Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Soil/Solid**

Evaluation: × = QC frequency outside specification; ✓ = QC frequency within specification.

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Conductivity in Soil (Saturated Paste)	E102 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/APHA 2510 (mod)/AER D50	Conductivity, also known as Electrical Conductivity (EC) or Specific Conductance, is measured by immersion of a conductivity cell with platinum electrodes into a filtered extract from a soil sample prepared using the saturated paste procedure. Conductivity measurements are temperature-compensated to 25°C.
pH by Meter (1:2 Soil:Water Extraction)	E108 Vancouver - Environmental	Soil/Solid	BC Lab Manual	pH is determined by potentiometric measurement with a pH electrode at ambient laboratory temperature (normally 20 ± 5°C), and is carried out in accordance with procedures described in the BC Lab Manual (prescriptive method). The procedure involves mixing the dried (at <60 ºC) and sieved (10mesh/2mm) sample with ultra pure water at a 1:2 ratio of sediment to water. The pH is then measured by a standard pH probe.
pH by Meter (1:2 Soil:0.01M CaCl2 Extraction)	E108B Saskatoon - Environmental	Soil/Solid	CSSS (2008) 16.3	A 10g portion of dried (<60°C) and ground (10 mesh/2 mm) sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil by centrifuging, settling or decanting and then analyzed using a pH meter and electrode.
pH by Meter (Saturated Paste)	E114 Vancouver - Environmental	Soil/Solid	Carter-CSSS / APHA 4500 H	pH is determined by potentiometric measurement with a pH electrode, and is conducted at ambient laboratory temperature (normally 20 ± 5°C) on a soil produced by the saturated paste extraction procedure.
Saturation Percentage	E141 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/AER D50	Saturation Percentage (SP) is determined as the total volume of water present in a saturated paste (in mL) divided by the dry weight of the sample (in grams), expressed as a percentage.
Moisture Content by Gravimetry	E144 Vancouver - Environmental	Soil/Solid	CCME PHC in Soil - Tier 1	Moisture is measured gravimetrically by drying the sample at 105°C. Moisture content is calculated as the weight loss (due to water) divided by the wet weight of the sample, expressed as a percentage.
Particle Size Analysis - Sieve >2mm	E181 Saskatoon - Environmental	Soil/Solid	ASTM D6913-17 (mod)	Soil samples are disaggregated and sieved through a 2mm sieve. Material retained on the sieve is then further sieved through a series of sieves. The amount passing through the sieves is measured gravimetrically.
Particle Size Analysis - Sieve <2mm	E182 Saskatoon - Environmental	Soil/Solid	ASTM D6913-17 (mod)	Soil samples are disaggregated and sieved through a 2mm sieve. Material passed through the sieve is then further disaggregated using calgon solution and passed through a series of sieves. The amount passing through the sieves is measured gravimetrically.
Particle Size Analysis - Hydrometer	E183 Saskatoon - Environmental	Soil/Solid	ASTM D7928-21 (mod)	Soil material is separated from coarse material (>2mm). A specimen is then disaggregated through mixing with Calgon solution. The material is then suspended in solution wherein regular hydrometer readings are taken at specific time intervals. The principles of Stokes' Law are applied to determine the amount of material remaining in solution as well as the maximum particle size remaining in solution at the specified time.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Grain Size Report (Attachment) Hydrometer/Sieve Method	E185 Saskatoon - Environmental	Soil/Solid	ASTM D6913/D7928	A grain size curve is a graphical representation of the particle sizing of a sample representing the percent passing against the effective particle size.
Loss On Ignition (550°C)	E205D Saskatoon - Environmental	Soil/Solid	CSSS (2008) 28.3 (mod)	Loss On Ignition (LOI) is determined by drying a portion of an air dried and ground sample at 105°C overnight, then igniting at 550°C for 16-20 hours. The weight loss after ignition is reported as % loss on ignition. LOI is reported on a dry weight basis. LOI at 550°C can be used as an estimation of Organic Matter (CSSS 2008).
Chloride by IC (Saturated Paste)	E239.Cl Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate by IC (Saturated Paste)	E239.NO3 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Sulfate by IC (Saturated Paste)	E239.SO4 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Available Nitrate and Nitrite by Colourimetry (0.01M Calcium Chloride Ext.)	E269.N+N Saskatoon - Environmental	Soil/Solid	Alberta Agriculture/APHA 4500-NO3 I (mod)	Plant available nitrate and nitrite are analyzed by colourimetry using a flow injection analyzer on a soil sample extract that has been extracted using 0.01M Calcium Chloride, then shaken well and filtered prior to analysis.
Alkalinity Species by Titration (Saturated Paste)	E293 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15/APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint on an extract produced by the saturated paste procedure. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Total Kjeldahl Nitrogen by Colourimetry	E319 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.2.3	The soil is digested with sulfuric acid in the presence of $CuSO_4$ and K_2SO_4 catalysts. Ammonia in the soil extract is determined colrimetrically at 660 nm.
Total Carbon by Combustion	E351 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 21.2 (mod)	Total Carbon is determined by the high temperature combustion method with measurement by an infrared detector.
Total Inorganic Carbon by Acetic Acid pH Standard Curve	E354 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 20.2	Total Inorganic Carbon is determined by acetic acid pH standard curve, where a known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.
Total Nitrogen by Combustion	E366 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.4	The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Available Phosphorus by FIALab (Modified Kelowna)	E384 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available phosphorus is extracted from air dried soil using a fixed ratio Modified Kelowna extraction. Phosphorus is determined by colorimetry using an flow injection analyzer.
Available Potassium by flame photometry (Modified Kelowna)	E390 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available potassium is extracted from soil using modified Kelowna solution. Potassium is determined by flame emission at 770 nm.
Metals in Soil/Solid by CRC ICPMS	E440 Vancouver - Environmental	Soil/Solid	EPA 6020B (mod)	This method is intended to liberate metals that may be environmentally available. Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Silicate minerals are not solubilized. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. This method does not adequately recover elemental sulfur, and is unsuitable for assessment of elemental sulfur standards or guidelines. Analysis is by Collision/Reaction Cell ICPMS.
Ca, K, Mg, and Na by CRC ICPMS (Saturated Paste, mg/L)	E442 Vancouver - Environmental	Soil/Solid	CSSS CH15/EPA 6020B (mod)	A soil extract produced by the saturated paste extraction procedure is analyzed for Calcium, Magnesium, Potassium and Sodium by Collision/Reaction Cell ICPMS as per "Soil Sampling Methods of Analysis" By M Carter.
Available Sulfate by ICPOES (0.01M Calcium Chloride Ext.)	E497.SO4 Saskatoon - Environmental	Soil/Solid	Alberta Agriculture	Plant available sulfate is determined by ICPOES. Soil is extracted using a 0.01M calcium chloride solution. This extraction may also produce organic sulfur in the extracts when organic soils are analyzed.
Mercury in Soil/Solid by CVAAS	E510 Vancouver - Environmental	Soil/Solid	EPA 200.2/1631 Appendix (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl, followed by CVAAS analysis.
Sodium Adsorption Ratio (SAR) Saturated Paste	EC102 Vancouver - Environmental	Soil/Solid	CCME Sodium Adsorption Ratio (SAR)	The Sodium Adsorption Ratio (SAR) for a sample is calculated from the Sodium, Calcium, and Magnesium concentrations from sediment paste extract.
Theoretical Gypsum Requirements (TGR) Saturated Paste	EC106 Vancouver - Environmental	Soil/Solid	J. Ashworth et al (1999)	Theoretical Gypsum Requirement is an estimate of the gypsum amendment required to remediate brine contaminated or sodic soils, and is provided in units of tonnes per hectare (t/ha) for a treatment depth of 15cm. TGR(brine), intended for brine-contaminated soils, is calculated using Method A from "A Comparison of Methods for Gypsum Requirement of Brine-Contaminated Soils", by J. Ashworth (Cdn J. of Soil Science, 1999), available at www.alsglobal.com. TGR(sodic), intended for naturally sodic soils, uses the Oster and Frenkel method (Method B) from the same paper. Reported TGR values are capped at 50 t/ha, considered the maximum practical gypsum amendment. To convert TGR from t/ha to tons/acre, multiply by 0.446. To determine a TGR value for an alternate treatment depth, multiply by [desired treatment depth (cm) / 15 cm].

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Chloride by IC (Saturated Paste) (mg/kg)	EC239A.Cl Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate by IC (Saturated Paste) (mg/kg)	EC239A.NO3 Vancouver - Environmental	Soil/Solid	Calculation	Results are reported in mg/kg dry weight
Sulfate by IC (Saturated Paste) (mg/kg)	EC239A.SO4 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Alkalinity Species by Titration (Saturated Paste) (mg/kg)	EC293 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15/APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint on an extract produced by the saturated paste procedure. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Total Organic Carbon (Calculated) in soil	EC356 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 21.2	Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon (TIC).
Ca, K, Mg, Na by ICPMS (Saturated Paste, mg/kg)	EC442 Vancouver - Environmental	Soil/Solid	CSSS CH15/EPA 6020B (mod)	A soil extract produced by the saturated paste extraction procedure is analyzed for Calcium, Magnesium, Potassium, Sodium by ICPMS.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Leach 1:2 Soil:Water for pH/EC	EP108 Vancouver - Environmental	Soil/Solid	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL	The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water.
Leach 1:2 Soil : 0.01CaCl2	EP108B Saskatoon - Environmental	Soil/Solid	CSSS (2008) 16.3	A 10g portion of dried (<60°C) and ground (10 mesh/2 mm) sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil by centrifuging, settling or decanting and then analyzed using a pH meter and electrode.
Fixed ratio 0.01M Calcium Chloride extraction for plant available nutrients	EP269 Saskatoon - Environmental	Soil/Solid	Alberta Agriculture	Plant available nutrients (N&S) extracted using 0.01M calcium chloride, then shaken well and filtered prior to analysis.
Kjeldahl Digestion for soils	EP319 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.2.3	The soil is digested with sulfuric acid in the presence of CuSO4 and K2SO4 catalysts.
Modified Kelowna Extraction for soil	EP384 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available phosphorus and potassium are extracted from the soil using fixed ratio Modified Kelowna solution.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Digestion for Metals and Mercury	EP440 Vancouver - Environmental	Soil/Solid	EPA 200.2 (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO_3 and HCl. This method is intended to liberate metals that may be environmentally available.
Dry and Grind in Soil/Solid <60°C	EPP442 Saskatoon - Environmental	Soil/Solid	Soil Sampling and Methods of Analysis, Carter 2008	After removal of any coarse fragments and reservation of wet subsamples a portion of homogenized sample is set in a tray and dried at less than 60°C until dry. The sample is then particle size reduced with an automated crusher or mortar and pestle, typically to <2 mm. Further size reduction may be needed for particular tests.

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Soil/Solid**

Qualifiers

Qualifier	*Description*
DUP-H	*Duplicate results outside ALS DQO, due to sample heterogeneity.*
RRQC	*Refer to report comments for information regarding this QC result.*

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Soil/Solid**

Reference Material (RM) Report

A Reference Material (RM) is a homogenous material with known and well-established analyte concentrations. RMs are processed in an identical manner to test samples, and are used to monitor and control the accuracy and precision of a test method for a typical sample matrix. RM results are expressed as percent recovery of the target analyte concentration. RM targets may be certified target concentrations provided by the RM supplier, or may be ALS long-term mean values (for empirical test methods).

Sub-Matrix:

Nancy Cruse	Laboratory Assistant	Inorganics, Saskatoon, Saskatchewan
Nancy Cruse	Laboratory Assistant	Sask Soils, Saskatoon, Saskatchewan
Qammar Almas	Lab Assistant	Metals, Burnaby, British Columbia

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
%	percent
dS/m	decisiemens per metre
mg/kg	milligrams per kilogram
mg/L	milligrams per litre
pH units	pH units
t/ha	tonnes per hectare

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLIS	*Detection Limit Adjusted due to insufficient sample.*
DLM	*Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).*
DUPH	*Duplicate results outside ALS DQO, due to sample heterogeneity.*

Project	: 22514095/42200/42213	Date Samples Received	: 17-Sep-2022 14:40
PO	: 5590008044	Issue Date	: 30-Sep-2022 10:04
C-O-C number	: 17-686092		
Sampler	: SL		
Site	: ----		
Quote number	: Golder/Mt. Polley (VA22-MPMC100-007)		
No. of samples received	: 10		
No. of samples analysed	: 10		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Laboratory Control Sample (LCS) outliers occur
- Duplicate outliers occur - please see following pages for full details.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- Analysis Holding Time Outliers exist - please see following pages for full details.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **Soil/Solid**

Analyte Group	Laboratory sample ID	Client/Ref Sample ID	Analyte	CAS Number	Method	Result	Limits	Comment
Duplicate (DUP) RPDs								
Metals	VA22C2364-001	22-S17-S-01	mercury	7439-97-6	E510	58.6 % DUP-H	40%	Duplicate RPD does not meet the DQO for this test.

Result Qualifiers

Qualifier	Description
DUP-H	*Duplicate results outside ALS DQO, due to sample heterogeneity.*

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Soil/Solid**

Evaluation: × = QC frequency outside specification; ✓ = QC frequency within specification.

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Conductivity in Soil (Saturated Paste)	E102 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/APHA 2510 (mod)/AER D50	Conductivity, also known as Electrical Conductivity (EC) or Specific Conductance, is measured by immersion of a conductivity cell with platinum electrodes into a filtered extract from a soil sample prepared using the saturated paste procedure. Conductivity measurements are temperature-compensated to 25°C.
pH by Meter (1:2 Soil:Water Extraction)	E108 Vancouver - Environmental	Soil/Solid	BC Lab Manual	pH is determined by potentiometric measurement with a pH electrode at ambient laboratory temperature (normally 20 ± 5°C), and is carried out in accordance with procedures described in the BC Lab Manual (prescriptive method). The procedure involves mixing the dried (at <60 ºC) and sieved (10mesh/2mm) sample with ultra pure water at a 1:2 ratio of sediment to water. The pH is then measured by a standard pH probe.
pH by Meter (1:2 Soil:0.01M CaCl2 Extraction)	E108B Saskatoon - Environmental	Soil/Solid	CSSS (2008) 16.3	A 10g portion of dried (<60°C) and ground (10 mesh/2 mm) sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil by centrifuging, settling or decanting and then analyzed using a pH meter and electrode.
pH by Meter (Saturated Paste)	E114 Vancouver - Environmental	Soil/Solid	Carter-CSSS / APHA 4500 H	pH is determined by potentiometric measurement with a pH electrode, and is conducted at ambient laboratory temperature (normally 20 ± 5°C) on a soil produced by the saturated paste extraction procedure.
Saturation Percentage	E141 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/AER D50	Saturation Percentage (SP) is determined as the total volume of water present in a saturated paste (in mL) divided by the dry weight of the sample (in grams), expressed as a percentage.
Moisture Content by Gravimetry	E144 Vancouver - Environmental	Soil/Solid	CCME PHC in Soil - Tier 1	Moisture is measured gravimetrically by drying the sample at 105°C. Moisture content is calculated as the weight loss (due to water) divided by the wet weight of the sample, expressed as a percentage.
Particle Size Analysis - Sieve >2mm	E181 Saskatoon - Environmental	Soil/Solid	ASTM D6913-17 (mod)	Soil samples are disaggregated and sieved through a 2mm sieve. Material retained on the sieve is then further sieved through a series of sieves. The amount passing through the sieves is measured gravimetrically.
Particle Size Analysis - Sieve <2mm	E182 Saskatoon - Environmental	Soil/Solid	ASTM D6913-17 (mod)	Soil samples are disaggregated and sieved through a 2mm sieve. Material passed through the sieve is then further disaggregated using calgon solution and passed through a series of sieves. The amount passing through the sieves is measured gravimetrically.
Particle Size Analysis - Hydrometer	E183 Saskatoon - Environmental	Soil/Solid	ASTM D7928-21 (mod)	Soil material is separated from coarse material (>2mm). A specimen is then disaggregated through mixing with Calgon solution. The material is then suspended in solution wherein regular hydrometer readings are taken at specific time intervals. The principles of Stokes' Law are applied to determine the amount of material remaining in solution as well as the maximum particle size remaining in solution at the specified time.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Grain Size Report (Attachment) Hydrometer/Sieve Method	E185 Saskatoon - Environmental	Soil/Solid	ASTM D6913/D7928	A grain size curve is a graphical representation of the particle sizing of a sample representing the percent passing against the effective particle size.
Loss On Ignition (550°C)	E205D Saskatoon - Environmental	Soil/Solid	CSSS (2008) 28.3 (mod)	Loss On Ignition (LOI) is determined by drying a portion of an air dried and ground sample at 105°C overnight, then igniting at 550°C for 16-20 hours. The weight loss after ignition is reported as % loss on ignition. LOI is reported on a dry weight basis. LOI at 550°C can be used as an estimation of Organic Matter (CSSS 2008).
Chloride by IC (Saturated Paste)	E239.Cl Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate by IC (Saturated Paste)	E239.NO3 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Sulfate by IC (Saturated Paste)	E239.SO4 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Available Nitrate and Nitrite by Colourimetry (0.01M Calcium Chloride Ext.)	E269.N+N Saskatoon - Environmental	Soil/Solid	Alberta Agriculture/APHA 4500-NO3 I (mod)	Plant available nitrate and nitrite are analyzed by colourimetry using a flow injection analyzer on a soil sample extract that has been extracted using 0.01M Calcium Chloride, then shaken well and filtered prior to analysis.
Alkalinity Species by Titration (Saturated Paste)	E293 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15/APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint on an extract produced by the saturated paste procedure. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Total Kjeldahl Nitrogen by Colourimetry	E319 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.2.3	The soil is digested with sulfuric acid in the presence of $CuSO_4$ and K_2SO_4 catalysts. Ammonia in the soil extract is determined colrimetrically at 660 nm.
Total Carbon by Combustion	E351 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 21.2 (mod)	Total Carbon is determined by the high temperature combustion method with measurement by an infrared detector.
Total Inorganic Carbon by Acetic Acid pH Standard Curve	E354 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 20.2	Total Inorganic Carbon is determined by acetic acid pH standard curve, where a known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.
Total Nitrogen by Combustion	E366 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.4	The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Available Phosphorus by FIALab (Modified Kelowna)	E384 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available phosphorus is extracted from air dried soil using a fixed ratio Modified Kelowna extraction. Phosphorus is determined by colorimetry using an flow injection analyzer.
Available Potassium by flame photometry (Modified Kelowna)	E390 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available potassium is extracted from soil using modified Kelowna solution. Potassium is determined by flame emission at 770 nm.
Metals in Soil/Solid by CRC ICPMS	E440 Vancouver - Environmental	Soil/Solid	EPA 6020B (mod)	This method is intended to liberate metals that may be environmentally available. Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Silicate minerals are not solubilized. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. This method does not adequately recover elemental sulfur, and is unsuitable for assessment of elemental sulfur standards or guidelines. Analysis is by Collision/Reaction Cell ICPMS.
Ca, K, Mg, and Na by CRC ICPMS (Saturated Paste, mg/L)	E442 Vancouver - Environmental	Soil/Solid	CSSS CH15/EPA 6020B (mod)	A soil extract produced by the saturated paste extraction procedure is analyzed for Calcium, Magnesium, Potassium and Sodium by Collision/Reaction Cell ICPMS as per "Soil Sampling Methods of Analysis" By M Carter.
Available Sulfate by ICPOES (0.01M Calcium Chloride Ext.)	E497.SO4 Saskatoon - Environmental	Soil/Solid	Alberta Agriculture	Plant available sulfate is determined by ICPOES. Soil is extracted using a 0.01M calcium chloride solution. This extraction may also produce organic sulfur in the extracts when organic soils are analyzed.
Mercury in Soil/Solid by CVAAS	E510 Vancouver - Environmental	Soil/Solid	EPA 200.2/1631 Appendix (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl, followed by CVAAS analysis.
Sodium Adsorption Ratio (SAR) Saturated Paste	EC102 Vancouver - Environmental	Soil/Solid	CCME Sodium Adsorption Ratio (SAR)	The Sodium Adsorption Ratio (SAR) for a sample is calculated from the Sodium, Calcium, and Magnesium concentrations from sediment paste extract.
Theoretical Gypsum Requirements (TGR) Saturated Paste	EC106 Vancouver - Environmental	Soil/Solid	J. Ashworth et al (1999)	Theoretical Gypsum Requirement is an estimate of the gypsum amendment required to remediate brine contaminated or sodic soils, and is provided in units of tonnes per hectare (t/ha) for a treatment depth of 15cm. TGR(brine), intended for brine-contaminated soils, is calculated using Method A from "A Comparison of Methods for Gypsum Requirement of Brine-Contaminated Soils", by J. Ashworth (Cdn J. of Soil Science, 1999), available at www.alsglobal.com. TGR(sodic), intended for naturally sodic soils, uses the Oster and Frenkel method (Method B) from the same paper. Reported TGR values are capped at 50 t/ha, considered the maximum practical gypsum amendment. To convert TGR from t/ha to tons/acre, multiply by 0.446. To determine a TGR value for an alternate treatment depth, multiply by [desired treatment depth (cm) / 15 cm].

