY SILT, ML - CLAYEY SILT OR SILT, ASPHALT, SC - CLAYEY SAND, SW - WELL GRADED SAND, SM - SILTY SAND, SP - POORLY GRADED SAND, GC - CLAYEY GRAVEL, GM - SILTY GRAVEL, GP - POORLY GRADED GRAVEL, GW - WELL GRADED GRAVEL, BEDROCK

SOIL STRATIGRAPHY

FILL, ABLATION TILL, GLACIOLACUSTRINE SUB-UNIT, BASAL TILL, GLACIOFLUVIAL SUB-UNIT (SAND DOMINATED), GLACIOFLUVIAL SUB-UNIT (GRAVEL DOMINATED)

BEDROCK / WEATHERED BEDROCK

BEDROCK / WEATHERED BEDROCK

NOTES

1. ALL UNITS ARE IN METRES UNLESS NOTED OTHERWISE.
2. DATA CONCERNING THE VARIOUS STRATA HAVE BEEN OBTAINED AT TEST HOLE LOCATIONS ONLY. THE SOIL STRATIGRAPHY BETWEEN TEST HOLES HAS BEEN INFERRED FROM GEOLOGICAL EVIDENCE AND MAY VARY FROM THAT SHOWN.
3. VARIOUS COMBINATIONS OF THE SYMBOLS HAVE BEEN USED TO REPRESENT TRANSITIONAL MATERIALS OR RANGES OF MATERIALS WITHIN A STRATUM.
4. PREFERENCE WAS GIVEN TO INCORPORATING GEOLOGIC DATA FROM BOREHOLES LOCATED CLOSE TO THE CROSS-SECTION LINES AND TO BOREHOLES THAT HAD THE MOST DETAILED GEOLOGIC DESCRIPTIONS OF THE SUBSURFACE CONDITIONS ENCOUNTERED. BOREHOLES THAT WERE FARTHER FROM CROSS-SECTION LINES WERE REVIEWED FOR GEOLOGICAL CORRELATION CRITERIA, INCLUDING INFORMATION ON THE SPECIFIC STRATIGRAPHIC SEQUENCE AND ELEVATIONS OF CONTACTS BETWEEN THE DIFFERENT GEOLOGIC UNITS. BOREHOLES WITH SIGNIFICANT LATERAL OFFSET FROM THE LINES OF CROSS-SECTION WERE GENERALLY OMITTED GIVEN THE HIGH DEGREE OF UNCERTAINTY IN PROJECTION OF THE DATA.

4. PREFERENCE WAS GIVEN TO INCORPORATING GEOLOGIC DATA FROM BOREHOLES LOCATED CLOSE TO THE CROSS-SECTION LINES AND TO BOREHOLES THAT HAD THE MOST DETAILED GEOLOGIC DESCRIPTIONS OF THE SUBSURFACE CONDITIONS ENCOUNTERED. BOREHOLES THAT WERE FARTHER FROM CROSS-SECTION LINES WERE REVIEWED FOR GEOLOGICAL CORRELATION CRITERIA, INCLUDING INFORMATION ON THE SPECIFIC STRATIGRAPHIC SEQUENCE AND ELEVATIONS OF CONTACTS BETWEEN THE DIFFERENT GEOLOGIC UNITS. BOREHOLES WITH SIGNIFICANT LATERAL OFFSET FROM THE LINES OF CROSS-SECTION WERE GENERALLY OMITTED GIVEN THE HIGH DEGREE OF UNCERTAINTY IN PROJECTION OF THE DATA.

Summary of Investigations

GEOTECHNICAL INVESTIGATIONS

KP (Knight and Piésold Ltd.). 1990. Report on Geotechnical Investigations and Design of Open Pit, Waste Dumps and Tailings Storage Facility. Prepared for Imperial Metals Corporation. 12 June 1990.

Purpose

The main objectives and considerations of this study were to:

- present the design for the open pit, waste dumps, and tailings storage facility (TSF)
- provide input for the Stage 1 report and permit applications and become part of the overall Mount Polley Mine Feasibility Study

Scope

The scope related to the TSF foundation includes the following:

- site characteristics including hydrometeorology, regional geology, and seismicity
- geotechnical investigations carried out in the proposed TSF location consisting of field mapping, test pits and diamond drilling with permeability testing
  - Eighteen test pits (TPB-01 to TPB-18) were excavated within the proposed TSF footprint on 27/28 August 1989.
  - Eight condemnation boreholes (MP89-229 to MP89-236) were drilled in the proposed TSF footprint from 29 October 1989 to 12 November 1989.
    - Completion depths ranged from 73.2 to 121.9 m below ground surface.
    - Piezometers – 10 piezometers were installed in 6 boreholes (4 pneumatic and 6 standpipe piezometers).
    - Permeability testing consisted of the following:
      - packer tests – 21 tests conducted in 6 boreholes
      - falling head tests – 3 tests conducted in 3 boreholes
  - Laboratory testing of till samples collected from the test pits consisted of the following:
    - water content – 2 tests
    - Atterberg limits – 2 tests
    - sieve analysis – 2 tests
    - hydrometer – 2 tests
    - specific gravity – 1 test
    - modified Proctor – 1 test
    - permeability – 1 test
- identification of construction materials for the TSF

Data

- Appendix A – Climatological Summaries
- Appendix B – Discontinuity Data and Point Load Test Results
- Appendix C – Waste Rock Acid Generation Potential Testwork
- Appendix D – Laboratory Testwork on Tailings
- Appendix E – Geochemical Tests on Tailings
- Appendix F – Tailings Area B. Test Pit Logs, Borehole Logs and Permeability Test Results

KP (Knight Piésold Ltd.). 1995. Report on 1995 Geotechnical Investigations for Mill Site and Tailings Storage Facility. Prepared for Imperial Metals Corporation. Document No. 1623/1. 14 March 1995.

Purpose

The main objectives and considerations for the geotechnical investigation were to evaluate the type and distribution of surficial materials and the near surface foundation conditions at the mill site, along access roads and pipeline routes, potential borrow areas, within the tailings basin, and at the Polley Lake dam site.

Scope

The geotechnical investigation program was undertaken from 11 to 17 January 1995.

- Four test pits (TP95-16 to TP95-19) were excavated north of the proposed TSF and partially along the proposed tailings and reclaim pipeline route.
- Three test pits (TP95-29 to TP95-31) were excavated on the ridge east of the tailings facility to investigate potential borrow sources for future embankment construction.
- Eleven test pits (TP95-26 to TP95-28 and TP95-32 to TP95-39) were excavated within the proposed TSF footprint.
- Laboratory testing of soil samples collected from the test pits consisted of the following:
  - visual description of soils
  - water contents – 7 tests
  - Atterberg limits – 6 tests
  - sieve analysis – 7 tests
  - hydrometer – 7 tests
  - specific gravity – 4 tests
  - consolidated undrained triaxial compression – 3 tests
  - modified Proctor – 3 tests
  - falling head permeameter – 5 tests

Data

- Appendix A – Test Pit Logs
- Appendix B – Detailed Laboratory Test Results

KP (Knight Piésold Ltd.). 1997. Stage 2A Tailings Facility Construction Selected Excerpts from Reference Information. Prepared for Mount Polley Mining Corporation. Document No. 10162/9-2. 6 November 1997.

Purpose

The main objective of this report was to provide further background information on the geotechnical conditions encountered within the TSF footprint for the tender of the Stage 2A construction.

The report presents the geotechnical investigations completed for the Stage 2A construction. The main objectives and considerations for the investigation were to:

- delineate suitable borrow materials within Borrow Area No. 4
- investigate foundation conditions at the Perimeter Embankment for future downstream expansions
- complete laboratory testing of waste dump materials and mill site processed rock

Scope

The geotechnical investigation program was undertaken from 30 September 1997 to 6 October 1997.

- Twenty-one test pits (TP97-BA4-F8 to TP97-BA4-J9) were excavated at Borrow Area No. 4. Completion depths ranged from 5.0 to 6.2 m below ground surface.
- Four test pits were excavated (TP97-PETP-1 to TP97-PETP-4) within the proposed Perimeter Embankment expansion footprint. Completion depths ranged from 5.0 to 5.4 m below ground surface.
- Laboratory testing of soil samples collected from the test pits consisted of the following:
  - visual description of soils
  - water contents – 95 tests

Data

- Appendix A – Stage 2A Investigations – Test Pit Logs
- Appendix B – Borrow Area #4 – Summary of Natural Moisture Content of Test Pit Samples
- Appendix C – Particle Size Analyses of Waste Dump Material and Millsite Processed Material
- Appendix D – Stage 1A/1B Construction Quality Assurance – Record Test Data
- Appendix E – Stage 1A/1B Construction Quality Assurance – Control Test Data and Gradation Plots
- Appendix F – Borrow Area #2 Test Pit Program – Summary of Natural Moisture Content of Test Pit Samples
- Appendix G – Borrow Area #3 Test Pit Program – Summary of Natural Moisture Content of Test Pit Samples

AMEC (AMEC Environment & Infrastructure, a division of AMEC Americas Limited). 2012. Mount Polley Mine Project: Tailings Storage Facility 2011 Geotechnical Site Investigation – Final. Prepared for Mount Polley Mining Corporation. Document No. VM00560.200.3. 28 March 2012.

Purpose

The main objectives and considerations for the geotechnical investigation were to:

- further characterize the glaciolacustrine soils within the TSF foundation
- install new instrumentation and replace non-functioning instrumentation in key locations for dam performance monitoring including pore pressure response and slope movements

Scope

The geotechnical investigation program was undertaken from 29 September 2011 to 11 October 2011.

- Fourteen sonic boreholes (VW11-01 to VW11-11 and SI11-01, SI11-02, and SI11-04) were drilled downstream of the Perimeter Embankment, Main Embankment and South Embankment.
  - Completion depths ranged from 11.1 to 49.4 m below ground surface.
  - Vibrating wire piezometers (VWPs) – 23 VWPs were installed in 11 boreholes.
  - Slope inclinometers (SIs) – Three SIs were installed.
  - Shelby tubes – Three thin-walled tubes were collected.
- Four sonic boreholes were drilled at two locations outside the TSF footprint (i.e., mine site area).
  - Monitoring wells – Four monitoring wells (GW11-1A/B and GW11-2A/B) were installed at two locations.
- Laboratory testing of soil samples collected from the boreholes consisted of the following:
  - visual description of soils
  - water contents – 199 tests
  - Atterberg limits – 20 tests
  - sieve analysis – 19 tests
  - hydrometer – 16 tests

Data

- Appendix A – 2011 Laboratory Testing Data
- Appendix B – 2011 Drill Hole Site Investigation Logs
- Appendix C – Drill Core Photographs
- Appendix D – Vibrating Wire Calibration Reports
- Appendix E – Instrumentation Readings
- Appendix F – Monitoring Well Drill Hole Logs

KCB (Klohn Crippen Berger Ltd.). 2015. Mount Polley Dam Failure – Site Investigation Progress Report No. 2. Prepared for BC Ministry of Energy and Mines. Document No. M09954A02.730. 21 January 2015.

Purpose

The main objectives and considerations for the geotechnical investigation were to:

- collect field data to help determine the August 2014 embankment failure mechanism
- characterize the profile and geotechnical properties of the foundation soils both inside and outside the failed area
- investigate and characterize any construction materials within the dam that may have influenced the failure mechanism
- locate the seat of the dam failure through the foundation materials, if applicable

This report supersedes the Site Investigation Progress Report No. 1 submitted to the BC Ministry of Energy and Mines on 12 December 2014.

Scope

The geotechnical investigation program was conducted between mid-September and late-November 2014.

- Visual reconnaissance and surficial mapping were conducted at the dam breach area to establish the post-failure configuration and provide insights into the nature of the failure mechanism.
- Geophysical surveys were conducted to estimate bedrock depth and approximate material boundaries within the dam failure area (Corner 1).
  - resistivity and induced polarity – 8 survey lines
  - seismic refraction – 6 survey lines
- Phase 1 – A sonic coring program was conducted to delineate the soil profile, obtain samples for geotechnical testing, and install instrumentation.
  - Thirty-two sonic boreholes (SH14-01 to SH14-22, with additional “A” and “B” designations) were drilled at 22 locations near the dam failure area (Corner 1).
    - Completion depths ranged from 1.8 to 72.4 m below ground surface.
    - Vibrating wire piezometers – Twenty-two VWPs were installed in 8 boreholes.
    - Slope inclinometers – Five SIs were installed.
    - Preserved core samples – Thirty-three preserved core samples were collected from three boreholes (SH14-03A, SH14-03B and SH14-10A).
    - Field tests – Pocket penetrometer, pilcon and/or torvane tests were conducted approximately every 0.5 m.

- Phase 2 – Cone penetration test (CPT) soundings and in situ testing were conducted to estimate the strength, hydraulic conductivity, and consolidation characteristics of the soil units.
  - Twenty-three CPTs were conducted at 19 locations within the dam failure area (Soundings CPT14-01 to CPT14-08, CPT14-10, CPT14-11, CPT14-13 to CPT14-19, CPT14-21, and CPT14-22).
    - Continuous resistivity measurements, and several shear wave velocity and porewater pressure tests, were completed.
  - Four vane shear test (VST) locations were completed within the dam failure area.
    - A total of 10 electronic VSTs were attempted in the upper glaciolacustrine unit.
  - Two boreholes contained standard penetration test (SPT) energy measurements.
- Phase 3 – Mud rotary drilling was carried out to conduct SPTs and retrieve high quality piston samples of relevant soils for laboratory test work.
  - Six mud rotary boreholes were drilled at three locations within the dam failure area (two per location).
    - Piston tubes – Seventeen thin-walled samples of the upper glaciolacustrine unit were collected.
    - Standard penetration tests – Thirty SPTs were conducted in the upper glacial till (VST14-22, VST14-10A, RH14-03, and CPT14-05A).
- Test pits and trenches were excavated to observe the conditions in the dam and foundation soils and recover block samples for laboratory testing.
  - One test trench was excavated in the dam till core.
  - One test pit was excavated in the up-thrusted toe bulge for block sampling (TP14-01).
    - A block sample of till and a block sample of upper glaciolacustrine material was collected from the test pit.
  - Bulk samples – Two bulk samples of till core were recovered for laboratory testing.
- Laboratory testing was conducted to determine the index, hydraulic conductivity, and strength properties of the various foundation soils and dam materials.
  - visual description of soils
  - water contents – 991 tests
  - Atterberg limits – 139 tests
  - sieve analysis – 127 tests
  - hydrometer – 125 tests
  - standard Proctor – 2 tests
  - specific gravity – 17 tests
  - organic contents – 3 tests
  - X-Ray diffraction – 12 tests on samples of upper and lower glaciolacustrine units
- The following advanced geotechnical tests were ongoing at the time of report preparation:
  - consolidated drained direct shear tests on samples of upper and lower glaciolacustrine units

- direct simple shear tests on samples of upper glaciolacustrine unit
- one-dimensional consolidation tests on samples of upper and lower glaciolacustrine units
- consolidated undrained monotonic triaxial compression tests on samples of till core, upper glacial till, and upper glaciolacustrine unit
- triaxial extension tests on samples of upper glacial till
- hydraulic permeability using triaxial cell (includes monotonic shear after completion of test)

- Appendix XIV – Frontier Geosciences Geophysics Report

IEEIRP (Independent Expert Engineering Investigation and Review Panel). 2015. Report on Mount Polley Tailings Storage Facility Breach. Prepared for BC Ministry of Energy and Mines. 30 January 2015.

Purpose

The main objectives and considerations for the forensic investigation were to:

- investigate and report on the cause of the TSF failure that occurred on 4 August 2014.
  - identify any mechanism(s) of failure of the TSF
  - identify any technical, management, or other practices that may have enabled or contributed to the mechanism(s) of failure; this may include an independent review of the design, construction, operation, maintenance, surveillance, and regulation of the TSF
  - identify any changes that could be considered to reduce the potential for future such occurrences
- make recommendations to government on actions that could be taken to ensure that a similar failure does not occur at other mine sites in BC
- comment on what actions could have been taken to prevent this failure and to identify practices or successes in other jurisdictions that could be considered for implementation in BC

Scope

The forensic investigation consisted of the following:

- Surface investigations were conducted to document geological and geotechnical features exposed in the breach area prior to disturbance by investigation activities or other operations.
- Subsurface investigations were conducted to examine the soil and groundwater conditions within the breach and surrounding area.
  - The sonic boreholes drilled by KCB in 2014 (SH14-01 to SH14-22, with additional “A” and “B” designations) were observed and independently logged.
    - No additional samples were collected for laboratory testing.
  - Rotary drilling was conducted to obtain disturbed and undisturbed samples of the upper glaciolacustrine unit and other soil units for laboratory testing.
    - Thirty-two mud rotary boreholes (MR14-101 to MR14-116) were drilled at 16 locations near the dam breach area (Corner 1).
      - Completion depths ranged from 2.6 to 16.9 m below ground surface.
      - Large penetration tests (LPTs) – Continuous LPTs were completed in boreholes MR14-116 and MR14-116A.
    - Three air rotary (ODEX) boreholes (RH14-117 to RH14-118) were drilled at two locations within the dam breach area.
      - Completion depths ranged from 13.1 to 18.0 m below ground surface.
    - Two soil core boreholes (SC14-103 and SC14-103A) were drilled at one location downstream of the Perimeter Embankment.
      - Completion depths were 9.8 m below ground surface.

  - In situ sampling methods consisted of direct push of thin-walled tubes, piston tube sampling and the Pitcher Sampler.
    - Pocket penetrometer and torvane testing was conducted on the soil at the end of the tubes after retrieval of a relatively undisturbed sample.
    - All undisturbed thin-walled tube samples were CT scanned.
  - CPTs and VSTs were conducted to characterize the foundation stratigraphy and to identify sampling locations for advanced laboratory testing.
    - Two CPTs and 15 resistivity cone penetration tests (RCPTs) were advanced at 15 locations near the dam breach area (soundings CPT14-101, CPT14-102, and RCPT14-103 to RCPT14-115).
      - Completion depths ranged from 1.3 to 17.1 m below ground surface.
      - Pore pressure dissipation tests were completed at selected locations.
    - Several in situ electronic VSTs were completed at five locations within the dam breach area, referred to as VST14-105 to VST14-107B, VST14-111, and VST14-112.
  - Pressuremeter testing (PMT) was conducted in the glacial till to obtain shear strength and shear modulus values.
    - Several PMTs were completed at three locations within the dam breach area, referred to as PMT14-105 to PMT14-106, and PMT14-108.
- Laboratory testing of soil samples collected from the test pits and boreholes.
  - visual description of soils
  - water contents – 261 tests
  - Atterberg limits – 121 tests
  - sieve analysis – 126 tests
  - hydrometer – 106 tests
  - specific gravity – 6 tests
  - consolidated undrained triaxial compression – 13 tests
  - one-dimensional consolidation using incremental loading – 19 tests
  - direct simple shear – 17 tests
  - direct shear – 1 test

KCB (Klohn Crippen Berger Ltd.). 2015. Mount Polley Dam Failure – Advanced Laboratory Testing Program Progress Report No. 4. Prepared for BC Ministry of Energy and Mines. Document No. M09954A02.730. 12 February 2015.

Purpose

The main objective of this report was to present the procedures and results of the advanced geotechnical laboratory testing program carried out on soil samples collected during the site investigation program.

This report supersedes the Advanced Laboratory Testing Program Progress Report No. 3 submitted to the BC Ministry of Energy and Mines on 21 January 2015.

Scope

The advanced geotechnical laboratory testing program began in October 2014.

- Advanced geotechnical laboratory testing was conducted on the following samples:
  - preserved (sonic) core samples of upper glacial till, and upper and lower glaciolacustrine units
  - thin-walled piston tube samples of upper glaciolacustrine unit
    - Five thin-walled tubes were selected for advanced testing.
  - block samples of upper glacial till and upper glaciolacustrine unit
    - One of each soil unit was selected for advanced testing.
  - bulk samples of the compacted till core (i.e., glacial till)
- Laboratory testing of soil samples collected from the test pit and boreholes consisted of the following:
  - one-dimensional consolidation using incremental loading – 10 tests
  - direct shear – 15 tests
  - direct simple shear (including cyclic) – 15 tests
  - permeability and consolidated undrained triaxial compression – 8 tests
  - consolidated undrained triaxial compression – 4 tests
  - consolidated undrained triaxial extension – 1 test

Data

- Appendix I – Laboratory Testing Program
- Appendix II – Specimen Preparation
- Appendix III – One-Dimensional Consolidation Results
- Appendix IV – Direct Shear Results
- Appendix V – Direct Simple Shear Results
- Appendix VI – Triaxial Test Results
- Appendix VII – Photographs
- Appendix VIII – Interpretation of Triaxial Tests on Block Samples of UGLU

Golder (Golder Associates Ltd.). 2015. Laboratory Testing Results from Mount Polley Mine. Prepared for Mount Polley Mining Corporation. Document No. 1413803-012-TM-Rev0-2000. 26 March 2015.

Purpose

The main objective of this technical memorandum was to present the results of the laboratory testing program carried out on the soil samples obtained at the Central Collection Sump

Scope

- Laboratory testing of soil samples collected from the Central Collection Sump consisted of the following:
  - visual description of soils
  - water contents – 3 tests
  - Atterberg limits – 3 tests
  - sieve analysis – 6 tests
  - hydrometer – 3 tests
  - specific gravity – 3 tests
  - consolidated undrained triaxial compression – 3 tests
  - one-dimensional consolidation using controlled-strain loading – 1 test
  - direct simple shear – 4 tests

Data

- Attachment 1 – Lab Results
- Attachment 2 – Photographs
- Attachment 3 – Calibration Certificates

Golder (Golder Associates Ltd.). 2015. 2015 Geotechnical Investigation Factual Report. Prepared for Mount Polley Mining Corporation. Document No. 1413803-061-R-RevB-2000. 7 July 2015.

Purpose

The main objectives and considerations for the geotechnical investigation were to:

- better define foundation conditions along the Perimeter, Main, and South embankments to support studies regarding the stability of the embankments
- install instrumentation to monitor the performance of the embankments

Scope

The geotechnical investigation program was conducted from January 2015 to May 2015.

- Twenty sonic boreholes (GA15-01 to GA15-20) were drilled downstream of the TSF embankments.
  - Completion depths ranged from 9.5 to 74.7 m below ground surface.
  - Vibrating wire piezometers – Thirty-three VWPs were installed in 20 boreholes.
  - Slope inclinometers – Twenty-two SIs were installed.
  - Standard penetration tests – Three SPTs were conducted in 2 boreholes.
  - Vane shear tests – Several VSTs were attempted in the initial boreholes with a Nilcon vane. However, the soil was too stiff to penetrate.
  - Grab samples and thin-walled tube samples were collected for laboratory testing.
- Three additional sonic boreholes (GA15-12B, GA15-15B, and GA15-21 [beside GA15-16]) were drilled for thin-walled tube sampling.
- One test pit was excavated downstream of the Perimeter Embankment for thin-walled tube sampling.
- Laboratory testing of soil samples collected from the boreholes consisted of the following:
  - visual description of soils
  - water contents – 795 tests
  - Atterberg limits – 113 tests
  - sieve analysis – 113 tests
  - hydrometer – 50 tests
  - specific gravity – 7 tests
  - vane shear – 73 tests conducted in the laboratory
  - consolidated undrained triaxial compression – 1 test
  - one-dimensional consolidation using incremental loading – 5 tests
  - one-dimensional consolidation using controlled-strain loading – 4 tests
  - direct simple shear – 5 tests

Data

- Appendix A – Records of Boreholes

- Appendix B – Photographs of Sonic Core
- Appendix C – Laboratory Testing Results from Mount Polley Mine Technical Memo (Golder 2014)
  - Attachment 1 – Lab Results
  - Attachment 2 – Photographs
  - Attachment 3 – Calibration Certificates
- Appendix D – Calibration Certificates
- Appendix E – Laboratory Testing Results
  - Appendix E-1 – Routine Laboratory Testing Summary Table
  - Appendix E-2 – Routine Laboratory Test Results
  - Appendix E-3 – Advanced Laboratory Tests Results

Golder (Golder Associates Ltd.). 2017. 2016 TSF Geotechnical Investigation Factual Report. Prepared for Mount Polley Mining Corporation. Document No. 1662612-114-R-Rev0-51121. 10 March 2017.

Purpose

The main objectives and considerations for the geotechnical investigation were to:

- better define foundation conditions downstream of the South Embankment around borehole VW11-02
- confirm the foundation conditions downstream of the buttress for the elevation 963 m Corner 1 Embankment
- assess the condition (i.e., dilative/contractive) of the tailings upstream of the Perimeter, Main, and South embankments
- install VWPs upstream of the embankments

Scope

The geotechnical investigation program was conducted from October 2016 to January 2017.

- Thirteen sonic boreholes (GA16-01 to GA16-09, GA16-15 to GA16-17, and GA16-19) were drilled downstream of the South Embankment and the Corner 1 Embankment. Four additional sonic boreholes were drilled to install vibrating wire piezometers within the TSF.
  - Completion depths ranged from 6.6 to 40.7 m below ground surface.
  - Vibrating wire piezometers – Eleven VWPs were installed in nine boreholes.
  - Slope inclinometers – Five SIs were installed.
  - Grab samples and four thin-walled piston tube samples were collected for laboratory testing.
- Nine CPTs were conducted from 6 to 17 January 2017.
  - Three CPTs were conducted on the tailings beach upstream of the Perimeter Embankment, Main Embankment, and South Embankment.
  - One CPT was conducted downstream of the South Embankment.
  - Five CPTs were conducted downstream of the Corner 1 Embankment.
- Laboratory testing of soil samples collected from the boreholes consisted of the following:
  - visual description of soils
  - water contents – 323 tests
  - Atterberg limits – 12 tests
  - sieve analysis – 3 tests
  - hydrometer – 3 tests
  - one-dimensional consolidation using controlled-strain loading – 1 test

Data

- Appendix A – Records of Boreholes
- Appendix B – Photographs of Sonic Core
- Appendix C – CPT Report
- Appendix D – Calibration Certificates
- Appendix E – Laboratory Testing

Golder (Golder Associates Ltd.). 2019. 2018 TSF Geotechnical Investigation Factual Report. Prepared for Mount Polley Mining Corporation. Document No. 1662612-210-R-Rev0-51121. 8 March 2019.

Purpose

The main objective of the geotechnical investigation was to install additional instrumentation downstream of the Corner 1 Embankment to improve monitoring of embankment performance.

Scope

The geotechnical investigation program was conducted from 16 to 20 January 2018.

- Four sonic boreholes (GA18-01, GA18-03, GA18-04A, and GA18-04B) were drilled downstream of the Corner 1 Embankment.
  - Completion depths ranged from 15.2 to 29.7 m below ground surface.
  - Vibrating wire piezometers – Nine VWPs were installed in three boreholes.
  - Slope inclinometers – Three SIs were installed.
  - Grab samples were collected for laboratory testing.
- Laboratory testing of soil samples collected from the boreholes consisted of the following:
  - visual description of soils
  - water contents – 156 tests
  - Atterberg limits – 5 tests

Data

- Appendix A – Records of Boreholes
- Appendix B – Photographs of Sonic Core
- Appendix C – VWP Calibration Certificates
- Appendix D – Laboratory Testing

WSP Golder (Golder Associates Ltd., a member of WSP). 2022. 2021/2022 Tailings Storage Facility Geotechnical Investigation Factual Report. Prepared for Mount Polley Mining Corporation. Document No. 22514095-011-R-Rev0-51300. 18 October 2022.

Purpose

The main objectives and considerations for the geotechnical investigation were to:

- confirm the foundation conditions downstream of the Perimeter Embankment buttress.
- complete additional in situ and laboratory testing to further refine the characterization of the glaciolacustrine units at the Main and Corner 1 embankments.

Scope

The geotechnical investigation program was conducted from 12 October 2021 to 4 December 2021 and 26 February 2022 to 1 March 2022.

- Eleven sonic boreholes (GA21-01 to GA21-11) were drilled downstream of the Corner 1 Embankment, Perimeter Embankment, and Main Embankment. Five additional sonic boreholes were drilled for thin-walled open tube sampling of encountered glaciolacustrine units.
  - Completion depths ranged from 20.9 to 75.0 m below ground surface.
  - Vibrating wire piezometers – Twenty VWPs were installed in eight boreholes.
  - Slope inclinometers – Five SIs were installed.
  - Monitoring wells – Two monitoring wells were installed.
  - Grab samples and thin-walled open tube samples were collected for laboratory testing. The Pitcher Sampler, Shelby tubes, and Lexan tubes were used to collect the thin-walled open tube samples.
- Six CPTs (soundings CPT21-02, CPT21-03, and CPT21-06 to CPT21-09) were conducted downstream of the Perimeter Embankment and Main Embankment.
- Laboratory testing of soil samples collected from the boreholes consisted of the following:
  - visual description of soils
  - water contents – 649 tests
  - Atterberg limits – 64 tests
  - sieve analysis – 80 tests
  - hydrometer – 45 tests
  - unit weight – 8 tests
  - one-dimensional consolidation using incremental loading – 6 tests
  - one-dimensional consolidation using controlled-strain loading – 8 tests
  - direct simple shear – 5 tests (with several points)
  - cyclic direct simple shear – 2 tests (with several points)

Data

- Appendix A – Records of Boreholes

- Appendix B – Photographs of Sonic Core
- Appendix C – Gregg Cone Penetration Test Summary Report
- Appendix D – Vibrating Wire Piezometer Calibration Certificates
- Appendix E – FP Innovations CT Scan Summary Report
- Appendix F – Laboratory Test Results
  - Appendix F1 – Particle Size Distribution
  - Appendix F2 – Atterberg Limits
  - Appendix F3 – Water Content
  - Appendix F4 – Unit Weight
  - Appendix F5 – Consolidation
  - Appendix F6 – Direct Simple Shear
  - Appendix F7 – Cyclic Direct Simple Shear

HYDROGEOLOGY INVESTIGATIONS

KP (Knight Piésold Ltd.). 1997. 1996 Groundwater Monitoring Well Installation Program. Prepared for Mount Polley Mining Corporation. Document No. 1628/4. 7 February 1997.

Purpose

The main objective was to install monitoring wells around the mine site for future groundwater quality sampling as part of the geotechnical evaluation of the open pits, waste dumps, and TSF.

Scope

The hydrogeological investigation program was conducted from 30 October 1996 to 6 December 1996.

- Eleven air rotary boreholes (GW96-1A/B to GW96-5A/B and GW96-9) were drilled at six locations around the perimeter of the TSF.
  - Completion depths ranged from 6.0 to 61.6 m below ground surface.
    - Monitoring wells – Eleven monitoring wells (GW96-1A/B to GW96-5A/B and GW96-9) were installed at six locations.
  - Standard penetration tests – SPTs were conducted in three boreholes (GW96-1A to GW96-3A).

Data

- Appendix A – Drillhole Logs
- Appendix B – Groundwater Monitoring Well Completion Details

AMEC (AMEC Environment & Infrastructure, a division of AMEC Americas Limited). 2013. Mount Polley Mine Hydrogeology Assessment and Data Review. Prepared for Mount Polley Mining Corporation. Document No. VM00560B. 26 March 2013.

Purpose

The main objectives of the hydrogeological assessment were to:

- provide a data gap analysis and attempt to resolve gaps in the available data
- characterize the local hydrogeological conditions at the mine site and develop a site-specific conceptual model
- identify surface and/or groundwater quality changes related to mining activity, specifically acid rock drainage
- determine infiltration rates into the Springer Pit and identify potential groundwater impacts related to the Springer Pit development
- identify areas of potential environmental concern and potential contaminants of concern

Scope

- A data review and compilation of relevant groundwater information collected from MPMC and the public domain was conducted.
  - Several existing monitoring wells where identified within the TSF area:
    - monitoring wells GW96-1A/B to GW96-5A/B
    - monitoring wells GW00-1A/B to GW00-3A/B
    - monitoring wells GW11-2A/B
- The hydrogeological investigation program was conducted from 14 November 2012 to 18 December 2012.
  - Two air rotary (ODEX) boreholes (SI12-01 and SI12-02) were drilled at two locations downstream of the Perimeter Embankment.
    - Completion depths were 41.5 and 42.7 m below ground surface.
    - Slope inclinometers – Two SIs (SI12-01 and SI12-02) were installed.
- A conceptual site model was developed and wells exhibiting significant changes in either baseline static water levels and/or water quality were identified.
  - Three monitoring wells installed downstream of the TSF began showing evidence of influence by mine operations:
    - GW96-2B – increased level of sulphates
    - GW96-4B – increased level of hardness, sulphates and nitrate
    - GW00-1B – increased level of hardness, sulphates, nitrates, cadmium, molybdenum, and selenium
- Hydrogeological mapping was conducted to define discharge and recharge areas.
- One monitoring well was decommissioned.

Data

- Appendix A – Borehole Logs

Golder (Golder Associates Ltd.). 2016. Installation and Testing of New Monitoring Wells near the TSF, SERDS, Cariboo Pit and Wight Pit – Mount Polley Mine. Prepared for Mount Polley Mining Corporation. Document No. 1662612-058-TM-Rev0-53100. 23 December 2016.

Purpose

The main objective of the hydrogeological investigation was to enhance the existing monitoring well network and facilitate monitoring during ongoing operations and closure of the mine.

Scope

- Hydrogeological investigation program was conducted from 24 October 2016 to 4 December 2016.
  - Eight sonic boreholes (GW16-02A/B to GW16-05A/B) were drilled at four locations around the perimeter of the TSF.
    - Completion depths ranged from 9.1 to 53.6 m below ground surface.
    - Monitoring wells – Eight monitoring wells (GW16-02A/B to GW16-05A/B) were installed at four locations. Single-well response tests were conducted following well development at each location.

Data

- Attachment 1 – Borehole Logs
- Attachment 2 – Photographs of Well Completions
- Attachment 3 – Well Development Sheets
- Attachment 4 – Results of Hydraulic Conductivity Testing

GEOLOGICAL INTERPRETATIONS

Golder (Golder Associates Ltd.). 2015. Surficial Geology and Quaternary Geological Overview of the Mt. Polley Tailings Storage Facility (TSF) Area, British Columbia. Prepared for Mount Polley Mining Corporation. Document No. 1413803-058-R-Rev0-2000. 6 July 2015.

Purpose

The main objective of the geological overview was to provide an assessment of the surficial geology using existing geological and geotechnical data to develop an interpretation of the Quaternary deposits and geological history in the area of the TSF.

Scope

The geological overview assessment involved the following steps:

- review, compilation, and interpretation of existing subsurface and surface geological information such as:
  - subsurface geotechnical investigation data from borehole investigations
  - regional geological mapping
  - previous geotechnical reports on the TSF (both pre- and post-dam breach)
  - existing data on surficial geology and subsurface Quaternary geology
- providing local and regional Quaternary geological context for the surficial and bedrock materials present in the TSF area
- development of surficial geological cross-sections of the subsurface conditions in the TSF area

Data

- Figure 3 – Overview of Borehole and Section Locations
- Figures 4 to 9 – Surficial Geology Cross-Sections
- Figure 10 – Uppermost Native Clay Layer Elevation, Thickness
- Figure 11 – Contact Between Advance and Recessional Stage Deposits – Elevation Contour Plan

DOCUMENTS RELATED TO TSF DESIGNS

KP (Knight Piésold Ltd.). 1996. Response to Review Comments on Tailings Embankment Design. Prepared for Imperial Metals Corporation. Reference No. 1625/6. 25 January 1996.

Purpose

The main objective of this study was to provide a response to the comments made by Mr. Brawner with respect to his review of the tailings embankment design. This report provides the following:

- modifications and recommendations pertaining to the embankment design
- review comments and concerns

Scope

The scope related to the TSF foundation includes the following:

- Test pit excavations near the Main Embankment to supplement the knowledge and understanding of the glacial materials within the valley.
  - Thirty-four test pits (TP95ME-01 to TP95ME-34) were excavated near the Main Embankment in early October 1995.
    - Completion depths ranged from 2.5 to 7.0 m below ground surface.
  - Six test pits were also excavated near the Seepage Collection Pond (TPS19, TPS20, TPS20.5, TPS21, TPS21.2, and TPS22).
    - Completion depths ranged from 4.0 to 6.5 m below ground surface.

Data

- Appendix A – Test Pit Logs from 1995 Supplementary Investigations

KP (Knight Piésold Ltd.). 1997. Mount Polley Project Tailings Storage Facility Updated Design Report. Prepared for Mount Polley Mining Corporation. Reference No. 1627/2. 6 June 1997.

Purpose

The main objective of this study was to provide an updated version of the original TSF design report. This report was prepared in response to:

- modifications to the embankment design
- review comments and concerns
- the additional detailed geological and geotechnical information gathered during the Stage 1A/1B construction program

Scope

The scope related to the TSF foundation includes the following:

- site characteristics including hydrometeorology, regional geology, and seismicity
  - seismic design parameters for the TSF embankments
- geotechnical investigations carried out during the Stage 1A/1B construction program in 1996 and 1997:
  - test pit excavations to identify suitable embankment fill materials in potential borrow sources including Borrow Areas No. 1, No. 2, and No. 3 (referred to as the Original Borrow Area, Future Borrow Area and Alternative Borrow Area, respectively), which are all within or near the TSF
    - Several test pits (96-43 to 96-55 and 96-84 to 96-108) were excavated in the three potential borrow sources during the 1996 construction program.
      - Completion depths ranged from 1.2 to 8.0 m below ground surface.
      - Laboratory testing of soil samples collected from the test pits consisted of the following:
        - index – water content, Atterberg limits, sieve analysis, hydrometer, and specific gravity
        - compaction – standard Proctor
        - permeability – falling head tests
        - shear strength – triaxial tests
    - Several test pits were also excavated in January 1997 (TP96-BA-E4 to TP96-BA-I9).
      - Completion depths up to 6.7 m below ground surface.
      - Laboratory tests were not specified in the report.
  - borehole investigations to define the maximum borrow depth in Borrow Areas No. 1 and No. 2
    - Twenty-eight boreholes (DH97-BA-F5 to DH97-BA-I8) were drilled with a solid and hollow stem auger in January 1997.
      - Completion depths were up to 17.0 m below ground surface.
      - SPTs were conducted in the boreholes.
    - Laboratory tests were not specified in the report.

- groundwater monitoring well drilling around the perimeter of the TSF for long-term groundwater quality monitoring
  - Eleven air rotary boreholes were drilled at six locations around the perimeter of the TSF from 30 October 1996 to 6 December 1996.
    - Monitoring wells – 11 monitoring wells (GW96-1A/B to GW96-5A/B and GW96-9) were installed at 6 locations.
    - Standard penetration tests – SPTs were conducted in three boreholes (GW96-1A to GW96-3A).
- test pit excavations to delineate the extent of the basin liners
  - Several test pits (96-1 to 96-42) were excavated to delineate the basin liner extents during the 1996 construction program.
    - Completion depths ranged from 1.1 to 7.3 m below ground surface.
    - In situ permeability testing consisted of field air entry permeameter tests of the underlying glaciolacustrine and glaciofluvial units.
  - Upper and lower basin liners were constructed near the Main Embankment.
- test pit excavations to investigate potential sand deposits for use as filter sand in the embankment drains
  - Several test pits (96-56 to 96-69 and 96-111 to 96-115) were excavated during the 1996 construction program.
    - Completion depths ranged from 4.3 to 8.2 m below ground surface.
  - Laboratory testing of soil samples collected from the test pits to evaluate suitability for filter sand consisted of the following:
    - 16 samples for index testing including water content, Atterberg limits, grain size analysis, and specific gravity
    - eight samples for effective strength parameters, compaction, and permeability testing
- borehole investigations to accompany the installation of instrumentation in the foundation soils of the Main Embankment
  - Four boreholes (96-A1, 96-B1a, 96-B1b, and 96-C1) were drilled with a solid and hollow stem auger in the Main Embankment footprint from 21 to 24 July 1996.
    - Completion depths ranged from 9.1 to 16.5 m below ground surface.
    - Vibrating wire piezometers – Six VWPs were installed in four boreholes.
    - Standard penetration tests – Sixty-four SPTs were conducted in three boreholes.
  - Laboratory tests were not specified in the report.
- CPT investigation to further investigate the foundation soils of the Main Embankment
  - Ten CPTs (soundings CPT96-1 to CPT96-5 and PRW96-1 to PRW96-4) were advanced in the Main Embankment footprint from 27 to 28 July 1996. Two soundings were advanced at PRW96-2, referred to as PRW96-2 (4) and PRW96-2 (4A).
    - Completion depths ranged from 7.65 to 15.85 m below ground surface.

    - Shear wave velocity tests were completed at 1 m intervals and several pore pressure dissipation tests.
  - Four boreholes (PRW96-1 to PRW96-4) were drilled with a solid stem auger beside their respective CPT location to serve as pressure relief wells from 27 to 28 July 1996.
    - Completion depths ranged from 9.9 to 22.1 m below ground surface.
    - Field tests – Pocket penetrometer and torvane tests were conducted at selected depths.
  - Four pressure relief trenches were also excavated downstream of the Main Embankment (test trenches PRT-01 to PRT-04).
- a detailed geological summary of the four main soil units encountered in the TSF foundation including ablation till, glaciolacustrine/glaciofluvial, basal till, and bedrock

Data

- Appendix A – Summary of Recent Geological Investigations
- Appendix B – Supplementary Investigation Reports
  - Appendix B1 – R.E. Graham Field Report
  - Appendix B2 – ConeTec Field Report

KP (Knight Piesold Ltd.). 2007. Mount Polley Stage 6 TSF Design. Letter to Mr. Chris Carr, Geotechnical Mines Inspector, Ministry of Energy, Mines and Petroleum Resources. Reference No. VA101-1/18-A.01. 19 December 2007.

Purpose

The main objective of this letter was to provide additional information on three items requested by Mr. Chris Carr:

- results of direct shear testing on lacustrine soils
- cross-sections showing stability analyses for dam raise to elevation 958 m
- slope inclinometer depth vs. cumulative displacement plots showing cumulative displacement from date of installation

Scope

The scope related to the TSF foundation includes the following:

- Two brass tube samples of a lacustrine unit were collected from a test pit (TP-07) excavated next to the Main Embankment Seepage Collection Pond on 13 May 2007.
- Testing consisted of the following:
  - direct shear – 1 test (with 3 points)

Data

- Appendix A – Direct Shear Testing Results

TSF CONSTRUCTION RECORD REPORTS

KP (Knight Piésold Ltd.). 1999. Mount Polley Mine Tailings Storage Facility Report on 1998 Construction and Annual Inspection. Prepared for Mount Polley Mining Corporation. Reference No. 11162/10-1. 16 June 1999.

Purpose

The main objectives of this report were to document the Stage 2A/2B construction program, which involved raising the Main and Perimeter embankments by 3 m to an elevation of 937 m and document the 1998 annual inspection. This report provides the following:

- discussion of the construction methods used during the program
- results of the quality assurance tests
- a review of the new instrumentation and monitoring results
- as-built drawings corresponding to the Stage 2A/2B construction program
- results of the investigations undertaken during the program
- results of the annual inspection

Scope

The scope related to the TSF foundation includes the following:

- Ten VWPs were installed in the foundation soils at the Main Embankment.
- Three pressure relief trenches (PRT98-01 to PRT98-03) and seven pressure relief wells (PRW98-01 to PRW98-07) were installed at the Main Embankment.
- Nineteen boreholes (DH98-BL-01 to DH98-BL-19) were drilled within the tailings basin to investigate the requirements for the basin liner in February 1998.
  - Completion depths ranged from 1.2 to 7.6 m below ground surface.
  - Grab samples were collected for laboratory testing.
- Forty-four boreholes (BH99-01 to BH99-44) were drilled within the tailings basin to investigate the requirements for the basin liner in 1999.
  - Completion depths ranged from 0.6 to 9.1 m below ground surface.
  - Grab samples were collected for laboratory testing.
- Laboratory testing of soil samples collected from the boreholes consisted of the following:
  - visual description of soils
  - ater contents
  - Atterberg limits
  - sieve analysis
  - hydrometer
  - consolidated undrained triaxial compression

Data

- Appendix A – Borrow Area and Basin Liner Investigations
- Appendix B – Construction Quality Assurance Record Test Summary Sheets
- Appendix C – Construction Quality Assurance Control Test Summary Sheets and Gradation Plots
- Appendix D – Consolidated Undrained Triaxial Test Results for R/ZS-12
- Appendix E – 1998 Construction Photos
- Appendix F – 1998 Annual Inspection Photos
- Appendix G – Piezometer Records
  - Appendix G1 – Tailings Piezometers
  - Appendix G2 – Embankment Foundation Piezometers
  - Appendix G3 – Embankment Fill Piezometers
  - Appendix G4 – Drain Piezometers

KP (Knight Piésold Ltd.). 2000. Mount Polley Mine Tailings Storage Facility Report on 1999 Construction. Prepared for Mount Polley Mining Corporation. Reference No. 11162/13-5. 30 August 2000.

Purpose

The main objective of this report was to document the Stage 2C construction program, which involved raising the Main and Perimeter embankments by 4 m to an elevation of 941 m. This report provides the following:

- discussion of the construction methods used during the program
- results of the quality assurance tests
- a review of the new instrumentation and monitoring results
- as-built drawings corresponding to the Stage 2C construction program
- results of the investigations undertaken during the program

Scope

The scope related to the TSF foundation includes the following:

- Ninety-one boreholes (DH99-45 to DH99-135) were drilled around the perimeter of the TSF to evaluate the potential for seepage infiltration into foundation materials during hydraulic placement of cycloned sand.
  - Completion depths ranged from 0.6 to 7.5 m below ground surface.
  - SPTs were conducted in some of the boreholes.
  - Grab samples were collected for laboratory testing.
- Twenty-four boreholes (DH99-136 to DH99-159) were drilled within Borrow Area No. 2 (downstream of the Main Embankment) to determine the availability and suitability of core zone material.
  - Completion depths ranged from 4.6 to 13.9 m below ground surface.

Data

- Appendix A – Investigations
- Appendix B – Construction Quality Assurance Control Test Summary Sheets and Gradation Plots
- Appendix C – Construction Quality Assurance Record Test Summary Sheets
- Appendix D – Stage 2C Construction Photos
- Appendix E – Stage 2C Design Modifications

KP (Knight Piésold Ltd.). 2001. Mount Polley Mine Tailings Storage Facility Report on Stage 3 Construction. Prepared for Mount Polley Mining Corporation. Reference No. 11162/14-3. 19 October 2001.

Purpose

The main objective of this report was to document the Stage 3 construction program which involved raising the TSF embankments to an elevation of 942.5 m. This report provides the following:

- discussion of the construction methods used during the program
- results of the quality assurance tests
- a review of the new instrumentation and monitoring results
- as-built drawings corresponding to the Stage 3 construction program
- results of the investigations undertaken during the program

Scope

The scope related to the TSF foundation includes the following:

- installation of four VWPs in the foundation soils
- geotechnical investigations conducted during the Stage 3 construction program
  - Three air rotary (ODEX) boreholes (GW00-01 to GW00-03) were drilled downstream of the South Embankment in August 2000.
    - Completion depths ranged from 21.0 to 24.3 m below ground surface.
    - Monitoring wells – Six monitoring wells (GW00-01A/B to GW00-03A/B) were installed at three locations.
    - SPTs were conducted in two boreholes.
  - Eighty boreholes (DH01-01 to DH01-80) were drilled to investigate the availability of glacial till within Borrow Areas No. 2, No. 3, and No. 5 in April 2001.
    - Completion depths ranged from 1.2 to 12.2 m below ground surface.
    - Grab samples were collected for laboratory testing.
  - Two air rotary (ODEX) boreholes (SI01-01 and SI01-02) were drilled downstream of the Main Embankment in July 2001.
    - Completion depths were 24.4 and 30.3 m below ground surface.
    - Slope inclinometers – Two SIs were installed.
    - SPTs were conducted in both boreholes.
  - Laboratory testing of soil samples collected from the boreholes consisted of the following:
    - visual description of soils
    - water contents
    - sieve analysis
    - hydrometer

Data

- Appendix A – Investigations
- Appendix B – Construction Quality Assurance Control Test Summary Sheets and Gradation Plots
- Appendix C – Construction Quality Assurance Record Test Summary Sheets
- Appendix D – Stage 3 Construction Photos
- Appendix E – Stage 3 Design Modifications

KP (Knight Piésold Ltd.). 2007. Mount Polley Mine Tailings Storage Facility Report on Stage 4 Construction. Prepared for Mount Polley Mining Corporation. Reference No. VA101-1/10-1. 13 March 2007.

Purpose

The main objective of this report was to document the Stage 4 construction program which involved raising the TSF embankments by 4 m to an elevation of 948 m. This report provides the following:

- discussion of the construction methods used during the program
- results of the quality assurance tests
- a review of the instrumentation monitoring results
- as-built drawings corresponding to the Stage 4 construction program
- results of the investigation undertaken during the program

Scope

The scope related to the TSF foundation includes the following:

- geotechnical investigation program conducted in May 2006
  - Three air rotary boreholes (SI06-01 to SI06-03) were drilled downstream of the Main Embankment.
    - Completion depths ranged from 34.7 to 42.2 m below ground surface.
    - Slope inclinometers – Three SIs were installed.
    - SPTs were conducted in all three boreholes.
- other relevant information:
  - Slope inclinometer SI01-01 was destroyed during Stage 4 construction.
- laboratory testing of soil samples collected from the boreholes:
  - visual description of soils
  - ater contents – 10 tests
  - Atterberg limits – 10 tests
  - sieve analysis – 10 tests
  - hydrometer – 10 tests
  - one-dimensional consolidation using incremental loading – 1 test

Data

- Appendix A – Laboratory Test Results
  - Appendix A1 – Zone S Control Results
  - Appendix A2 – Zone S Record Results

KP (Knight Piésold Ltd.). 2009. Mount Polley Mine Tailings Storage Facility Report on Stage 6A Construction. Prepared for Mount Polley Mining Corporation. Reference No. VA101-1/23-1. 10 July 2009.

Purpose

The main objective of this report was to document the Stage 6A construction program which involved raising the TSF embankments by 3 m to an elevation of 954 m. This report provides the following:

- discussion of the construction methods used during the program
- results of the quality assurance tests
- a review of the instrumentation monitoring results
- as-built drawings corresponding to the Stage 6A construction program
- results of the investigation undertaken during the program

Scope

The scope related to the TSF foundation includes the following:

- geotechnical investigation program conducted in May 2008
  - Eleven sonic boreholes (KP08-01, KP08-02, KP08-04, KP08-06, KP08-08, KP08-09, KP08-11, KP08-12, and KP08-14 to KP08-16) were drilled in a potential borrow area downstream of the Perimeter Embankment.
    - Completion depths ranged from 8.5 to 23.8 m below ground surface.
    - SPTs were conducted in most of the boreholes.
    - Grab samples were collected for laboratory testing.

Data

- Appendix A – Laboratory Test Results

Golder (Golder Associates Ltd.). 2015. 2015 Freshet Management Embankment As-Built Construction. Prepared for Mount Polley Mining Corporation. Document No. 1413803-065-R-Rev0-2000. 4 September 2015.

Purpose

The main objective of this report was to document the Freshet Management Embankment construction program. This report provides the following:

- summary of design and adjustments to accommodate conditions encountered during construction
- description of the major construction activities including water management
- summary of the construction quality assurance and construction quality control information
- as-built drawings
- as-built instrumentation installation
- construction documentation

Scope

The scope related to the TSF foundation includes the following:

- installation of five slope inclinometers (SI15-26 to SI15-30) during the construction program
  - Four slope inclinometers were installed in the cut-off wall, while the other was installed to replace two damaged slope inclinometers downstream of the Perimeter Embankment.
- installation of two shape accel arrays (SAAs) within existing slope inclinometers downstream of the Freshet Management Embankment
  - SAA15-01 was installed within slope inclinometer SH14-03.
  - SAA15-02 was installed within slope inclinometer SH14-16.

Data

Evaluation of the Time-Average Shear-Wave Velocity

DISCLAIMERS AND LIMITATIONS

Seismic hazard analysis and geotechnical earthquake engineering are dynamic and fast-evolving fields of research and engineering practice. The standard of practice in this technical area continues to develop as new information about the sources of earthquakes becomes available. Consequently, the results presented in this report should be reviewed when new data and/or new scientific theory becomes available.

WSP USA Inc (WSP USA). has prepared this report exclusively for the use of WSP Canada Inc (WSP Canada). for the Mount Polley TSF site. If there are significant changes in the nature, design, location, or site ground conditions, then WSP should be notified so that we can review our conclusions and recommendations. A written modification or verification of the changes can be provided, if required.

EXECUTIVE SUMMARY

This report presents the results of a site-specific probabilistic seismic hazard analysis (PSHA) undertaken by WSP USA Inc. (WSP USA) for the Mount Polley Tailings Storage Facility (TSF) site approximately 380 km northeast of Vancouver, British Columbia. The PSHA has been undertaken for a site at 52.509º N latitude and 121.588º W longitude. Appendix A provides details of the development of earthquake acceleration time histories. Appendix B presents the evaluation of the time-average shear-wave velocity in the 30 m below the ground surface (V_{S30}) used in this assessment.

The site-specific PSHA is based on seismic source models developed for the 6th Generation Canadian National Seismic Hazard Model (CanadaSHM6). WSP USA's review of the tectonic setting, historical earthquake activity rates, and earthquake epicenter distribution within about 500 km of Mount Polley found that the CanadaSHM6 seismic source models are appropriate for estimating the seismic hazard of the TSF site.

Source-to-site attenuation ground motion models (GMMs) for active shallow crustal sources were applied as in CanadaSHM6. For sources associated with the Cascadia subduction zone to the southwest of the site, WSP USA applied a weighted suite of the 2020 NGA-Sub GMMs to model the source-to-site attenuation of subduction earthquake strong ground motions.

Earthquake ground motions are reported as 5%-damped, mean uniform hazard acceleration response spectra at annual exceedance probabilities (AEPs) of 1/1,000, 1/2,475, 1/5,000 and 1/10,000 for the site-specific V_{S30} of 849 m/s. Table S-1 below lists the mean uniform hazard spectral ordinates for selected AEPs at horizontal peak ground acceleration (PGA), 0.5 s, 1.0 s, and 1.5 s spectral periods developed from the site-specific PSHA at the Mount Polley TSF site. The results at an AEP of 1/2,475 are slightly lower than CanadaSHM6 at spectral periods below ~2.0 s and slightly higher at spectral periods above 2.0 s. These differences are attributed to the different ground motion model selection and weighting, and site-specific V_{S30} of 847 m/s used in this assessment.

Deaggregations were performed for the total hazard and separately for active shallow crustal and subduction sources at 1/2,475 and 1/10,000 AEPs at selected spectral periods. The results show that both near-field, moderate-magnitude crustal earthquakes and far-field subduction interface earthquakes contribute to the site seismic hazard. The shallow crustal earthquake sources are dominated by moderate-magnitude earthquakes (**M**6.0 to **M**6.5) close to the site (i.e., <60 km) at all AEPs. The contribution to hazard at the site from Cascadia subduction zone sources is from large earthquakes (**M**8+) at 450 to 550 km from these at all AEPs and spectral periods of interest.