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Chloride by IC (Saturated Paste) (mg/kg)	EC239A.Cl Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate by IC (Saturated Paste) (mg/kg)	EC239A.NO3 Vancouver - Environmental	Soil/Solid	Calculation	Results are reported in mg/kg dry weight
Sulfate by IC (Saturated Paste) (mg/kg)	EC239A.SO4 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Alkalinity Species by Titration (Saturated Paste) (mg/kg)	EC293 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15/APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint on an extract produced by the saturated paste procedure. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Total Organic Carbon (Calculated) in soil	EC356 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 21.2	Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon (TIC).
Ca, K, Mg, Na by ICPMS (Saturated Paste, mg/kg)	EC442 Vancouver - Environmental	Soil/Solid	CSSS CH15/EPA 6020B (mod)	A soil extract produced by the saturated paste extraction procedure is analyzed for Calcium, Magnesium, Potassium, Sodium by ICPMS.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Leach 1:2 Soil:Water for pH/EC	EP108 Vancouver - Environmental	Soil/Solid	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL	The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water.
Leach 1:2 Soil : 0.01CaCl2	EP108B Saskatoon - Environmental	Soil/Solid	CSSS (2008) 16.3	A 10g portion of dried (<60°C) and ground (10 mesh/2 mm) sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil by centrifuging, settling or decanting and then analyzed using a pH meter and electrode.
Fixed ratio 0.01M Calcium Chloride extraction for plant available nutrients	EP269 Saskatoon - Environmental	Soil/Solid	Alberta Agriculture	Plant available nutrients (N&S) extracted using 0.01M calcium chloride, then shaken well and filtered prior to analysis.
Kjeldahl Digestion for soils	EP319 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.2.3	The soil is digested with sulfuric acid in the presence of CuSO4 and K2SO4 catalysts.
Modified Kelowna Extraction for soil	EP384 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available phosphorus and potassium are extracted from the soil using fixed ratio Modified Kelowna solution.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Digestion for Metals and Mercury	EP440 Vancouver - Environmental	Soil/Solid	EPA 200.2 (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO_3 and HCl. This method is intended to liberate metals that may be environmentally available.
Dry and Grind	EPP442 Saskatoon - Environmental	Soil/Solid	Soil Sampling and Methods of Analysis, Carter 2008	After removal of any coarse fragments and reservation of wet subsamples a portion of homogenized sample is set in a tray and dried at less than 60°C until dry. The sample is then particle size reduced with an automated crusher or mortar and pestle, typically to <2 mm. Further size reduction may be needed for particular tests.

QUALITY CONTROL REPORT

Work Order	: **VA22C2364**	Page	: 1 of 16
Client	: Golder Associates Ltd.	Laboratory	: Vancouver - Environmental
Contact	: Samantha Lundquist	Account Manager	: Amber Springer
Address	: PO Box 12 Likely BC Canada V0L 1N0	Address	: 8081 Lougheed Highway Burnaby, British Columbia Canada V5A 1W9
Telephone	: ----	Telephone	: +1 604 253 4188
Project	: 22514095/42200/42213	Date Samples Received	: 17-Sep-2022 14:40
PO	: 5590008044	Date Analysis Commenced	: 21-Sep-2022
C-O-C number	: 17-686092	Issue Date	: 30-Sep-2022 10:04
Sampler	: SL		
Site	: ----		
Quote number	: Golder/Mt. Polley (VA22-MPMC100-007)		
No. of samples received	: 10		
No. of samples analysed	: 10		

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percent Difference (RPD) and Data Quality Objectives
- Reference Material (RM) Report; Recovery and Data Quality Objectives
- Method Blank (MB) Report; Recovery and Data Quality Objectives
- Laboratory Control Sample (LCS) Report; Recovery and Data Quality Objectives

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Soil/Solid**

Qualifiers

Qualifier	*Description*
DUP-H	*Duplicate results outside ALS DQO, due to sample heterogeneity.*

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Soil/Solid**

Reference Material (RM) Report

A Reference Material (RM) is a homogenous material with known and well-established analyte concentrations. RMs are processed in an identical manner to test samples, and are used to monitor and control the accuracy and precision of a test method for a typical sample matrix. RM results are expressed as percent recovery of the target analyte concentration. RM targets may be certified target concentrations provided by the RM supplier, or may be ALS long-term mean values (for empirical test methods).

Sub-Matrix:

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
%	percent
dS/m	decisiemens per metre
mg/kg	milligrams per kilogram
mg/L	milligrams per litre
pH units	pH units
t/ha	tonnes per hectare

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLIS	*Detection Limit Adjusted due to insufficient sample.*
DLM	*Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).*

Telephone	: ----	Telephone	: +1 604 253 4188
Project	: 22514095/42200/42213	Date Samples Received	: 17-Sep-2022 14:40
PO	: 5590008044	Issue Date	: 30-Sep-2022 10:05
C-O-C number	: 17-686093		
Sampler	: SL		
Site	: ----		
Quote number	: Golder/Mt. Polley (VA22-MPMC100-007)		
No. of samples received	: 5		
No. of samples analysed	: 5		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Laboratory Control Sample (LCS) outliers occur
- Duplicate outliers occur - please see following pages for full details.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- Analysis Holding Time Outliers exist - please see following pages for full details.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **Soil/Solid**

Analyte Group	Laboratory sample ID	Client/Ref Sample ID	Analyte	CAS Number	Method	Result	Limits	Comment
Duplicate (DUP) RPDs								
Metals	Anonymous	Anonymous	mercury	7439-97-6	E510	58.6 % DUP-H	40%	Duplicate RPD does not meet the DQO for this test.

Result Qualifiers

Qualifier	Description
DUP-H	*Duplicate results outside ALS DQO, due to sample heterogeneity.*

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Soil/Solid**

Evaluation: × = QC frequency outside specification; ✓ = QC frequency within specification.

Quality Control Sample Type			Count		Frequency (%)		
Analytical Methods	*Method*	*QC Lot #*	*QC*	*Regular*	*Actual*	*Expected*	*Evaluation*

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Conductivity in Soil (Saturated Paste)	E102 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/APHA 2510 (mod)/AER D50	Conductivity, also known as Electrical Conductivity (EC) or Specific Conductance, is measured by immersion of a conductivity cell with platinum electrodes into a filtered extract from a soil sample prepared using the saturated paste procedure. Conductivity measurements are temperature-compensated to 25°C.
pH by Meter (1:2 Soil:Water Extraction)	E108 Vancouver - Environmental	Soil/Solid	BC Lab Manual	pH is determined by potentiometric measurement with a pH electrode at ambient laboratory temperature (normally 20 ± 5°C), and is carried out in accordance with procedures described in the BC Lab Manual (prescriptive method). The procedure involves mixing the dried (at <60 ºC) and sieved (10mesh/2mm) sample with ultra pure water at a 1:2 ratio of sediment to water. The pH is then measured by a standard pH probe.
pH by Meter (1:2 Soil:0.01M CaCl2 Extraction)	E108B Saskatoon - Environmental	Soil/Solid	CSSS (2008) 16.3	A 10g portion of dried (<60°C) and ground (10 mesh/2 mm) sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil by centrifuging, settling or decanting and then analyzed using a pH meter and electrode.
pH by Meter (Saturated Paste)	E114 Vancouver - Environmental	Soil/Solid	Carter-CSSS / APHA 4500 H	pH is determined by potentiometric measurement with a pH electrode, and is conducted at ambient laboratory temperature (normally 20 ± 5°C) on a soil produced by the saturated paste extraction procedure.
Saturation Percentage	E141 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/AER D50	Saturation Percentage (SP) is determined as the total volume of water present in a saturated paste (in mL) divided by the dry weight of the sample (in grams), expressed as a percentage.
Moisture Content by Gravimetry	E144 Vancouver - Environmental	Soil/Solid	CCME PHC in Soil - Tier 1	Moisture is measured gravimetrically by drying the sample at 105°C. Moisture content is calculated as the weight loss (due to water) divided by the wet weight of the sample, expressed as a percentage.
Particle Size Analysis - Sieve >2mm	E181 Saskatoon - Environmental	Soil/Solid	ASTM D6913-17 (mod)	Soil samples are disaggregated and sieved through a 2mm sieve. Material retained on the sieve is then further sieved through a series of sieves. The amount passing through the sieves is measured gravimetrically.
Particle Size Analysis - Sieve <2mm	E182 Saskatoon - Environmental	Soil/Solid	ASTM D6913-17 (mod)	Soil samples are disaggregated and sieved through a 2mm sieve. Material passed through the sieve is then further disaggregated using calgon solution and passed through a series of sieves. The amount passing through the sieves is measured gravimetrically.
Particle Size Analysis - Hydrometer	E183 Saskatoon - Environmental	Soil/Solid	ASTM D7928-21 (mod)	Soil material is separated from coarse material (>2mm). A specimen is then disaggregated through mixing with Calgon solution. The material is then suspended in solution wherein regular hydrometer readings are taken at specific time intervals. The principles of Stokes' Law are applied to determine the amount of material remaining in solution as well as the maximum particle size remaining in solution at the specified time.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Grain Size Report (Attachment) Hydrometer/Sieve Method	E185 Saskatoon - Environmental	Soil/Solid	ASTM D6913/D7928	A grain size curve is a graphical representation of the particle sizing of a sample representing the percent passing against the effective particle size.
Loss On Ignition (550°C)	E205D Saskatoon - Environmental	Soil/Solid	CSSS (2008) 28.3 (mod)	Loss On Ignition (LOI) is determined by drying a portion of an air dried and ground sample at 105°C overnight, then igniting at 550°C for 16-20 hours. The weight loss after ignition is reported as % loss on ignition. LOI is reported on a dry weight basis. LOI at 550°C can be used as an estimation of Organic Matter (CSSS 2008).
Chloride by IC (Saturated Paste)	E239.Cl Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate by IC (Saturated Paste)	E239.NO3 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Sulfate by IC (Saturated Paste)	E239.SO4 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Available Nitrate and Nitrite by Colourimetry (0.01M Calcium Chloride Ext.)	E269.N+N Saskatoon - Environmental	Soil/Solid	Alberta Agriculture/APHA 4500-NO3 I (mod)	Plant available nitrate and nitrite are analyzed by colourimetry using a flow injection analyzer on a soil sample extract that has been extracted using 0.01M Calcium Chloride, then shaken well and filtered prior to analysis.
Alkalinity Species by Titration (Saturated Paste)	E293 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15/APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint on an extract produced by the saturated paste procedure. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Total Kjeldahl Nitrogen by Colourimetry	E319 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.2.3	The soil is digested with sulfuric acid in the presence of $CuSO_4$ and K_2SO_4 catalysts. Ammonia in the soil extract is determined colrimetrically at 660 nm.
Total Carbon by Combustion	E351 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 21.2 (mod)	Total Carbon is determined by the high temperature combustion method with measurement by an infrared detector.
Total Inorganic Carbon by Acetic Acid pH Standard Curve	E354 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 20.2	Total Inorganic Carbon is determined by acetic acid pH standard curve, where a known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.
Total Nitrogen by Combustion	E366 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.4	The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Available Phosphorus by FIALab (Modified Kelowna)	E384 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available phosphorus is extracted from air dried soil using a fixed ratio Modified Kelowna extraction. Phosphorus is determined by colorimetry using an flow injection analyzer.
Available Potassium by flame photometry (Modified Kelowna)	E390 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available potassium is extracted from soil using modified Kelowna solution. Potassium is determined by flame emission at 770 nm.
Metals in Soil/Solid by CRC ICPMS	E440 Vancouver - Environmental	Soil/Solid	EPA 6020B (mod)	This method is intended to liberate metals that may be environmentally available. Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Silicate minerals are not solubilized. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. This method does not adequately recover elemental sulfur, and is unsuitable for assessment of elemental sulfur standards or guidelines. Analysis is by Collision/Reaction Cell ICPMS.
Ca, K, Mg, and Na by CRC ICPMS (Saturated Paste, mg/L)	E442 Vancouver - Environmental	Soil/Solid	CSSS CH15/EPA 6020B (mod)	A soil extract produced by the saturated paste extraction procedure is analyzed for Calcium, Magnesium, Potassium and Sodium by Collision/Reaction Cell ICPMS as per "Soil Sampling Methods of Analysis" By M Carter.
Available Sulfate by ICPOES (0.01M Calcium Chloride Ext.)	E497.SO4 Saskatoon - Environmental	Soil/Solid	Alberta Agriculture	Plant available sulfate is determined by ICPOES. Soil is extracted using a 0.01M calcium chloride solution. This extraction may also produce organic sulfur in the extracts when organic soils are analyzed.
Mercury in Soil/Solid by CVAAS	E510 Vancouver - Environmental	Soil/Solid	EPA 200.2/1631 Appendix (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO3 and HCl, followed by CVAAS analysis.
Sodium Adsorption Ratio (SAR) Saturated Paste	EC102 Vancouver - Environmental	Soil/Solid	CCME Sodium Adsorption Ratio (SAR)	The Sodium Adsorption Ratio (SAR) for a sample is calculated from the Sodium, Calcium, and Magnesium concentrations from sediment paste extract.
Theoretical Gypsum Requirements (TGR) Saturated Paste	EC106 Vancouver - Environmental	Soil/Solid	J. Ashworth et al (1999)	Theoretical Gypsum Requirement is an estimate of the gypsum amendment required to remediate brine contaminated or sodic soils, and is provided in units of tonnes per hectare (t/ha) for a treatment depth of 15cm. TGR(brine), intended for brine-contaminated soils, is calculated using Method A from "A Comparison of Methods for Gypsum Requirement of Brine-Contaminated Soils", by J. Ashworth (Cdn J. of Soil Science, 1999), available at www.alsglobal.com. TGR(sodic), intended for naturally sodic soils, uses the Oster and Frenkel method (Method B) from the same paper. Reported TGR values are capped at 50 t/ha, considered the maximum practical gypsum amendment. To convert TGR from t/ha to tons/acre, multiply by 0.446. To determine a TGR value for an alternate treatment depth, multiply by [desired treatment depth (cm) / 15 cm].