Table S-1: Site-specific accelerations (5%-damped) for selected annual exceedance probabilities and spectral periods at the Mount Polley TSF site, British Columbia, Canada (V_{S30} = 849 m/s)

Performance Level - AEP	Spectral Period (s)	Acceleration (g)[1]

	1.0	0.057	0.050	0.052	0.057	0.060	0.065
	1.5	0.041	0.032	0.034	0.039	0.047	0.048

Note:

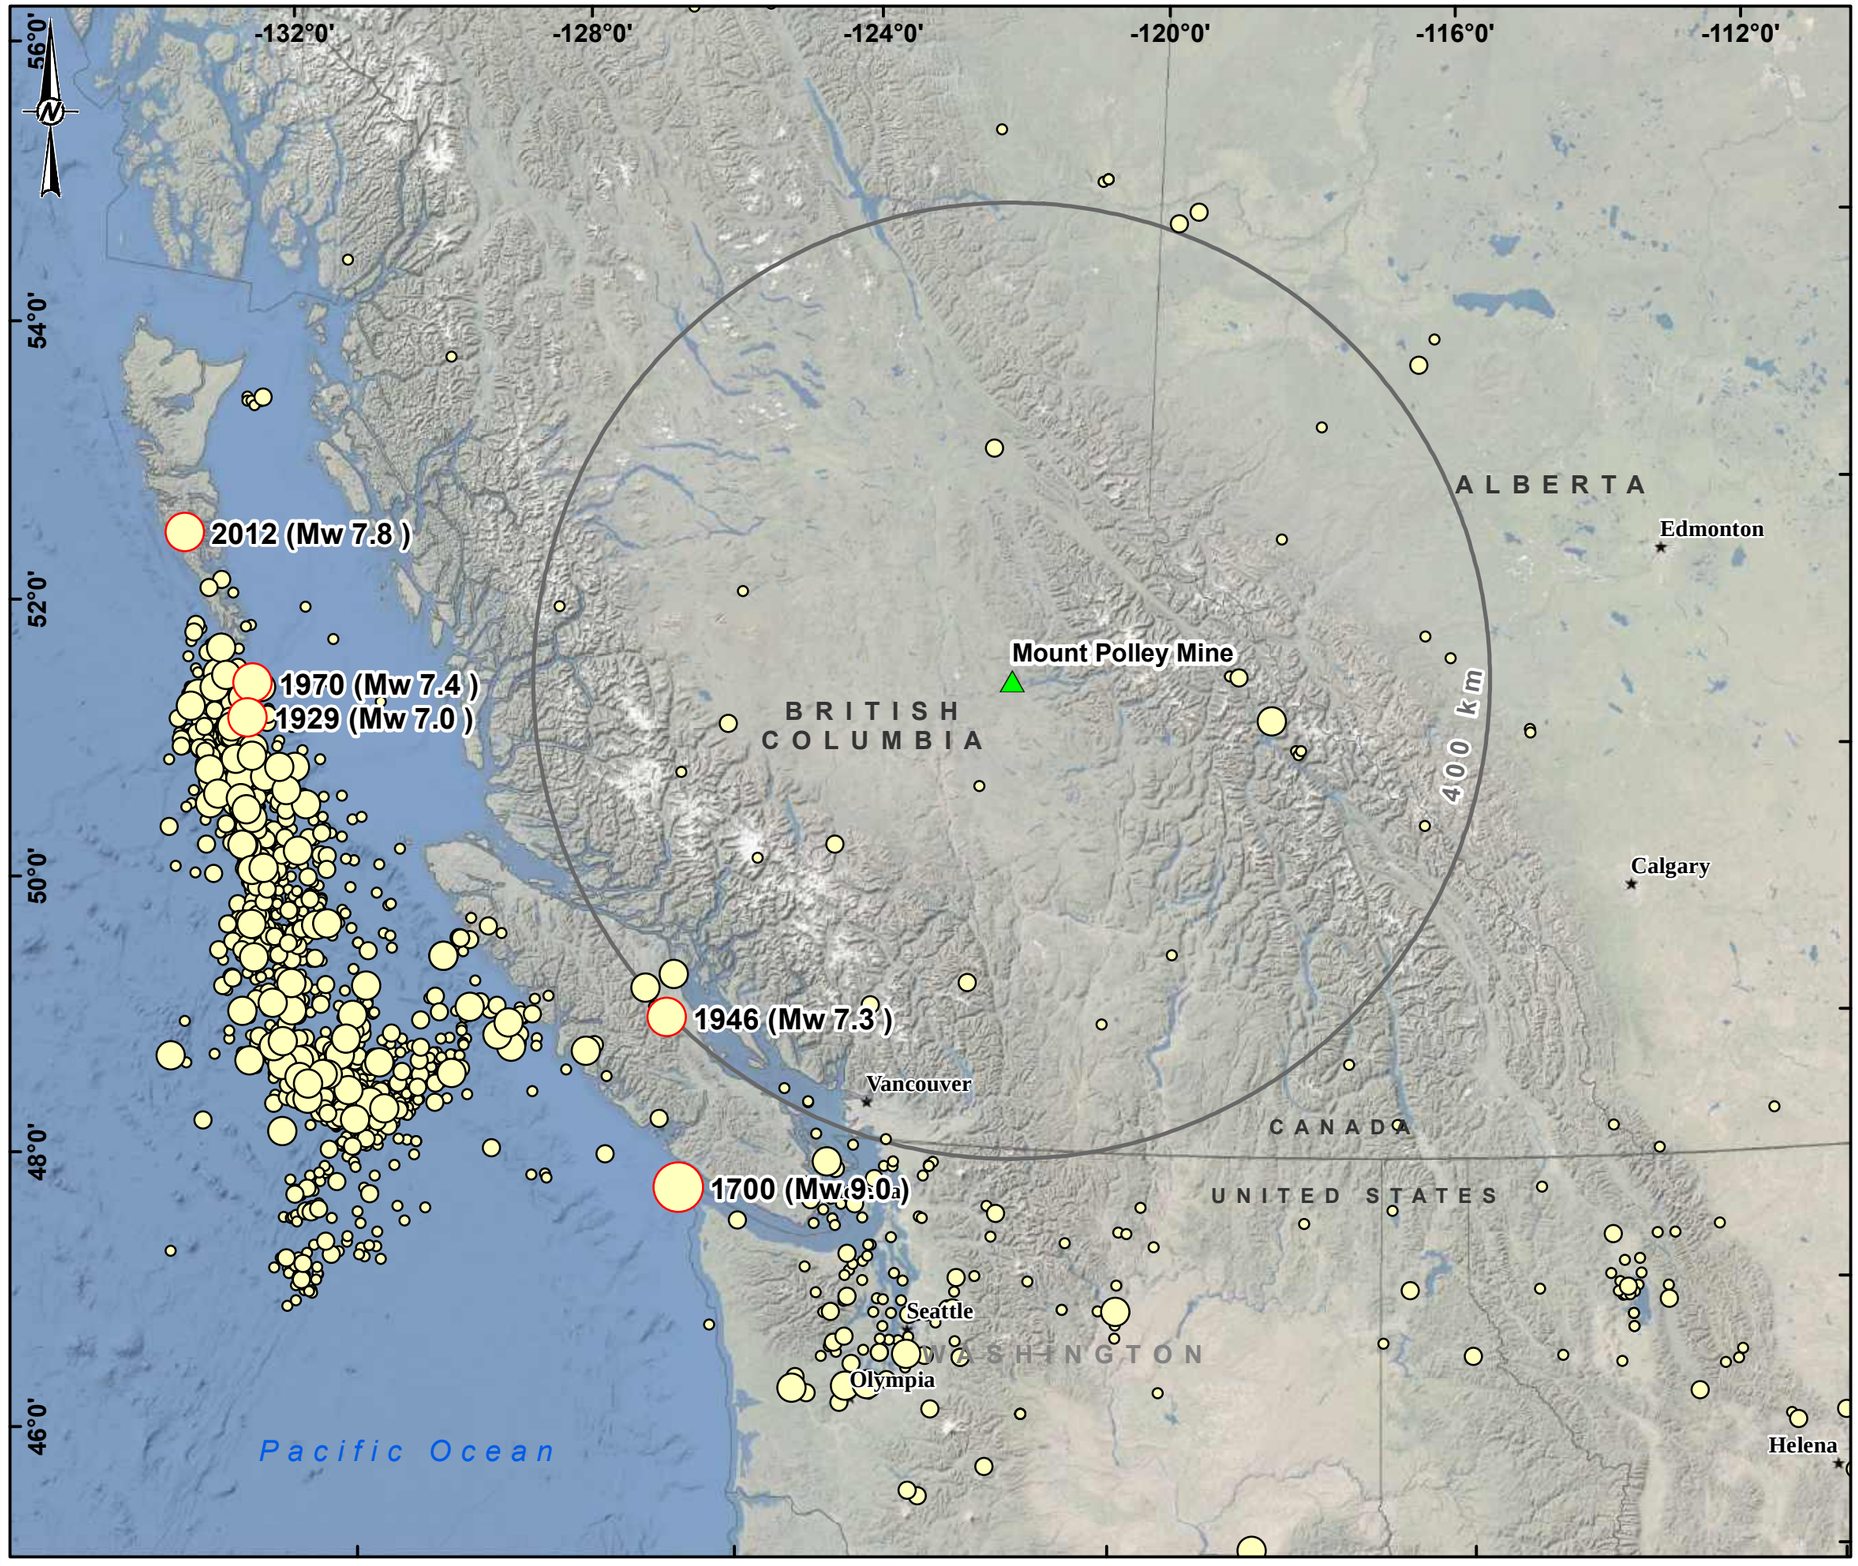
1. 5%-damped, mean, geometric-mean, peak horizontal acceleration.

Eleven two-horizontal-component EATHs (22 records) were developed using amplitude scaling to the site-specific 1/2,475 AEP uniform hazard acceleration response spectrum within the period range of interest of 0.5 to 1.5 seconds (Appendix A). These 22 EATHs were developed with eight two-component (16) records from crustal earthquakes and three two-component (6) subduction interface earthquake records. Comparison of the intensity measures of the scaled EATHs to predicted $D_{5\text{-}75}$, $D_{5\text{-}95}$, CAV, and AI intensity measures indicates that the scaled EATHs are generally within the 16th and 84th percentile range of the empirically predicted values.

1.0 INTRODUCTION

This report provides earthquake ground motions estimated from a site-specific probabilistic seismic hazard analysis (PSHA) and deterministic seismic analysis (DSA) undertaken by WSP USA Inc. (WSP USA) for the Tailings Storage Facility (TSF) at the Mount Polley mine TSF site in British Columbia, Canada. Seismic parameters presented in this report can be used to support future engineering analysis at the Mount Polley TSF site.

1.1 Site Location



The Mount Polley TSF site is in British Columbia, about 380 km northeast of Vancouver (Figure 1). The site is at 52.509º N latitude and 121.588º W longitude, and hereinafter referred to as the 'site'.

1.2 Background

Mount Polley Mining Corporation (MPMC) requested WSP Canada Inc. (WSP Canada) to provide a series of work plans for ongoing engineering support of the Mount Polley Mine site development. One key task is to update the feasibility design for raising of the South, Main, and Perimeter embankments for the Mount Polley TSF. The design to be updated is that described in Golder (2015).

Dynamic analysis modelling requires input acceleration time histories that represent realistic earthquake ground motions for the annual exceedance probability (AEP) being considered. In turn, these acceleration time histories should reflect a state-of-practice seismic hazard analysis at the site. Because there have been several major developments in the assessment of seismic hazards in North America in recent years, and importantly the publication of the NGA-Subduction ground motion models, a revised site-specific seismic hazard analysis was included as part of Golder's work plan for stability analysis for the Mount Polley TSF.

This report presents the data, methods, and results of the site-specific PSHA undertaken to support seismic stress deformation modeling for the Mount Polley TSF. The work was undertaken by specialist staff from WSP USA Inc. and WSP New Zealand Limited (formerly Golder Associates New Zealand Ltd.) under an intercompany agreement with WSP Canada Inc. (WSP Canada). The agreed work scope of work for the PSHA and development of earthquake acceleration time histories provided in Appendix A is described in proposal 21452039-078-WP-Rev0-50000-TSF2022_28JAN_22. Further details are provided in Section 1.3 below.

1.3 Work Scope

WSP USA has completed the following major tasks to develop earthquake ground motions, acceleration time histories (Appendix A), and evaluation of site time-average shear-wave velocity (Appendix B) for site-specific seismic hazard analysis at the Mount Polley TSF site:

- Reviewed existing reports and readily available published, unpublished, and on-line records of the tectonic, geologic and earthquake history of the region surrounding the site.
- Assessed available information and estimated the time-averaged shear-wave velocity of the site ground conditions beneath the Mount Polley TSF site (Appendix B).
- Developed a seismic source model based on the seismic sources in CanadaSHM6 within about 400 km of the Mount Polley TSF site.
- Evaluated and weighted appropriate site-to-source attenuation ground motion models (GMM) for southwest Canada.
- Developed probabilistic hazard curves for a ground condition with a V_{S30} of 849 m/s (i.e., time-averaged shear-wave velocity in the upper 30 m below a reference depth).
- Prepared site-specific, 5%-damped, spectral acceleration hazard curves for an AEP range from 1/10 to 1/10,000, and for discrete spectral periods at horizontal peak ground acceleration (PGA), 0.2 s, and 1.0 s.
- Developed site-specific, 5%-damped, uniform hazard response spectra (UHRS) horizontal mean values at AEPs of 1/2,475, 1/5,000, and 1/10,000 and spectral periods (T_S) up to 10 s.
- Developed spectral accelerations (S_a) mean values, and median values ± one and two standard deviations (i.e., ±1 sigma and ±2 sigma) for discrete spectral periods at PGA, 0.2 s, and 1.0 s or the selected AEPs.
- Developed probabilistic deaggregation analysis by magnitude, distance, and epsilon for mean values of PGA and S_a of 0.1 s, 0.2 s, 0.5 s, 1.0 s, 2.0 s, 5.0 s, and 10.0 s, and at AEPs of 1/2,475, 1/5,000, and 1/10,000.
- Evaluated the PGA and S_a values for the dam performance levels (e.g., OBE and SEE) as specified by CDA (2014) and ICMM (2019) bulletins.
- Assessment and incorporation of model uncertainties used to estimate mean ground motions at the site.
- Earthquake acceleration time histories as presented in Appendix A.
- Prepared this report with the data, methods, and results of the seismic hazard analysis used to develop the recommended seismic parameters at the site.

1.4 Terminology

The terminology used in PSHA is specialised and is often used inappropriately. Use of variable and different terms can result in some confusion. Table 2 lists key terms used in this report as well as alternative, similar terms that relate terms used in this report to other commonly used terms with similar definitions.

Table 2: Terminology Used in this Report

Terms and Units	Alternative Similar Terms (units and definition may very)
Spectral period (seconds, s)	Period, natural-period, period-of-vibration, natural frequency.
Acceleration[1] (percentage of gravitational acceleration, g)	Peak geometric-mean horizontal acceleration, spectral acceleration.
Annual exceedance probability (AEP, likelihood of being exceeded in 1 year)	Return period[2] (years), frequency, annual probability of exceedance (AEP).
Uniform hazard acceleration response spectrum	Uniform hazard curve, acceleration response spectrum, response spectrum, spectral response spectrum, uniform hazard mean acceleration response spectrum.
Ground motion model (GMM)	Ground motion prediction equation (GMPE), attenuation equation.
Deaggregation	Disaggregation, de-aggregation.

Notes:

1. Where we use the term 'acceleration' it refers to the mean (geometric-mean) horizontal peak acceleration response of a 5 %-damped, single degree of freedom pendulum.
2. The inverse of the AEP is approximately equal to the return period for AEP values less than about 1/100 (0.01).

1.5 Report Structure

This report has the following structure:

- **Section 2.0: Site Ground Conditions**
  Describes the near-surface ground conditions used in this assessment
- **Section 3.0: Seismic Source Models**
  Describes the approach adopted in this assessment to model the magnitude, location, and frequency of earthquakes in the region around the site that contribute to the earthquake ground motion hazard.
- **Section 4.0: Ground Motion Model Selection and Weighting**
  Describes the ground motion models selected to undertake the PSHA, including the rationale for their selection and weighting.
- **Section 5.0: Probabilistic Seismic Hazard Analysis**
  Describes the PSHA analytical procedures of this site-specific assessment.
- **Section 6.0: Deterministic Assessment**
  Describes consideration of an MCE scenario for this assessment.
- **Section 7.0: Site-specific Probabilistic Seismic Hazard Analysis Results**
  Describes the results from the PSHA for this site-specific assessment.
- **Section 8.0: Seismic Hazard Analysis Discussion and Recommendations**
  Presents comparison of results with previous studies, and discussion of applying the results to assist in selection of engineering design.
- **Section 9.0: Closing**

- **Appendix A**

  Earthquake Acceleration Time History Development for Mount Polley TSF, British Columbia, Canada

- **Appendix B**

  Evaluation of the Time-Average Shear-Wave Velocity

2.0 SITE GROUND CONDITIONS

Near-surface site ground conditions can have a significant influence on the earthquake ground motion at a site. The effects of near surface ground conditions are spectral period dependent. Softer site ground conditions cause damping of short period waves and amplification of long period waves, and the inverse is observed at stiffer sites. Site ground conditions are incorporated into PSHA using parameters related to the shear-wave velocity profile beneath the site as used in GMMs. The shear-wave velocity related parameters are:

- V_{S30}: The time-averaged shear-wave velocity of the upper 30 m of ground or a reference surface below the site.
- $Z_{1.0}$: The depth to a shear wave velocity of 1,000 m/s.
- $Z_{2.5:}$ The depth to a shear wave velocity of 2,500 m/s.

These parameters are typically derived from the ground surface. However, they can also be developed for a reference depth such as engineering bedrock, especially in the case where the outputs of the PSHA are being used as an input for seismic ground response analysis to model the effects of non-linear behavior of near surface materials on the seismic hazard or the base of geotechnical models to assess dynamic stability. In general, there should be a negligible amount of non-linear behavior of earth materials beneath the reference depth.

Earthquake ground motions reported in this seismic hazard assessment are for V_{S30} of 849 m/s for engineering bedrock. This value was estimated through communication with the project engineering team and is based on VSP analysis at three borehole locations along the Mount Polley TSF. Appendix B provides further details for the site V_{S30} analysis used for this assessment.

The Kaklamanos et al. (2011) method based on the ground surface V_{S30} was used to estimate the $Z_{1.0}$ and $Z_{2.5}$ parameter values of 20.5 m and 590 m, respectively.

3.0 SEISMIC SOURCE MODELS

Seismic source models are an input into site-specific PSHA. They describe the spatial distribution, likelihood and magnitude of future earthquakes that may affect the site. Because the location and magnitude of future earthquakes is unknowable, a range of methods is used to predict the location, likelihood, and magnitude of future earthquakes creating a set of weighted alternative seismic source models.

The seismic source model used for this assessment adopts seismic sources and their parameters as developed for the preliminary release of the 2020 National Hazard Model of Canada (Kolaj et al. 2020b). The following sections describe the seismotectonic setting of the Mount Polley TSF site, and the source model adopted from CanadaSHM6 for this site-specific analysis.

3.1 Seismotectonic and Geological Setting

The Mount Polley TSF site is located within the Canadian Cordillera, part of the North American Cordillera that was formed by convergent tectonic processes and the successive accretion of a number of allochthonous terranes[1] to the ancient western margin of the North American plate, likely beginning sometime in the Late Triassic to Early Jurassic (~180 to 200 million years ago (Ma)) (Ricketts 2008; Price, 2000, 1994; Monger 1989; Monger and Price 1979). The accretion of allochthonous terranes was diachronous along the North American plate margin, with numerous complexities related to the amalgamation of terranes prior to accretion (e.g., Monger 1989). The Mount Polley mine site is located within the Quesnel terrane, which consists of an island arc assemblage that developed outboard of the ancient North American continental margin and was accreted to the North American plate sometime in the latest Triassic or earliest Jurassic (~200 Ma) (Beatty et al. 2006). The Quesnel terrane hosts numerous porphyry copper-gold and other important mineral deposits related to various metallogenetic processes (Nelson and Colpron 2007). East of this terrane is the Foreland Fold and Thrust Belt, comprising amalgamated volcanic, island arc and oceanic terranes that were accreted onto the western edge of the North American craton during the Late Jurassic to Paleocene about 150 to 60 Ma, together with highly deformed sedimentary sequences mostly represented by the Canadian Rocky Mountains.

The seismotectonic setting of western Canada is complex and with a diverse range of earthquake sources. The present-day tectonics of western Canada are strongly influenced by the effects of relative motions of the Pacific and North America plates and remnants of the former Farallon plate that was largely subducted. The modern Explorer, Juan de Fuca, and Gorda plates are the remain of the much larger Farallon plate.

The Cascadia subduction zone (CSZ) marks the boundary where the Juan de Fuca, Explorer, and Gorda plates are being subducted beneath western North America. The 1,200-km-long CSZ extends from northern California to British Columbia and is ~460 km west of Mount Polley at its closest approach. The present-day convergence (subduction) velocity ranges from about 43 mm/yr for the Juan de Fuca plate that decreases to the northwest to about 20 mm/yr for the Explorer plate (North America fixed). The CSZ has produced repeated great earthquakes (i.e., greater than moment magnitude (**M**)8.0 throughout the Holocene Epoch (i.e., last 11,700 years). The most recent CSZ great earthquake was an estimated **M**9.0 in January of 1700. The Cascadia subduction interface is currently locked and accumulating strain toward a future large or great earthquake (e.g., Dragert et al. 1994, Hyndman and Wang 1995, Mazzotti et al. 2003). The CSZ has a high rate of historical seismicity relative to the southern Canadian Cordillera where the Mt Polley TSF site is located.

The southern Cordillera has relatively low rates of historical seismicity relative to the northern Cordillera and CSZ to the west. However, intermediate-to-large magnitude earthquakes have been recorded. For example, an **M**6.0 earthquake in 1918 had an epicenter ~ 220 km east of the site (Halchuk et al. 2015). An **M**5.5 earthquake occurred in 1986 with an epicenter ~200 km north of the site (Table 3). Both earthquakes occurred in the “Rocky Mountain Trench” that marks the boundary between the western Foreland Fold and Thrust Belt and the Quesnel terrane and other terranes. The 1986 earthquake had a thrust fault mechanism, which is consistent with the general structural trends mapped in the area (e.g., Rogers et al. 1990).

[1] Allochthonous terranes are assemblages or packages of rocks that are stratigraphically and structurally distinct from their neighbours. Each terrane has a distinct geological history that precedes its amalgamation to other terranes. Terranes are created by crustal- and lithosphere-scale plate tectonic processes. Many allochthonous terranes have been identified throughout western North America, including Alaska.

3.2 Canadian National Seismic Source Model

The preliminary 6th Generation Seismic Hazard Model of Canada (CanadaSHM6) was released in 2020 as the basis for the 2020 National Building Code of Canada (NBCC 2020). The CanadaSHM6source modelling approach is described in more detail by Kolaj et al. (2020b). Information and digital files for the model used in this assessment were gathered from GSC Open File 8630 by Kolaj et al. (2020b; updated 29 November 2021), downloaded directly from the Natural Resources Canada website.

The Kolaj et al. (2020b) model is divided into three main components based on location — western Canada, eastern Arctic Canada, and southeast Canada. This assessment used only the western Canada component of CanadaSHM6. Between CanadaSHM5 and CanadaSHM6 significant updates were made to the western Canada model, including improved characterization of the CSZ and addition of the Leech River Valley Fault – Devil's Mountain Fault system in southern Vancouver Island. This has resulted in an increase in the estimated seismic hazard in southern British Columbia.

The Kolaj et al. (2020a) seismic source model includes sources for the CSZ interface, CSZ in-slab, active crustal, and stable crustal earthquakes. The seismic sources adopted for this assessment are described in Section 3.4 and Section 3.5 below.

3.3 Earthquake Catalog

Development of a site-specific SHA requires a comprehensive understanding of the spatial and temporal distribution of historical earthquakes for the region surrounding the site. The Seismic Hazard Earthquake Epicenter File (SHEEF2010), developed by Halchuk et al. (2015), was used to compute the earthquake occurrence rates for areal sources in CanadaSHM5 and CanadaSHM6.

The SHEEF2010 catalog includes earthquakes with an original catalog earthquake magnitude of 2.5 or higher. The estimated earthquake moment magnitude (**M**) used in the catalog can be less. The SHEEF2010 is estimated by Halchuk et al. (2015) to be complete from 1900 through 2010 for all reported magnitudes.

Although the catalog ends in 2010, updating the catalog and recalculating the activity rates has not been considered for this analysis. The update was not undertaken because there are insufficient recorded earthquakes in the region surrounding the site since 2010 to cause a change in calculated earthquake activity rates. Figure 1 presents **M**4 and larger earthquakes from SHEEF2010 within ~700 km from the site. Table 3 lists the key parameters for historical earthquakes that have occurred within 200 km from the site. Only three of the recorded earthquakes exceeded **M**4, indicating a relatively low rate of historical earthquake activity.

Table 3: Earthquakes with M>3 Magnitude Recorded within 200 km of the Mount Polley TSF Site

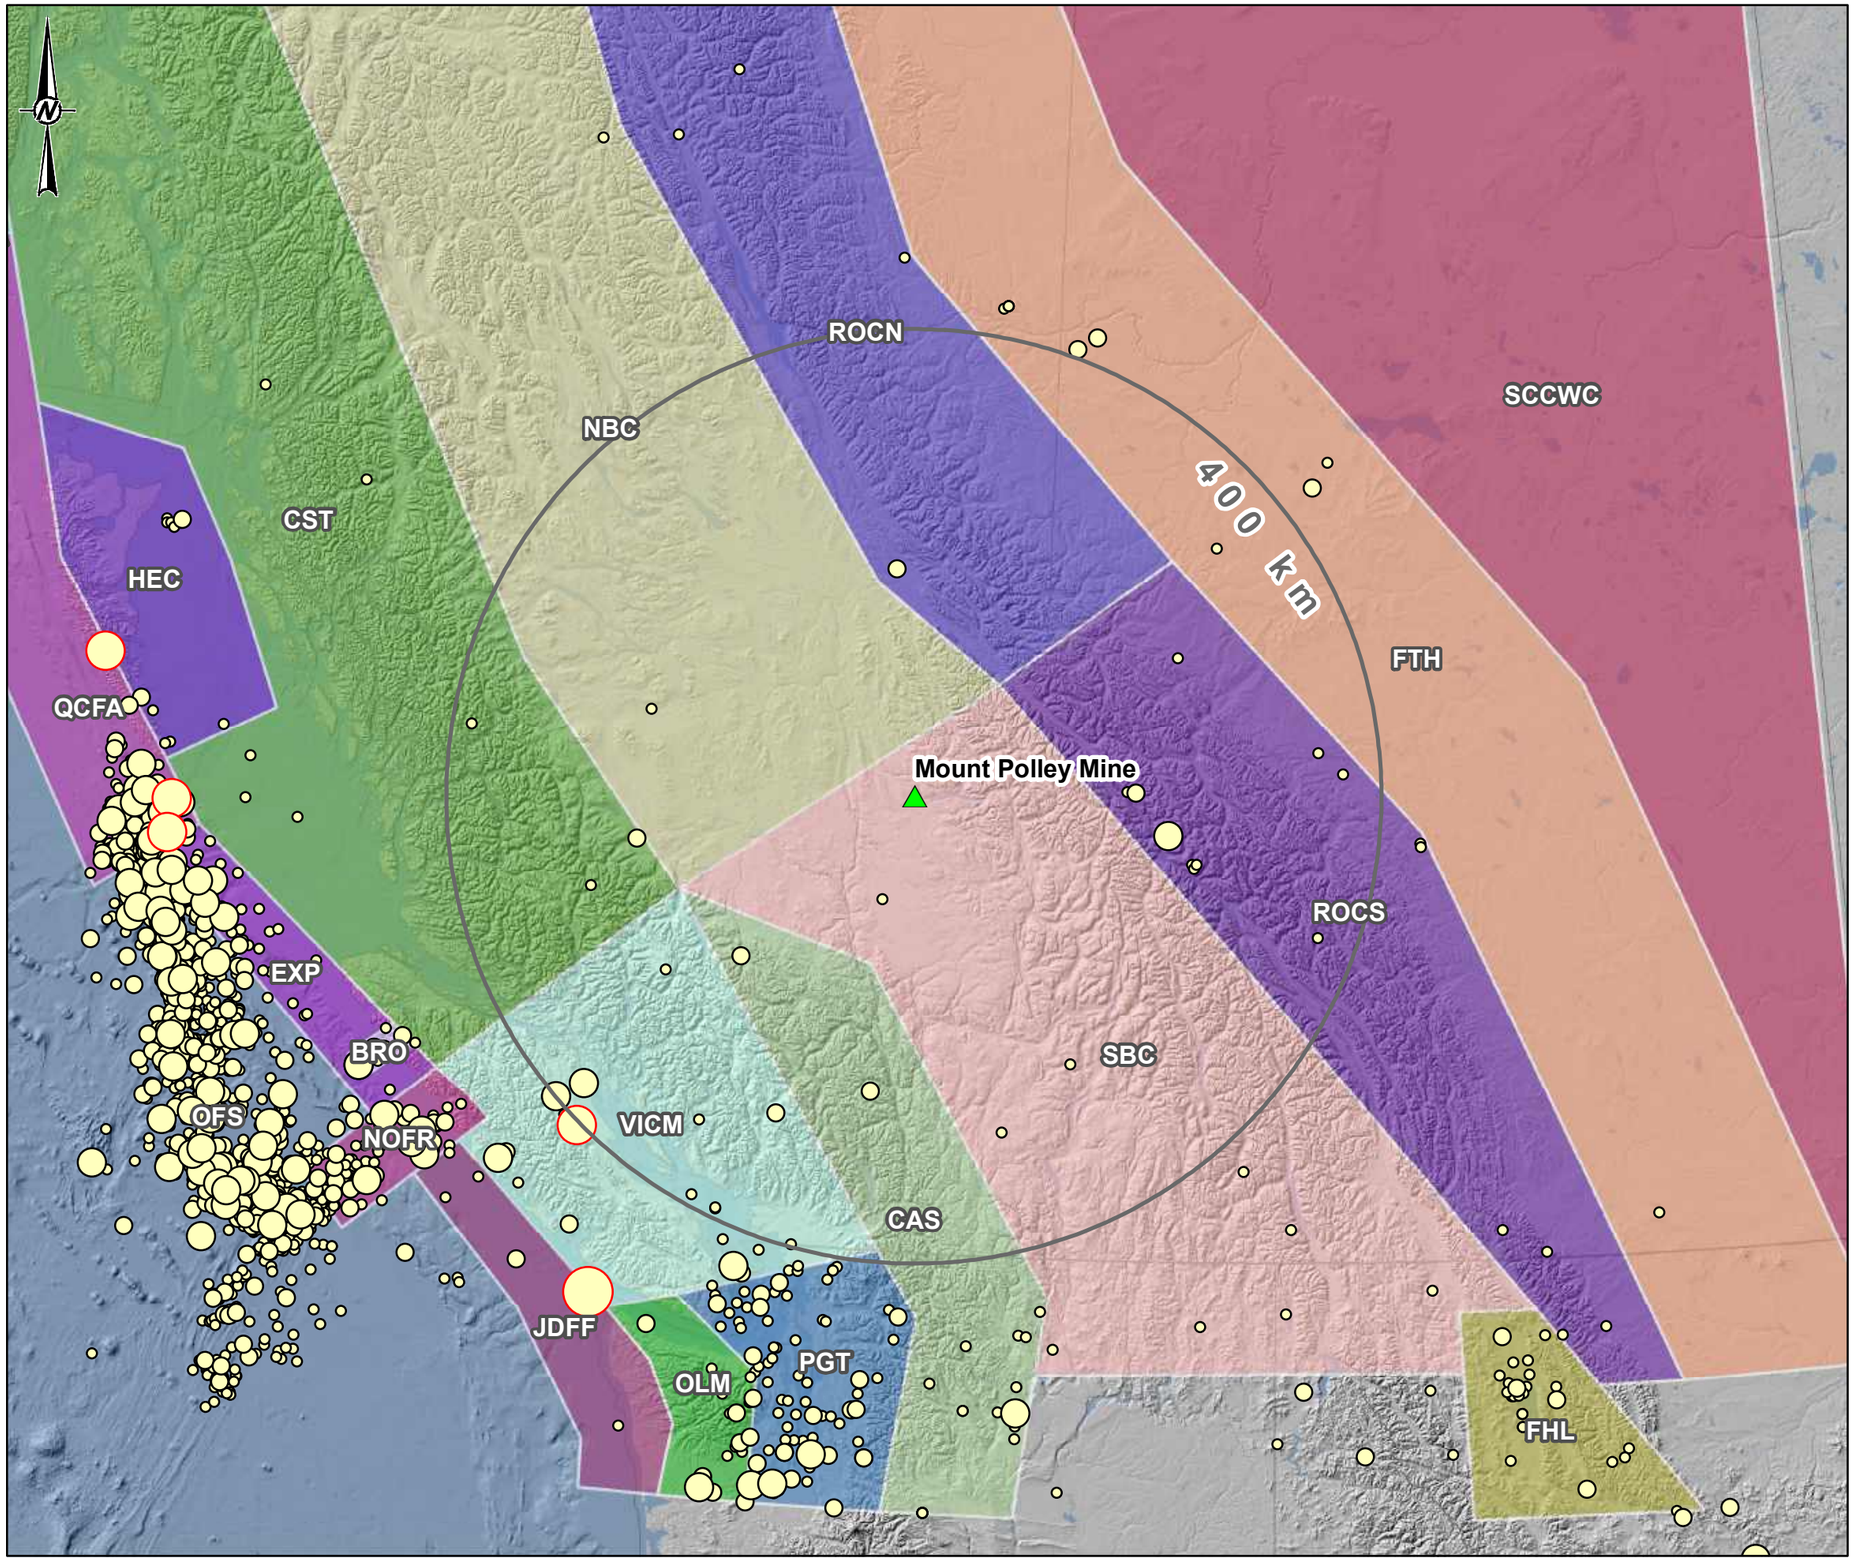
3.4 Shallow Crustal Sources

3.4.1 Uniform-area sources



CanadaSHM6 uses uniform-area sources to model the occurrence of crustal seismicity not associated with known mapped seismogenic features such as seismically active faults or other seismogenic structures. There are eight crustal uniform-area sources within the Western CanadaSHM6 model within ~400 km of the site. These sources are described further below and shown in Figure 2.

- **Foothills (FTH):** Foreland Basin rocks located within the interior platform of western Canada immediately adjacent and east of the Canadian Cordillera. Characterized by very low rates of natural historical seismicity. In recent years oil and gas exploration has greatly increased the number of small earthquakes in the region. These “induced” earthquakes are not incorporated into this analysis because they contribute only to the short-term hazard locally and not the longer-term hazard considered here.
- **Rocky Mountain Fold/Thrust Belt North (ROCN):** Foreland fold and thrust belt of the Canadian Cordillera. This zone is characterized by slightly higher rates of historical seismicity compared to NBC and SBC. This source zone hosted an **M**5.5 earthquake in 1986.
- **Rocky Mountain Fold/Thrust Belt South (ROCS):** Foreland fold and thrust belt of the Canadian Cordillera. This zone is characterized by slightly higher rates of seismicity compared to the NBC and SBC sources zones (see below). This source zone hosted an **M**6.0 earthquake in 1918.
- **Northern British Columbia (NBC):** Interior of the Canadian Cordillera. This source zone has very low rates of historical seismicity. The eastern boundary of the NBC is the Rocky Mountain Trench. The northern boundary is marked by elevated seismicity rates interpreted to result from the transfer of strain from the Yakutat collision about 600 to 800 km to the west.
- **Southern British Columbia (SBC):** Interior of the Canadian Cordillera. This source zone has very low rates of historical seismicity. The Mount Polley TSF site is within this source zone. The eastern boundary of the SBC is the Rocky Mountain Trench. The western boundary is the Cascade Fold Belt.
- **Coastal Mountains (CST):** This source zone is underlain by the Middle Jurassic to Eocene Coastal Plutonic Complex with a relatively low rate of historical seismicity. The northern boundary is marked by elevated seismicity associated with the collision of the Yakutat Block with the North American Plate. The Yakutat Block is a composite oceanic-continental allochthonous terrane on the Pacific Plate.
- **Cascade Mountains (CAS):** The Cascade Fold Belt has historical seismicity rates higher than NBC and SBC source zones to the east.
- **Vancouver Island Coast Mountains (VICM):** This source zone is underlain by the Middle Jurassic to Eocene Coastal Plutonic Complex. This VICM has hosted numerous large crustal earthquakes in historical times including the 1949 **M**7.3 Vancouver Island earthquake. This source zone has earthquakes associated with ongoing arc volcanism.

Table 4 lists the parameters for the uniform-area sources adopted from CanadaSHM6.

The truncated Gutenberg-Richter (G-R) distribution is used to model earthquake occurrence rates within each uniform-area source zone. Three separate activity rates and three maximum earthquake magnitude (M_{max}) values are used to represent uncertainty in the estimation of the magnitude-recurrence parameters (Kolaj et al. 2020a).

For computational efficiency, these activity-rate- M_{max} pairs are collapsed down to a single weighted magnitude frequency distribution (MFD) for each area-source zone.

Notes:

a. Mmin is the minimum magnitude included in the source model and defines the lower magnitude truncation of the Gutenberg-Richter distribution.

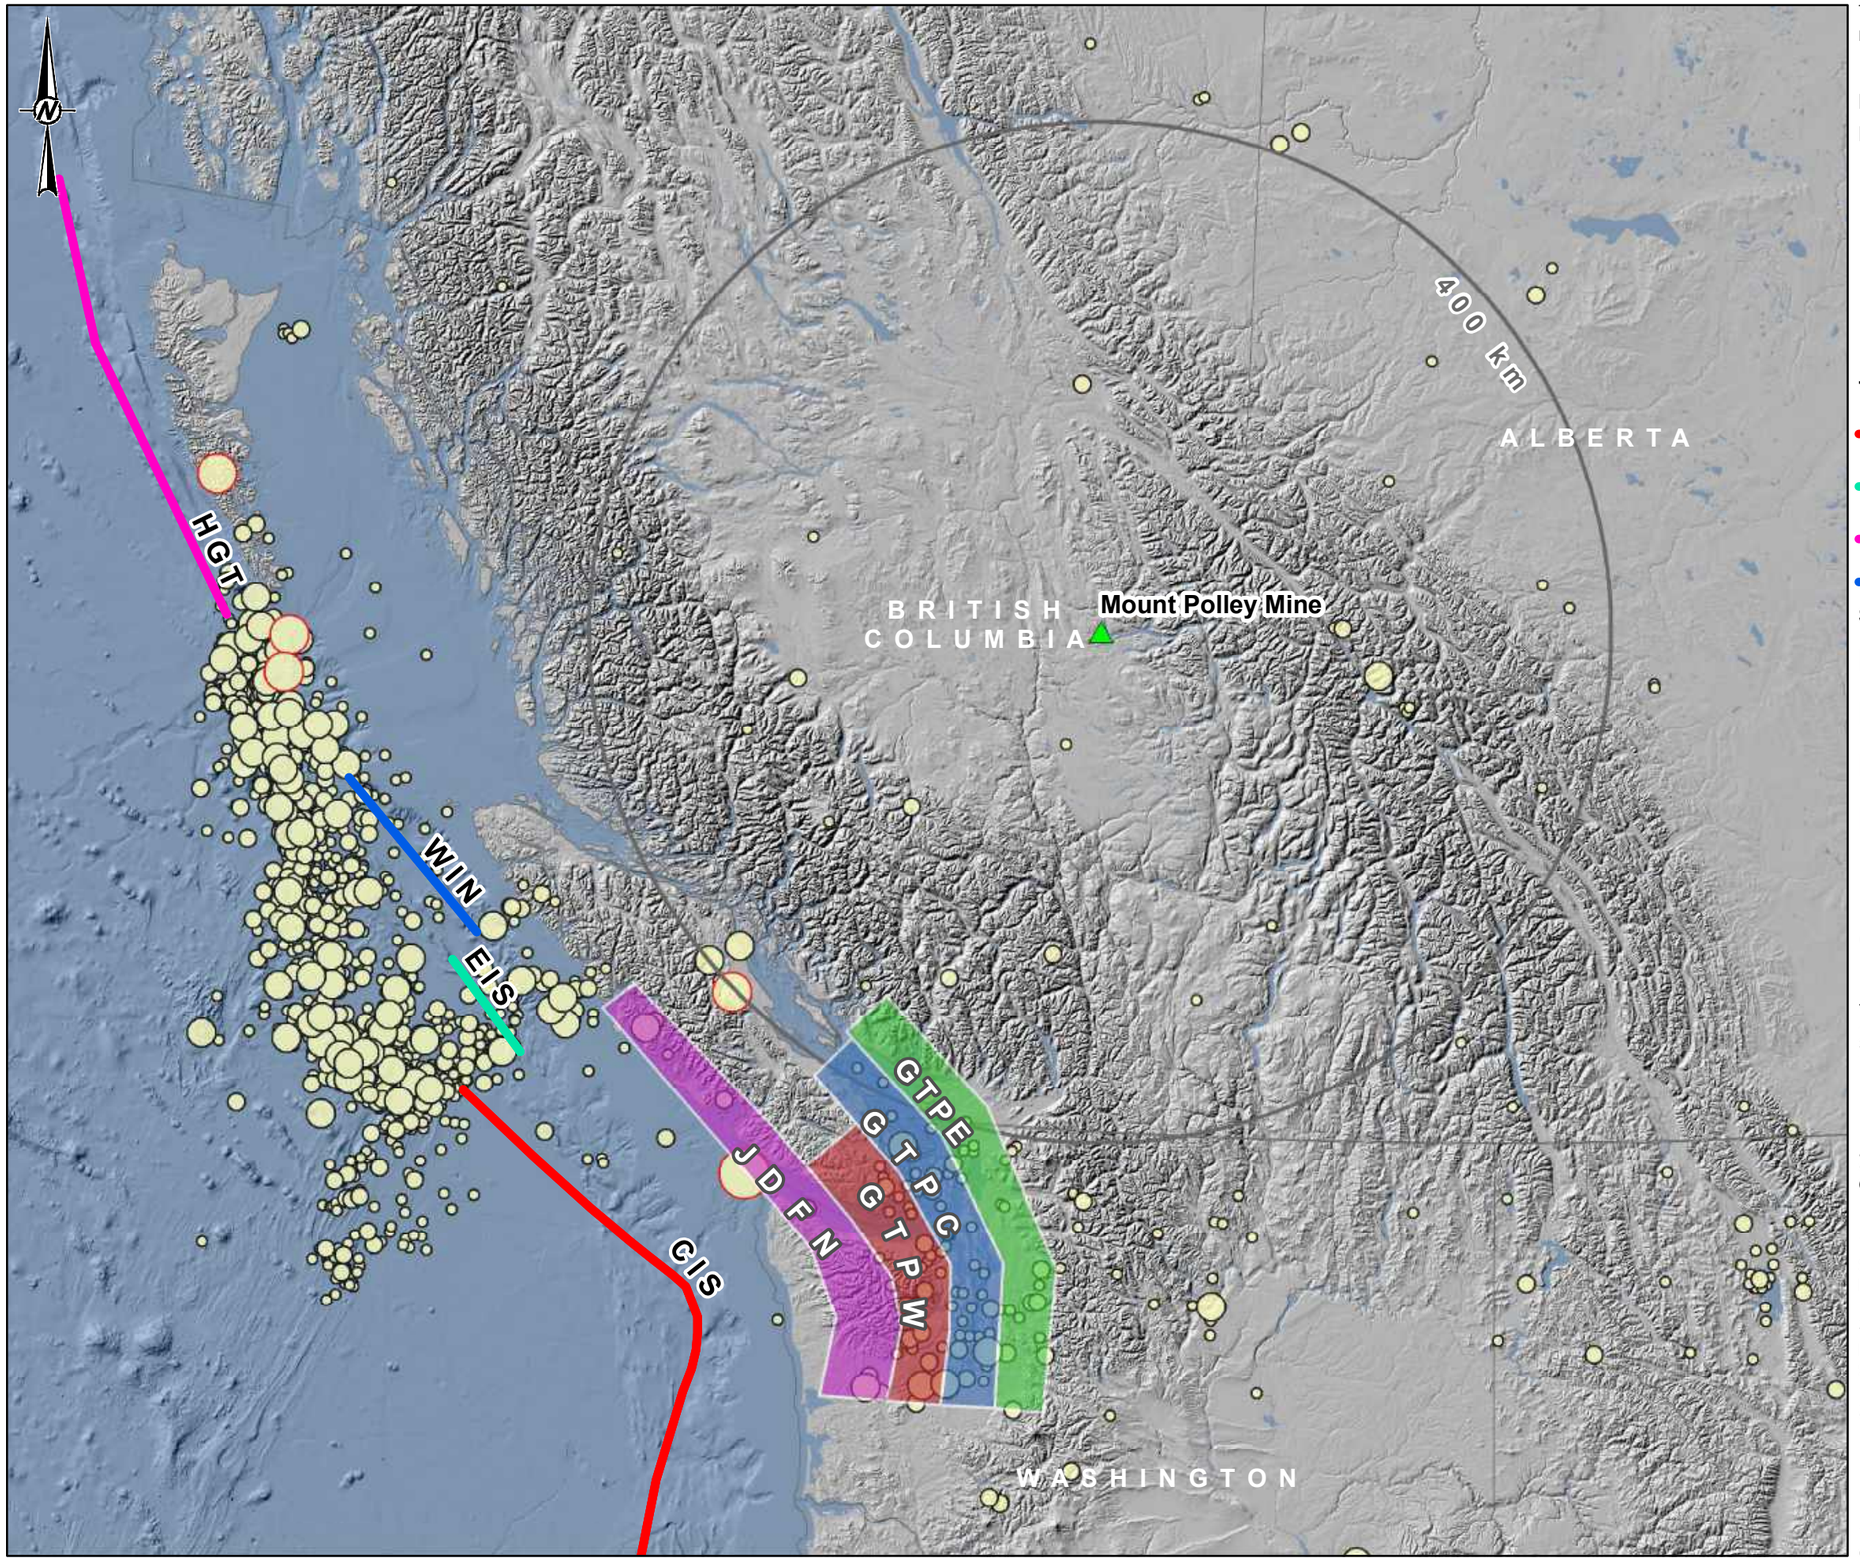
b. Mmax is the maximum magnitude included in the source model and defines the upper magnitude truncation of the Gutenberg-Richter distribution. The Mmax is the weighted sum of the collapsed MFD.

c. N(0) is the annual number of earthquakes (N) at magnitude zero – this is the same as the a-value, a constant in the Gutenberg-Richter relationship. The N(0) value is the weighted sum of the collapsed MFD.

d. b-value is a constant in the Gutenberg-Richter relationship that describes the proportion of large magnitude earthquakes to small magnitude earthquakes. The b value is the weighted sum of the collapsed MFD.

3.4.2 Crustal Fault Sources

There are no known crustal seismogenic fault sources within 400 km of the Mount Polley TSF site. Accordingly, linear active crustal fault sources are not in the seismic source model. Earthquake occurrence near the site is instead modelled using shallow crustal uniform-area sources (Section 3.4.1) and CSZ sources (Section 3.5).



3.5 Subduction Sources

The CSZ marks the boundary where the Explorer, Juan de Fuca, and Gorda plates (i.e., remnants of the older Farallon plate) subduct beneath the North America plate. The CSZ is about 460 km from the site at its closest approach. CanadaSHM6 has separate subduction source models for the subduction interface fault and the subduction in-slab sources as shown in Figure 3. These models are used for this assessment.

3.5.1 Subduction Interface

The CSZ interface fault is the surface trace of the boundary between the subducting Juan de Fuca plate system, comprised of the Gorda, Juan de Fuca, and Explorer plates, and the overriding North American plate. The CSZ is a “mega-thrust” source known to generate great earthquakes (**M**>8.5) such as in 1700. In CanadaSHM6, the CSZ interface fault has four sections: the Cascadia Interface, the Explorer Interface, the Winona thrust fault, and the Haida Gwaii thrust fault. Compared to CanadaNSHM5, CanadaSHM6 incorporates an improved model for the Juan de Fuca segment of the Cascadia subduction zone by incorporating current understanding of the paleoseismic history rather than a simple deterministic scenario. The more refined approach has reduced the average inter-event period for great earthquakes to increase the estimated seismic hazard for many sites in the coastal regions of Western Canada.

Table 5 lists the parameters for the subduction interface sections adopted from CanadaSHM6.

1 Values for Mmax and Weighted Activity parameters are listed as U = Upper, P = Preferred, L = Lower

3.5.2 Subduction In-slab

The CanadaSHM6 defines four in-slab sources within about 500 km of the site. Table 6 lists the parameters from CanadaSHM6 used in this assessment. These sources represent earthquakes occurring in the subducting Juan de Fuca plate that extends beneath most of Vancouver Island, Puget Sound, and northern Washington state in the USA (Figure 3).

.

Table 6: Cascadia Subduction Zone In-slab Seismic Source Parameters

Tectonic Region	Seismic Source Zone	Closest distance to site (km)	Mmin	Mmax			Upper Seimogenic Depth [km]	Lower Seismogenic Depth [km]	Weighted Activity Parameters[1]					
				U	P	L			N(0)			b-value		
									U	P	L	U	P	L
Subduction In-slab	Georgia Strait Puget Sound Central	375	4.8	7.5	7.2	7.0	45	65	15.4	20	72.8	0.413	0.478	0.69

1. Values for Mmax and Weighted Activity parameters are listed as U = Upper, P = Preferred, L = Lower

3.6 Source Model Parameters

There are important parameter limits included in PSHA:

- **Source-to-site distance (R)** is the maximum distance from the site considered in the hazard calculation. The maximum r parameter (r_{max}) is selected considering the distribution of historical earthquake epicenters, limitations of the GMMs, and the AEPs and spectral periods of interest to the project. The r_{max} in CanadaSHM6 is defined depending on the tectonic region with the longest distance for the subduction sources (1000 km) and shorter distances for the crustal sources (400 to 600km).
- **Maximum earthquake magnitude (M_{max})** is the maximum earthquake magnitude expected from an earthquake source. Refer to Sections 3.4 and 3.5 for further details.
- **Minimum earthquake magnitude (M_{min})** is the minimum earthquake magnitude expected to result in some damage to the facility or site under study. Refer to Sections 3.4 and 3.5 for further details for M_{min} for the defined seismic sources.
- **Epsilon (ε)** is a standard deviation of the ground motion models above and below the median ground motion calculated from each GMM. Inclusion of excessively unlikely ground motions is computationally demanding with minimal gain in the earthquake ground motion prediction. Epsilon (ε) is truncated at five in CanadaSHM6, and was also applied in this assessment (i.e., the ground motions above and below five standard deviations of the median are not included in the hazard integral).

Epistemic uncertainty is incorporated using a logic-tree approach. GMMs are weighted and propagated through the logic tree to provide a suite of weighted results that are then summed. The CanadaSHM6 model trial version logic tree was collapsed (Kolaj et al. 2020b) to reduce the time required for calculation of the magnitude recurrence branches. The logic tree collapsing does not impact the mean hazard value obtained, only the hazard fractiles.

4.0 GROUND MOTION MODEL SELECTION AND WEIGHTING

Empirical ground motion models (GMM) are used to estimate the earthquake ground motions at a site for an earthquake with a magnitude, a rupture mechanism (e.g., normal, strike-slip, reverse or thrust), and a known source-to-site distance. The GMMs are developed for defined tectonic regions and seismic types (e.g., subduction zones or shallow crust). The GMMs used in this assessment are selected based on the similarity between the tectonic and geologic conditions in the region surrounding the site and the conditions in the regions from which earthquake recordings were selected to derive the GMMs.

4.1 Active Shallow Crustal Ground Motion Models

CanadaSHM6 uses the Pacific Earthquake Engineering Research Center (PEER) Next Generation of Ground Motion Attenuation Phase 2 Project (NGA-West2) GMMs to model source-to-site attenuation for all active shallow crustal sources. The NGA-West2 GMMs were developed for active tectonic regions based mostly on earthquake strong ground motion data recorded at seismically active, present-day tectonic plate boundaries, primarily from western United States, Japan, New Zealand, and other seismically active regions around the world.

The NGA-West2 GMMs were developed in a systematic process using improved strong ground motion recordings and considered the soil conditions at the ground motion recording stations, near-source saturation effects, and sedimentary basin and fault hanging-wall effects. These GMMs have been employed globally to model source-to-site attenuation from shallow crustal sources in PSHA. Spectral accelerations are estimated as a function of

earthquake magnitude, source-to-site distance, fault geometry, and time-averaged shear-wave velocity in the upper 30 m below the site ground reference surface (i.e., V_{S30}).

Table 7 lists the crustal GMMS used, their weights, and key distance measures.

4.2 Subduction Ground Motion Models

Subduction zone earthquake sources include both the subduction interface and subduction in-slab sources. GMMs have been developed for each of the interface and in-slab sources independently, but there is significant overlap in the development of GMMs for these sources because they are typically both used when a site is near a major subduction zone.

The selection and weighting of subduction GMMs for CanadaSHM6 is based on 15 discrete V_{S30} values. The V_{S30} value used in this assessment is not one of the pre-defined values in CanadaNSH6. Consequently, the use of GMMs in this assessment differs from that in CanadaSHM6.

This assessment uses three of the GMMs developed for the NGA-Sub project to model source-to-site attenuation for the subduction interface sources: Abrahamson and Gülerce (2020), Kuehn et al. (2020), and Parker et al. (2020). The Si (2020) GMM was developed specifically for Japanese subduction zones using only Japanese strong motion data. This GMM is not yet recommended for use outside Japan. The NGA-Sub project followed a similar methodology as the NGA-West2 project. The 2020 NGA-Sub GMMs are now considered the more advanced GMMs for subduction zone earthquakes because they have been developed using the similar robust and peer reviewed approach as used for the NGA-West2.

The Abrahamson et al. (2018) pre-NGA-Sub GMM was also used in this analysis because it was specifically developed for the CSZ as part of the BC Hydro assessment in 2012. Abrahamson et al. (2018) is an updated version of the BC Hydro GMM. The Abrahamson et al. (2018) central model was included with a relatively low weight to capture the epistemic uncertainty in CSZ ground motion predictions. The central, low, and high alternatives of Abrahamson et al. (2018) were included to capture the epistemic uncertainty for the in-slab sources.

Table 7: Selected Ground Motion Models and Weights used in this Assessment

Tectonic Region	GMMs	Weight	Primary distance metric[1]	Moment Magnitude (M) range	Source-to-site distance (km)
Active Shallow Crust	Abrahamson et al. (2014)	0.25	Rrup	3.0-8.5	0-300
	Boore et al. (2014)	0.25	Rjb	3.0-7.9	0-400
	Campbell and Bozorgnia (2014)	0.25	Rrup	3.3-8.5	0-300
	Chiou and Youngs (2014)	0.25	Rrup	3.5-8.5	0-300
Subduction Interface	Abrahamson and Gülerce (2020) *Cascadia-specific coefficients	0.35	Rrup	5.0-9.5	0-800
	Abrahamson et al. (2018)	0.15	Rrup	5.0-9.5	0-1000
	Kuehn et al. (2020)	0.35	Rrup	5.0-9.5	10-1000
	Parker et al. (2020)	0.15	Rrup	4.5-9.5	20-1000
Subduction In-slab	Abrahamson et al. (2018)	0.2	Rrup	5.0-9.5	0-1000
	Abrahamson and Gülerce (2020) *Cascadia-specific coefficients	0.4	Rrup	5.0-9.5	0-800
	Kuehn et al. (2020)	0.4	Rrup	5.0-9.5	10-1000

1. Distances metrics are Rrup for rupture plane distance, Rjb for Joyner-Boore distance as closest distance to the surface projection of the fault plane.

5.0 PROBABILISTIC SEISMIC HAZARD ANALYSIS

This section provides a general overview of the PSHA method as applied in the site-specific hazard assessment, including incorporation of uncertainties.

5.1 Methodology

PSHA is based on a method proposed by Cornell (1968) that essentially relates the recurrence of earthquakes in the seismic source models to the probability that an earthquake ground motion exceeds a certain value in a specific time period at a specific location (see following equation). This approach relies on the assumption that earthquakes occur randomly in space and time (i.e., Poisson process).

$$P(IM > s) = 1 - e^{-\varphi(s)t}$$

Where:

- *P* = probability
- *IM* = ground motion (also known as ground motion intensity measure)
- s = a specific value of ground motion
- φ(s) = annual exceedance probability (AEP)
- t = time period

For this assessment, the target annual exceedance probabilities (AEP) are 1/1,000, 1/2,475, 1/5,000 and 1/10,000. The annual probability of exceedance is calculated following equation:

$$(IM > x) = \sum_{i=1}^{n_{sources}} \lambda(M > m_{min}) \int_{m_{min}}^{m_{max}} \int_{0}^{r_{max}} P(IM > x|m,r) f_M(m,r) f_R(r) dr dm$$

Where:

- $n_{sources}$ = number of sources considered
- $\lambda(M>m_{min})$ = the rate of occurrence of earthquakes greater than m_{min} from the i_{th} source
- $P(IM>x \mid m,r)$ = the probability that *IM* exceeds x given magnitude *m* and distance *r*
- $f_M(m)f_R$® = probability density functions for magnitude *m* and distance r

The probabilistic analysis for this site was undertaken using the OpenQauke software (v.3.11.4) developed by the Global Earthquake Model Foundation (GEM, 2022).

5.2 Logic Tree Analysis

Epistemic uncertainty is the uncertainty associated with the simplified and imprecisely known scientific model of a natural process. This uncertainty is typically parameterized by considering alternative model input parameters to the PSHA (e.g., Abrahamson 2006, 2009). The input model parameters include the seismic source models, their recurrence parameters and maximum earthquake magnitudes, hypocentral depth, and ground motion model. Epistemic uncertainty is commonly accommodated through a logic-tree approach.

One of the planned changes for CanadaSHM6 was to implement the model in OpenQuake—an open-source seismic hazard and risk calculation software developed and maintained by the Global Earthquake Model Foundation (GEM 2022). Allen et al. (2020) converted CanadaSHM5 to OpenQuake to ensure the change in calculation software did not result in a change in hazard values.

As part of this implementation of the seismic source models in OpenQuake, the two magnitude-frequency distribution (MFD) branches of the logic tree, the three-alternative a- and b-value branches and three alternative M_{max} branches, were collapsed into a single MFD branch. This approach was used by Allen et al. (2020) to reduce the unreasonably long runtimes in OpenQuake v3.2 with nine weighted source model sub-branches for each earthquake source.

Variations in occurrence rates and M_{max} were collapsed into a combined, weighted average branch for computational efficiency. Allen et al. (2020) outlines in detail the implementation of CanadaSHM5 in OpenQuake and the differences in results between the two calculation software programs. While collapsing these two branches in the logic tree had a negligible impact on median hazard values, it limits the ability to perform a detailed analysis of the fractiles or model input sensitivity test. Improvements in computation runtimes in OpenQuake v.3.11 allow for a sensitivity analysis of a subset of spectral periods and return periods. The input parameters, logic tree, and weighting values used in this assessment are adopted from the Kolaj et al. (2020b) model and presented in Figure 4.

Figure 4 shows the source model logic tree used in this site-specific analysis.