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Chloride by IC (Saturated Paste) (mg/kg)	EC239A.Cl Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate by IC (Saturated Paste) (mg/kg)	EC239A.NO3 Vancouver - Environmental	Soil/Solid	Calculation	Results are reported in mg/kg dry weight
Sulfate by IC (Saturated Paste) (mg/kg)	EC239A.SO4 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15 (mod)/EPA 300.1 (mod)	Inorganic anions are analyzed by obtaining a soil extract produced by the saturated paste extraction procedure which is then analyzed by Ion Chromatography with conductivity and/or UV detection.
Alkalinity Species by Titration (Saturated Paste) (mg/kg)	EC293 Vancouver - Environmental	Soil/Solid	CSSS Ch. 15/APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint on an extract produced by the saturated paste procedure. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Total Organic Carbon (Calculated) in soil	EC356 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 21.2	Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon (TIC).
Ca, K, Mg, Na by ICPMS (Saturated Paste, mg/kg)	EC442 Vancouver - Environmental	Soil/Solid	CSSS CH15/EPA 6020B (mod)	A soil extract produced by the saturated paste extraction procedure is analyzed for Calcium, Magnesium, Potassium, Sodium by ICPMS.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Leach 1:2 Soil:Water for pH/EC	EP108 Vancouver - Environmental	Soil/Solid	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL	The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water.
Leach 1:2 Soil : 0.01CaCl2	EP108B Saskatoon - Environmental	Soil/Solid	CSSS (2008) 16.3	A 10g portion of dried (<60°C) and ground (10 mesh/2 mm) sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil by centrifuging, settling or decanting and then analyzed using a pH meter and electrode.
Fixed ratio 0.01M Calcium Chloride extraction for plant available nutrients	EP269 Saskatoon - Environmental	Soil/Solid	Alberta Agriculture	Plant available nutrients (N&S) extracted using 0.01M calcium chloride, then shaken well and filtered prior to analysis.
Kjeldahl Digestion for soils	EP319 Saskatoon - Environmental	Soil/Solid	CSSS (2008) 22.2.3	The soil is digested with sulfuric acid in the presence of CuSO4 and K2SO4 catalysts.
Modified Kelowna Extraction for soil	EP384 Saskatoon - Environmental	Soil/Solid	Comm. Soil Sci. Plant Anal, 25 (5&6)	Plant available phosphorus and potassium are extracted from the soil using fixed ratio Modified Kelowna solution.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Digestion for Metals and Mercury	EP440 Vancouver - Environmental	Soil/Solid	EPA 200.2 (mod)	Samples are dried, then sieved through a 2 mm sieve, and digested with HNO_3 and HCl. This method is intended to liberate metals that may be environmentally available.
Dry and Grind	EPP442 Saskatoon - Environmental	Soil/Solid	Soil Sampling and Methods of Analysis, Carter 2008	After removal of any coarse fragments and reservation of wet subsamples a portion of homogenized sample is set in a tray and dried at less than 60°C until dry. The sample is then particle size reduced with an automated crusher or mortar and pestle, typically to <2 mm. Further size reduction may be needed for particular tests.

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Soil/Solid**

Qualifier	*Description*
DUP-H	*Duplicate results outside ALS DQO, due to sample heterogeneity.*

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Sub-Matrix: **Soil/Solid**

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Soil/Solid**

Reference Material (RM) Report

A Reference Material (RM) is a homogenous material with known and well-established analyte concentrations. RMs are processed in an identical manner to test samples, and are used to monitor and control the accuracy and precision of a test method for a typical sample matrix. RM results are expressed as percent recovery of the target analyte concentration. RM targets may be certified target concentrations provided by the RM supplier, or may be ALS long-term mean values (for empirical test methods).

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QC Interpretive report to assist with Quality Review and Sample Receipt Notification (SRN).

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Signatories	*Position*	*Laboratory Department*
Alex Thornton	Analyst	Metals, Burnaby, British Columbia
Dan Gebert	Laboratory Analyst	Metals, Burnaby, British Columbia
Kevin Duarte	Supervisor - Metals ICP Instrumentation	Metals, Burnaby, British Columbia
Owen Cheng		Metals, Burnaby, British Columbia
Parnian Sane	Analyst	Metals, Burnaby, British Columbia
Salimah Khimani	Lab Assistant	Metals, Burnaby, British Columbia

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances

LOR: Limit of Reporting (detection limit).

Unit	*Description*
%	percent
mg/kg	milligrams per kilogram
mg/kg wwt	milligrams per kilogram wet weight

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLA	*Detection Limit adjusted for required dilution.*
DLI	*Detection Limit Raised: Dilution required to address Internal Standard response problems caused by matrix interference.*
DLM	*Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).*

ALS Canada Ltd.

QUALITY CONTROL INTERPRETIVE REPORT

Work Order	: **VA22C2369**	Page	: 1 of 109
Client	: **Golder Associates Ltd.**	Laboratory	: Vancouver - Environmental
Contact	: Samantha Lundquist	Account Manager	: Amber Springer
Address	: 200-2920 Virtual Way Vancouver BC Canada V5M 0C4	Address	: 8081 Lougheed Highway Burnaby, British Columbia Canada V5A 1W9
Telephone	: ----	Telephone	: +1 604 253 4188
Project	: 22514095/42200/42213	Date Samples Received	: 17-Sep-2022 14:40
PO	: 5590008044	Issue Date	: 03-Nov-2022 16:04
C-O-C number	: 17-686095A-095M		
Sampler	: SL		
Site	: ----		
Quote number	: Golder/Mt. Polley (VA22-MPMC100-007)		
No. of samples received	: 131		
No. of samples analysed	: 131		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Duplicate outliers occur.
- No Laboratory Control Sample (LCS) outliers occur
- Method Blank value outliers occur - please see following pages for full details.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- Reference Material (RM) Sample outliers occur - please see the following pages for full details.

Outliers : Analysis Holding Time Compliance (Breaches)

- No Analysis Holding Time Outliers exist.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Outliers : Quality Control Samples

Duplicates, Method Blanks, Laboratory Control Samples and Matrix Spikes

Matrix: **Biota**

Analyte Group	Laboratory sample ID	Client/Ref Sample ID	Analyte	CAS Number	Method	Result	Limits	Comment
Method Blank (MB) Values								
Metals	QC-MRG6-7231200 01	----	zinc	7440-66-6	E440	0.66 mg/kg B	0.5 mg/kg	Blank result exceeds permitted value
Metals	QC-MRG6-7231200 01	----	zinc	7440-66-6	E440A	0.13 mg/kg wwt B	0.1 mg/kg wwt	Blank result exceeds permitted value

Result Qualifiers

Qualifier	Description
B	*Method Blank exceeds ALS DQO. Associated sample results which are < Limit of Reporting or > 5 times blank level are considered reliable.*

Reference Material (RM) Sample								
Metals	QC-MRG6-7231100 03	----	chromium	7440-47-3	E440	134 % MES	70.0-130%	Recovery greater than upper control limit
Metals	QC-MRG6-7154750 03	----	lead	7439-92-1	E440	132 % MES	70.0-130%	Recovery greater than upper control limit
Metals	QC-MRG6-7231100 03	----	lead	7439-92-1	E440	134 % MES	70.0-130%	Recovery greater than upper control limit
Metals	QC-MRG6-7231100 03	----	chromium	7440-47-3	E440A	134 % MES	70.0-130%	Recovery greater than upper control limit
Metals	QC-MRG6-7154750 03	----	lead	7439-92-1	E440A	132 % MES	70.0-130%	Recovery greater than upper control limit
Metals	QC-MRG6-7231100 03	----	lead	7439-92-1	E440A	134 % MES	70.0-130%	Recovery greater than upper control limit

Result Qualifiers

Qualifier	Description
MES	*Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).*

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Biota**

Evaluation: × = *QC frequency outside specification*; ✓ = *QC frequency within specification.*

Quality Control Sample Type			Count		Frequency (%)

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Moisture Content by Gravimetry	E144 Vancouver - Environmental	Biota	Puget Sound Water Quality Authority/CCME PHC in Soil - Tier 1	Moisture is measured gravimetrically by drying the sample at 105°C. Moisture content is calculated as the weight loss (due to water) divided by the wet weight of the sample, expressed as a percentage.
Metals in Biota by CRC ICPMS (DRY units, Routine)	E440 Vancouver - Environmental	Biota	EPA 200.3/6020B (mod)	Tissue samples are homogenized and sub-sampled prior to hotblock digestion with HNO3, HCl, and H2O2. Analysis is by Collision/Reaction Cell ICPMS. Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.
Silver in Biota by CRC ICPMS (DRY units, Routine)	E440.Ag Vancouver - Environmental	Biota	EPA 200.3/6020B (mod)	Tissue samples are homogenized and sub-sampled prior to hotblock digestion with HNO3, HCl, and H2O2. Analysis is by Collision/Reaction Cell ICPMS. Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.
Metals in Biota by CRC ICPMS (WET units, Routine)	E440A Vancouver - Environmental	Biota	EPA 200.3/6020B (mod)	Tissue samples are homogenized and sub-sampled prior to hotblock digestion with HNO3, HCl, and H2O2. Analysis is by Collision/Reaction Cell ICPMS. Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.
Silver in Biota by CRC ICPMS (WET units, Routine)	E440A.Ag Vancouver - Environmental	Biota	EPA 200.3/6020B (mod)	Tissue samples are homogenized and sub-sampled prior to hotblock digestion with HNO3, HCl, and H2O2. Analysis is by Collision/Reaction Cell ICPMS. Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.
Mercury in Biota by CVAAS (DRY units, Routine)	E510 Vancouver - Environmental	Biota	EPA 200.3/1631 Appendix (mod)	Samples are homogenized and sub-sampled prior to hotblock digestion with HNO3, HCl, and H2O2. Analysis is by CVAAS.
Mercury in Biota by CVAAS (WET units, Routine)	E510A Vancouver - Environmental	Biota	EPA 200.3/1631 Appendix (mod)	Samples are homogenized and sub-sampled prior to hotblock digestion with HNO3, HCl, and H2O2. Analysis is by CVAAS.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Metals and Mercury Biota Digestion	EP440 Vancouver - Environmental	Biota	EPA 200.3	This method uses a heated strong acid digestion with HNO_3, HCl, and H_2O_2 and is intended to provide a conservative estimate of bio-available metals.

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Biota**

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Qualifiers

Qualifier	Description
B	*Method Blank exceeds ALS DQO. Associated sample results which are < Limit of Reporting or > 5 times blank level are considered reliable.*

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Biota**

Reference Material (RM) Report

A Reference Material (RM) is a homogenous material with known and well-established analyte concentrations. RMs are processed in an identical manner to test samples, and are used to monitor and control the accuracy and precision of a test method for a typical sample matrix. RM results are expressed as percent recovery of the target analyte concentration. RM targets may be certified target concentrations provided by the RM supplier, or may be ALS long-term mean values (for empirical test methods).

JULY 2017 FRONT

Failure to complete all portions of this form may delay analysis. Please fill in this form LEGIBLY. By the use of this form the user acknowledges and agrees with the Terms and Conditions as specified on the back page of the white - report copy.

1. If any water samples are taken from a Regulated Drinking Water (DW) System, please submit using an Authorized DW COC form.

APPENDIX D

Soil Screening Results

Table D-1:
Soil Screening Analytical Results
Ecological Risk Assessment
Mount Polley Mine, British Columbia

Notes:
Value = RPD is greater than 35%

BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; dS/m = deciSiemens per metre; FDA = field duplicate available; FD = field duplicate; G = generic; mg/kg = milligram per kilogram; mg/L = milligram per liter; QAQC = quality assurance quality control sample type; T = toxicity to soil invertebrates and plants; t/ha = tonnes per hectare; WLR = wildlands reverted; % = percent; < = indicates parameter was below laboratory equipment detection limit.

APPENDIX E

Vegetation Screening Results

Table E-1: List of identified vegetation species at Mt. Polley (13-16 September 2022)

Common Name	Scientific Name
Trees	
black cottonwood	*Populus trichocarpa*
lodgepole pine	*Pinus contorta* var. *latifolia*
Rocky Mountain Douglas-fir	*Pseudotsuga menziesii* var. *glauca*
Sitka alder	*Alnus alnobetula* ssp. *Sinuate*
trembling aspen	*Populus tremuloides*
western hemlock	*Tsuga heterophylla*
western redcedar	*Thuja plicata*
Shrubs (Berries)	
black elderberry	*Sambucus racemosa* var. *melanocarpa*
red raspberry	*Rubus idaeus* ssp. *Strigosus*
soopolallie	*Shepherdia canadensis*
Forbs	
bunchberry	*Cornus canadensi*
dandelion	*Taraxacum* sp.
false Solomon's-seal	*Maianthemum racemosum* ssp. *Amplexicaule*
Lindley's aster	*Symphyotrichum ciliolatum*
Loesel's tumble-mustard	*Sisymbrium loeselii*
pearly everlasting	*Anaphalis margaritacea*
pink wintergreen	*Pyrola asarifolia* ssp. *asarifoli*
red clover	*Trifolium pratense*
wild chamomile	*matricaria chamomilla*
yarrow	*Achillea millefolium*
yellow salsify	*Tragopogon dubius*
rattlesnake-plantain	*Goodyera oblongifoli*
Graminoid	
common timothy	*Phleum pratense* ssp. *pratense*
mountain brome	*Bromus carinatus* var. *marginatus*
nodding trisetum	*Trisetum cernuum*
slender wheatgrass	*Elymus trachycaulus* ssp. *Trachycaulus*

Note: see Appendix B – Photo Log for Site photographs.

APPENDIX F

Sample Calculations

SOIL AND FOOD INGESTION BY SMALL MAMMALS AND BIRDS

Exposure equations used to estimate the daily dose of copper to mammals and birds are based on CCME (2020), as presented below:

Estimated Dose via Ingestion of Soil

Soil dose (mg/kg bw/day) = SIR x C_s (Equation 1)

Where:

- SIR = soil ingestion rate (kg dw/kg bw/day)
- C_s = measured concentration of POPC in soil (mg/kg dw)
- mg = milligram
- kg = kilogram
- dw = dry weight concentration
- bw = body weight of receptor

Estimated Dose via Ingestion of Food

Food dose (mg/kg bw/day) = FIR x $\sum_1^j (C_{Fj} \times P_{Fj})$ (Equation 2)

Where:

- FIR = food ingestion rate (kg dw/kg bw/day)
- C_{Fj} = measured concentration of POPC in food item j in the diet of the receptor (mg/kg dw)
- p_{Fj} = proportion of food item j in the diet of the receptor (unitless)
- mg = milligram
- kg = kilogram
- dw = dry weight concentration
- bw = body weight of receptor

Total Dose

Total dose = Soil dose + Food dose* (Equation 3)

*The dose from water is not considered in this ERA.

Sample calculations

Sample calculations are provided below for the meadow vole (herbivore) exposure to **copper:**

STEP 1: CALCULATE DOSE VIA SOIL INGESTION

The dose from soil ingestion is calculated as follow:

$$Soil\ dose\ (mg/kg\ bw/day) = SIR \times C_s \qquad \text{(Equation 1)}$$

The input values are as follows:

Parameter	Value	Units	Source
SIR	3.2E-03	kg dw/kg bw/day	FCSAP, 2012
C_s	830	mg/kg	Maximum concentration measured in soil on-site (from Station S-11)

Based on the above parameter, the dose via soil ingestion:
2.6E+00

STEP 2: CALCULATE DOSE VIA FOOD INGESTION

The dose from food ingestion (comprised of plants) is calculated as follow:

$$Food\ dose\ (mg/kg\ bw/day) = FIR \times \sum_1^j (C_{Fj} \times P_{Fj}) \qquad \text{(Equation 2)}$$

The input values are as follows:

Parameter	Value	Units	Source
FIR	1.3E-01	kg dw/kg bw/day	FCSAP, 2012
C_{Fj}	2.3E+01	mg/kg dw	Maximum concentration of copper measured in plant tissue on-site (red raspberry leaves at S-1)
P_{Fj}	1.0	unitless	FCSAP, 2012 (Diet is assumed to be 100% plants)

Based on the above parameters, the dose from food ingestion (diet comprised exclusively of plants) is:
3.1E+00

STEP 3: CALCULATE THE TOTAL DAILY DOSE

The unadjusted total dose is calculated as follow:

$$Total\ dose^* = Soil\ dose + Food\ dose \qquad \text{(Equation 3)}$$

The input values are as follows:

Parameter	Value	Units	Source
Food dose	3.1E+00	mg/kg bw/day	Step 2
Soil dose	2.6E+00	mg/kg bw/day	Step 1

Based on the above parameters, the total daily dose is:
5.7E+00

3	Annual Review	Dec. 2020	GH

1 Introduction

The BC Ministry of Forest, Lands and Natural Resource Operations (as per the British Columbia [BC] Inter-Ministry Invasive Plant Working Group) defines invasive plants as “non-native (alien) plants whose introduction into BC cause, or are likely to cause, economic or environmental damage, or harm to human health” (MFLNRO, 2014). The Invasive Species Council of BC has a similar definition, and notes that invasive plants can establish quickly and easily on both disturbed and un-disturbed sites, causing widespread negative economic, social, and environmental impacts (ISCBC, 2015).

Mining operations result in disturbed areas, which can be susceptible to invasion of invasive plants. Such invasions have the potential to hinder reclamation efforts or interfere with regional invasive plant management programs. To manage this risk, Mount Polley Mining Corporation (MPMC) has developed this Invasive Plant Management Plan (the “Plan”). The purpose of the Plan is to outline procedures for the prevention and, if necessary, control (mitigation) of the establishment of invasive plants or noxious weeds in the Mount Polley Mine (the “Mine”) area throughout the Mine project life, including closure.

1.1 Regulatory Framework

The BC *Weed Control Act* (RSBC, 1996) requires owners or occupiers of crown and private lands in BC (excluding those under federal jurisdiction) to control listed noxious weeds. As such, MPMC is under legal obligation to control these species. At the time of last update of this Plan, the BC Proposed Prohibited Noxious Weeds List (MFLNRO, 2016) was the most up to date applicable listing.

As per the BC *Mines Act* Section 10.7, mine land surfaces must be reclaimed to an approved end land use at closure, excluding lands that are not to be reclaimed, and the average land capability should be equal to or greater than the average land capability present prior to mining. While these requirements do not specifically mention invasive plants, they are inherently included; given the undesirable nature of invasive plants, their associated negative environmental and economic impacts, and the fact that invasive plants are non-native, such species are likely inconsistent with closure revegetation objectives and could result in a mining company not meeting their closure revegetation targets.

In addition, under MPMC’s *Mines Act* Permit M-200, the following additional specific conditions apply to invasive species management at the site:

- The Permittee shall manage and control invasive species that establish on the site and shall take reasonable efforts to ensure that invasive species do not move from the site to adjacent areas.
- The Permittee shall ensure that all seed mixes are certified as weed-free.
- Revegetation species shall be selected based on the principles of ecological succession and traditional use and cultural significance, including all reasonable efforts to use only native species unless short-lived agronomic species are required to temporarily control erosion or prevent ingress of invasive species.

While not associated with regulatory requirements, the Cariboo Chilcotin Coast Invasive Plant Council (CCCIPC) is a non-profit organization that coordinates the invasive plant management efforts of government agencies, individuals, communities and industry sectors, and promotes awareness and education about invasive plants in the region. Each year, the CCCIPC produces an Annual Strategic Plan (http://cccipc.ca/index.php/S=0/resources/regional-strategic-plans/) which incorporates provincial requirements (e.g., noxious weeds listings) and is to be used as a guide for invasive plant management activities and resource allocation in region.