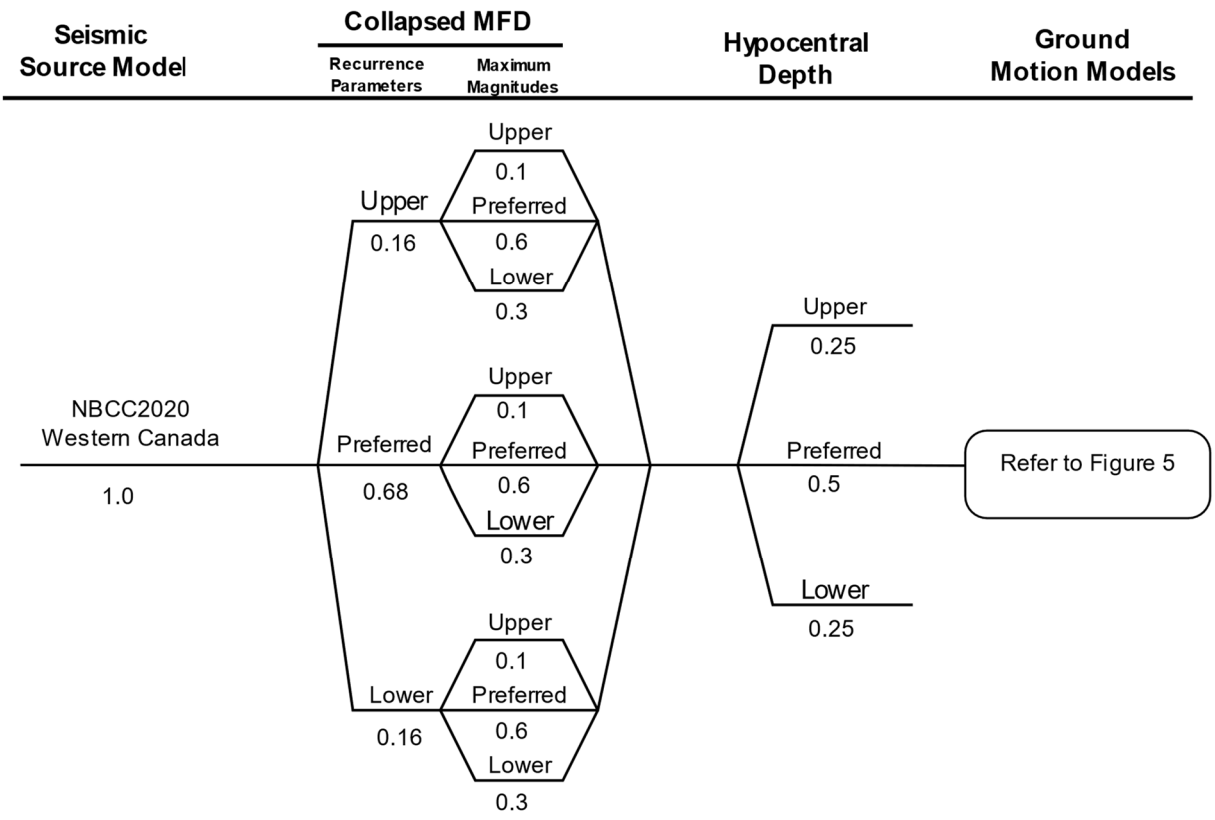

Figure 4 Seismic Source Model Logic Tree used in this assessment

Figure 5 shows the GMM logic and weighting as described in Section 4.0.

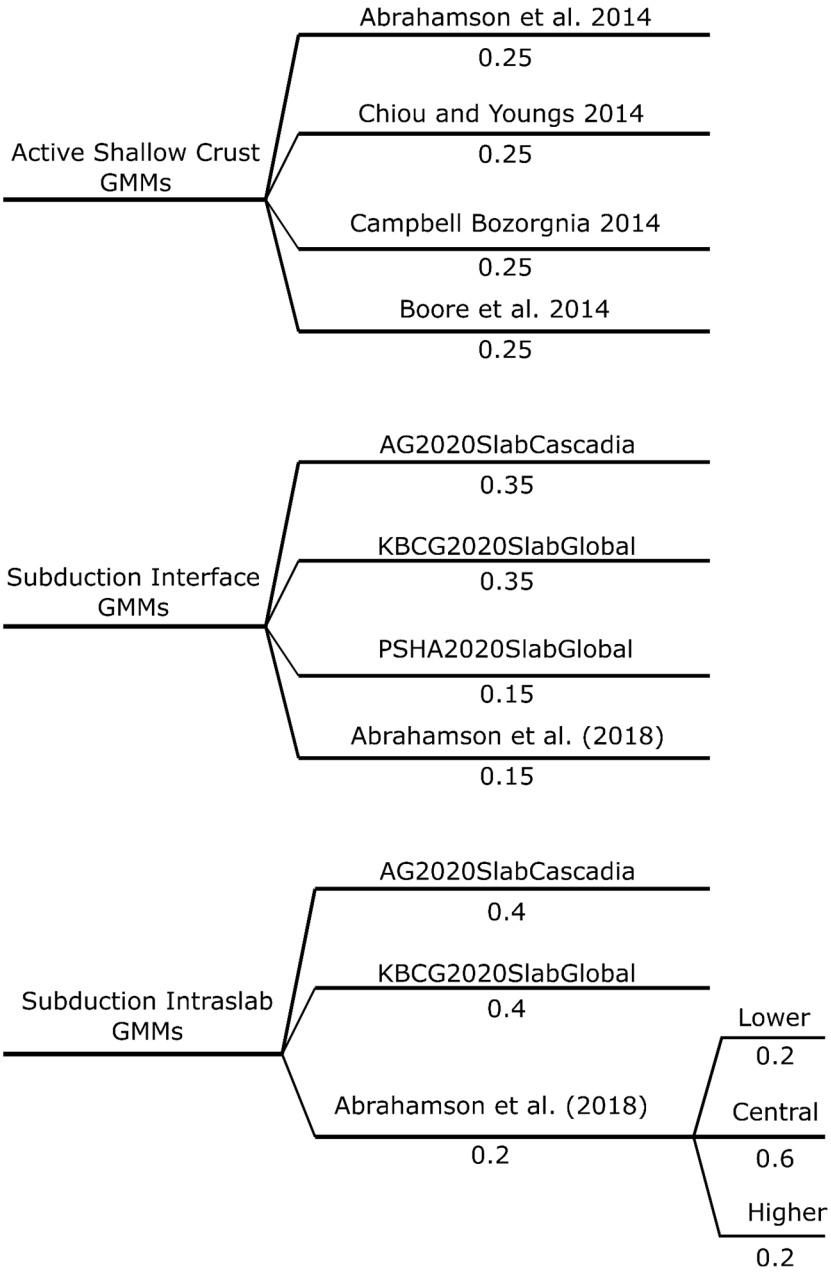

Figure 5 Logic trees for selected ground motion models and their weights for crustal, subduction interface, and subduction in-slab sources

5.3 Validation of Model Implementation

The results of a full CanadaSHM6 model (unmodified) run for the site is compared to results derived from the Seismic Hazard Tool calculator available online (Natural Resources Canada (NRCan) 2020) as the basis to validate our implementation of the CanadaSHM6 source models and GMMs in OpenQuake. Table 8 lists results for the 1/475 and 1/2475 AEPs.

The results from our implementation of CanadaSHM6 in OpenQuake and those available from the seismic hazard tool for the two AEPs are almost identical. The discrepancies in acceleration values in this validation test are negligible and can be attributed to changes in the versions of the OpenQuake software engine. From this validation test, our implementation of CanadaSHM6 is considered valid.

Table 8 also lists the 1/475 AEP and 1/2475 AEP mean hazard results using the site-specific source model developed for the site. The site-specific results are generally lower than CanadaSHM6, although the absolute value of the total hazard and differences in hazard are low. Differences in the results are primarily attributed to the different ground motion model selection and weighting, and the V_{S30} used in this assessment.

Table 8: Accelerations for Validation of Models at 1/475 AEP and 1/2475 AEP

Parameter		Mean acceleration (g)			
AEP	Spectral period (s)	CanadaSHM6 results[1] V_{S30}= 760 m/s	This assessment		
			CanadaSHM6 model[2] V_{S30}= 760 m/s	Site-specific[3] V_{S30}= 760 m/s	Site-specific [4] V_{S30} = 849 m/s
1/475	PGA	0.019	0.018	0.016	0.015
	0.2	0.037	0.036	0.031	0.029
	0.5	0.027	0.027	0.024	0.021
	1.0	0.018	0.018	0.015	0.013
	2.0	0.014	0.013	0.009	0.010
	5.0	0.006	0.006	0.004	0.008
	10.0	0.003	0.003	0.002	0.004
1/2,475	PGA	0.057	0.055	0.051	0.048
	0.2	0.115	0.111	0.107	0.098
	0.5	0.067	0.064	0.061	0.054
	1.0	0.043	0.042	0.043	0.030
	2.0	0.034	0.032	0.035	0.020
	5.0	0.018	0.017	0.011	0.011
	10.0	0.013	0.012	0.006	0.006

Notes:

1. Natural Resources Canada (2020). Obtained using NRCan Seismic Hazard Tool: https://earthquakescanada.nrcan.gc.ca/hazard-alea/interpolat/nbc2020-cnb2020-en.php for V_{S30} of 760m/s at site location.
2. Variations between these results and the CanadaSHM6 results are due to minor changes between OpenQuake versions. Results presented in this assessment are from OpenQuake v3.11.4.
3. Variations between these results and the CandaSHM6 published results are due to the source models and weightings developed for this assessment.
4. As per note 3, and the difference in V_{S30}.

6.0 DETERMINISTIC ANALYSIS

The Canadian Dam Association (CDA) guidelines for tailings dams (CDA 2019, Table 3.1) permit the use of a maximum credible earthquake (MCE) for Very High and Extreme consequence facilities. The Mount Polley TSF is located within a relatively tectonically stable continental region in western North America. Major systems or segments of faults with seismogenic potential needed to estimate an MCE within about 400 km of the site are unknown based on our review of readily available information. Consequently, the magnitude-distance pair required to generate discrete, single-valued earthquakes to estimate the site-specific MCE ground motions is not possible for the Mount Polley TSF site. Probabilistically based mean accelerations developed from this assessment, therefore, are recommended for earthquake ground motion analyses at the Mount Polley TSF site.

7.0 SITE-SPECIFIC PROBABILISTIC SEISMIC HAZARD ANALYSIS RESULTS

Sections below present the site-specific earthquake ground motions for the Mount Polley TSF site. Section 8.0 provides discussion of the results and recommendations. The results presented here are for a V_{s30} of 849 m/s (Appendix B).

The ground motion hazard results from the PSHA are described in three ways:

- Hazard curves that describe the acceleration at a specific spectral period at a range of AEPs. Section 7.1 describes hazard curves for the site.
- Uniform hazard acceleration response spectrum that describes the acceleration for a range of spectral periods at a specific AEP. The response spectrum is “uniform hazard” because each acceleration value has the same AEP. Section 7.2 presents uniform hazard response spectra for the site.
- Magnitude-distance deaggregations that describe the joint probability mass distribution of earthquake-magnitude and source-to-site distance that contribute to the mean hazard at a specific AEP and spectral period. Section 7.3 present magnitude-distance deaggregations for the site.

7.1 Hazard Curves

Hazard curves describe earthquake acceleration values at different AEPs at a given spectral period. Figure 6 shows mean hazard curves for selected spectral periods. The 1/1,000, 1/2,475, 1/5,000, and 1/10,000 AEPs are also shown. The mean hazard curves are the result of summing weighted hazard curves as developed from the logic tree.

Figure 7 shows PGA, 0.5 s, 1.0 s, and 1.5 s spectral period mean hazard curves with 5th, 15th, 50th (median), 85th, and 95th fractiles (median ± 1 and 2 standard deviations). The fractiles reflect the uncertainty in the hazard results as incorporated in the logic trees in this site-specific PSHA. As described in Section 5.2 the b-value and maximum earthquake magnitude uncertainties from the areal source models are not incorporated in the fractile analysis.

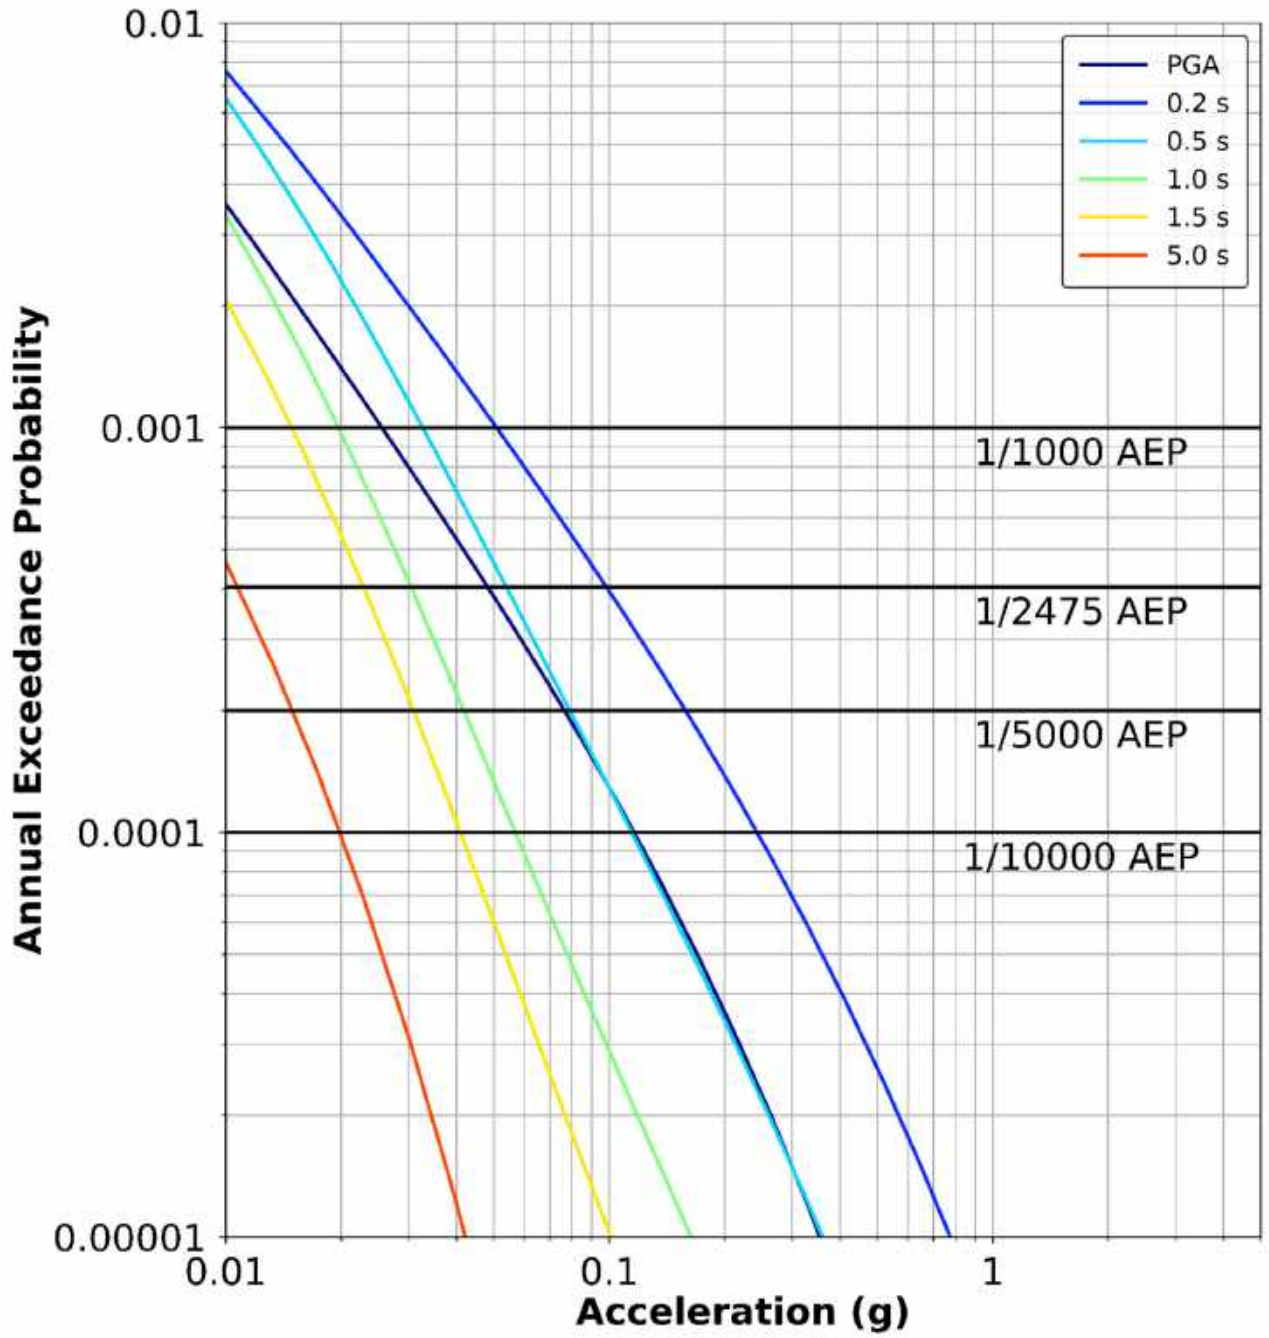

Figure 6: Mean hazard curves for selected spectral periods for top of engineering bedrock ground condition (V_{S30} = 849 m/s)

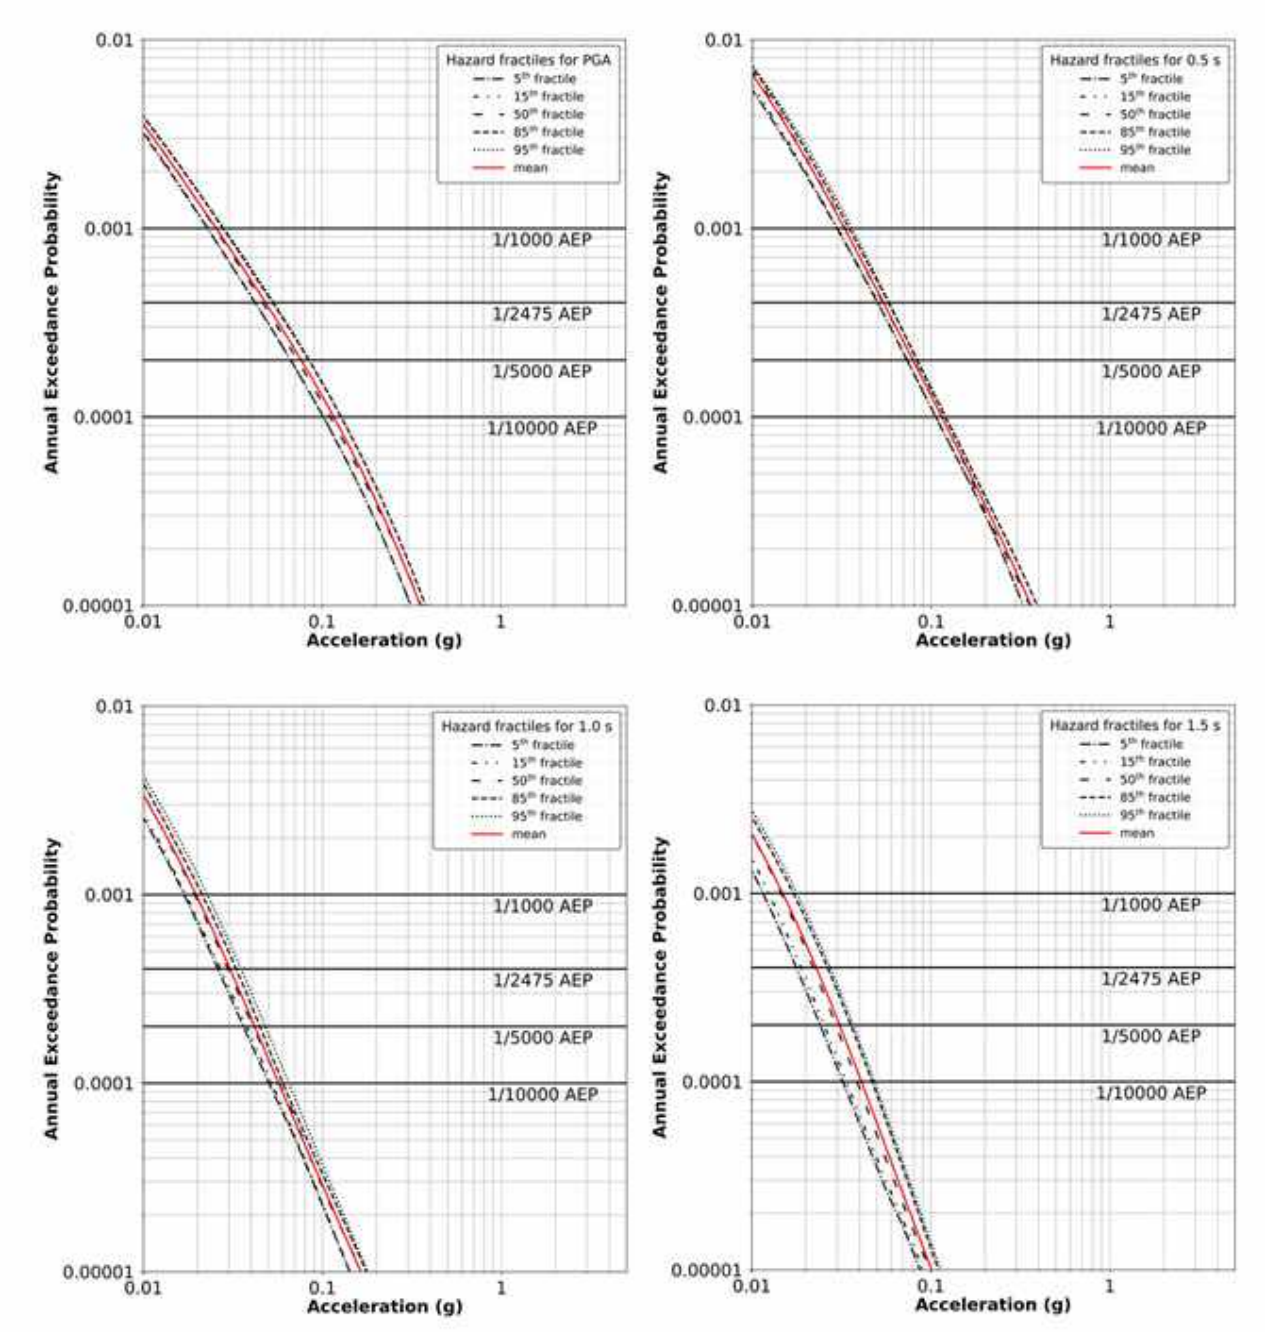

Figure 7: Mean hazard curves, showing 5th, 15th, 50th (median), 85th, and 95th fractiles for PGA (top left), 0.5 s (top right), 1.0 s (bottom left), and 1.5 s (bottom right) spectral periods

7.2 Uniform Hazard Acceleration Response Spectra

Figure 8 shows the mean uniform hazard acceleration response spectra (5%-damped) (UHRS) for the 1/1,000 AEP, 1/2,475 AEP, 1/5,000, and 1/10,000 AEP, respectively. These mean values are for the top of engineering bedrock ground condition (V_{S30} of 849 m/s). Table 9 lists the spectral ordinates for these UHRS.

Figure 9 to Figure 12 show the mean uniform hazard acceleration response spectra (5%-damped) (UHRS) along with the 5th, 15th, 50th (median), 85th, and 95th fractiles for AEPs of 1/1,000, 1/2,475, 1/5,000, and 1/10,000 AEP, respectively. Table 10 to Table 13 list the spectral ordinates for these UHRS for the 1/1,000, 1/2,475, 1/5,000, and 1/10,000 AEP, respectively. These values are for the top of engineering bedrock ground condition with a V_{S30} of 849 m/s.

7.3 Magnitude-distance Deaggregation

Magnitude-distance deaggregation allows identification of earthquake sources that contribute to the total mean hazard at a specified spectral acceleration and AEP. Epsilon (described in Section 3.6) is a parameter of ground-motion uncertainty that further improves the diagnostic capability of magnitude-distance hazard deaggregation. Seismic hazard assessments are concerned with probabilities of exceedance of given ground motions, so the distribution of epsilon greater than zero is important. The magnitude-distance deaggregations are color-coded by epsilon in one-epsilon bins. Selected magnitude-distance deaggregations are plotted in the following figures:

- Figure 13 shows the magnitude-distance deaggregation results of the mean spectral acceleration at PGA, 0.5 s, 1.0 s, and 1.5 s spectral periods for 1/2,475 AEP. This figure represents relative contributions to the total hazard.
- Figure 14 shows the magnitude-distance deaggregation results of the mean spectral acceleration at PGA, 0.5 s, 1.0 s, and 1.5 s spectral periods for 1/10,000 AEP. This figure represents relative contributions to the total hazard.
- Figure 15 shows the magnitude-distance deaggregation results of the mean spectral acceleration at PGA, 0.5 s, 1.0 s, and 1.5 s spectral periods for 1/2,475 AEP. This figure represents relative contribution of the crustal sources located within 400 km of the site.
- Figure 16 shows the magnitude-distance deaggregation results of the mean spectral acceleration at PGA, 0.5 s, 1.0 s, and 1.5 s spectral periods for 1/10,000 AEP. This figure represents relative contribution of the crustal sources located within 400 km of the site.
- Figure 17 shows the magnitude-distance deaggregation results of the mean spectral acceleration at PGA, 0.5 s, 1.0 s, and 1.5 s spectral periods for 1/2,475 AEP. This figure represents relative contribution of the subduction (i.e., interface and in-slab) sources located within 1000 km of the site.
- Figure 18 shows the magnitude-distance deaggregation results of the mean spectral acceleration at PGA, 0.5 s, 1.0 s, and 1.5 s spectral periods for 1/10,000 AEP. This figure represents relative contribution of the subduction (i.e., interface and in-slab) sources located within 1000 km of the site.

The mean and mode of the magnitude-distance joint probability mass distribution is often used for earthquake acceleration time history development. Table 14, Table 15 and Table 16 list the mean, median, and mode of the magnitude, distance, and epsilon values, for the 1/2,475 and 1/10,000 AEPs at PGA, and spectral periods of PGA, 0.5 s, 1.0 s, and 1.5 s, for the total hazard, crustal (within 400 km of the site), and subduction (within 1000 km of the site) sources, respectively.

These results indicate that at AEPs of 1/2,475 and 1/10,000 both crustal earthquakes and subduction interface earthquakes contribute to the total hazard at the Mount Polley TSF site. Subduction earthquakes are the dominant contributor to hazard at periods of about 1 s and longer, while the crustal earthquakes dominate the hazard contributions at the short periods, including at PGA. Appendix A describes how these results were used to develop a representative suite of acceleration time histories suitable for deformation analysis.

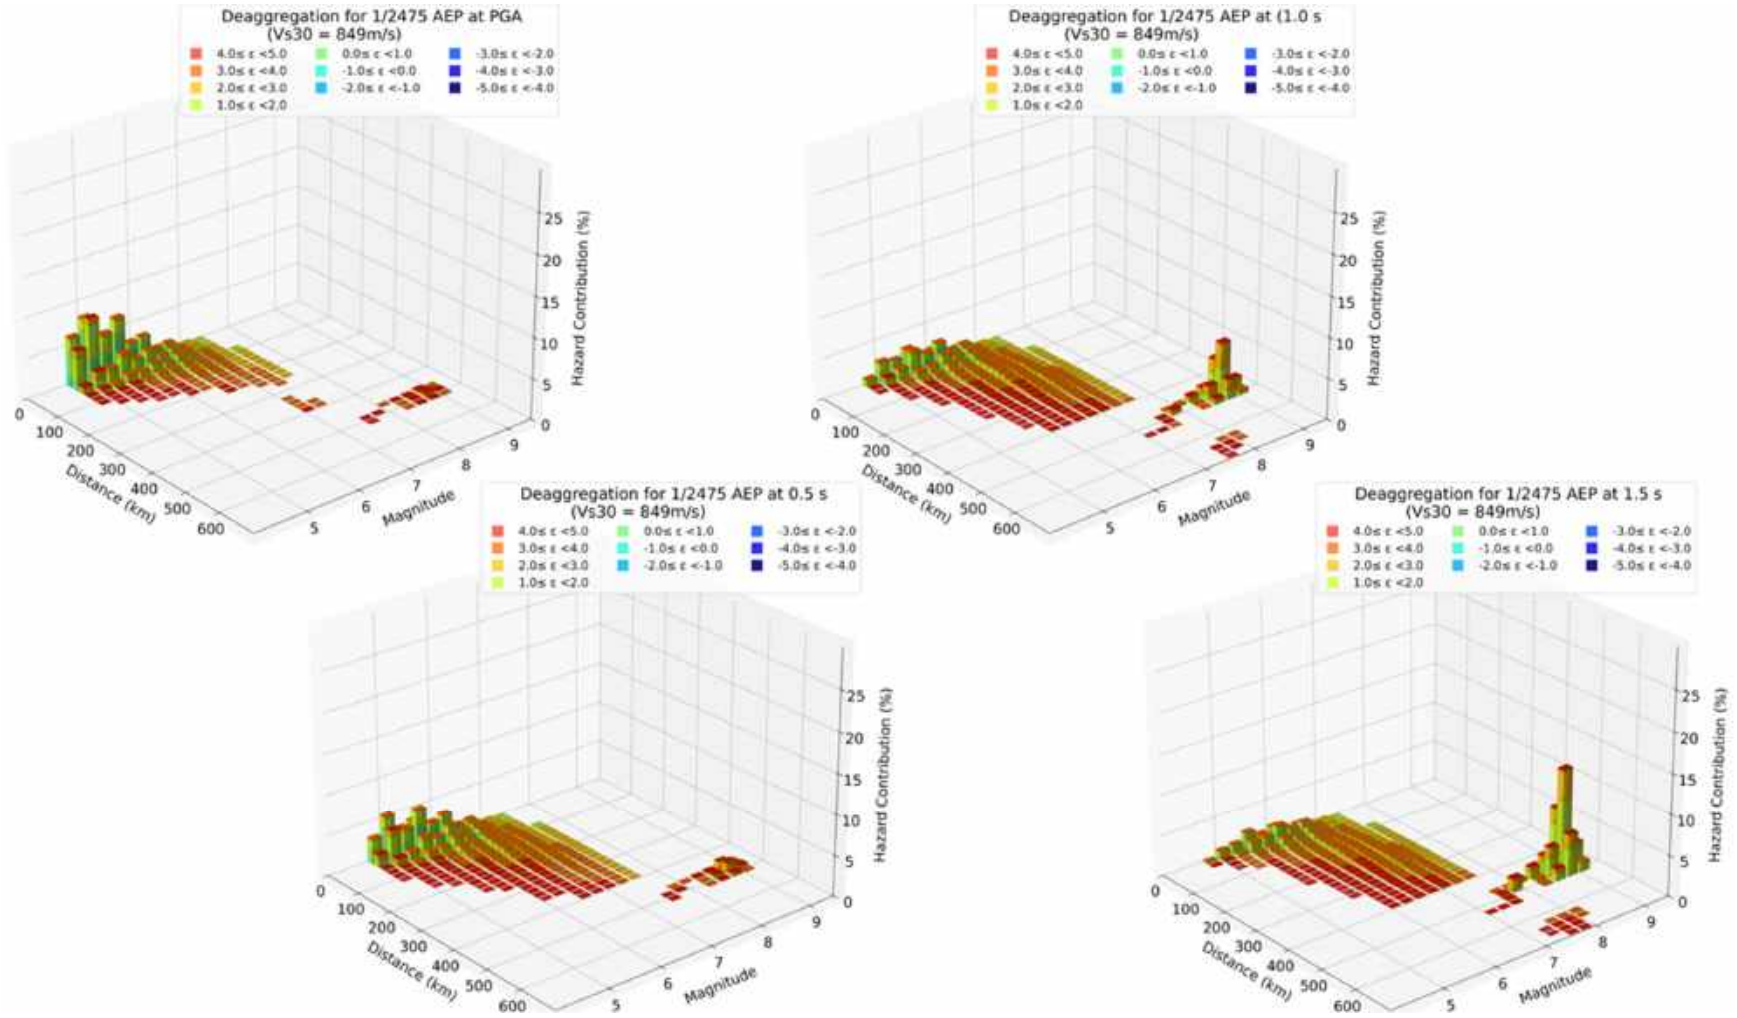

Figure 13: Magnitude-distance deaggregation of the mean PGA (upper left), 0.5 s (lower left), 1.0 s (upper right) and 1.5 s (lower right) spectral periods for the 1/2,475 AEP from full source model, color coded by epsilon in one-epsilon intervals

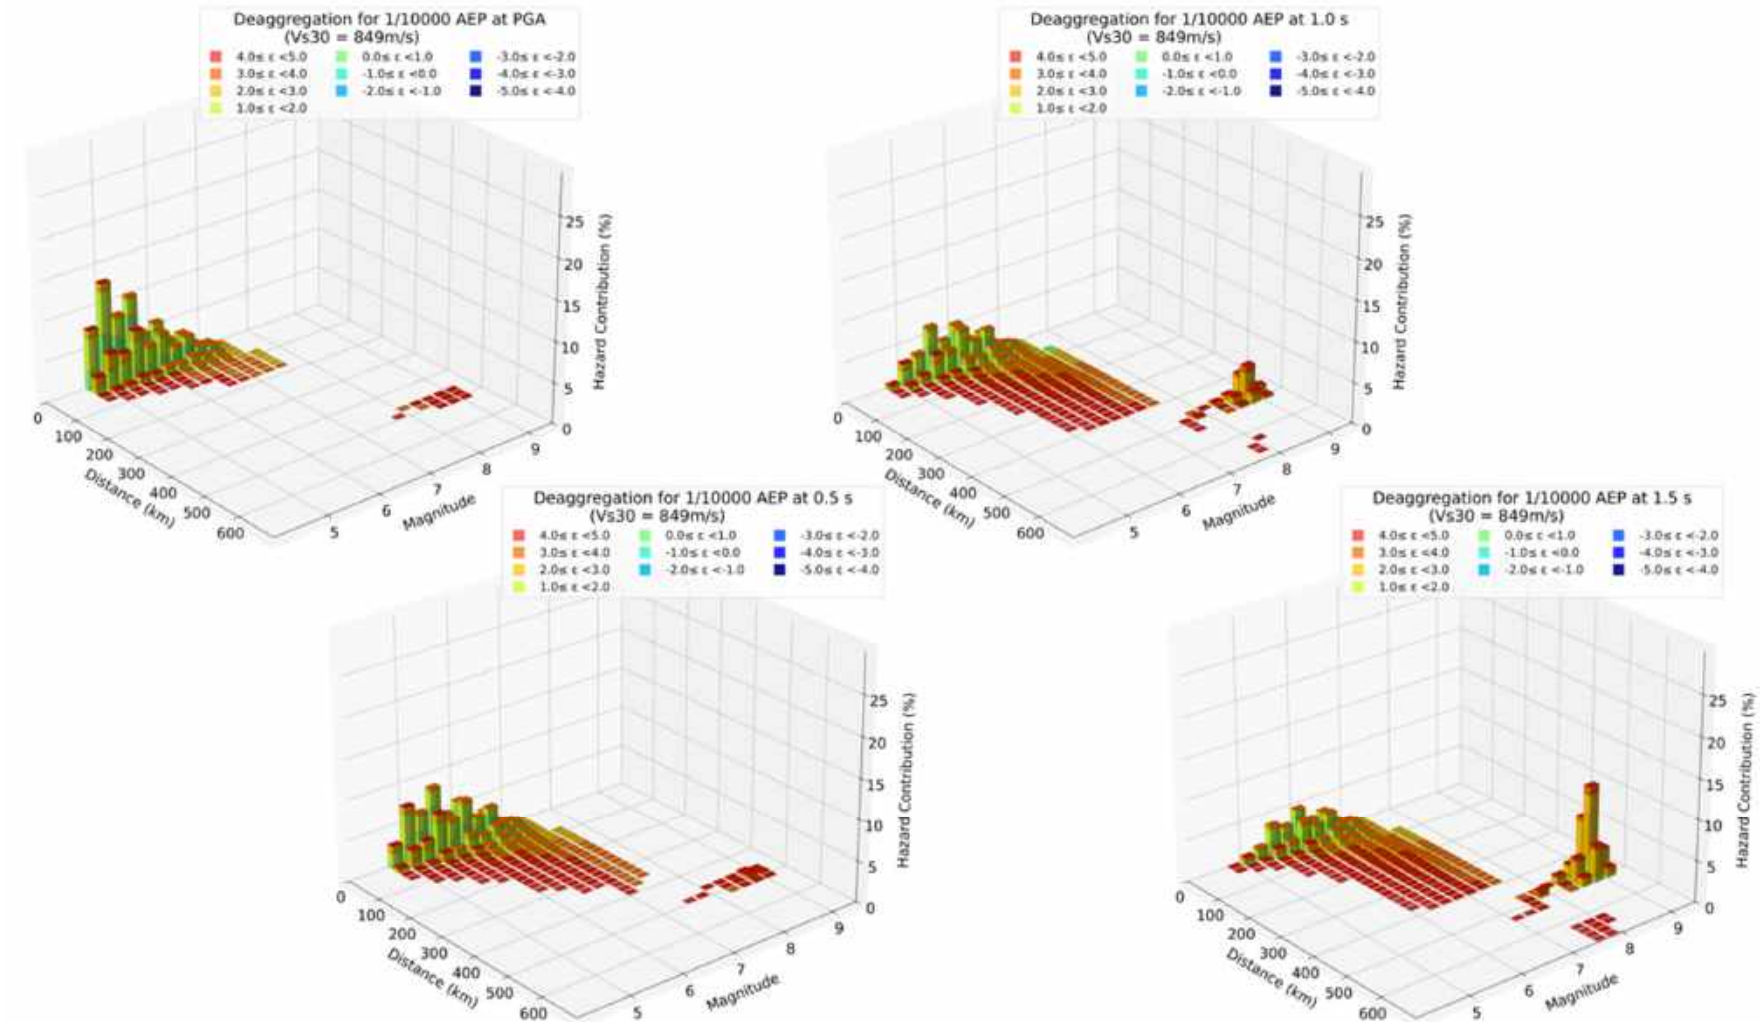

Figure 14: Magnitude-distance deaggregation of the mean PGA (upper left), 0.5 s (lower left), 1.0 s (upper right) and 1.5 s (lower right) spectral periods for the 1/10,000 AEP from full source model, color coded by epsilon in one-epsilon intervals

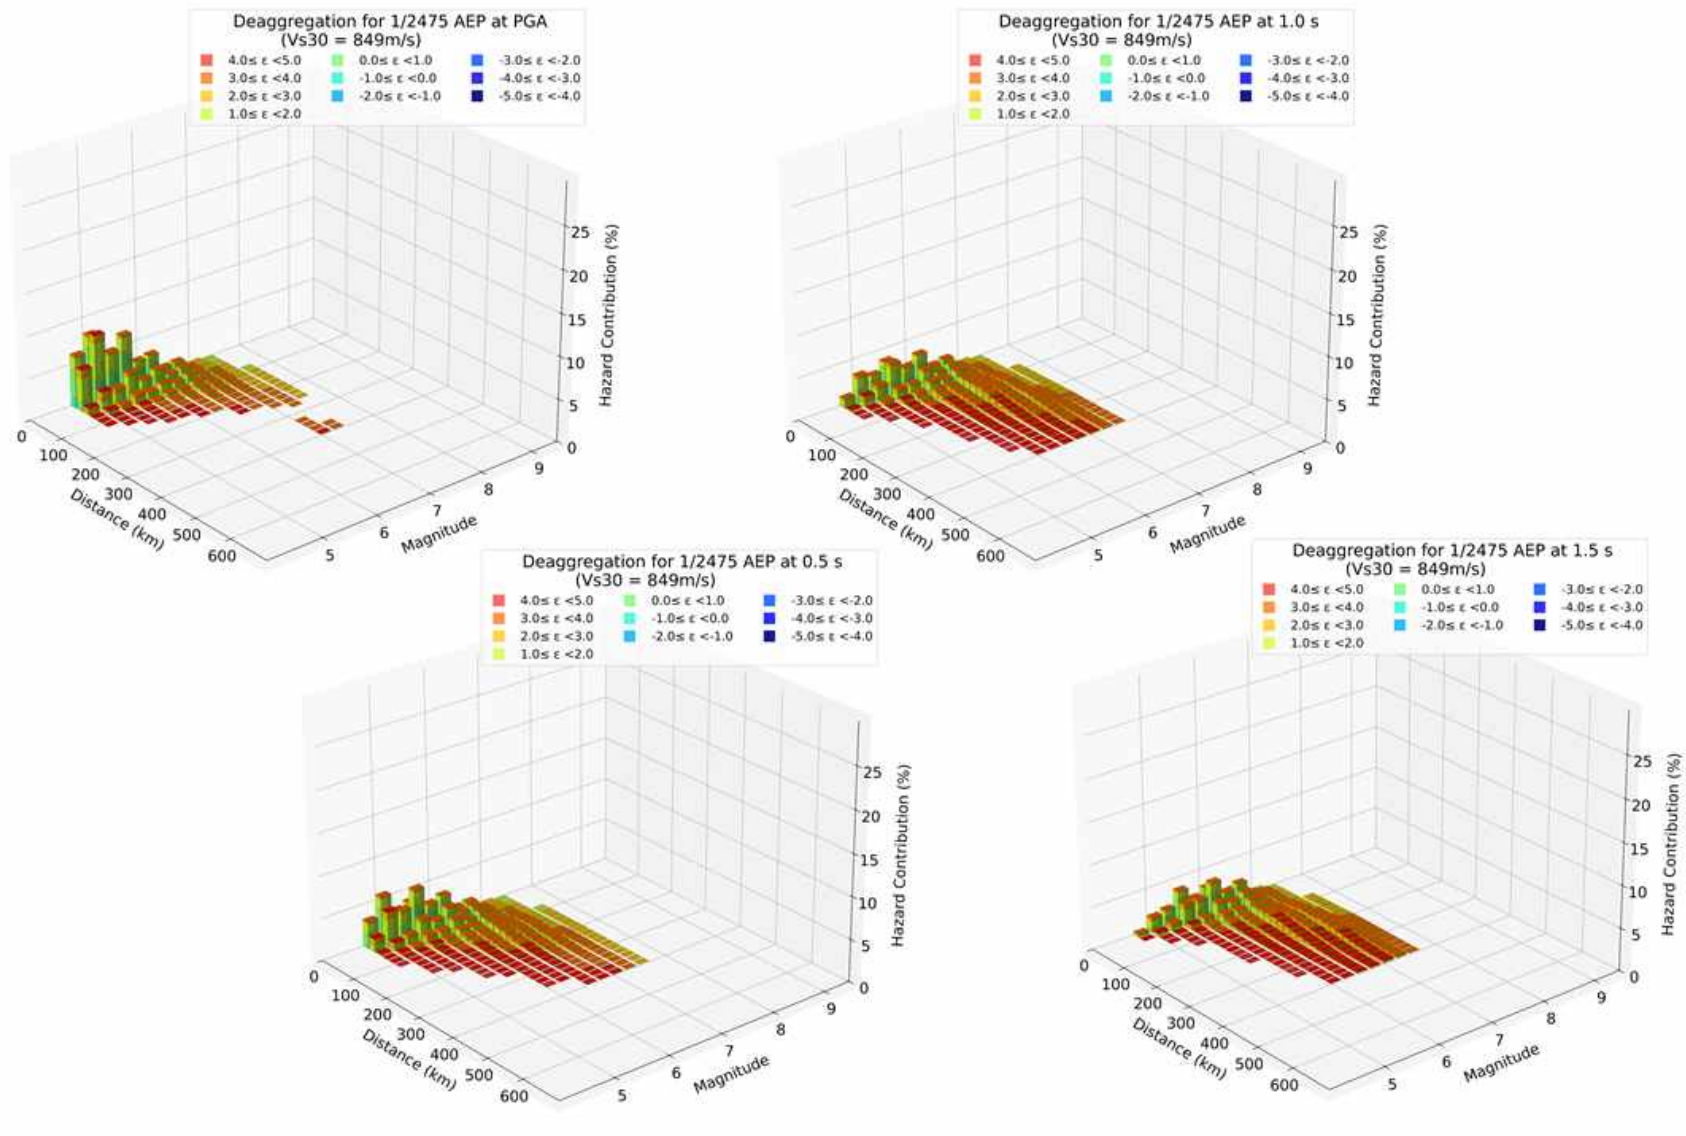

Figure 15: Magnitude-distance deaggregation of the mean PGA (upper left), 0.5 s (lower left), 1.0 s (upper right) and 1.5 s (lower right) spectral periods for the 1/2,475 AEP from crustal sources, color coded by epsilon in one-epsilon intervals

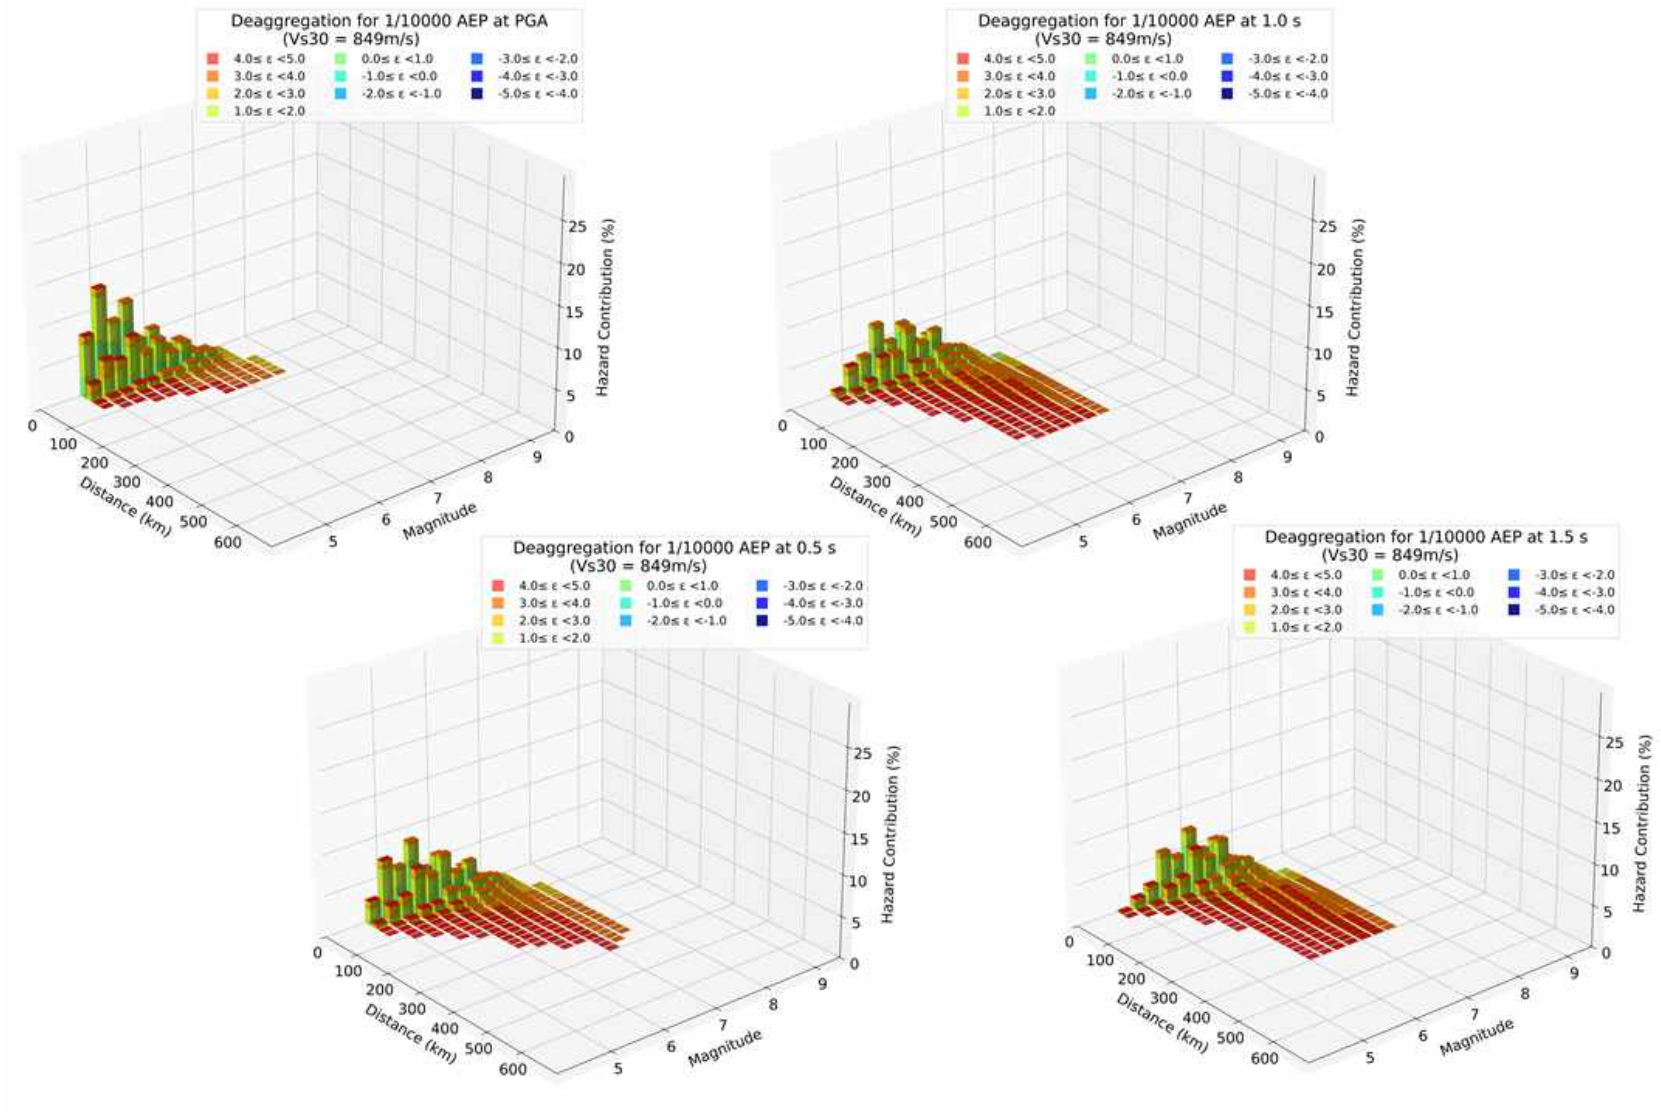

Figure 16: Magnitude-distance deaggregation of the mean PGA (upper left), 0.5 s (lower left), 1.0 s (upper right) and 1.5 s (lower right) spectral periods for the 1/10,000 AEP from crustal sources, color coded by epsilon in one-epsilon intervals

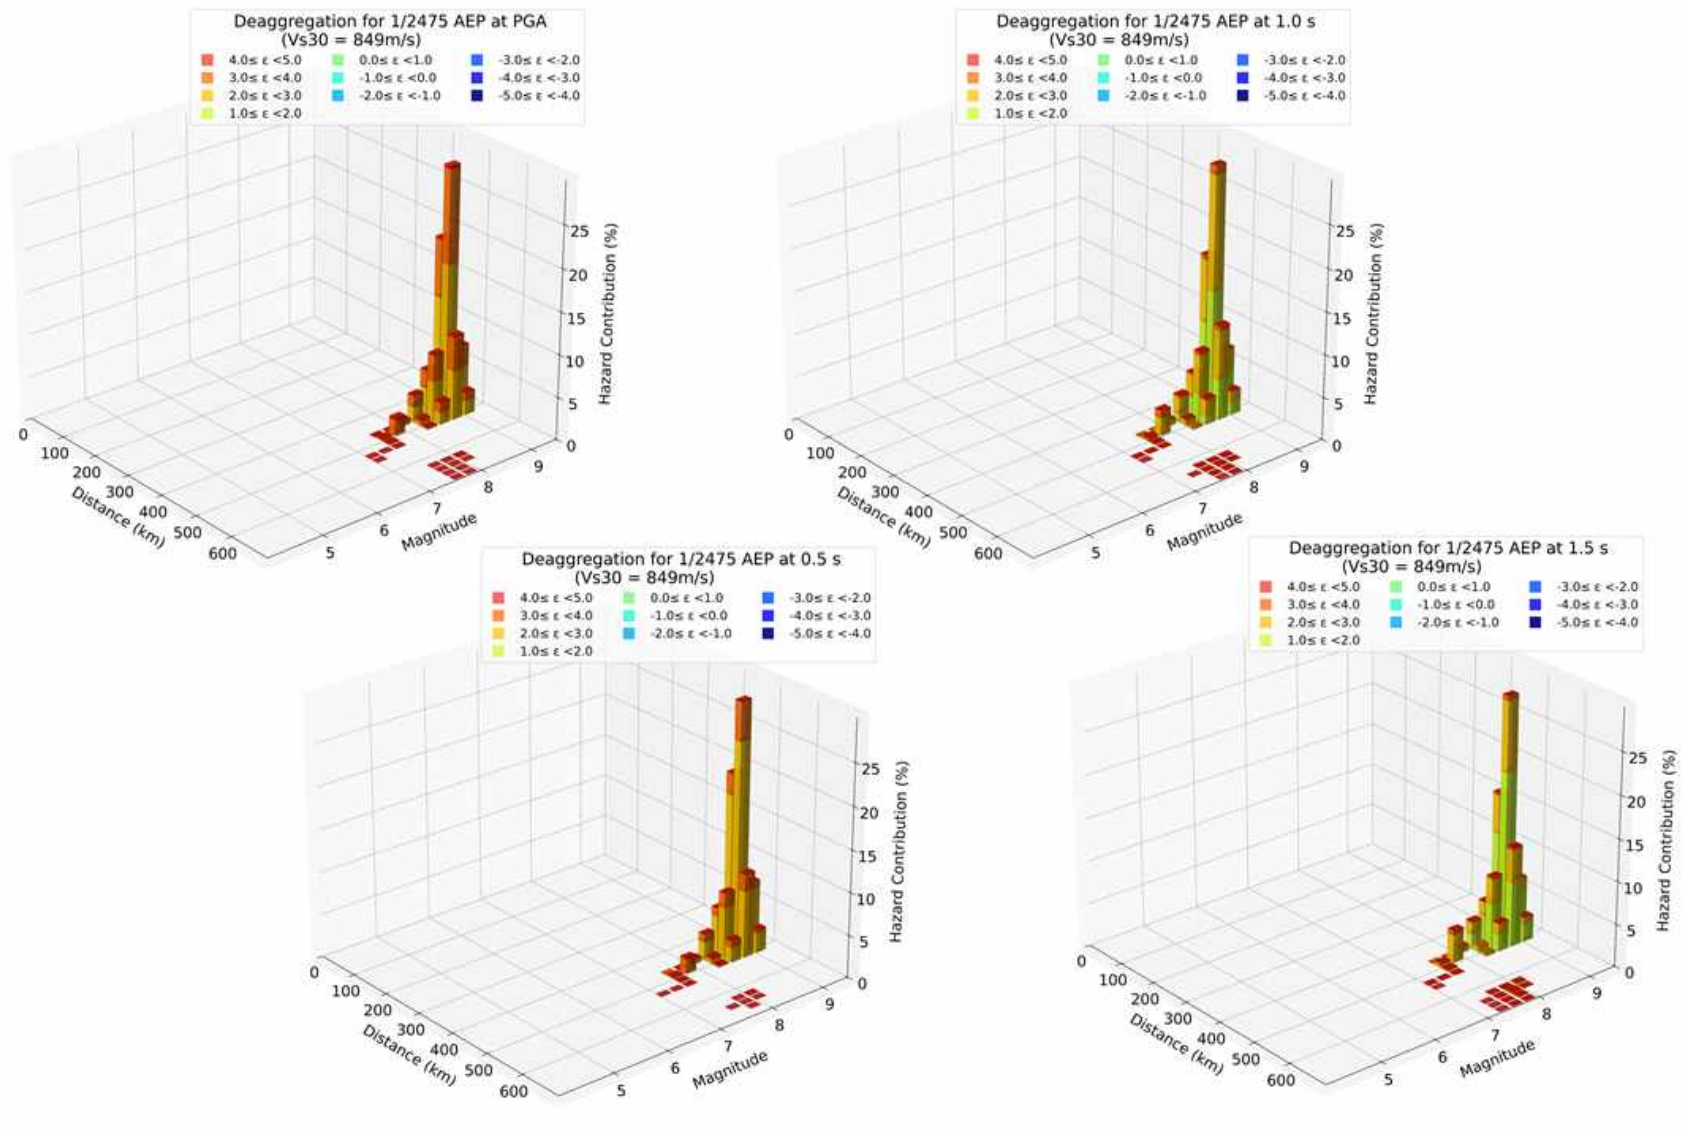

Figure 17: Magnitude-distance deaggregation of the mean PGA (upper left), 0.5 s (lower left), 1.0 s (upper right) and 1.5 s (lower right) spectral periods for the 1/2,475 AEP from subduction sources, color coded by epsilon in one-epsilon intervals