2 Objectives

As described above, the purpose of the Plan is to outline procedures for the prevention and, if necessary, mitigation of the establishment of invasive plants or noxious weeds in the Mount Polley Mine area throughout the Mine project life and closure. The specific objectives are to:

- Control invasive plant establishment on the site, such that reclamation objectives are achieved. Reclamation objectives include establishing self-sustaining vegetative covers on disturbed areas at the Mine site with native vegetation this is appropriate to the target site series and consequently promotes the target end land use(s); and
- Implement invasive plant control measures consistent with the Regional Strategic Plan and the BC Proposed Prohibited Noxious Weeds List.

This Plan applies to the operations footprint of the Mine as well as areas being rehabilitated following the tailings dam embankment breach. However, only the Mine site is regulated under the BC *Mines Act* and associated items (e.g., permit requirements and land capability requirements) do not apply to breach rehabilitation areas. Instead, reclamation revegetation objectives for the breach area will be defined by the Remediation Plan due for submission in the third quarter of 2017.

The Plan follows the Plan, Do, Check, and Act cycle developed by the International Standards Organization guidelines. The cycle is described as follows:

- **PLAN** - identifies potential sources of invasive plant ingress that may challenge achieving the objectives of the program;
- **DO** - documents the prevention and control management practices in place at the Mine;
- **CHECK** - describes the monitoring procedures and methods for evaluating monitoring results against the objectives; and
- **ACT** - describes review of the management program and update of procedures based on monitoring results in order to promote its continuous improvement and mitigate identified deficiencies.

3 Plan: Identification of Potential Sources of Invasive Plant Ingress

Mining activities can facilitate the introduction or spread of invasive plants by removing native vegetation, which decreases competition for weedy plants, and creating exposed soil in disturbed areas. Exposed areas create a soil bed which may allow invasive plants to establish. These areas include:

- Soil stockpiles and areas from which the soil was salvaged;
- Soil applied to reclamation areas;
- Road and powerline construction and maintenance activities; and
- Exposed areas around the Mill site, maintenance areas and other associated infrastructure.

Table 1 provides an overview of potential sources of invasive plant ingress to the site. Each potential source is classified into if control is possible or not. If control is not possible, for example the movement of wildlife or wind transport of seed, only prevention methods (and, if necessary, mitigation measures) are applicable to management.

Table 1 Potential sources of invasive plant ingress and/or spread at the Mount Polley Mine site

Category	Source	Control Method Possible
Animals	Livestock	×
	Wildlife	×
Natural spread	Wind (long-distance)	×
	Rhizome spread or seed drop (short-distance)	✓ (within Mine site only)
Human-mediated spread	People – on-site (e.g., employees, and contractors)	✓
	People – off-site (e.g., tourists and recreationists; spread to areas immediately adjacent to site)	×
	Vehicles and equipment – on-site	✓
	Vehicles and equipment – off-site (spread to areas immediately adjacent to site)	×
Reclamation Activities	Application of soil from contaminated soil stockpiles	✓
	Use of contaminated seed or soil amendments	✓
	Use of contaminated soil amendments	✓

4 Do: Prevention and Control Measures

4.1 Preventative Measures

The primary goal involved in managing invasive plant infestations in the project area is to carry out mining activities in a manner that prevents the introduction or spread of invasive plants and supports the ability to establish desired species during site reclamation activities.

MPMC is to implement the following best management practices for preventing invasive plant establishment on disturbed areas at the Mine, which are to minimize disturbance during all phases of the mining operation in order to limit the availability of exposed, un-vegetated ground to invasive plant seed deposition; and establish a vegetative cover as soon as possible after ground disturbance. Specifics for establishing ground cover vegetation are as follows:

- Seed ground disturbed due to construction or mining activity with a rapidly establishing seed mix for erosion protection and invasive plant control if reclamation of the area is not imminent. Active areas (e.g., open pits or areas without appropriate substrates for vegetation growth) at the Mine do not require invasive plant control as vegetation does not have a chance to become established;
- Seed soil stockpiles; water management features such as ditches and sediment pond berms; borrow pits; road edges; powerline access roads and power pole installation sites; inactive sections of mill site areas, storage and equipment yards; and generally any disturbed ground where invasive plant establishment is possible;
- Use only high quality grade seed in the reclamation and interim invasive plant control seed mixtures. Low quality grade seed may contain a higher portion of weed seed in the seed lot. At minimum, ensure that the seed used for revegetation is of the grade Common #1 Forage Mixture or Canada No. 1 Ground Cover Mixture.
- Assess soil amendments that may contain invasive plant seeds or propagules. This is currently only applicable to biosolids, and MPMC's supplier (Metro Vancouver) tests the material to verify that invasive plant seeds are not present.

MPMC typically conducts a seeding program annually in the spring and/or fall, and any disturbed areas (as described above) or areas that were previously seeded but lack appropriate native vegetative cover, should be added to the list of areas to be seeded.

4.2 Control Measures

If monitoring results (Section 5) show areas of invasive species infestation that are not consistent with the objectives of this Plan (Section 2), available control or mitigation options for managing established invasive plants include mechanical, biological, and chemical methods.

Mechanical methods include:

- Hand weeding or pulling (if plants are hand-pulled, propagules are to be removed from the site and disposed of in a way that does not allow the spread of seeds. i.e., burned, not composted);
- Mowing or cutting; and
- Burning.

Biological control agents are natural organisms that are another option for reducing invasive species populations. Typically, they are insects, nematodes, fungi or viruses that infect or invade the invasive plants and weaken the target species by decreasing seed production and reducing density. Biological control is only an option for select invasive species

Chemical control through application of herbicides will be the method of last resort because applications are limited by proximity to watercourses and can potentially have detrimental effects on native vegetation.

In addition to these mitigation methods, contingency control programs that could be reviewed for feasibility and implemented are:

- Inspection and/or cleaning of vehicles or equipment coming from offsite or moving from an infested area to an uninfested area within the site;
- Refraining from driving through areas infested with invasive plants;
- Limiting road maintenance to the road surface to retain vegetation along the roadsides;
- Keeping equipment yards and vehicle storage facilities free of invasive plants; and
- Training personnel on preventing invasive plant spread by checking and removing seeds from clothing and equipment.

It is important to note that majority of the invasive plants observed at the Mine are designated in the CCCIPC Regional Strategic Plans as “established” or are designated as non-native species (not invasive species), and management options are not implemented regionally because control of these species is not currently feasible. As such, MPMC does not actively manage these species, unless they are directly impeding reclamation efforts. These aforementioned control measures are listed as options for future use, as required, and are currently not a routine component of MPMC’s invasive plant management activities, as the Plan objectives are being met without their use.

Mitigation measures will focus on the “new invaders” and “containment” categories, as well as any “established” species if they are directly impeding reclamation efforts. Consistent with the Regional Strategic Plan, the treatment goal for “new invaders” is eradication (elimination of all individuals and their propagules), while the treatment objective for species listed for “containment” is prevention of invasive

plants from spreading to uninfested areas. For species that are impeding reclamation revegetation, but are regionally listed under “containment” or “established” categories, the primary option will be suppression (reduction in plant population size and abundance). These control measures generally follow the following process, based on the level of infestation:

1. Prevent new infestations from becoming established;
2. Eradicate small or isolated “satellite” infestations;
3. Contain the perimeter of large “core” infestations; and
4. Suppress the interior of large “core” infestations.

If control measures area applied in the future, any sites that have treatments applied will be monitored through the established methods (described in Section 5) in subsequent years to assess if treatment measures have been successful.

5 Check: Monitoring Program

The MPMC invasive plant monitoring program includes visual surveys conducted in combination with routine assessments of progressive reclamation sites and annual soil stockpiles inspections; invasive plant species present and their percent cover are documented and compiled with revegetation results.

In addition, more formal invasive plant inventories are to be conducted routinely at the Mine site. These inventories should encompass disturbed areas, including any that are undergoing reclamation, as well as adjacent undisturbed areas from which invasive plants could ingress. Inventories may be conducted by MPMC Environmental Department staff with sufficient expertise or an external consultant. Each inventory should include the following items, with the results presented in a report:

- Surveying and mapping of infestation locations, with a focus on reclamation areas and soil stockpiles;
- Identification of invasive plant species present;
- Assessment of the degree of invasive plant growth, distribution, and density present at infestation sites;
- Assessment of success of any prevention and control measures that were previously implemented;
- Recommendations for any prevention and control measures that should be implemented; and
- Recommendations for when the next inventory should be conducted.

Where possible, all assessments and inventories should take place in the late spring/early summer so that eradication measures can be undertaken prior to seed dispersal in late summer/early fall. Alternatively, assessments and inventories can be conducted in mid to late summer, when plants are readily identifiable, with interpretation of results to take place over winter and management applications to be implemented early the following growing season.

6 Act: Program Review and Continuous Improvement

Each year, the results of invasive species monitoring should be reviewed with respect to the objectives outlined in Section 2, and the Plan and associated site invasive plant management activities should be updated accordingly. Specific items that should be reviewed and associated actions are listed in Table 2. When the Plan is updated, it is to be submitted to the Ministry of Energy and Mine with the Annual Environmental and Reclamation Report. In addition, an update on invasive plant monitoring, prevention

and control activities at the Mine (including any pertinent results from progressive reclamation and soil stockpile inspections, and site invasive plant inventory reports) is to be included in the Annual Environmental and Reclamation Report each year.

Table 2 Invasive plant management program review process

Item to Review	Associated Actions
Verify that all seed mixes used were certified weed-free (i.e., comply with Canadian Food Inspection Agency standards).	If seed utilized is not certified weed-free (or invasive plants were suspected to be present in the seed mixtures used): • Change seed suppliers and/or seed mixtures.
Verify that all soil amendments (where appropriate) were tested to confirm they did not contain invasive plant propagules or seeds.	If soil amendments were not tested: • Conduct post-application assessments for any soil amendments not tested; • Discontinue use of any soil amendments not tested until appropriate testing has been completed; and • Plan appropriately to test all amendments prior to use in the future.
Verify that no invasive plants identified in monitoring are on provincial noxious weed lists.	If any noxious weeds are identified: • Implement appropriate control measures (Section 4.2), with the objective of eradication; and • Ensure that measures taken are monitored as per the program in Section 5.
Verify that all invasive plants identified in monitoring are being managed according to the most recent CCCIPC Annual Strategic Plan.	If invasive plant management is inconsistent with the Regional Strategic Plan: • Implement prevention and/or control actions (Section 4) until management actions are consistent with the Regional Strategic Plan; and • Ensure that measures taken are monitored as per the program in Section 5.
Verify that results from reclamation revegetation assessments are consistent with closure objectives (with respect to species composition and/or functional groups). If results are not consistent, verify that invasive plants are not a constraining factor. The prioritization matrix in Figure 1 can be used to aid in separating innocuous from disruptive species in reclamation areas and prioritize management actions accordingly.	If invasive plants are identified as a constraint to meeting revegetation objectives: • Delineate the specific species and areas of concern; • Implement prevention and/or control actions (Section 4) appropriate for the level of infestation, the life history of the identified invasive plants, and available control options; and • Ensure that measures taken and target native reclamation species are monitored in the identified reclamation areas as per the program in Section 5.

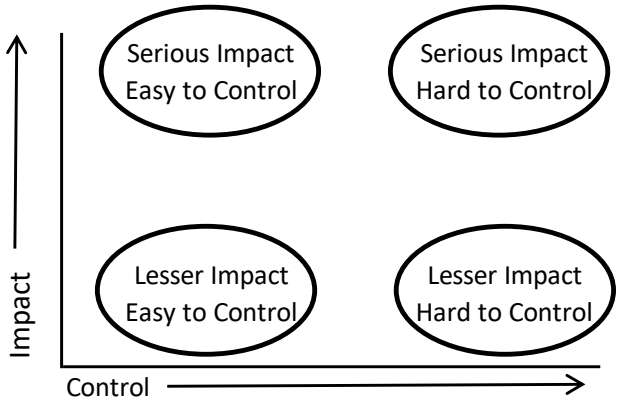

Figure 1 Invasive plant management prioritization matrix (adapted from USFWS, 2009)

7 Responsibilities

Responsible individuals for implementing this Plan are described below.

Environmental Superintendent or designate (e.g., Environmental Supervisor):

- Be knowledgeable of, adhere to, and coordinate implementation of all aspects of this Plan;
- Ensure all other responsible individuals have reviewed the most up to date version of this Plan;
- Ensure this Plan and monitoring data are reviewed annually and updated accordingly, with updates submitted in the Annual Environmental and Reclamation Report and appropriate management actions implemented;
- Be aware of high level mine planning to ensure that seeding of disturbed areas can be done in a timely manner and transport of soil is appropriately managed;
- Review updates to the MPMC *Mines Act* Permit 11678, BC *Mines* Act, CCCIPC Regional Strategic Plan and provincial noxious weed lists and regulations;
- Schedule and assign staff or external contractors to carry out all requirements of this Plan, including monitoring programs and reporting;
- Plan and budget for necessary invasive plant control measures;
- Obtain and permits or authorizations required for control measures that are implemented; and
- Ensure that individuals conducting monitoring, data interpretation, reporting, and planning and implantation of prevention and control measures have appropriate training.

Qualified individual conducting monitoring and reporting (e.g., Environmental Technician, contractor):

- Be knowledgeable of and adhere to all aspects of this Plan;
- Conduct assigned activities, such that all requirements of this Plan (at minimum) are met; and
- Have appropriate training and expertise for assigned components of this Plan.

Staff or contractors conducting control measures

- Have appropriate training and expertise for prevention and control actions they are implementing.

Mine Planning Engineer and General Foreman:

- Notify the Environmental Superintendent or designate of planned disturbances and any transport of soil materials;
- Where possible, minimize the disturbance of vegetated areas; and
- Transmit relevant information related to the aforementioned points to the Mine Operations Supervisors.

Mine Operations Supervisors:

- Supervise operators such that new disturbances and soil handling are conducted as planned.

1 INTRODUCTION

The following describes the Dust Management Plan (the Plan) for the Mount Polley Mine (the Facility), which is located approximately 100 km northeast of the city of Williams Lake, British Columbia (BC), near the town of Likely, BC.

The purpose of the Plan is to:

- identify the sources of fugitive dust emissions associated with the Mount Polley Mine;
- describe how fugitive dust can be controlled from each significant source and describe the best management practices in place and planned for at the Mount Polley Mine;
- describe how the Plan will be implemented, including the training of personnel;
- describe inspection and maintenance procedures; and,
- describe methods of monitoring and appropriate actions/response framework to feedback into refining management actions, as needed, based on monitoring and inspection results (i.e., Act component described below).

The Plan is structured as follows:

- Section 2 provides an overview of the Facility;
- Section 3 provides an overview of the existing meteorological conditions;
- Section 4 provides an overview of the dust monitoring programs;
- Section 5 identifies the responsibilities for each employment level as they relate to the Plan; and,
- Section 6 describes the fugitive dust control measures that are implemented at the Facility. This section follows the Plan, Do, Check, and Act (PDCA) cycle according to the International Standards Organization guidelines. The PDCA cycle is described below:
    - Section 6.1 **PLAN** - identifies the emission sources at the Facility;
    - Section 6.2 **DO** - documents the schedule for implementation of the management practices;
    - Section 6.3 **CHECK** - describes the monitoring procedures and a record keeping system; and
    - Section 6.4 **ACT** - describes the management practice review and update procedures in order to promote its continuous improvement.

According to Section 2.5 of the BC Ministry of Environment (MoE) PA-15087, the Permittee (Mount Polley Mine) shall supress fugitive dust created within the operations area. This plan is an update to the *Fugitive Dust Management Plan Mount Polley* (Golder 2015a) for the tailings storage facility (TSF) submitted by Golder Associates Ltd. (Golder) on May 26, 2015 to the BC MoE. This update includes the entire site of Mount Polley Mine.

2 FACILITY DESCRIPTION

As shown in Figure 2.1, the Mount Polley Mine can be separated into:

- the TSF and surrounding areas (including Polley Flats);
- the crusher and mill processing site; and,
- operations areas (open pits, waste rock dumps, stockpiles, roads, etc.) and surrounding areas.

The Mount Polley mine has been in Care and Maintenance since May 31, 2019. Care and Maintenance operations are focussed on general site maintenance, predominantly ensuring that all pumps, sumps and water management systems are functioning properly. Eleven full time employees work in 4 shifts including day shifts and night shifts.

All environmental monitoring and samplings as per all permits and Comprehensive Monitoring Plan (CEMP) will be followed during this temporary care and maintenance period.

2.1 TSF AND SURROUNDING AREAS

The TSF at Mount Polley Mine consists of tailings material and a single embankment made up of three dams: the Main Embankment, the Perimeter Embankment, and the South Embankment. During the TSF dam failure which occurred on August 4, 2014, water (both supernatant and interstitial) was released from the TSF, resulting in much of the tailings within the TSF being exposed to the elements (i.e., no longer submerged).

The breach of the Mount Polley TSF resulted in the deposition of tailings between Polley Lake and Hazeltine Creek (known as the Polley Flats). Polley Flats covers an approximately 900 m long section of Hazeltine Creek south of Polley Lake. Prior to the breach, the area immediately south of Polley Lake included a wetland. The materials deposited in the Polley Flats are observed to include the following:

- tailings (sandy silt or silty sand, and clay-textured material);
- dam construction materials (gravel, rock fill and till);
- organic matter transported by the tailings flow (including trees and wood debris); and,
- re-worked organic and inorganic materials from the wetland.

Under current conditions, the exposed tailings are retaining moisture, particularly at depth, though the exposed tailings surface will dry in the summer. Dried and exposed tailings combined with high winds could cause the particulates to become airborne, which may potentially affect onsite and offsite air quality.

In addition to the exposed tailings in the TSF and those deposited in the Polley Flats, other identified potential sources for fugitive dust emissions at the Facility are construction emissions related to the disturbance of waste rock during TSF construction and Hazeltine Creek remediation activities. Planting of alder and conifer species has been conducted in the upper and lower Hazeltine Creek areas from 2016 to 2018, resulting in improved vegetation cover and therefore, reduced risk of airborne particulate in the area since the breach.

2.2 CRUSHER AND MILL PROCESSING SITE

The crusher and mill area includes the crusher and mill building, the coarse ore pile, the tertiary pile, the fine ore (mill feed) pile, and the pebble pile (Figure 2.1). No crushing operations are conducted during Care and Maintenance period.