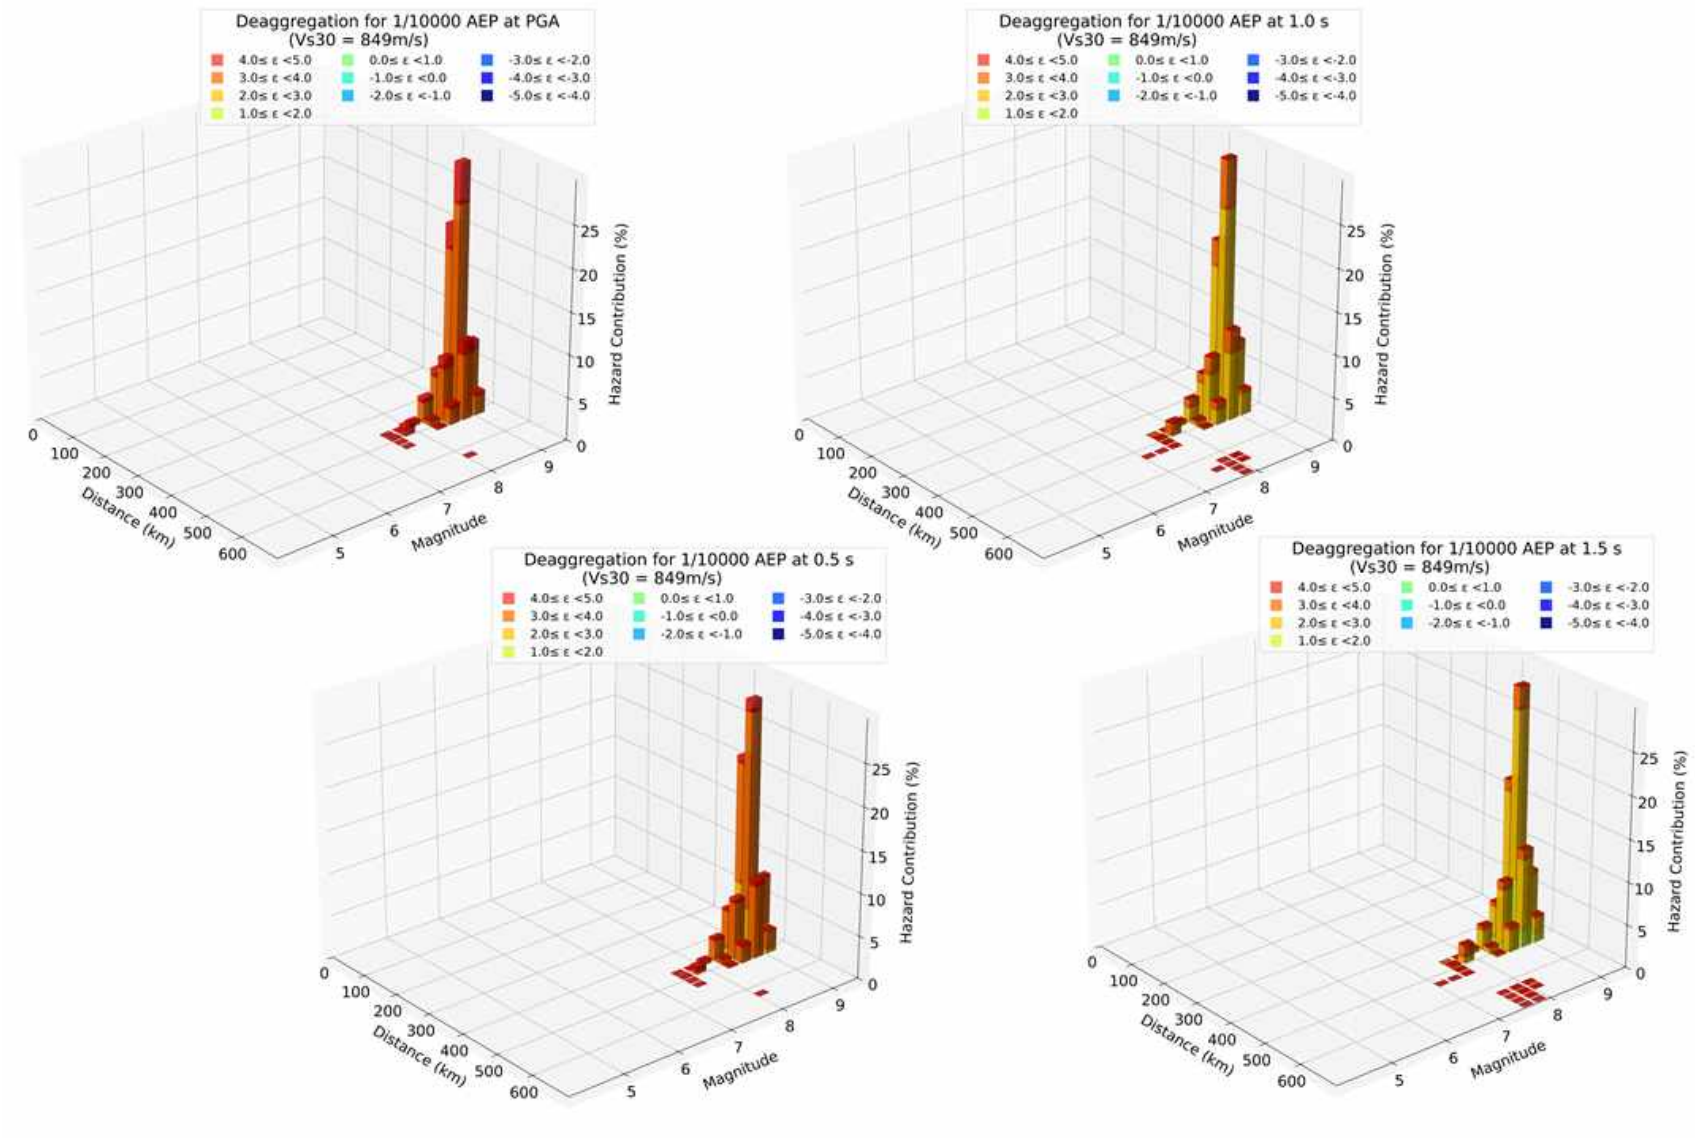

Figure 18: Magnitude-distance deaggregation of the mean PGA (upper left), 0.5 s (lower left), 1.0 s (upper right) and 1.5 s (lower right) spectral periods for the 1/10,000 AEP from subduction sources, color coded by epsilon in one-epsilon intervals

Table 14: Average Distance, Magnitude, and Epsilon for Magnitude-distance Deaggregation for the Total Hazard

AEP	Spectral period (s)	Distance (km)			Magnitude (M_w)			Epsilon[1]		
		Mean	Median	Mode	Mean	Median	Mode	Mean	Median	Mode

Notes:

1. Epsilon values are based on the range of values for the median-distance and median-magnitude.

8.0 SEISMIC HAZARD ANALYSIS: DISCUSSION AND RECOMMENDATIONS

In this section:

- The results of this site-specific seismic hazard assessment are compared to results from the CanadaSHM6
- Earthquake acceleration time history development.

8.1 Comparison of Seismic Hazard Assessment Results to CanadaSHM6

The CanadaSHM6 seismic hazard assessment is not site-specific because it was developed for a national seismic source model and for a series of fixed V_{S30} values. As part of the validation for this assessment (Section 5.3) the CanadaSHM6 results are compared to the results of this assessment at selected AEPs. The results of this site-specific assessment are slightly lower at spectral periods below 2.0 s and slightly higher at spectral periods above 2.0 s. These changes are attributed to the different ground motion model selection and weighting, and V_{S30} used in this assessment.

8.3 Earthquake Acceleration Time History Development

A principal purpose for the site-specific seismic hazard assessment reported here is to support the development of earthquake acceleration time histories. Appendix A presents the data, methods, and results from the development of a suite of 11 two-horizontal-component earthquake acceleration time histories for the Mount Polley TSF site. The 22 EATHs were developed for the site-specific, mean horizontal acceleration response spectrum with an AEP of 1/2,475 years. Electronic files with the developed EATHs were transmitted separately.

9.0 CLOSING

WSP USA appreciates the opportunity to provide WSP Canada with site-specific earthquake hazard assessment for the Mount Polley TSF site. We have applied the best-available science and our understanding of the generally accepted practice in seismic hazard assessment. If you have any questions about the content or use of this report, please contact the undersigned.

EARTHQUAKE ACCELERATION TIME HISTORY DEVELOPMENT FOR MOUNT POLLEY MINE, BRITISH COLUMBIA, CANADA

This technical memorandum (TM) presents a suite of 11 two-horizontal-component earthquake acceleration time histories (EATHs, a.k.a. motions) developed by WSP USA Inc. (WSP USA) for the Mount Polley Mine TSF site in British Columbia, Canada. The 22 EATHs were developed for the target spectrum—the site-specific, mean horizontal acceleration response spectrum with an annual exceedance probability (AEP) of 1/2,475 years as presented in Golder (2022). Electronic files with the developed EATHs were transmitted separately.

1.0 INTRODUCTION

WSP USA developed 11, two-horizontal-component EATHs to support ongoing engineering analyses for the Mount Polley Mine site. WSP USA used the amplitude scaling method to develop the EATHs. The target spectrum is the uniform hazard response spectrum (UHRS) with a 1/2,475 AEP as presented in Golder (2022). The key steps to develop the EATHs were:

- Select seed EATHs that have similar spectral shape to the target spectrum.
- Apply the amplitude scaling method to adjust seed records to match the target spectrum.
- Compare the geometric-mean spectrum of the scaled EATHs to the target spectrum.
- Select a suite of eleven, two-component EATHs suitable for subsequent analyses at the Mount Polley Mine site.
- Prepare this TM to document the approach, procedures, and results.

Figure 1 shows the site-specific mean acceleration response spectrum (i.e., the target spectrum) for an AEP of 1/2,475 as presented in Golder (2022).

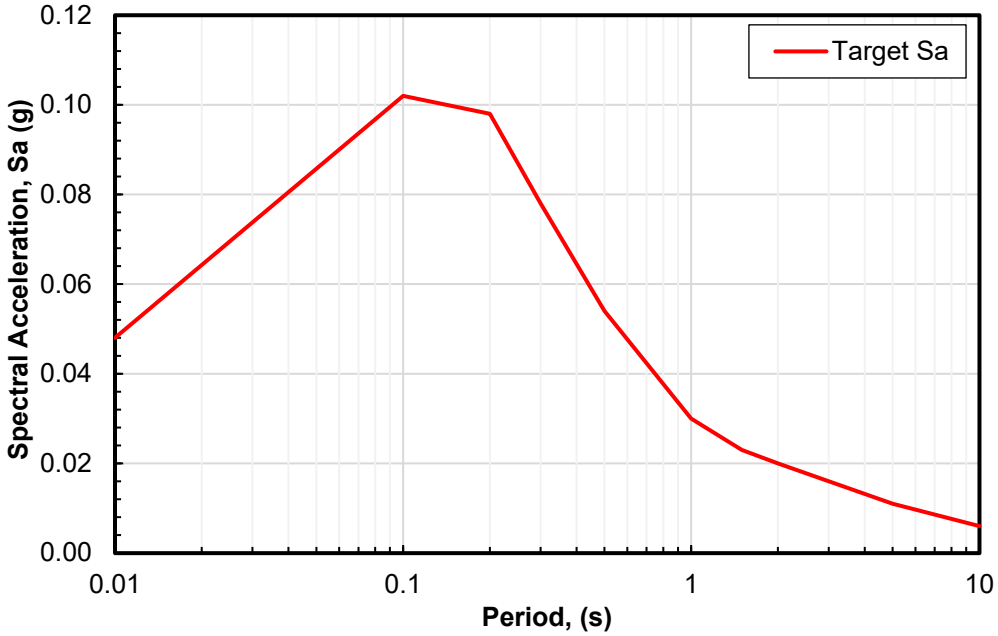

Figure 1: Site-Specific Target Acceleration Response Spectrum for an Annual Exceedance Probability (AEP) of 1/2,475 for Mt Polley TSF Site

2.0 EARTHQUAKE ACCELERATION TIME HISTORY DEVELOPMENT

The following sections describe the EATH selection criteria, process to scale the records, and the resulting EATHs.

2.1 Selection Criteria

WSP USA selected seed EATHs from the Pacific Earthquake Engineering Research Center (PEER) Next Generation Attenuation Phase 2 Project (NGA-West2) strong-motion database. Typical time history selection criteria included earthquake magnitude, source-to-site distance, style of faulting, rupture directivity, and near-surface ground condition at the recording station.

Key EATH selection criteria were:

- Earthquake records should reflect both the near-field moderate-magnitude crustal earthquakes and the far-field subduction interface earthquakes as indicated by the deaggregation analysis. WSP USA judged that eight two-component records from near-field crustal earthquakes and three two-component subduction earthquakes provided a reasonable representation of the 1/2,475 AEP hazard sources.
- Source earthquakes are of moment magnitude (**M**) 5.5 to 6.5 centered at about **M**6.0 that is the preferred modal magnitude in Golder (2022) for crustal motions. The magnitude criterion was relaxed to **M**5.5 to include more seed EATHs. For subduction interface motions, source earthquakes are of **M**8.0 to **M**9.5 centered at **M**9.0.

- Seed EATHs were recorded at stations less than 50 km for the source earthquake for crustal motions and less than 500 km for subduction interface motions.
- Seed EATHs recorded at stations with a V_{S30} (i.e., the time-averaged shear-wave velocity for the top 30 m of earth materials below the ground or reference surface) from 360 to 1500 m/s assuming the site V_{S30} of interest is 849 m/s.
- The shape of the acceleration response spectra of the seed EATHs agrees well with the shape of the target spectrum within the period range of interest of 0.5 to 1.5 seconds, which covers the estimated fundamental period of 1 second for the facility of interest.
- Scaling factors for the seed EATHs are preferred to be between 0.25 and 4.
- No more than two seed EATHs are from the same earthquake.
- No EATHs with velocity pulses were included because the site is more than 10 km away from a known seismically active fault.
- The style-of-faulting criterion was relaxed to include all fault rupture styles.

2.2 Results

The 11 EATHs were selected that meet the selection criteria described above. Figures 2 and 3 show the geometric-mean acceleration response spectrum of the selected and scaled EATHs for crustal and subduction interface motions, respectively, compared with the target response spectrum and 90% and 130% of the target (i.e., -10% and +30% of the target). Typical practice in earthquake geotechnical engineering requires the geometric-mean response spectrum to be within about 90% to 130% of the target response spectrum within the period range of interest (Figure 2).

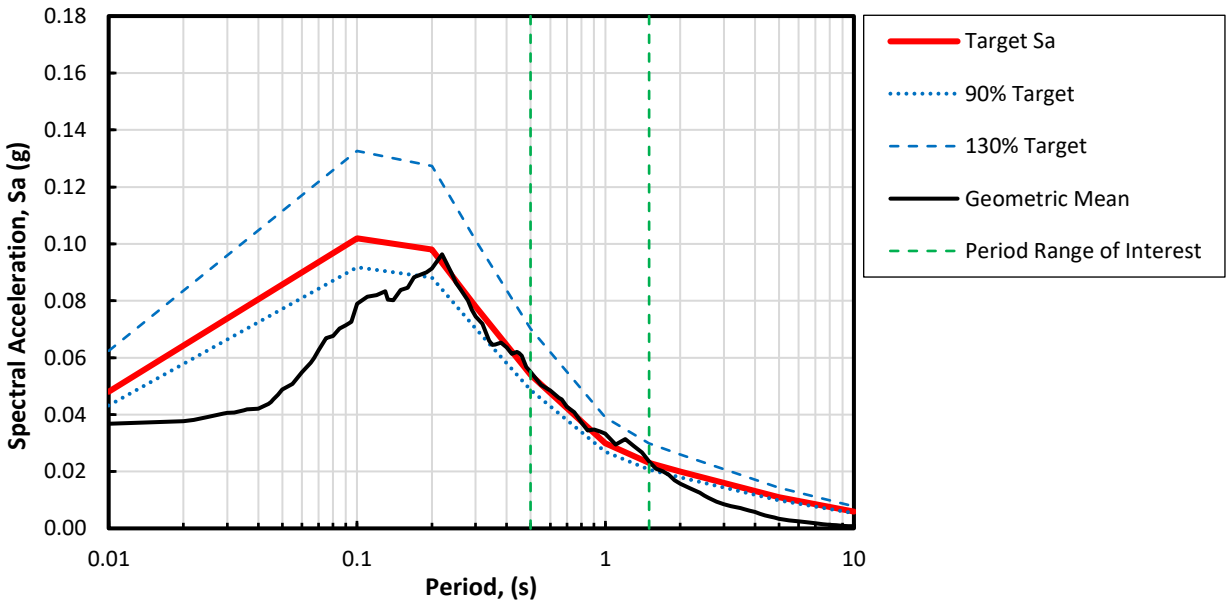

Figure 2: Target Acceleration Response Spectrum and the Geometric-Mean Response Spectrum of Selected and Scaled Crustal Earthquake Acceleration Time Histories

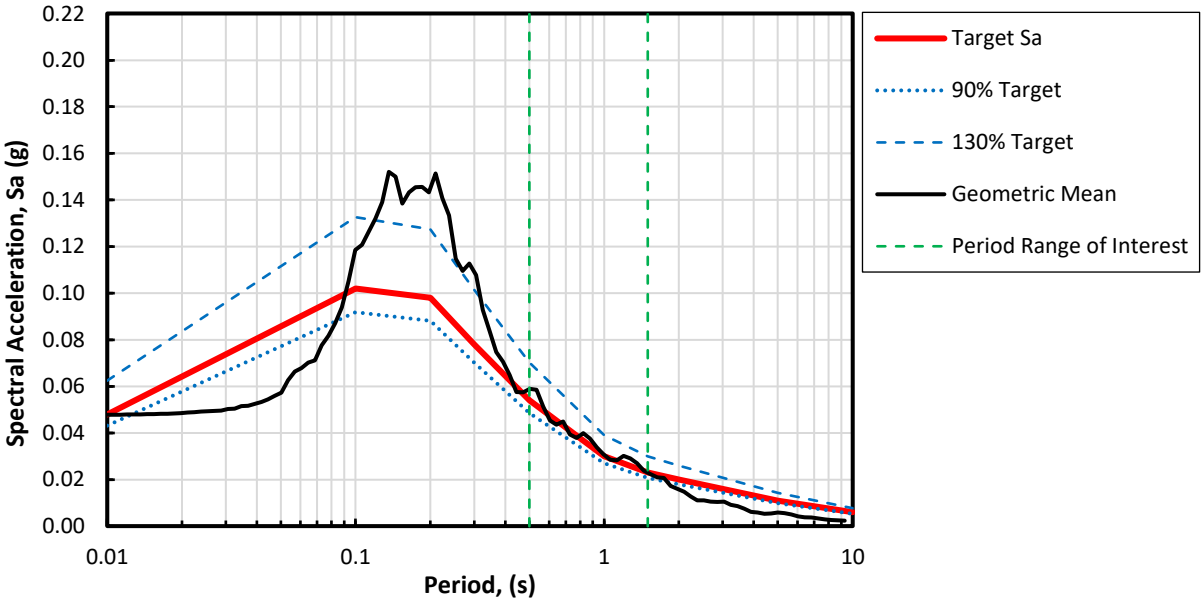

Figure 3: Target Acceleration Response Spectrum and the Geometric-Mean Response Spectrum of Selected and Scaled Interface Earthquake Acceleration Time Histories

Figures 4 and 5 show the response spectra of individual scaled EATHs compared with the target spectrum for both crustal and subduction interface motions. Figures 4 and 5 show that the individual response spectra agree reasonably well with the target. Table 1 lists key parameters of the selected and scaled EATHs.

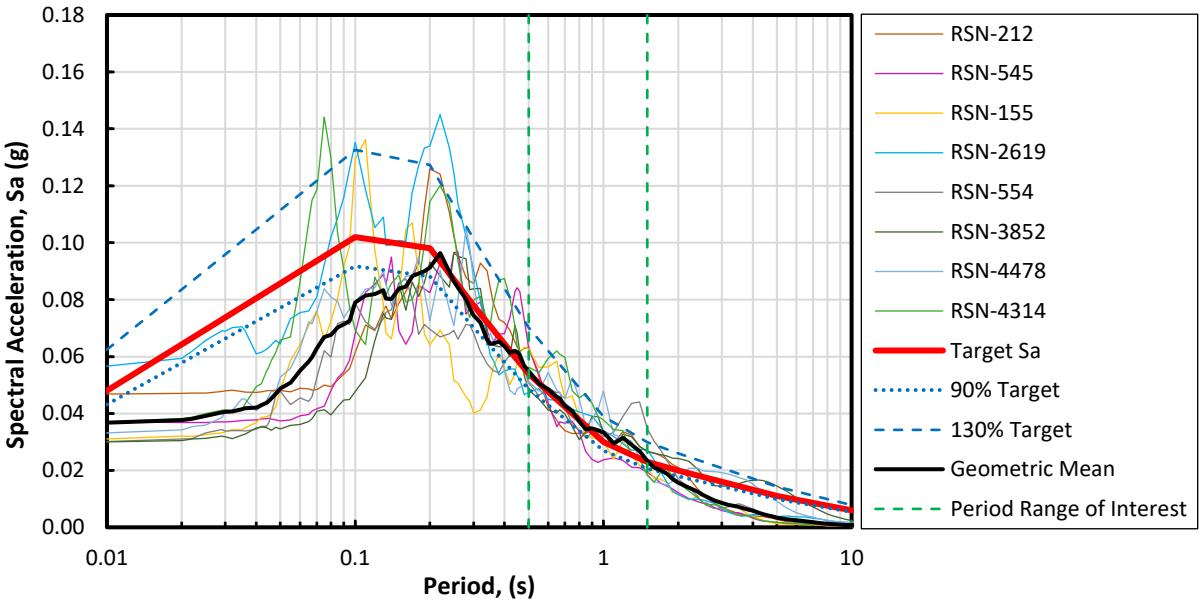

Figure 4: Target Acceleration Response Spectrum and Response Spectra of Individual Crustal Earthquake Acceleration Time Histories

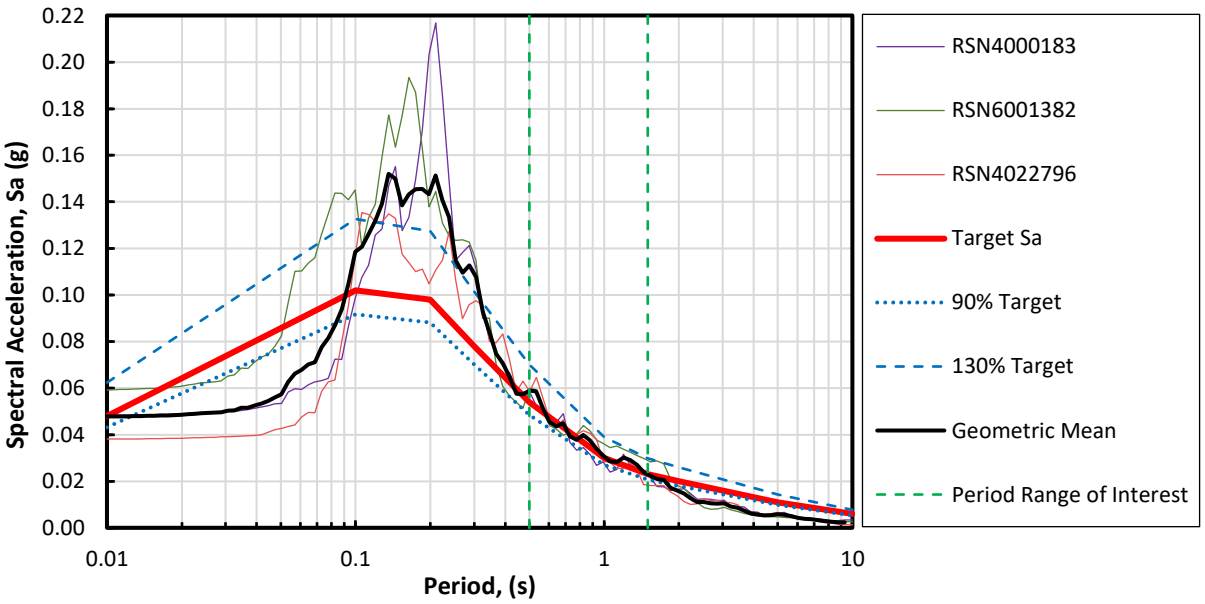

Figure 5: Target Acceleration Response Spectrum and Response Spectra of Individual Subduction Interface Earthquake Acceleration Time Histories

Table 1: Key Parameters of Selected and Scaled Earthquake Acceleration Time Histories

Record Sequence Number (RSN)[a]	Moment Magnitude (M)	Earthquake Name	Year	Station Name	Scale Factor	R_{rup}[b] (km)	R_{jb}[c] (km)	V_{S30}[d] (m/s)	Fault Type	Component	D_{5-75} (s)[e]	D_{5-95} (s)[f]	AI[g] (m/s)	CAV[h] (m/s)

a. The record sequence number is assigned to individual records in the PEER NGA-West2 database.
b. R_{rup} = closest distance to fault rupture.
c. R_{jb} = closest horizontal distance to the surface projection of the surface fault rupture.
d. V_{s30} = the time-averaged shear-wave velocity for the upper 30 m of earth materials below the ground surface.
e. D_{5-75} = significant duration; the time between 5% and 75% of the cumulative Arias intensity.
f. D_{5-95} = significant duration; the time between 5% and 95% of the cumulative Arias intensity.
g. AI = Arias intensity
h. CAV = cumulative absolute velocity

Earthquake magnitude and source-to-site distance are causal parameters that are indirect measures of the source and travel path characteristics of the selected EATHs. Direct intensity measures, including significant durations (e.g., D_{5-75}), CAV, and AI were compared to predictions from the empirical relations listed in Tables 2 and 3. The predicted intensity measures were calculated for a representative earthquake scenario as listed in Tables 2 and 3. The target scenarios for crustal and subduction interface earthquakes were based on the deaggregation results for the period range of interest from Golder (2022). We used the mode magnitude and mode distance from the deaggregation results.

Table 2: Predicted Intensity Measures from Empirical Relations for a Selected Representative Crustal Earthquake Scenario

Empirical Relation Source	Intensity Measure	Median	16th Percentile	84th Percentile	Closet Distance to Rupture, R_{rup} (km)	Moment Magnitude (M)
Bommer et al. (2009)	D_{5-75}[a] (s)	4	3	7	20	6.0
	D_{5-95}[b] (s)	9	6	15		
Macedo et al. (2021)	CAV[c] (m/s)	1.0	0.7	1.4		
Abrahamson et al. (2016)	AI[d] (m/s)	0.023	0.016	0.034	-	

a. D_{5-75} = significant duration; the time between 5% and 75% of the total energy
b. D_{5-95} = significant duration; the time between 5% and 95% of the total energy
c. CAV = cumulative absolute velocity
d. AI = Arias intensity

Table 3: Predicted Intensity Measures Using Empirical Relations for a Selected Representative Subduction Interface Earthquake Scenario

Empirical Relation	Intensity Measure	Median	16th Percentile	84th Percentile	Closet Distance to Rupture, R_{rup} (km)	Moment Magnitude (M)
Macedo et al. (2019)	CAV[a] (m/s)	6.5	4.9	8.5	450	9
Liu and Macedo (2022)	AI[b] (m/s)	0.12	0.09	0.18		

a. CAV = cumulative absolute velocity
b. AI = Arias intensity

Figures 6 and 7 are comparisons of the intensity measures of the scaled EATHs to the predicted intensity measures. Comparison of the intensity measures of the scaled EATHs to the predicted intensity measures indicates that the D_{5-75}, D_{5-95}, CAV, and AI of the scaled EATHs are generally within the 16th and 84th percentile range of the empirically predicted values. Figures 6 and 7 show that the CAVs of the selected and scaled motions meet the target reasonably well, whereas the AIs are relatively less than the corresponding empirically based targets for both crustal and subduction interface records. It is almost always challenging to meet all four direct measures satisfactorily. For the Mt Polley TSF site, we consider that meeting the CAV criterion is more important than meeting the AI criterion. This is because CAV was observed to correlate better to durations than AI and can potentially be a more efficient intensity measure for predicting ground deformation that depends on the number of shaking cycles above some acceleration threshold (Macedo et al. 2021).

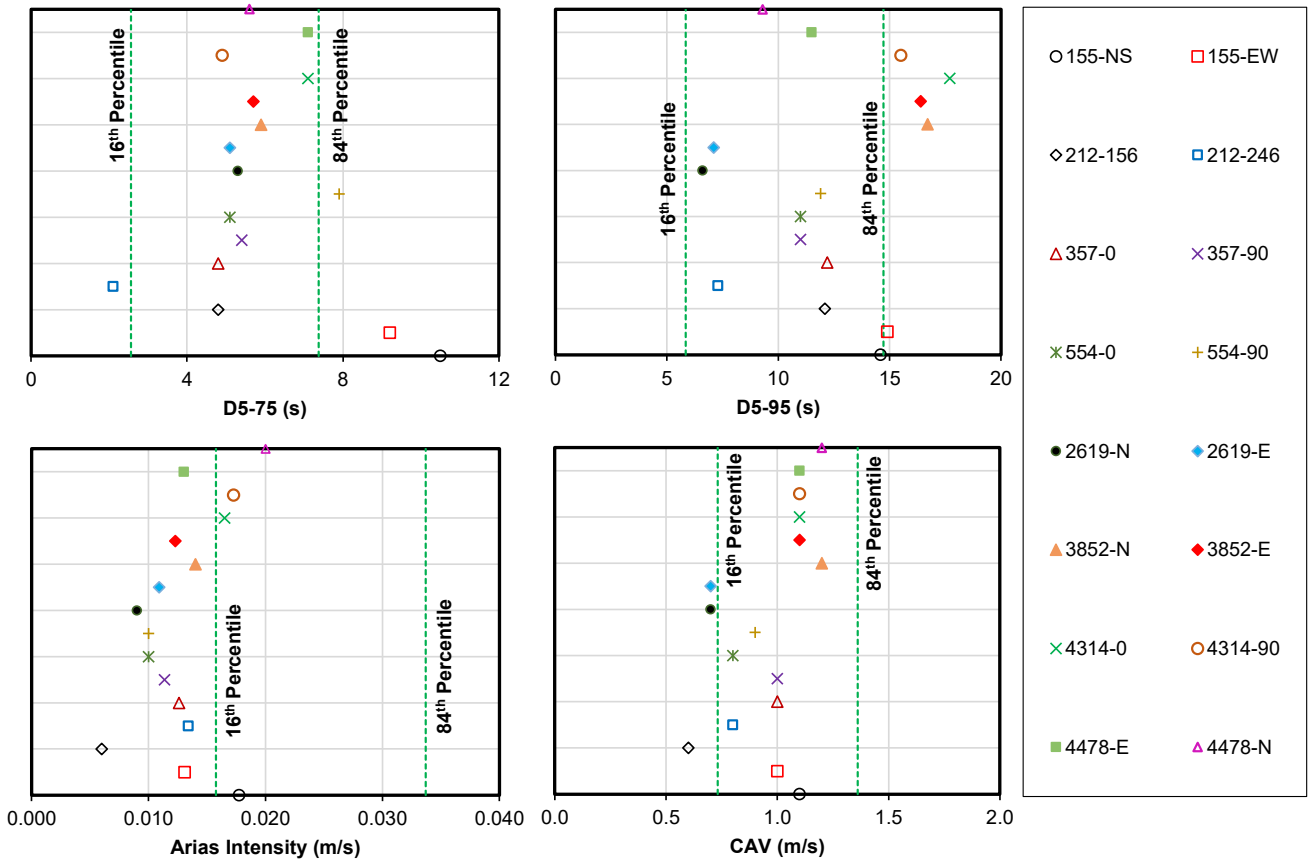

Figure 6: Comparison of Direct Intensity Measures of Selected Scaled Crustal Motions to Predictions Using Empirical Relations for the Mean 1/2,475 AEP Target Spectrum

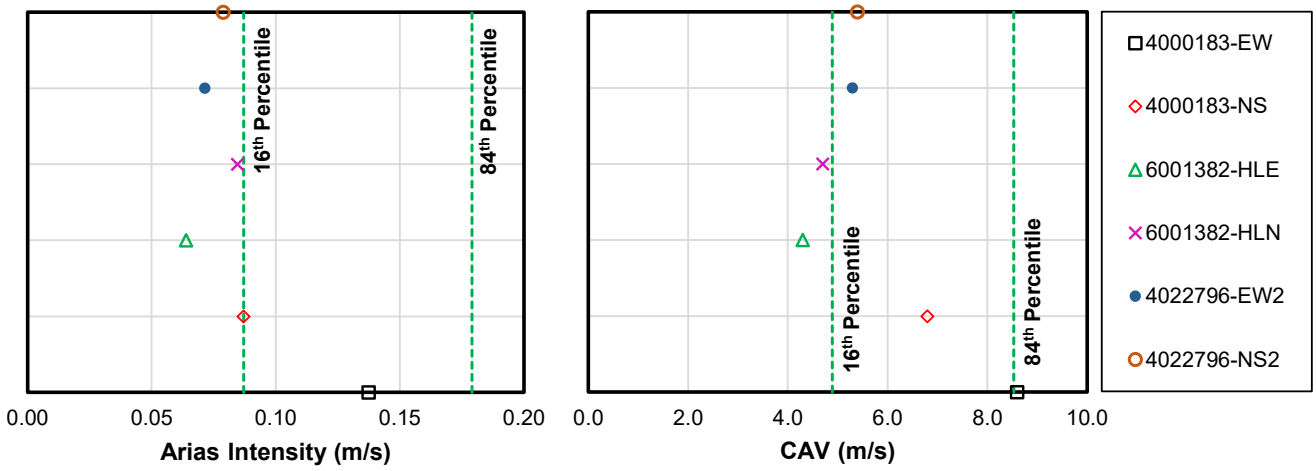

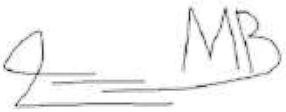

Figure 7: Comparison of Direct Intensity Measures of Selected Scaled Subduction Interface Motions to Predictions Using Empirical Relations for the Mean 1/2,475 AEP Target Spectrum

3.0 LIMITATIONS

Eleven two-horizontal-component EATHs were developed using amplitude scaling to support ongoing engineering analyses for the Mount Polley TSF site in British Columbia, Canada. These EATHs were developed specifically to address the conditions and requirements at the Mount Polley TSF site. They should not be used for other sites or projects without prior review and authorization by WSP USA.