2.3 PITS AND SURROUNDING AREAS

No mining activities are being conducted during Care and Maintenance period. Open pits include Cariboo and Springer Pits and waste rock dumps include the Temporary NW PAG Stockpile, North East Zone (NEZ) Rock Dump and the South East Rock Dump (SERD). Potential sources for fugitive dust include road dust. (Figure 2.1)

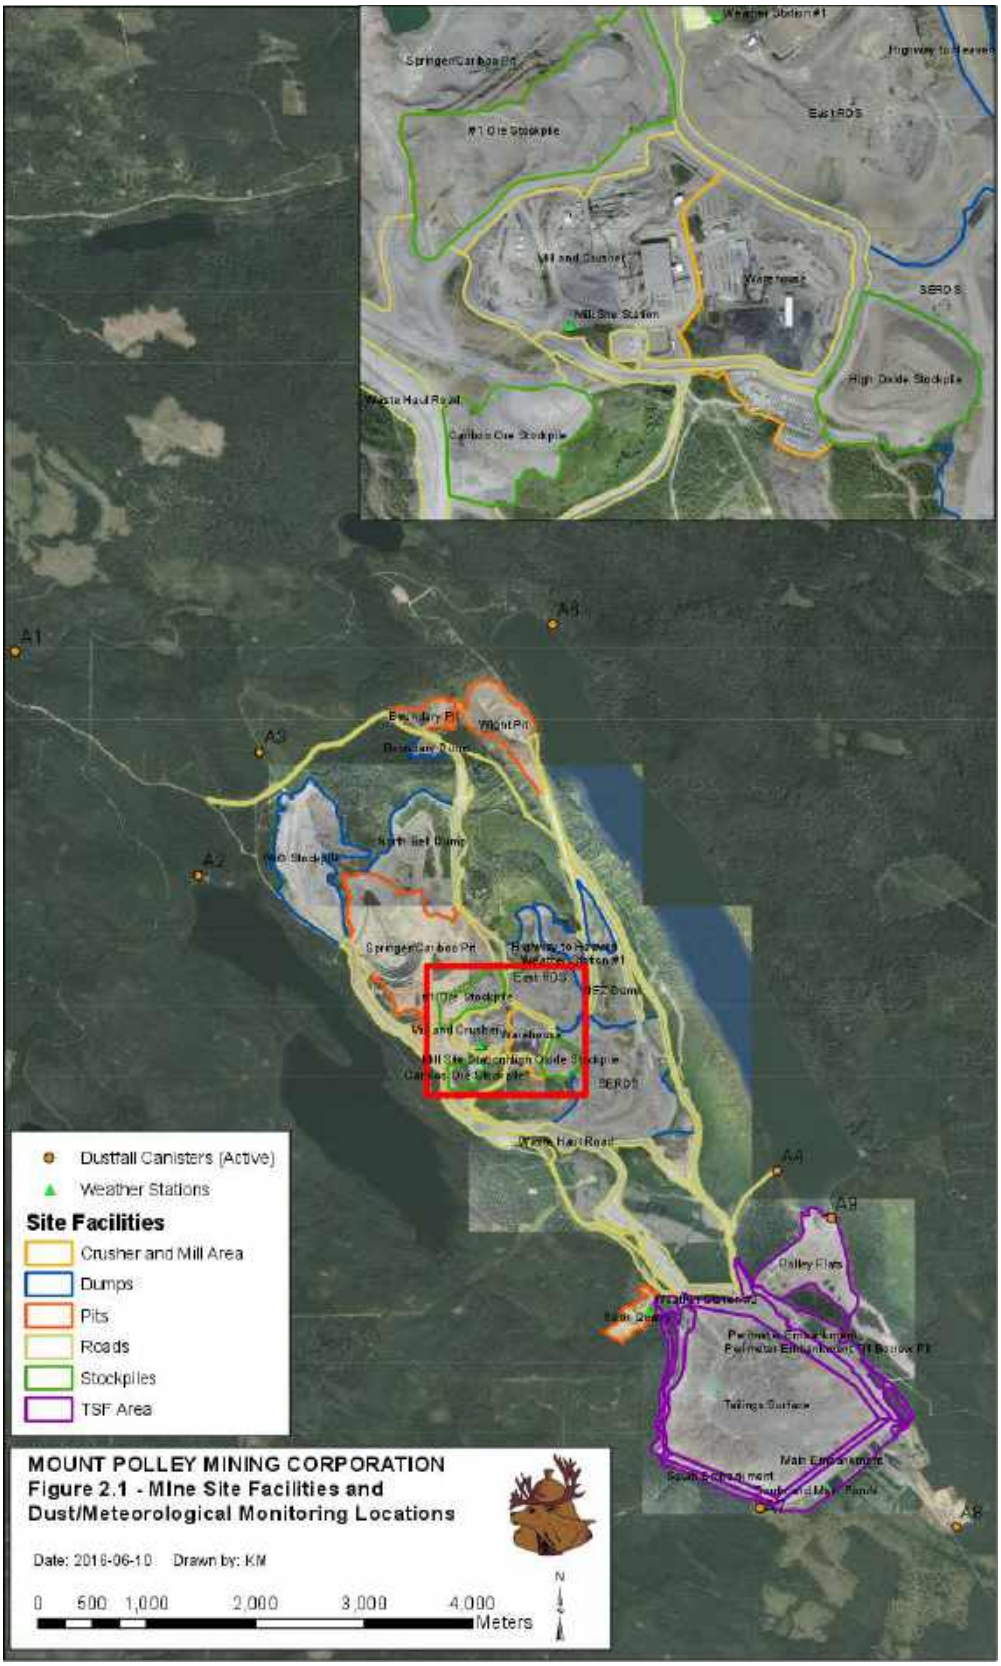

Figure 2.1. Mine Site Facilities and Dust/Meteorological Monitoring Locations

3 METEOROLOGY

Mount Polley Mine has two meteorological monitoring stations on site that have been operating since 2012 (see Figure 2.1). The first station (Station #1) is located southwest of the Polley Mountain summit, at an elevation of 1,171 metres above sea level (masl) near the Mill Site. The second station (Station #2) is located northwest of the TSF, along the access road to the old rock quarry. Station #2 is located atop a topographical rise at an elevation of 964 masl. The two stations are approximately 3.5 km apart, with an elevation difference of approximately 200 m. These stations monitor and record rainfall, temperature, relative humidity, wind speed, wind direction, and solar radiation every 30 minutes. From 1995 to 2012, a single meteorological station located beside the crusher building, northwest of the TSF, was in operation. This station monitored rainfall and temperature only. See Section 2.1 in *Fugitive Dust Management Plan Mount Polley* (Golder 2015a) for data from the three stations.

4 DUST MONITORING

4.1 DUSTFALL MONITORING

Five airborne particulate stations monitored dustfall at the Mount Polley Mine from November 2011 to December 2019; one was added in 2013 and three were added in June 2015. The station A5 was discontinued in August 2014. Station names and locations are presented in Table 4.1 and are shown in Figure 2.1. These air quality monitoring stations provided the fixed, volatile, and total dustfall measured in milligrams per decimetre squared per day (mg/dm^2/d) over a monthly period.

Table 4.1. Airborne Particulate Station Description

Station Name and Description	Easting (m)	Northing (m)	Years Active
A1 – by W12 (6km Creek water monitoring station)	588,221	5,826,043	2011-2019
A2 – at cabin on Bootjack Lake	589,906	5,823,978	2011-2019
A3 – near New Access Road	590,471	5,825,114	2011-2019
A4 – Polley Lake Boat Launch	595,241	5,821,259	2011-2019
A5 – by W7 (Hazeltine Creek water monitoring station)	597,010	5,819,075	2011-2014
A6 – Polley Lake Cabin	593,170	5,826,290	2013-2019
A7 – by Corner 3 (southwest) of TSF	592,969	5,818,320	2015-2019
A8 – southeast of TSF	596,911	5,817,991	2015-2019
A9 – Polley Flats (northeast of TSF)	596,020	5,821,407	2015-2019

The technical memorandum titled *Dustfall Monitoring and Pollution Control Objectives* written by the Air Quality Section of the MoE (2016), states that the Air Quality Section considers dustfall monitoring to be an outdated methodology and no longer recommends its use. For protection of human health, the Air Quality Section recommends particulate monitoring, specifically, monitoring of particulates with a diameter of 10 µm or less and 2.5 µm or less, be conducted instead of dustfall monitoring (MoE 2016; Appendix A). As such, dustfall monitoring will no longer be collected at the Mount Polley Mine. Particulate monitoring at the mine site in discussed in Section 4.2.

4.2 PARTICULATE MONITORING

Particulate matter is generally defined into three size fractions:

- Particulates of all size classes are referred to as total suspended particulate (TSP);
- Particulates with a diameter of 10 µm or less are referred to as PM_{10}; and
- Particulates with a diameter of 2.5 µm or less are referred to as $PM_{2.5}$.

Exposure to respirable (PM_{10}) and fine particulate matter ($PM_{2.5}$) may aggravate a number of respiratory illnesses. Smaller particles are generally thought to be of greater concern to human health than larger particles (US EPA 2016).

The deposition of TSP is generally considered dustfall. Deposition of PM_{10} and $PM_{2.5}$ are limited relative to TSP and these smaller particles can generally travel farther distances than TSP. Currently, there is no monitoring of TSP, PM_{10}, and $PM_{2.5}$ at the Facility, but these parameters were continuously monitored from July to October 2015 at four locations around the TSF and Polley Flats. The monitoring for TSP, PM_{10}, and $PM_{2.5}$ was discontinued based on the monitored results. Of the 82 days that were monitored, only three days had PM_{10} and $PM_{2.5}$ concentrations greater than the AAQO; however, these exceedances were most likely attributable to local and regional forest fires (Golder 2015b). Also, despite August 2015 being a dry month when compared to historical averages, particulate concentration data showed fugitive dust control measures were effective in the TSF and Plug area. For more information see *Continuous Particulate Monitoring at Mount Polley September 17 to 29, 2015: Summary of Particulate Monitoring July 7 to September 29, 2015* (Golder 2015b).

4.3 RECEPTORS

Table 4.3 summarizes offsite sensitive receptors near the Facility, arranged by the least distance from the Facility, which may be affected by fugitive dust (Golder 2015a). There are a number of recreational areas within 10 km of the Facility and the nearest town site is the community of Likely located 12 km northeast of the TSF and 9.5 km northeast of the Mount Polley Mine mill site.

Table 4.2. Sensitive Receptor Locations

Receptor Description	Receptor Name	Easting (m)	Northing (m)	Direction from Facility
Recreation	Polley Lake Campsite	596,031	5,821,197	North
Recreation	Polley Lake	595,508	5821,029	North
Recreation	Bootjack Lake	592,240	5,820,738	Northwest
Recreation	Raft Creek Campsite	601,094	5,818,449	East
Recreation	Bootjack Mountain	589,454	5,820,753	West northwest
Recreation	Quesnel Lake	599,055	5,823,901	Northeast
Recreation	Campsite at Bootjack Lake	590,183	5,823,874	Northwest
Residence	Cedar Creek Rd Residences by Quesnel Lake	599,755	5,826,365	Northeast
Residence	Cabins at Polley Lake	593,105	5,826,547	North northwest

5 RESPONSIBILITIES

The following sections detail the responsibilities held by each of the employment levels at the Facility as they pertain to this Plan.

5.1 SENIOR MANAGEMENT REPRESENTATIVE: MINE MANAGER

The Senior Management Representative, or designate, is responsible for:

- ensuring the required resources are in place to execute the Plan.

5.2 ACCOUNTABLE FACILITY REPRESENTATIVE: ACTING GENERAL MANAGER

The Accountable Facility Representative, or designate, is responsible for:

- reviewing the effectiveness of the current dust control measures at the Facility;
- scheduling and coordinating the implementation of fugitive dust control measures; and,
- training of site personnel and contractors on the Plan and best management practices to be implemented.

5.3 OPERATIONS SUPERVISOR: GENERAL FOREMAN

The Operations Supervisor, or designate, are responsible for:

- reviewing the effectiveness of the current dust control measures at the Facility;
- maintaining documentation of schedules and logs;
- implementing fugitive dust control measures;
- forwarding dust observation reports from site personnel to the Accountable Facility Representative; and,

- completing daily dustfall observations of the TSF and surrounding area as part of the daily Water Management Inspection Manual checklist (Appendix B).

5.4 FACILITY PERSONNEL AND CONTRACTORS

All Facility Personnel and Contractors are responsible for:

- following the dust control procedures that are currently in place; and,
- reporting dust observations to appropriate supervisor.

5.5 TECHNICAL SERVICES SUPERINTENDENT

The Technical Services Superintendent is responsible for:

- providing feedback on the effectiveness of the current dust control measures at the Facility;
- conducting internal audits of the dust control measures at the Facility;
- coordinating external audits of the dust control measures at the Facility;
- coordinating dust sampling programs; and,
- reporting results to regulatory authorities.

6 FUGITIVE DUST EMISSIONS MANAGEMENT

This section describes the fugitive dust control measures that are implemented at the Facility. This section follows the PDCA cycle as described below:

- Section 6.1 **PLAN** - identifies the emission sources at the Facility.
- Section 6.2 **DO** - documents the schedule for implementation of the management practice(s).
- Section 6.3 **CHECK** - describes the monitoring procedures and a record keeping system.
- Section 6.4 **ACT** - describes the management practice review and updating procedures in order to promote its continuous improvement.

6.1 PLAN – IDENTIFICATION AND CLASSIFICATION OF FUGITIVE DUST EMISSIONS

6.1.1 Identification of the Sources of Fugitive Dust Emissions

Fugitive dust emissions occur due to mechanical disturbances of granular materials exposed to the air. Dust generated from these open sources is termed "fugitive" as it is not discharged to the atmosphere in a confined flow stream, such as through an exhaust pipe or stack (US EPA 1995).

Mechanical disturbances are often created from activities such as vehicle movement, crushing and material transfer activities, but can also be created from wind action, which promotes lifting of fine particles from sources such as open fields and stockpiles. Therefore, some fugitive dust emissions occur, or are intensified during, certain operations and/or by natural means (e.g., wind action).

Factors that would affect the quantity of fugitive dust emitted from a source include the material's particulate size distribution, moisture content, and frequency of the mechanical and natural disturbances. Precipitation and evaporation conditions can affect the moisture content of the material being disturbed

and have an influence on the amount of fugitive dust emitted. Precipitation acts to prevent emissions through cohesive bonding of small particles, while evaporation elevates the potential for dust emissions.

Once dust is emitted (suspended in air), it will disperse from the source according to various factors such as wind speed and direction, precipitation rates, and particle size distribution (OMoE 2005). Higher wind speeds increase the potential distance travelled by the particulates, while precipitation can facilitate particulate deposition (wet deposition). Particles that are less than 2.5 µm in diameter can travel further before settling and are of higher concern as they have the potential to present a health problem to humans if inhaled.

Main sources of activities which contribute to fugitive dust emissions from the Facility are summarized in Table 6.1.

Table 6.1: Main Sources and Factors Contributing to Fugitive Dust

Process/Activity	Causes	Factors that may Produce Fugitive Dust Emissions
TSF	• Wind erosion off of surface of TSF from dried material	• Fines content of tailings • Surface moisture content of tailings • Wind speed and direction • Precipitation and snow cover (natural control measures) • Vegetation cover – control measures • Sprinklers – control measures • Pond volume – control measure
Polley Flats	• Wind erosion off of surface of Polley Flats from dried material	• Fines content of tailings • Surface moisture content of tailings • Wind speed and direction • Precipitation and snow cover (natural control measures) • Vegetation cover – control measures • Surface treatment – control measures
Material Handling (Limited)	• Disturbance of material (waste rock, ore and stockpiles) caused by loading/unloading (dumping into haul trucks and dumping onto stockpiles/dumps/gyratory crusher) • Wind erosion of material from material being handled	• Drop height of loading/unloading activities • Moisture content of material • Fines content of material • Wind speed
Ore Processing (No Activity)	• Processing of material (waste rock and ore) through crusher • Wind erosion off of stockpiles	• Drop height of loading/unloading activities • Moisture content of material • Fines content of material • Wind speed
Dozing Activity (Limited)	• Disturbance of material (waste rock, ore and stockpiles) caused by machinery • Wind erosion of material from material being dozed	• Height of material being dozed • Fines content in material handled • Moisture content in the material • Vehicle weight and speed • Wind speed
Grading (Limited)	• Disturbance of surface material caused by grading machinery	• Surface fines content • Surface material moisture content • Vehicle weight and speed
Hauling/Access Road Traffic	• Disturbance of granular material on the road surface caused by motion of vehicles • Wind erosion on the road surface	• Surface fines content • Surface material moisture content • Wind speed

(Light Vehicles Only)		• Vehicle weight and speed

6.1.2 Fugitive Dust Management Practices

Control measures to reduce fugitive dust emissions should take into account the sources of the dust emission, the dispersion conditions and the location of sensitive areas in order to avoid significant impacts of dust emissions on receptors. Control measures tend to impact one or more factors affecting the generation and/or dispersion of fugitive dust emissions. These control measures can be classified as follows:

- **Preventative Procedure**: Measure pertaining to the design and installation of structures and the operating procedures which are implemented on a regular basis in order to prevent the generation of dust and/or the dispersion of dust generated from reaching sensitive areas.
- **Reactive Control Measures**: Measures which are implemented in the event of unexpected circumstances which can lead to the generation of dust and/or the dispersion of dust generated reaching sensitive areas.

Table 6.2 provides a description of the preventative procedures and control measures at the Facility.