The CAVs of the selected and scaled motions meet the target reasonably well, whereas the AIs are relatively lower than the corresponding target. For this project site, we assumed CAV is better related to the performance of the structure of interest, and hence consider the selected and scaled motions are acceptable. If subsequent analysis shows that this assumption is incorrect, then WSP USA recommends re-evaluation and reselection of the motions, if required.

APPENDIX B

Evaluation of the Time-Average Shear-Wave Velocity

Memorandum

To	Alan Hull
Copy	Erin Todd
From	Matt Harris
Office	Auckland
Date	20 June 2022
File/Ref	6-DY039.00
Subject	Mt Polley VSP Reanalysis and V_{S30} Discussion

Introduction

This memo presents the results of reanalysis of VSP data from three boreholes at the tailings storage facility, Mount Polley Mine, BC Canada. The VSP measurements were originally presented in Technical Memorandum 22514095-040-TM-RevA-51344, dated 10 June 2022.

Approach to Reanalysis

Reanalysis focussed on BH15-10, as this had the deepest penetration, and is the only borehole that penetrated 30 m into material classified as bedrock. A number of approaches were taken to determination of V_{S30} for bedrock, using both the original and revised picks of shear-wave arrivals. The results are presented in Table 1 below, listed in order of reducing confidence. Based on a weighted average these velocities, the V_{S30} for bedrock at BH15-10 is considered to be 849 +/- 33 m/s.

Table 1: Summary of V_{S30} of bedrock from reanalysis of BH15-10 VSP data

Approach to Analysis	V_{S30} from Revised picks (m/s)	V_{S30} from Original picks (m/s)
Revised layer model	857	865
Initial layer model	826	877
Single layer method	852	864
1 m Interval Velocities (defined by 3-point regression)	831	850
1 m Interval Velocities (defined by 5-point regression)	864	890
1 m Interval Velocities (defined by successive arrival times)	820	873

The presented velocities were derived as follows:

Level 3 The Westhaven
100 Beaumont St
Auckland 1010, New Zealand
+64 9 355 9500
wsp.com/nz

150 YEARS IN AOTEAROA

- Revised layer model - the velocity of each layer was calculated based on a linear regression of the vertical component of arrival times within that layer. Assignment of layer boundaries revised during reanalysis, based on slope breaks on a plot of arrival time against depth. V_{S30} calculated as the traveltime-weighted average shear wave velocity from 31.8 m to 61.8 m.
- Initial layer model – As above, without reassignment of layer boundaries.
- Single layer method - An estimate of V_{S30} obtained by assuming a single "layer" over 30 metres from top of bedrock. Based on picks at 31.8 m and 62.5 m depth.
- 1 m Interval Velocities (defined by 3-point regression) - traveltime-weighted average shear wave velocity from 31.8 m to 61.8 m, using 1 m layers with layer velocities derived from a 3-point linear regression of the slope of vertical traveltime data.
- 1 m Interval Velocities (defined by 5-point regression) - traveltime-weighted average shear wave velocity from 31.8 m to 61.8 m, using 1 m layers with layer velocities derived from a 5-point linear regression of the slope of vertical traveltime data.
- 1 m Interval Velocities (defined by successive arrival times) - traveltime-weighted average shear wave velocity from 31.8 m to 61.8 m, using 1 m layers with layer velocities derived from successive shear-wave arrival picks.

The shear-wave arrivals at 31.8 m and 62.5 m in BH15-10 are well defined. These are useful for assessing the travel time of the shear wave through the upper 30 m of material defined as bedrock, using the 'single layer' method of Hunter and Crow (2012). To assess the likely minimum and maximum V_{S30} using this method, both arrivals were picked as early and late as considered reasonable, and results compared. Based on this approach, estimated extreme minimum and maximum V_{S30} for bedrock at this borehole location are 706 m/s and 981 m/s, respectively.

Summary of Results

At borehole BH15-10, which penetrated into bedrock, V_{S30} is considered to be 849 +/- 33 m/s based on reanalysis of available VSP data. Extreme minimum and maximum V_{S30} for bedrock at BH15-10 are estimated at 706 m/s and 981 m/s, respectively.

Borehole BH15-18 only penetrated 6 m into bedrock, though showed good data quality; V_S of the upper bedrock here is considered to be 523 +/- 59 m/s. For comparison, V_S of the upper 6 m of bedrock at BH15-10 is considered to be 643 +/- 51 m/s.

At BH15-06, signal quality is poor, though estimated V_S values for the upper 10 m to 15 m of bedrock were made as roughly 350 m/s to 600 m/s.

Considerations/Data Quality

The data quality is rather variable between the three boreholes, which influences the confidence that can be attributed to each. The signal quality is best at BH15-18, though penetration into bedrock here is only around 6 m.

Signal quality at BH15-10 is considered reasonably good, and worthy of thorough analysis as this borehole penetrates over 30 m into material identified as bedrock.

At BH15-06, signal quality is poor and clear shear-wave arrivals are not able to be identified with confidence at most traces. Any velocities determined here should be treated with caution. Detailed reanalysis of this borehole has not been performed. The high V_S (up to 2820 m/s) initially reported for this borehole seems to be influenced by data quality. Single layer estimates within bedrock suggest V_S values for the upper 10 m to 15 m of bedrock here may be roughly 350 m/s to 600 m/s.

The interpretation of bedrock depths has not been changed. It should be appreciated though that the contrast between bedrock and overlying material at the site is subtle and has been noted as "pretty variable and hard to define".

During the reanalysis, discussed the data and data quality with Rob Luzitano, who performed the initial data analysis. He noted that the boreholes that were used for testing were originally installed in 2015, for use with inclinometers. This meant they were cased with PVC of a suitable diameter, though the approach taken to grouting was unknown. There may therefore be some areas where poor bonding between casing and grout has impacted data quality.

Data was not acquired at every ~1 m (3 foot) interval, as the crew on site were under time pressure during acquisition. At BH15-06 there is 3.5 m below the deepest two recorded intervals. The arrival on the lowest record is indistinct, so additional data here would have been useful.

Particularly high velocities are noted at shallow depth at BH15-06. While not repicked, note that these velocities are based on a small number of ambiguous picks and therefore considered unreliable.

Closure

I trust that this memo meets your needs. If you have any questions regarding the material contained within, please contact the undersigned.

Matt Harris

Senior Geophysicist

Geophysical Services Limitation Statement

WSP geophysical services are conducted in a manner consistent with the level of care and skill ordinarily exercised by other members of the geophysical community currently practicing under similar conditions and subject to the time limits, financial and physical constraints applicable to the services.

The inherent uncertainty in geophysical results should be considered during the interpretation process. To help reduce uncertainties in the interpretation, the interpreter will typically make use of prior knowledge and any external complementary datasets, such as existing geologic information, drilling data, the location of underground services, borehole geophysical logs and other geophysical datasets.

Functioning monitoring wells installed around the TSF.

Table C4 (b): Summary of Wireline Packer Test Results (IMC 1990 - Table 4-14)

TABLE 4-14
IMPERIAL METALS CORPORATION
MT. POLLEY PROJECT

TAILINGS AREA B SITE INVESTIGATION
SUMMARY OF WIRELINE PACKER PERMEABILITY TEST RESULTS

Hole No.	Depth Interval (m)	Permeability (cm/s)	Material Description
MP89-231	9 to 12	6.4×10^{-6}	Overburden
	30 to 37	1.6×10^{-6}	Soft Volcanics
	37 to 43	2.9×10^{-7}	Competent Rock
MP89-232	15 to 18	7.7×10^{-6}	Overburden
	32 to 37	3.2×10^{-6}	Fractured Volcanics
	43 to 46	1.0×10^{-5}	Competent Rock
MP89-233	12 to 18	1.1×10^{-5}	Overburden
	30 to 37	2.2×10^{-5}	Soft Rock
	37 to 46	1.6×10^{-5}	Broken Rock
	49 to 55	1.7×10^{-5}	
MP89-234	6 to 12	1.4×10^{-5}	Overburden
	30 to 37	3.2×10^{-7}	Competent Bedrock
	46 to 49	3.3×10^{-6}	Competent Bedrock
MP89-235	6 to 12	5.1×10^{-4}	Heavily Fractured Bedrock at Contact with Overburden
	12 to 18	8.6×10^{-8}	Very Competent Bedrock
	18 to 30	4.0×10^{-7}	Competent Bedrock
	30 to 43	1.1×10^{-5}	Slightly Fractured Bedrock
MP89-236	8 to 12	2.7×10^{-5}	Bedrock
	14 to 24	2.7×10^{-6}	Bedrock
	24 to 37	2.0×10^{-6}	Bedrock
	35 to 46	7.7×10^{-7}	Bedrock

Table C5: Summary of Index Test Results

Year	Consultant	Borehole / Test Pit ID	General Location Description	Sample Type	Sample No.	Depth (m)		Elevation (m)			Soil Unit	Specific Gravity	Water Content (%)	Unified Soil Classification System (USCS)	Atterberg Limits				Atterberg Classification	Dry Density (kg/m³)	Wet Density (kg/m³)	Standard Proctor		Modified Proctor		Hydraulic Conductivity (m/s)	Particle Size Distribution					Advanced Testing Completed

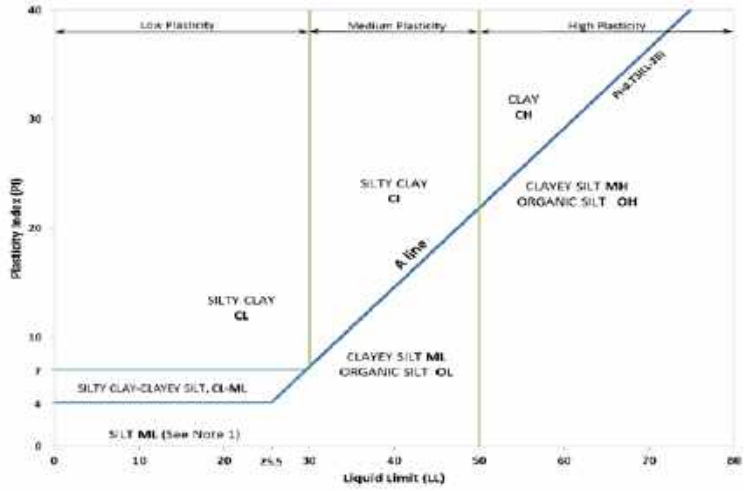
1. Soil unit was redefined from original description based on further assessment.
2. Soil unit was redefined from glaciolacustrine to either upper glaciolacustrine or lower glaciolacustrine.

APPENDIX D

Borehole GA22-01



Appendix D1
Record of Borehole

METHOD OF SOIL CLASSIFICATION

The Golder Associates Ltd. Soil Classification System is based on the Unified Soil Classification System (USCS)

Organic or Inorganic	Soil Group	Type of Soil		Gradation or Plasticity	$Cu = \frac{D_{60}}{D_{10}}$	$Cc = \frac{(D_{30})^2}{D_{10} x D_{60}}$	Organic Content	USCS Group Symbol	Group Name
INORGANIC (Organic Content ≤30% by mass)	COARSE-GRAINED SOILS (>50% by mass is larger than 0.075 mm)	GRAVELS (>50% by mass of coarse fraction is larger than 4.75 mm)	Gravels with ≤12% fines (by mass)	Poorly Graded	<4	≤1 or ≥3	≤30%	GP	GRAVEL
				Well Graded	≥4	1 to 3		GW	GRAVEL
			Gravels with >12% fines (by mass)	Below A Line	n/a			GM	SILTY GRAVEL
				Above A Line	n/a			GC	CLAYEY GRAVEL
		SANDS (≥50% by mass of coarse fraction is smaller than 4.75 mm)	Sands with ≤12% fines (by mass)	Poorly Graded	<6	≤1 or ≥3		SP	SAND
				Well Graded	≥6	1 to 3		SW	SAND
			Sands with >12% fines (by mass)	Below A Line	n/a			SM	SILTY SAND
				Above A Line	n/a			SC	CLAYEY SAND

Organic or Inorganic	Soil Group	Type of Soil	Laboratory Tests	Field Indicators					Organic Content	USCS Group Symbol	Primary Name
				Dilatancy	Dry Strength	Shine Test	Thread Diameter	Toughness (of 3 mm thread)			
INORGANIC (Organic Content ≤30% by mass)	FINE-GRAINED SOILS (≥50% by mass is smaller than 0.075 mm)	SILTS (Non-Plastic or PI and LL plot below A-Line on Plasticity Chart below)	Liquid Limit <50	Rapid	None	None	>6 mm	N/A (can't roll 3 mm thread)	<5%	ML	SILT
				Slow	None to Low	Dull	3mm to 6 mm	None to low	<5%	ML	CLAYEY SILT
				Slow to very slow	Low to medium	Dull to slight	3mm to 6 mm	Low	5% to 30%	OL	ORGANIC SILT
			Liquid Limit ≥50	Slow to very slow	Low to medium	Slight	3mm to 6 mm	Low to medium	<5%	MH	CLAYEY SILT
				None	Medium to high	Dull to slight	1 mm to 3 mm	Medium to high	5% to 30%	OH	ORGANIC SILT
		CLAYS (PI and LL plot above A-Line on Plasticity Chart below)	Liquid Limit <30	None	Low to medium	Slight to shiny	~ 3 mm	Low to medium	0% to 30% (see Note 2)	CL	SILTY CLAY
			Liquid Limit 30 to 50	None	Medium to high	Slight to shiny	1 mm to 3 mm	Medium		CI	SILTY CLAY
			Liquid Limit ≥50	None	High	Shiny	<1 mm	High		CH	CLAY
HIGHLY ORGANIC SOILS (Organic Content >30% by mass)		Peat and mineral soil mixtures							30% to 75%	PT	SILTY PEAT, SANDY PEAT
		Predominantly peat, may contain some mineral soil, fibrous or amorphous peat							75% to 100%		PEAT

Note 1 – Fine grained materials with PI and LL that plot in this area are named (ML) SILT with slight plasticity. Fine-grained materials which are non-plastic (i.e. a PL cannot be measured) are named SILT.
Note 2 – For soils with <5% organic content, include the descriptor "trace organics" for soils with between 5% and 30% organic content include the prefix "organic" before the Primary name.

Dual Symbol — A dual symbol is two symbols separated by a hyphen, for example, GP-GM, SW-SC and CL-ML.
For non-cohesive soils, the dual symbols must be used when the soil has between 5% and 12% fines (i.e. to identify transitional material between "clean" and "dirty" sand or gravel.
For cohesive soils, the dual symbol must be used when the liquid limit and plasticity index values plot in the CL-ML area of the plasticity chart (see Plasticity Chart at left).

Borderline Symbol — A borderline symbol is two symbols separated by a slash, for example, CL/CI, GM/SM, CL/ML.
A borderline symbol should be used to indicate that the soil has been identified as having properties that are on the transition between similar materials. In addition, a borderline symbol may be used to indicate a range of similar soil types within a stratum.

ABBREVIATIONS AND TERMS USED ON RECORDS OF BOREHOLES AND TEST PITS

PARTICLE SIZES OF CONSTITUENTS

Soil Constituent	Particle Size Description	Millimetres	Inches (US Std. Sieve Size)
BOULDERS	Not Applicable	>300	>12
COBBLES	Not Applicable	75 to 300	3 to 12
GRAVEL	Coarse Fine	19 to 75 4.75 to 19	0.75 to 3 (4) to 0.75
SAND	Coarse Medium Fine	2.00 to 4.75 0.425 to 2.00 0.075 to 0.425	(10) to (4) (40) to (10) (200) to (40)
SILT/CLAY	Classified by plasticity	<0.075	< (200)

MODIFIERS FOR SECONDARY AND MINOR CONSTITUENTS

Percentage by Mass	Modifier
>35	Use 'and' to combine major constituents (*i.e.,* SAND and GRAVEL)
> 12 to 35	Primary soil name prefixed with "gravelly, sandy, SILTY, CLAYEY" as applicable
> 5 to 12	some
≤ 5	trace

PENETRATION RESISTANCE

Standard Penetration Resistance (SPT), N:

The number of blows by a 63.5 kg (140 lb) hammer dropped 760 mm (30 in.) required to drive a 50 mm (2 in.) split-spoon sampler for a distance of 300 mm (12 in.). Values reported are as recorded in the field and are uncorrected.

Cone Penetration Test (CPT)

An electronic cone penetrometer with a 60° conical tip and a project end area of 10 cm^2 pushed through ground at a penetration rate of 2 cm/s. Measurements of tip resistance (q_t), porewater pressure (u) and sleeve frictions are recorded electronically at 25 mm penetration intervals.

Dynamic Cone Penetration Resistance (DCPT); N_d:

The number of blows by a 63.5 kg (140 lb) hammer dropped 760 mm (30 in.) to drive uncased a 50 mm (2 in.) diameter, 60° cone attached to "A" size drill rods for a distance of 300 mm (12 in.).

PH: Sampler advanced by hydraulic pressure
PM: Sampler advanced by manual pressure
WH: Sampler advanced by static weight of hammer
WR: Sampler advanced by weight of sampler and rod

SAMPLES

AS	Auger sample
BS	Block sample
CS	Chunk sample
DD	Diamond Drilling
DO or DP	Seamless open ended, driven or pushed tube sampler – note size
DS	Denison type sample
GS	Grab Sample
MC	Modified California Samples
MS	Modified Shelby (for frozen soil)
RC	Rock core
SC	Soil core
SS	Split spoon sampler – note size
ST	Slotted tube
TO	Thin-walled, open – note size (Shelby tube)
TP	Thin-walled, piston – note size (Shelby tube)
WS	Wash sample

SOIL TESTS

w	water content
PL , w_p	plastic limit
LL , w_L	liquid limit
C	consolidation (oedometer) test
CHEM	chemical analysis (refer to text)
CID	consolidated isotropically drained triaxial test[1]
CIU	consolidated isotropically undrained triaxial test with porewater pressure measurement[1]
D_R	relative density (specific gravity, Gs)
DS	direct shear test
GS	specific gravity
M	sieve analysis for particle size
MH	combined sieve and hydrometer (H) analysis
MPC	Modified Proctor compaction test
SPC	Standard Proctor compaction test
OC	organic content test
SO_4	concentration of water-soluble sulphates
UC	unconfined compression test
UU	unconsolidated undrained triaxial test
V (FV)	field vane (LV-laboratory vane test)
γ	unit weight

1. Tests anisotropically consolidated prior to shear are shown as CAD, CAU.

NON-COHESIVE (COHESIONLESS) SOILS

Compactness[2]

Term	SPT 'N' (blows/0.3m)[1]
Very Loose	0 to 4
Loose	4 to 10
Compact	10 to 30
Dense	30 to 50
Very Dense	>50

1. SPT 'N' in accordance with ASTM D1586, uncorrected for the effects of overburden pressure.
2. Definition of compactness terms are based on SPT 'N' ranges as provided in Terzaghi, Peck and Mesri (1996). Many factors affect the recorded SPT 'N' value, including hammer efficiency (which may be greater than 60% in automatic trip hammers), overburden pressure, groundwater conditions, and grainsize. As such, the recorded SPT 'N' value(s) should be considered only an approximate guide to the soil compactness. These factors need to be considered when evaluating the results, and the stated compactness terms should not be relied upon for design or construction.

Field Moisture Condition

Term	Description
Dry	Soil flows freely through fingers.
Moist	Soils are darker than in the dry condition and may feel cool.
Wet	As moist, but with free water forming on hands when handled.

COHESIVE SOILS

Consistency

Term	Undrained Shear Strength (kPa)	SPT 'N'[1,2] (blows/0.3m)
Very Soft	<12	0 to 2
Soft	12 to 25	2 to 4
Firm	25 to 50	4 to 8
Stiff	50 to 100	8 to 15
Very Stiff	100 to 200	15 to 30
Hard	>200	>30

1. SPT 'N' in accordance with ASTM D1586, uncorrected for overburden pressure effects; approximate only.
2. SPT 'N' values should be considered ONLY an approximate guide to consistency; for sensitive clays (e.g., Champlain Sea clays), the N-value approximation for consistency terms does NOT apply. Rely on direct measurement of undrained shear strength or other manual observations.

Water Content

Term	Description
w < PL	Material is estimated to be drier than the Plastic Limit.
w ~ PL	Material is estimated to be close to the Plastic Limit.
w > PL	Material is estimated to be wetter than the Plastic Limit.

Unless otherwise stated, the symbols employed in the report are as follows:

I. GENERAL

π	3.1416
ln x	natural logarithm of x
$\log_{10}$	x or log x, logarithm of x to base 10
g	acceleration due to gravity
t	time

II. STRESS AND STRAIN

γ	shear strain
Δ	change in, e.g. in stress: $\Delta\sigma$
ε	linear strain
ε_v	volumetric strain
η	coefficient of viscosity
υ	Poisson's ratio
σ	total stress
σ'	effective stress ($\sigma' = \sigma - u$)
σ'_{vo}	initial effective overburden stress
$\sigma_1, \sigma_2, \sigma_3$	principal stress (major, intermediate, minor)
σ_{oct}	mean stress or octahedral stress $= (\sigma_1 + \sigma_2 + \sigma_3)/3$
τ	shear stress
u	porewater pressure
E	modulus of deformation
G	shear modulus of deformation
K	bulk modulus of compressibility

III. SOIL PROPERTIES

(a) Index Properties

$\rho(\gamma)$	bulk density (bulk unit weight)*
$\rho_d(\gamma_d)$	dry density (dry unit weight)
$\rho_w(\gamma_w)$	density (unit weight) of water
$\rho_s(\gamma_s)$	density (unit weight) of solid particles
γ'	unit weight of submerged soil ($\gamma' = \gamma - \gamma_w$)
D_R	relative density (specific gravity) of solid particles ($D_R = \rho_s / \rho_w$) (formerly G_s)
e	void ratio
n	porosity
S	degree of saturation

* Density symbol is ρ. Unit weight symbol is γ where $\gamma = \rho g$ (i.e. mass density multiplied by acceleration due to gravity)

(a) Index Properties (continued)

w	water content
w_l or LL	liquid limit
w_p or PL	plastic limit
I_p or PI	plasticity index = $(w_l - w_p)$
NP	non-plastic
w_s	shrinkage limit
I_L	liquidity index = $(w - w_p) / I_p$
I_C	consistency index = $(w_l - w) / I_p$
e_{max}	void ratio in loosest state
e_{min}	void ratio in densest state
I_D	density index = $(e_{max} - e) / (e_{max} - e_{min})$ (formerly relative density)

(b) Hydraulic Properties

h	hydraulic head or potential
q	rate of flow
v	velocity of flow
i	hydraulic gradient
k	hydraulic conductivity (coefficient of permeability)
j	seepage force per unit volume

(c) Consolidation (one-dimensional)

C_c	compression index (normally consolidated range)
C_r	recompression index (over-consolidated range)
C_s	swelling index
C_α	secondary compression index
m_v	coefficient of volume change
c_v	coefficient of consolidation (vertical direction)
c_h	coefficient of consolidation (horizontal direction)
T_v	time factor (vertical direction)
U	degree of consolidation
σ'_p	pre-consolidation stress
OCR	over-consolidation ratio = σ'_p / σ'_{vo}

(d) Shear Strength

τ_p, τ_r	peak and residual shear strength
ϕ'	effective angle of internal friction
δ	angle of interface friction
μ	coefficient of friction = tan δ
c′	effective cohesion
c_u, s_u	undrained shear strength ($\phi = 0$ analysis)
p	mean total stress $(\sigma_1 + \sigma_3)/2$
p′	mean effective stress $(\sigma'_1 + \sigma'_3)/2$
q	$(\sigma_1 - \sigma_3)/2$ or $(\sigma'_1 - \sigma'_3)/2$
q_u	compressive strength $(\sigma_1 - \sigma_3)$
S_t	sensitivity

Notes: 1 $\tau = c' + \sigma' \tan \phi'$

2 shear strength = (compressive strength)/2

Vibrating Wire Piezometer

Customer:	HUCKLEBERRY MINES LTD.
Sales Order:	228638
Customer ID:	
Model:	VW2100-0.35
Serial Number:	VW136218
Mfg Number:	P136218
Range:	350 kPa
Cable Length:	20 meters
Cable Marking:	551052 m to 551073 m
Cable Type:	EL380004
Cable Colour Code:	Red/Black (Coil) Green/White (Thermistor)
Thermistor Type:	3K

Applied Pressure (kPa)	First Reading (B units)	Second Reading (B units)	Average Reading (B units)	Calculated Linear (kPa)	Linearity Error (%FS)	Calculated Polynomial (kPa)	Polynomial Error (%FS)
0.0	9010	9010	9010	0.1	0.02	0.1	0.03
70.0	8328	8329	8329	69.8	-0.04	69.8	-0.05
140.0	7644	7644	7644	140.0	0.01	140.0	0.00
210.0	6960	6960	6960	210.1	0.02	210.1	0.01
280.0	6277	6277	6277	280.1	0.02	280.1	0.02
350.0	5596	5595	5595	349.9	-0.03	349.9	-0.02
Max Error (%)					0.04		0.05

Linear Calibration Factor: **CF = 1.0246e-01 kPa/B unit**
Temperature Correction Factor: **Tk = -7.3641e-02 kPa/°C rise**

Polynomial Gauge Factor:
A = 2.2220e-08 kPa/(B unit)² **B = -1.0278e-01 kPa/B unit** **C = calculate (see below) kPa**

Users must establish site zero readings for calculation purposes
Polynomial C = -[A(L_0^2) + B(L_0)]

Pressure is calculated with the following equations:
Linear: $P = CF(L_0 - L) - Tk(T_0 - T) + (S_0 - S)$
Polynomial: $P = A(L^2) + B(L) + C - Tk(T_0 - T) + (S_0 - S)$

L_0, L = initial (installation) and current readings, in B units
T_0, T = initial (installation) and current temperature, in °C
S_0, S = initial (installation) and current barometric pressure readings, in kPa
B units = $Hz^2/1000$ ie: 1700 Hz = 2890 B units

	Date	VW Reading (B Units)	Temperature (°C)	Baro (mbar)
Shipped Zero Readings:	15 Jul 2021	8986	21.6	1016.0

This instrument has been calibrated using standards traceable to the NIST in compliance with ANSI Z540-1

Technician: Ora Nygren **Date:** 15/07/2021

Approved: Samantha Shaw **Date:** 15/07/2021