Table 6.2: Description of Preventative Procedures and Control Measures for Fugitive Dust Emissions

Preventative Procedure/ Control Measure	Emission Source Effected	Description	Application Frequency
Visual Inspection	TSF and Polley Flats	Daily visual inspections of the TSF and Polley Flats	Daily during non-frozen periods. If inspection indicates potential for dust emissions another follow up inspection will be conducted later that day
Wet Suppression	TSF and unpaved site roads	Fugitive dust generated from the TSF and unpaved site roads are controlled by using water	Daily observations (water management inspections, when wind speeds measured over 3.6 m/s are observed, and/or incidents)
Progressive Reclamation	TSF and Polley Flats	Growth media and vegetation applied progressively as either planting, broadcast seeding, heli-seeding or natural re-vegetation	One-time event, with ongoing planting, as required
Use of Dedicated Routes/Areas	Unpaved Site Roads (excluding the Mine and Ore Stockpile Area)	Haul traffic has designated routes. Have a procedure that all vehicles comply with these routes. Regular application of appropriate dust suppression (e.g. water, flocc, CaCl)	When necessary
Controlled Loading and Unloading Techniques	Dust from Material Handling	Trucks are loaded/unloaded in a slow and controlled manner to minimize drop height and avoid spillage	When necessary based on daily observations, inspections, and/or incidents

Fugitive dust may be emitted from the TSF and Polley Flats under strong wind conditions (wind speeds >5.4 m/s) (Golder 2015a). If wind erosion from the TSF is observed, it can be controlled by stabilizing the affected surfaces by use of chemical suppressants or regular watering. Control measures that have been implemented to reduce wind erosion from the TSF include:

- Installation of 5 water sprayers along the Main Embankment of the TSF. Each sprayer has a spray radius of 40-70 m and are adjacent to each other. Water is being pumped from the Main Embankment Seepage Collection Pond below the Main Embankment to a sprinkler line connected to all other sprinklers.
- Pond volume size parameters take into account dust management in regards to amount of surface area exposed.

Winter temperatures, below freezing, will prohibit the use of water as a dust suppressant; however, snow cover will act as dust suppressant in the winter months. Based on weather data presented in Golder (2015a), the average temperature is below freezing from November to March, where there is snow cover present.

Table 6.3 summarizes the fugitives dust emission activities and processes along with the proactive and reactive mitigation practices that can be implemented to control fugitive dust.

Table 6.3: Summary Table of Mitigation

Source	Proactive Mitigation Practices	Reactive Mitigation Practices
TSF	• Sprinklers as a dust suppressant on TSF • Rain/snow cover as a natural dust suppressant during winter • Interim seeding	• Wet suppression • Visual inspection of nearby sensitive receptor locations (<2 km) during dust events
Polley Flats	• Rain/snow cover as a natural dust suppressant during winter • Progressive reclamation (including ongoing removal and/or capping of tailings)	• Wet suppression • Visual inspection of nearby sensitive receptor locations (<2 km) during dust events
Crusher Building/Stockpiles (No or very limited activity during care and maintenance)	• Sprayers located on conveyers, transfer chutes, screens, and at the top of stockpiles • Dust control scrubber system for crusher building • Turbomister installed by crusher stockpiles	• Wet suppression • Removal of dust emissions from building
Road Dust	• Use of water trucks to wet roads	• Wet suppression

The effectiveness of watering practices for the TSF and Polley Flats are expected to be the same as for stockpiles. From Environment Canada (2014), wet suppression effectiveness rates are a function of the amount of water applied and range between 50-95% efficiency (Table 6.4).

Table 6.4: Wet Suppression Efficiency (Environment Canada 2014)

Efficiency (%)	Application Rate (L/m^2)
50	1.591
60	2.232
70	3.172
80	4.748
85	6.077
90	8.306
95	13.337

It is expected that there are 151 days during the year where there are either subfreezing ground conditions, based on average monthly temperature in Golder (2015a), or days where there is at least 1 cm of snow on the ground (Horsefly Lake Gruhs Lake Environment Canada Climate normal) which would act as a natural dust control measure. Furthermore, it is expected that during the non-freezing period there are approximately 98 days where there is at least 0.254 mm of rainfall (Station #1 and Station #2). Therefore, using the precipitation adjustment factor published by Environment Canada (2014) for stockpiles, it is expected that precipitation and snow cover would have approximately 68% percent effectiveness at controlling fugitive dust on an annual basis.

The effectiveness of vegetation covers to control fugitive dust has been observed to vary with the type and amount of cover. In the southwest regions of the United States, vegetation cover, which were sparse, resulted in dust control effectiveness of 25%; whereas, dense vegetation cover can result in dust control effectiveness of up to 100% (US EPA 1984). Visual inspections can be undertaken at receptor locations near (within 2 km of the Facility) during dust events (i.e., wind events >5.4 m/s).

6.2 DO – Implementation of the Dust Management Plan

Dust generating activities performed on-site should meet the requirements of this Plan.

6.3 CHECK – Inspection, Maintenance and Documentation

Routine inspections at the Facility should be performed to firstly check that the proactive and reactive mitigation measures are being implemented, and secondly, confirm that the mitigation practices are effectively reducing fugitive dust emissions. Daily inspections of the TSF and surrounding area are incorporated into MPMC's Water Management Inspection Manual checklist. Outstanding or overdue inspection findings are reviewed monthly by the Joint Occupational Health Safety and Environment Committee.

Routine reviews of results are also performed by MPMC's Environmental Department. This includes review of the documented observations to confirm that that mitigation (control) measures were implemented to reflect the observations recorded.

It is expected that all deficiencies identified in inspections will be addressed. Reasonable corrective action will be undertaken and documented. Reviews of the non-conformance should be done quarterly as a

method for continual improvement. The Operations Supervisor should be responsible for recordkeeping the information listed above.

The annual and monthly wind roses for Station #2 (the station with representative winds at the TSF and Polley Flats) demonstrates that the predominant wind directions during the summer months are from the north and south (with more southerly winds).

6.4 ACT – DUST MANAGEMENT PLAN REVIEW AND CONTINUOUS IMPROVEMENT

Inspections and monitoring procedures will assist MPMC personnel with the maintenance of an effective Dust Management Plan. The Dust Management Plan should be monitored and updated, as follows:

- when there are significant changes in the fugitive dust emissions sources;
- periodically, every five (5) years (minimum);
- when there are verified grievances associated with fugitive dust emissions from the Facility; and,
- when there are visible dust emissions occurring more frequently and/or at a higher rate (excluding seasonal conditions).

Review of the Plan is intended to evaluate the effectiveness of the proactive and reactive dust control practices and focus on the identification of improvement opportunities that can reduce the risk of complaints or health concerns related to fugitive dust emissions.

6.4.1 Contingency Measures

Possible contingency measures to be implemented at a later date, if required, include:

- Application of calcium chloride on Bootjack Forest Service Road.
- Installation of additional turbomisters, sprayers and sprinklers to periodically wet the TSF, thereby increasing the moisture content of the surface material which will result in greater surface cohesion and a reduction from fugitive windblown dust.

Air Quality Section

Monitoring, Assessment and Stewardship

Date: January 21, 2016 **File: 21610-00\Dustfall**

To: Robyn Roome, Director, Monitoring, Assessment & Stewardship

Re: Dustfall Monitoring and Pollution Control Objectives

The Air Quality Section has recently reviewed the use of dustfall monitoring in mining assessments and EMA authorizations/permits. Based on the review, the Air Quality Section considers dustfall monitoring and the dustfall Pollution Control Objectives as outdated methodology/criteria and, with the exception of specific limited circumstances, is no longer recommending or supporting their use based on the following reasons:

- The BC dustfall objectives were originally developed under the old BC Pollution Control Objectives (PCOs) back in 1979 as a 'soiling index' or method of assessing the "dustiness" of an area from an aesthetic or nuisance perspective. Their effectiveness for determining impacts on human or environmental health (soil, water, vegetation) is extremely limited.
- The PCOs were rescinded in 2006, although the dustfall objectives were retained on the BC air quality website "for reference purposes".
- Dustfall sampling methodology (passive open canister exposure) does not perform well (severely underestimates) during high wind events (often associated with fugitive dust).
- Dustfall monitoring is often used around mining projects with the stated intention of tracking metals impacts associated with fugitive dust. However, results are poor indicators for metals effects monitoring as there is no indication of the bioavailability of any metal contained in the samples and no established relationship between deposition rates and protection of soil, water or vegetation health.
- Dustfall results cannot be used for dust episode management actions as the 30-day sample periods (and subsequent laboratory analyses) are too long to be of any use for this purpose.
- While dispersion modelling may assist with determining the possible affected areas from fugitive dust generated during mining operations, the modelled concentrations are highly uncertain due to the poor quality of the model inputs, namely simplistic emission factors, added to the inherent uncertainties and limitations in modelling dust dispersion and deposition. This is particularly the case with road dust.

Based on the rationale above, it is suggested that before requiring dustfall as a component of any assessment process or inclusion within a regulatory authorization, that the objectives of the monitoring and/or dust management plans be clearly defined. Some possible considerations:

- If the concern is simply one of an aesthetic or nuisance nature, the use of dustfall monitoring and the objectives may be justified, with careful selection of the appropriate criteria, e.g.
    - 'residential/parkland' PCO (1.75mg/dm^2/day),
    - 'industrial/other' PCO (2.90mg/dm^2/day), or
    - facility/site specific deposition rate.
- If the objective is to protect of human health (i.e. nearby human receptors), monitoring of $PM_{2.5}$/PM_{10} would be more appropriate, including compliance with associated Ambient Air Quality Objectives.
- If the objective is to the protect the soil/water/vegetation and/or tracking accumulation of metals or other contaminants in the environment, including impacts to 'country foods', sampling of the specific media of concern would be more appropriate and specialists from the related disciplines should be involved in the development of baseline and on-going monitoring programs and determination of protective criteria.
- For episode management of fugitive dust, continuous monitoring of TSP or PM_{10} would provide more timely information for triggering actions under a dust mitigation plan.
- If there are concerns regarding other emission sources and possible impacts to ambient air quality and the environment, the emissions/impacts should be characterized, assessed and the appropriate monitoring determined.

When dispersion modelling is used in an assessment, the BC modelling guidelines recommend that a modelling plan be developed with input and subsequent sign-off from an Air Quality Meteorologist; it is recommended that a similar approach be used when developing baseline monitoring plans used to support assessments, compliance monitoring programs, or permit monitoring clauses. Proponents and permitting staff should consult with Air Quality Meteorologists to determine the contaminant(s) of concern, the monitoring methods, sampling locations and air quality criteria to be used.

Sincerely,

Arvind Saraswat, P.Eng.

Appendix Q
2015 Contaminated Sites Assessment Procedure

September 30, 2015 Reference No. 1411734-085-L-Rev0-15000-6000

Katie McMahen
Mount Polley Mining Corporation
Box 12
Likely, BC V0L 1N0

CONTAMINATED SITE ASSESSMENT PLAN

Dear Ms. McMahen:

This letter provides an outline of the conceptual contaminated sites assessment (CSA) plan for closure of the Mount Polley Mine ("the Site") required by the BC Ministry of Energy and Mines in a permit amendment issued to Mount Polley Mining Corporation on July 9, 2015. Specifically, the CSA plan to address potential contamination on closure of the mine will follow the technical guidance and protocols outlined in the Contaminated Sites Regulation (http://www2.gov.bc.ca/gov/content/environment/air-land-water/site-remediation/laws-regulations-compliance), and tailored to the conditions of the Site. The CSA work will be conducted in consultation with a Contaminated Sites Approved Professional

Stage I Preliminary Site Investigation

MPMC has identified the activities or areas of potential environmental concern (APECs) associated with mining operations and the contaminants of potential concern (COPC) associated with these APECs (Table 1, Figure 1). On closure of the mine, or areas of the mine, each of the APECs will be inspected for visual signs of contamination. Photos of each APEC will be taken to include in documentation. Interviews will be held with MPMC personnel familiar with the APECs to determine standard practice for each APEC and records of spills or other historical activities that could have resulted in contamination. This process is consistent with a Stage I Preliminary Site Investigation. MPMC will track each APEC recording site inspections, interviews and photos of those closed, such that documentation can be supplied, if requested. The estimated costs associated with the Stage I PSI are outlined in Table 2.

Stage II Preliminary Site Investigation and Detailed Site Investigation

If there is evidence of contamination associated with the APEC, soil will be sampled and analyzed for the COPCs associated with the APEC in accordance with the guidelines and protocols for a Stage II Preliminary Investigation (Stage II PSI). If contamination is found, step out soil samples will be collected to delineate soil contamination in a Detailed Site Investigation (DSI). Depending on the extent of soil contamination found, an investigation of groundwater quality may be needed. If the COPCs are listed on Schedule 11 of the CSR, it may be necessary to conduct an investigation of soil vapour. The estimated costs associated with a Detailed Site Investigation are dependent on the results of the PSI, and are therefore difficult to predict. For planning purposes, an estimate is provided in Table 3.

Golder Associates Ltd.
Suite 200 - 2920 Virtual Way, Vancouver, BC, V5M 0C4
Tel: +1 (604) 296 4200 Fax: +1 (604) 298 5253 www.golder.com

Golder Associates: Operations in Africa, Asia, Australasia, Europe, North America and South America

Golder, Golder Associates and the GA globe design are trademarks of Golder Associates Corporation.

Using Site Knowledge

MPMC has conducted many detailed site investigations related to contamination, contaminant fate and transport, as well as restoration work including site-specific assessments of geochemistry and contaminant toxicity as part of their exploration work and work related to the tailings dam failure. Reclamation plans have been developed for both terrestrial and aquatic areas surrounding the mine. This work should be consulted if contamination is found related to the mine APECs, as this work provides valuable context for data interpretation.

Following delineation of contamination, a remediation plan will be developed to address contamination such that it meets the requirements of the BC *Environmental Management Act*. It is anticipated that the remediation plan will build off of studies conducted and lessons learned and successes from the remediation and restoration work conducted for the tailings dam failure.

The plan provides an outline of the CSA plan required in the July 9, 2015 permit amendment issued to MPMC. The cost associated with the stages of investigation are difficult to determine as it will depend the extent of contamination encountered. For planning purposes, MPMC should expect the costs to be similar to those estimated in this report. As APECs are investigated and closed, the costs should be updated such that they provide a meaningful budgeting tool moving forward.

Yours very truly,

GOLDER ASSOCIATES LTD.

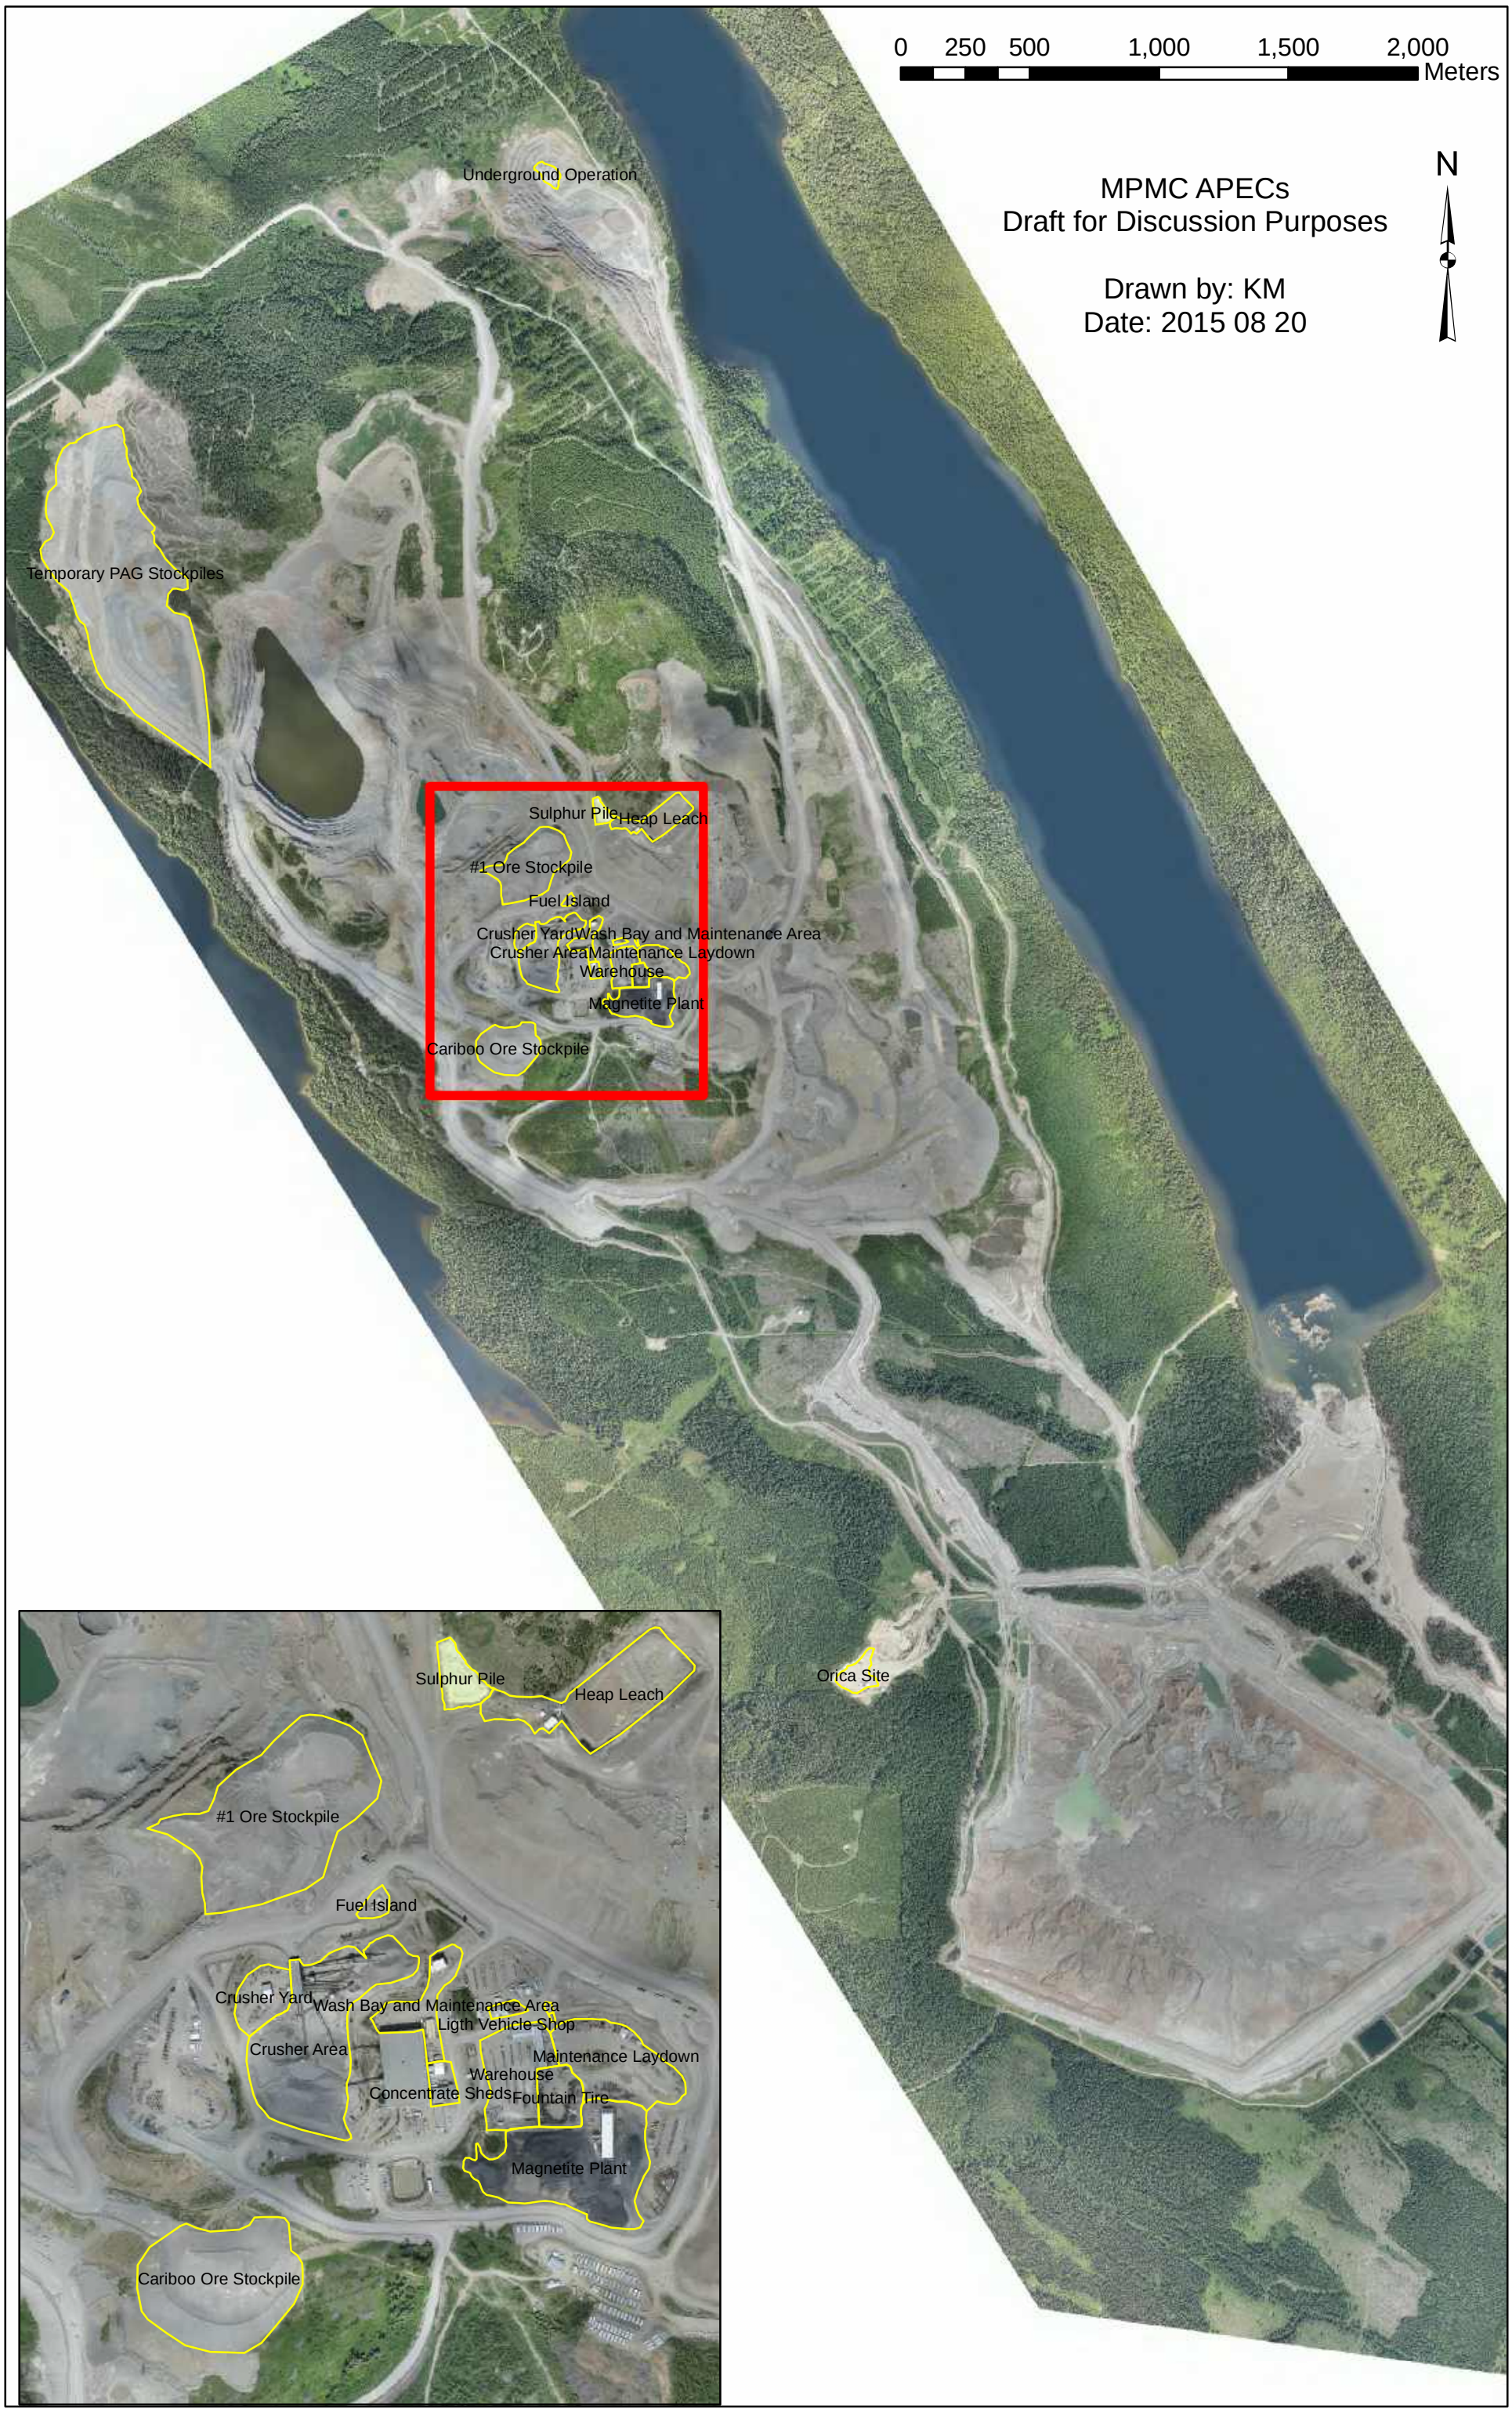
Cleaning Products	Hazardous Constituents (from MSDS)
ACTION DSC	Didecyl Dimethyl Ammonium Chloride; sodium carbonate; ethyl acoho
ALL PURPOSE WASHROOM CLEANER	Organic acid salt
AQUARESS HAND & BODY SHAMPOO	Water, Sodium Laureth Sulfate, Cocamide DEA, Sodium Chloride, Citric Acid, Diazolidinyl Urea, Glycol Distearate, Tetrasodium EDTA, Fragrance, Cocamide MEA, Laureth-10, Magnesium Nitrate, Methylchloroisothiazolinone, Magnesium Chloride, Methylisothiazolinone, Blue 1 (CI 42090
BLEACH-SODIUM HYPOCHLORITE	Sodium Hypochlorite
BORAXO POWDERED HAND SOAP	Sodium Borate Decahydrate (Borax); sodium soap
CITRUS AIR	Ethanol; D-Limonene; propylene glycol; isobutane; propane
CITRUSOLV-HF	Distillates (petroleum), hydrotreated light; (R)-p-mentha-1,8-diene
CLEAN SPRAY	Ethylene glycol mono butyl ether; tetrapotassium pyrophosphate; tetrasodium salt of ethylenediaminetetraacetic acid
COMPARE	No hazardous ingredients listed on MSDS
COMET DISINFECTANT CLEANER WITH CHLORINOL	Dipropylene glycol N-butyl ether; citric acid
ENGINE DEGREASER	Diethylene gloycol monoethyl ether; ethanol; propane; butane; citrus terpenes; ethanol
FAST ORANGE PUMICE CLEANER	Pumic; ethoxylated C11-C16 alcohol; D-limonene
FLOOR SWEEP-CANOLA OIL BASED	No hazardous ingredients listed on MSDS
GLASS CLEANER WITH AMMONIA	Isopropyl alcohol; propoxy propanol; cipropylene glycol; monomethyl ether; monobutyl ether; ammonia
KLINGER BOWL CLEANER	Citric acid
KRYSTAL GREEN	Ethylene glycol mono butyl ether; monoethanolamine
LEMINEE 23 CLEANER-DISINF.	Alcohols, C12-15, ethoxylated; soda ash; alkyl dimethylbenzylammonium chloride; alkyl dimethyl ethylbenzylammonium chloride; ethyl alcohol
LIQUID HAND SOAP-6000	No hazardous ingredients listed on MSDS
MULTI-KLEEN	2-propanol; 2-propanol; Alcohol Ethoxylate; caustic potash (45%); sodium metasilicate; sodium tripolyphosphate
MULTI-KLEEN-INDUSTRIAL	Sodium metasilicates; 2-butoxyethanol; Alcohol Ethoxylated; sodium tripolyphosphates
NEUTRAL FLOOR CLEANER	Sodium lauriminodipropionate; alcohols C12-C13 ethoxylated; dipropylene glycol monomethyl ether; alcohol ethoxylate (C9-C11)
ORDERLY-DISINFECTAND	Di-(C8-10)-alkyl dimethyl ammonium chlorides; alkyl dimethyl benzyl ammonium chlorides; ethanol; alcohol ethoxylate
PINOSAN	Alkyl dimethyl ammonium chlorides; Didecyl dimethyl ammonium chloride
PLEDGE	Hydrocarbons, C16-C20, n-alkanes, isoalkanes, cyclics,<2% aromatics; white mineral oil (petroleum)
SHOWER SHINE	Phosphoric acid; ethoxylated nonionic detergent; lauryl dimethylamine oxide
STAIN REMOVER AND DEODORIZER-SR (unbelievable)	No hazardous ingredients listed on MSDS
STRATE FLUSH	Hydrochloric acid
SUNLIGHT DISH SOAP	Magnesium oxide; ethyl alcohol; dodecylbenzene sulfonic acid
SUPER-CLEAN DEGREASER (DETERGENT)	Sodium metasilicate; sodium hydroxide; surfactant, glycol blend
SUPER 90 FLOOR FINISH	No hazardous ingredients listed on MSDS
TOUGH GUY LAUNDRY DETERGENT	Sodium carbonate
TOUGH GUY NEUTRAL CLEANER	No hazardous ingredients listed on MSDS
TRISODIUM PHOSPHATE-TSP	Trisodium phosphate dodecahydrate
URINAL BLOCKS	1,4-Dichlorobenzene
VELVA SHEEN	1,8-p-menthadiene; isoparaffinic hydrocarbon; propane/N-butane

Lube Products	Hazardous Constituents (from MSDS)
2-CYCLE MOTOR OIL	Distillates, petroleum, solvent-refined heavy paraffinic; petroleum distillates, hydrotreated light
ANTIFREEZE/COOLANT 50/50	CH_2OHCH_2OH
ANTIFREEZE/COOLANT HEAVY DUTY	CH_2OHCH_2OH
ANTIFREEZE/COOLANT-UNIVERSAL	CH_2OHCH_2OH
ANTIFREEZE - AIR BREAK	CH_3OH
ATF-SUPER	Distillates, petroleum, hydrotreated heavy paraffinic; distillates, petroleum, hydrotreated light paraffinic
ATF-TYPE F	Distillates, petroleum, hydrotreated heavy paraffinic; N-Phenyl-1-naphthylamine
BATTERY CLEANER	2-butyloxyethanol; sodium bicarbonate; detergent; liquefied petroleum gas
BEARING MOUNTS FOR CLOSE FITS	Methacrylate monomer; 2-hydroxyethyl methylate; coumarone-indene resin (mixture); poly(ethyl methacrylate); dimethylbenzyl hydroperoxide
BREAK CLEAN	Heptane; methanol; 2-propane
BREAK FLUID DOT 3 HEAVY DUTY	http://armoredautogroup.com/pdf/STP/STP-Heavy-Duty-Brake-Fluid,-DOT-3-(1-2011).pdf
COMPRESSOR OIL	Hydrotreated light paraffinic distillates, petroleum
FUEL-DIESEL	Diesel; distillates (petroleum), hydrotreated middle; distillates, hydrotreated light (may contain: alkyl nitrate, polyisobutenyl succinic anhydride nitrogen functionalized dispersant, and mixed cyclic amines)
FUEL-GASOLINE	Gasoline, toluene, ethanol, benzene
FULL SYNTHETIC MITOR OIL-KENDALL	Distillates, petroleum, hydrotreated heavy paraffinic
FULL SYNTHETIC MITOR OIL-HIGH PERFORMANCE	Distillates, petroleum, hydrotreated heavy paraffinic
GEAR LUBE-EXTRA DUTY	Residual oils, petroleum, solvent-refined; distillates, petroleum, solvent-dewaxed heavy paraffinic; residual oils, petroleum, solvent-dewaxed; distillates, petroleum, hydrotreated heavy paraffinic; residuum resins
GEAR LUBE-MOLYLUBE SF 100 SEMI-SYN. LIGHT	Graphite, hydrotreated light distillates (petroleum); carbon black; Stoddard solvent; silica, crystalline, quartz; mineral oil; molybdenum compounds; trymethylbenzne
GEAR LUBE- MOLYLUBE SF 100 SEMI-SYN ARCTIC	Distillates (petroleum), hydrotreated heavy naphthenic; distillates (petroleum), hydrotreated heavy paraffinic; distillates (petroleum), solvent-refined heavy paraffinic; hydrotreated light distillates (petroleum); Stoddard solvent
GEAR LUBE-MP	Lubricant base oil (light)
GEAR LUBE- TRITON SYN	1-Decene, homopolymer, hydrogenated
GEAR SHIELD NC	Bitumen; distillates (petroleum), hydrotreated light; distillates (petroleum), hydrotreated middle; zinc compounds
GEAR SHIELD-HEAVY	Heavy hydrotreated naphthenic distillates (petroleum); petroleum hydrocarbon; residual oils (petroleum), solvent dewaxed; petroleum asphalt; zinc oxide; 12 hydroxystearic acid; carbon black; inedible animal grease; lithium hydroxide monohydrate
GUARDOL ECT-MOTOR OIL (TITANIUM)	Lubricant base oil (petroleum); proprietary additives
GUARDOL QLT-MOTOR OIL	Distillates, petroleum, hydrotreated heavy paraffinic
HT/4 FLUID	Distillates, petroleum, hydrotreated heavy paraffinic; distillates, petroleum, solvent-refined heavy paraffinic; residual oils, petroleum, solvent-dewaxed; distillates, petroleum, solvent-dewaxed heavy paraffinic
HYDRAULIC/TRACTOR FLUID	Distillates, petroleum, hydrotreated heavy paraffinic; distillates, petroleum, solvent-dewaxed heavy paraffinic
HYDRAULIC OIL-MEGAFLOW AW	Distillates, petroleum, hydrotreated heavy paraffinic;
HYDRAULIC OIL-SUPER	Zinc compounds; lubricant base oil (petroleum)
KOPR-KOTE	Talc; graphite; copper; molybdenum disulphide
LUBRIPLATE CHAIN AND CABLE FLUID	Heavy and light hydrotreated naphthenic distillates (petroleum); carbon dioxide; 2-butoxyethanol; light distillate; aliphatic petroleum distillate
MAROK-ROCK DRILL OIL	Distillates, petroleum, hydrotreated light naphthenic
MEGAPLEX XD3	Lubricant base oil (petroleum); molybdenum disulfide; carbonic acid, calcium salt
MEGAPLEX XD5	Lubricant base oil (petroleum); molybdenum disulfide; zinc dialkyl dithiophosphate
MOLY LOW TEMP	Distillates, petroleum, hydrotreated light naphthenic; distillates, petroleum, hydrotreated heavy naphthenic; molybdenum (IV) sulfide
MULTIPLEX-RED	Phosphorodithioic acid, O,O-di-C1-14-alkyl esters, zinc salts; lubricating oils (petroleum), hydrotreated solvent-refined bright stock-based; alkyl Imidazoline; lubricant base (petroleum)
OMNIGUARD	Lubricant base (petroleum); calcium carbonate
OSBORN BLUE LAYOUT FLUID	Acetone; methyl ethyl ketone; liquified petroleum gas; ethyl acetate; xylene; butyl acetate; isopropyl alcohol; nitrocellulose
POLYTAC EP	Distillates, petroleum, hydrotreated heavy naphthenic; distillates, petroleum, solvent-refined heavy paraffinic; N-Phenyl-1-naphthylamine
PYROSHIELD 9011	Amines, C12-14-alkyl, reaction products
QUIK PENETRATING SOLVENT	Mineral spirits; white mineral oil; propane
REDTAC	Naphthenic acids, zinc salts; lubricating oils (petroleum)
SKF GREASE (LGEP 2)	Phosphorodithioic acid, O,O-di-C1-14-alkyl esters, zinc salts; lubricating oils (petroleum), hydrotreated solvent-refined bright stock-based
SOLVENT	Stoddard solvent
SUPER MOTOR OIL	Distillates, petroleum, hydrotreated heavy paraffinic
SUPER SYNTHETIC BLEND MOTOR OIL	Distillates, petroleum, hydrotreated heavy paraffinic
TRANSFORMER OIL	Distillates, petroleum, hydrotreated light naphthenic
TRITON 220	Synthetic lubricant base oil
UNIMIX 2-CYCLE OIL	Lubricant base oil (petroleum); hydrotreated distillate, light C9-C16
UNOBA EP	Lubricant base oil (petroleum); calcium carbonate; proprietary additives
VICTAULIC LUBRICANT	Fatty acids, tall-oil, potassium salts; 1,2-Propylene glycol; mica
WASHER FLUID	Methanol
WHITE LITHIUM GREASE	Hexane isomers; n-hexane; heavy napthenic petroleum distillates; liquefied petrolum gas



Chemial Products	Hazardous Constituents (from MSDS)
AERO 208 PROMOTER	phosphorodithioic acid, O,O-bis(methylpropyl) ester, sodium salt, phosphorodithioic acid, o,o-diethyl ester, sodium salt, sodium hydroxide
AERO 3477 PROMOTER	phosphorodithioic acid, O,O-bis(methylpropyl) ester, sodium hydroxide
AERO 7048 PROMOTER	phosphorodithioic acid, O,O-bis(methylpropyl) ester, sodium salt, carbamothioic acid, 2-propenyl-, O-(2-methylpropyl) ester, isobutanol, sec-butyl alcohol, sodium hydroxide
AERO 7279 PROMOTER (DISCONTINUED)	carbamothioic acid, 2-propenyl-, O-(2-methylpropyl) ester, isobutanol, phosphorodithioic acid, O,O-bis(2-methylpropyl) ester, sodium salt, nonylphenol ethoxylate, sec-butyl alcohol
AERO 5100 PROMOTER	modified thionocarbamate #1, sec-butyl alcohol, isobutanol, modified thionocarbamate #2
DANAFLOAT 262	carbamothioic acid, ethyl-, *O*-(1-methylethyl) ester, isopropanol
DANAFLOAT 262T (unavailable)	carbamothioic acid, ethyl-, O-(1-methylethyl) ester, isopropanol, 1-dodecanethiol
DANAFLOAT 468	phosphorodithioic acid, O,O-bis(methylpropyl) ester, sodium salt, phosphorodithioic acid, o,o-diethyl ester, sodium salt, sodium hydroxide
CARBON DIOXIDE	carbon dioxide
HELIUM	helium
HIGHT CALCIUM QUICKLIME	calcium oxide, crystalline silica quartz
IPAC 6832	no hazardous ingredents listed on MSDS
IRON CHIP ACCELERATOR	iron; iron oxide dust
LECOCEL II and II HP	tungsten, tin
LECOSORB	non-fibrous silicate
LIQUID HEAT	diethylene glycol; non-hazardous ingredients held as trade secret
MAGNETITE	iron oxide
MIBC	methyl isobutyl carbinol
POLYCLEAR 2529	anionic water-soluble polymer
POLYCLEAR 2528	anionic water-soluble polymer
POLYCLEAR 2532	long-chain polymer
POLYCLEAR 2530	long-chain polymer
POLYFROTH W22C FROTHER	polyoxyalkylene alkyl ether, methyl isobutyl carbinol
POTASSIUM AMYL XANTHATE 85%	potassium amyl xanthate
POTASSIUM AMYL XANTHATE 90%	potassium amyl xanthate
SODIUM HYDROSULFIDE 36% SOLUTION	sodium hydrosulfide, sodium carbonate, sodium sulfide, nonahydrate
SODIUM HYDROXIDE SOLUTIONS	sodium hydroxide
SULPHUR	sulphur
TMT 15	1,3,5-triazine-2,4,6(1H,3H,5H)-trithione, triosodium salt
VULTREX-TOOL JOINT COMPOUND-	zinc, talc, mixture of severely hydrotreated and hydrocracked base oil (petroleum

Welding Products	Hazardous Constituents (from MSDS)
Arcair Electrodes	Iron; manganese; copper; chromium; iron; molybdenum; nickel; silicon; niobium
Arcair Slice Cutting Rod	Nicel; steel
Hardfacing allyed electrode	Titanium dioxide; nickel; silicon dioxide; calcium fluride
ER70S2	Iron; carbon; copper; manganese; phosphorus; molybdenum; silicon; titanium; zirconium
Carbon ring	Sulfur dioxide; nitrogen
Welding rods	Iron; chromium; nickel; maganese; silicon; molybdenum; columbium; titanium dioxide; sodium fluoride; talc; calcium fluoride; crystalline silica respirable; silicon; molybdenum; titanium; cobalt; copper
Welding wire	Iron; manganese; titanium dioxide; nickel; calcium flouride
WIA Fabshield 4 Hobart	Metals (numberous)
Wearsheild BU	Iron; limestone and/or calcium carbonate; silicates; fluorides; silicon and/or silicon alloys and compounds; manganese and/or manganese alloys and compounds; chromium and chromium alloys and/or compounds; quartz; cellulose and other carbohydrates; iron oxides; carbon steel core wire
Wearhshield ME	Chromium and chromium alloys or compounds; titanium dioxides; mineral silicates; silicates; limestone and/or calcium carbonate; magnesite; fluride; cellulose and other carbohydrates; iron; silicon and/or silicon alloys and compounds; quartz
Acetylene	Acetylene
Blueshield	Argon

Stage 1 Preliminary Site Investigation Scope and Estimated Costs for Budget Planning Purposes

Task	Scope	Cost
Baseline report	MCMC collects information on all APECs, prepare working tables, figures and photos. Golder organizes report in CSR format and checks information in the field and through meetings with MCMC.	$25,000
Update reports	The Stage 1 PSI is updated when an APEC is decommissioned or at 5 year intervals. Estimated cost of $2,500/update	$25,000
Total		$50,000

Area	~Size(m^2)	Material(s) Stored/Used	Characteristics	Scope	Cost
Fuel Island (light vehicle)	170	Diesel, gasoline	AST with spill protection. No observed or reported spills. Likelihood of contamination is low.	> Limited soil sampling using hand dug pits or excavator test pits > no groundwater sampling > Reporting	$ 5,000
Waste Disposal Area (adjacent to light vehicle fuel island)	90	Batteries, hydrocarbon contaminated waste, used paint, plastic jug recycling	Potential for surface spills	> Soil sampling using hand dug test pits > No groundwater sampling > Reporting	$ 5,000
Fuel Island	1,600	Diesel	AST with spill protection. No observed or reported spills. Likelihood of contamination is low to moderate.	> Soil sampling using excavator test pits > Groundwater sampling > Reporting	$ 25,000
Outside maintenance shop + wash bay	8,200	**Lube Products**, **Welding Products,** diesel	Potential for surface spills	> Soil sampling using excavator test pits > Limited shallow groundwater sampling > Reporting	$ 25,000
Maintenance laydown	17,700	**Lube Products**, diesel	Potential for surface spills	> Soil sampling using excavator test pits > Limited shallow groundwater sampling > Reporting	$ 25,000
Light vehicle maintenance shop + weld barn	1,100	**Lube Products**, **Welding Products,** diesel	Potential for surface spills	> Soil sampling using excavator test pits > Limited shallow groundwater sampling > Reporting	$ 10,000
Warehouse	1,400	waste hydrocarbons contained hydrocarbon products, mill reagents, cleaning products, lube products	Indoor storage on concrete floor. Liklihood of contamination is neglible.	No sampling	$ -
Crusher Yard	6,500	**Lube Products**, diesel	Potential for surface spills	> Limited soil sampling using hand dug pits or excavator test pits > no groundwater sampling > Reporting	$ 25,000
Crusher Area	38,400	Ore	Potential for residual contamination of soil and shallow groundwater	> Limited soil sampling using hand dug pits or excavator test pits > limited shallow groundwater sampling > Reporting	$ 35,000
Temporary PAG Stockpile	428,400	Potentially acid generating rock	Potential for residual contamination of surface soil and groundwater after PAG stockpile has been backfilled into Springer Pit	> Soil sampling using excavator test pits > Groundwater sampling > Reporting	$ 50,000
#1 Ore Stockpile	55,500	Ore	Potential for residual contamination of surface soil and groundwater after ore stockpile has been removed.	> Limited soil sampling using hand dug pits or excavator test pits > limited shallow groundwater sampling > Reporting	$ 35,000
Cariboo Ore Stockpile	39000	Ore	Potential for residual contamination of surface soil and groundwater after ore stockpile has been removed.	> Soil sampling using excavator test pits > Groundwater sampling > Reporting	$ 35,000
Sulphur Pile	5,200	Sulphur compounds	Potential for residual contamination of surface soil and groundwater after sulphur pile has been removed.	> Soil sampling using excavator test pits > Groundwater sampling > Reporting	$ 25,000
Heap Leach (test facility)	24,000	Sulphur compounds	Potential for residual contamination of surface soil and groundwater after sulphur has been removed.	> Soil sampling using excavator test pits > Groundwater sampling > Reporting	$ 35,000
Underground Operation and Maintenance Area	6,000	Blasting products	Potential for residual contamination of surface soil and shallow groundwater.	> Limited soil sampling using hand dug pits or excavator test pits > limited shallow groundwater sampling > Reporting	$ 15,000
Magnetite Plant	33,600	Magnetite	Potential for residual contamination of surface soil and shallow groundwater.	> Limited soil sampling using hand dug pits or excavator test pits > limited shallow groundwater sampling > Reporting	$ 35,000

SPRINGER PIT SPILLWAY CONCEPTUAL DESIGN

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) has retained Golder Associates Ltd. (Golder) to develop a conceptual-level spillway design for the Springer Pit. The Springer Pit is located in the northwest part of the Mount Polley Mine site. The spillway is intended to operate after closure of the Springer Pit. The function of the spillway will be to safely discharge overflow from the Springer Pit caused by storm water runoff and other inflows from the surrounding catchment. This document reflects ultimate pit conditions following completion of the restricted operations and a return to full operations over a combined period of approximately four (4) years.

This document presents the data that Golder used to develop the spillway design.

2.0 DATA FOR DESIGN

2.1 Design Flows

Precipitation depths used to estimate inflows to Springer Pit for various return periods are presented in Table 1.

Table 1: 24-Hour Precipitation Depths

Return Period	Depth (mm)
2-year	34.2
10-year	46.8
25-year	52.5
100-year	60.7
200-year	64.7
1000-year	73.8
Probable Maximum Precipitation	188.1

Golder, Golder Associates and the GA globe design are trademarks of Golder Associates Corporation.

The total catchment area draining to the Springer Pit spillway is estimated to be 1.1 km^2. The design event for the Springer Pit was selected as the 1-in-200-year 24-hour rainfall plus the 1-in-2-year snowmelt. The flows to Springer Pit were calculated using Hydrologic Engineering Centre Hydrologic Modelling System (HEC-HMS) software (USACE 2010), and are presented below in Table 2. The Soil Conservation Service (SCS) curve number (CN) method (USDA 1986) was used to calculate catchment losses. A CN value of 95 and a lag time of 15 minutes were used for the HEC-HMS calculations.

The peak outflow was estimated by routing the inflow through the pit.

Table 2: Design Event Flows

Description	Flow (m^3/s)
Peak rainfall inflow	3.64
Peak snowmelt inflow	0.17
Peak combined inflow	3.81
Peak outflow	0.52

2.2 Design Elevations

Elevations used for the design are presented below in Table 3. All elevations are in MPMC's mine grid.

Table 3: Design Elevations

Description	Value (masl)
Spillway crest elevation	1050.0
Top of spillway channel	1050.5

3.0 DESIGN SUMMARY

A summary of the conceptual spillway design for the Springer Pit is provided in this section. The spillway design consists of a weir crest and a rock-lined, 40 m-long channel to convey flows, as shown on Drawings 100 through 300 in Attachment A.

The channel dimensions are shown below in Table 4.

Table 4: Spillway Channel Dimensions

Description	Value	Comment
Design flow depth	0.16 m	Calculated
Channel depth	0.5 m	Provides freeboard
Bottom width	3.0 m	Allows for vehicle passage across channel
Side slope	10H:1V	Allows for vehicle passage across channel

The spillway channel has been sized with constructability and vehicle passage along the existing haul road as main considerations. The wide channel base and gradually-sloped banks allow for vehicles using the existing haul road to cross the spillway channel safely when no water is flowing. The spillway channel has been sloped towards the Springer Pit to eliminate the risk of normal runoff from the haul road discharging into the environment. Additional design information is presented in the drawing package that was provided with this memorandum.

The outlet channel design does not include a specific termination point and is only intended to convey flows beyond the Springer Pit area. Golder recommends that the final discharge location for the spillway channel be confirmed at a later date and based on site conditions existing at the anticipated time of construction (i.e., water quality and closure scenario).

Golder understands that there are several scenarios that could apply for the closure of Springer Pit.

There are two potential discharge options for the case of permanent closure: Bootjack Lake or a temporary storage location (i.e., the Tailings Storage Facility (TSF) or the Perimeter Embankment Till Borrow Pit). The water quality in Springer Pit is an important factor in selecting one of these locations. If the water quality in Springer Pit, perhaps following enhancement with a passive treatment system, is suitable, the water could be discharged into Bootjack Lake. If it is not feasible to meet water quality targets, the water could be conveyed to and retained in a temporary storage location, where it would be treated and eventually discharged to Quesnel Lake.

If the closure of Springer Pit is temporary, the preferred option would be to pump the water into the West Ditch, which conveys water to the Central Collection Sump.

4.0 CLOSURE

We trust this document meets your present requirements. Please direct any questions, comments, or concerns to the undersigned.

Executive Summary

This report presents a summary of the observations that were made and the discussions that were held with Mount Polley Mining Corporation (MPMC) staff during Golder Associates Ltd.'s (Golder) annual pit slope and waste rock dump slope stability review at the Mount Polley Mine. The report provides the following:

- a description of the engineering geology of Mount Polley Mine
- a description of the existing and proposed open pit mine and waste rock dump operations
- a summary of the slope stability performance of the existing pit slopes and waste rock dumps at the time of the 2021 review
- a discussion of the pit slope and waste rock dump monitoring data
- geotechnical recommendations for the pit slopes and the waste rock dumps, and the geotechnical monitoring program

The following mine areas were included in the review:

- the Cariboo Pit
- the Springer Pit
- the Wight Pit
- the Northwest Potentially Acid Generating (PAG) Dump
- the Southeast Rock Disposal Site (SERDS)
- the Northeast Non-acid Generating (NAG) Rock Dump (inactive)
- the Tailings Road

This slope stability review covers the time between October 2020 and October 2021.

The recommendations following the 2021 review are summarized in Table E-1. The ID column has a unique number for each recommendation, prefixed with the year the recommendation was originally made. New recommendations and comments from 2021 are marked with *italic text.*

Table E-1: Summary of Recommendations for 2021 Review

Area	ID	Recommendation	Timeline
Cariboo Pit	2019-03	If access is needed below the east wall on the haul road switchback or mining resumes, a rock rollout berm should be built and maintained below the east wall unload zone.	If access is needed or mining resumes, immediately.
	2020-01	Install three new prisms on the unload zone.	*Completed in fall 2020; however, the new prisms failed over the winter. These prisms should be replaced in Q2 2022, before monitoring resumes.*
		Replace broken head on existing prism.	*Completed in 2021; however, prism head broke again. Replace in Q2 2022 and install a cover to protect the prisms on the east wall from the elements. The cover could be made of plywood or metal.*
	2021-01	*Rock rollout berm in front of wedge instability along haul ramp and below C2 Pit due to limited catchment available.*	*Q2 2022 – personnel enter the Cariboo Pit to access the pumping infrastructure and a rollout berm should be in place to protect the pump equipment and personnel.*
Springer Pit	*2021-01*	*Remove boulders from haul ramp on west wall and establish a rock rollout berm in front of overhang in bench.*	*Q2 2022 – personnel enter the Springer Pit to access the pumping infrastructure.*
Wight Pit	2018-02	Clean catch ditch along east wall below Rusty Fault.	Once per year or as required
	2020-02	Install two to four additional prisms along the west wall, between Prisms 595 and 543.	*Complete – two prisms were installed on the west wall in early 2021.*
	2020-03	Move the location of the monitoring base station farther back from the crest of the east wall.	*Incomplete – a new station was installed that monitors the existing base station for movement.*
Tailings Road	2019-06	Remediate failure scarp area.	*Incomplete in 2020 and 2021. Divert water away from the Tailings Road to limit ponding in the area of the scarp area until it is remediated.*
All areas – prism monitoring data	2019-07	Collect slope distance measurements.	*Incomplete – Q2 2022*

Study Limitations

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by Golder for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents Golder's professional judgement based on the knowledge and information available at the time of completion. APPENDIX B
Prism Monitoring Data

1.0 INTRODUCTION

This report presents a summary of the observations that were made and the discussions that were held with Mount Polley Mining Corporation (MPMC) staff during Golder Associates Ltd.'s (Golder) annual pit slope and waste rock dump slope stability review at the Mount Polley Mine. The review was carried out on 20 October 2021 by Ms. Alannah Gray Hubbard, P.Eng., and Mr. Caleb Lee, P.Geo., of Golder, in the accompaniment of Mr. Mathieu O'Leary and Mr. Chad Cameron of MPMC. The report provides the following:

- a description of the engineering geology of Mount Polley Mine
- a description of the existing and proposed open pit mine and waste rock dump operations
- a summary of the slope stability performance of the existing pit slopes and waste rock dumps at the time of the 2021 review
- a discussion of the pit slope and waste rock dump monitoring data
- geotechnical recommendations for the pit slopes, waste rock dumps, and geotechnical monitoring program

The following mine areas were included in the review and are shown in Figure 1:

- the Cariboo Pit
- the Springer Pit
- the Wight Pit
- the Northwest Potentially Acid Generating (PAG) Dump
- the Southeast Rock Disposal Site (SERDS)
- the Northeast Non-acid Generating (NAG) Rock Dump (inactive)
- the Tailings Road

This slope stability review covers the time between October 2020 and October 2021.

All coordinates presented in this report are in mine grid coordinates, and elevations are relative to a local mine site datum.

2.0 MOUNT POLLEY MINE ENGINEERING GEOLOGY

The Mount Polley deposits are located within an alkalic intrusive complex within the northwest–southeast trending Quesnel Trough, a 35 km wide, northwest trending volcanic sedimentary belt. The copper and gold mineralization is contained predominately within north–south trending, elongated intrusive breccia stocks that have intruded late-phase diorites and monzonite porphyries. Later-stage north–south trending dykes have been intruded along the regional structural trend.

In general, the rocks in the Cariboo Pit consist of monzonite intrusion breccias that have intruded the host monzonite rocks. Monzonite is exposed in the majority of the pit walls, while breccias are exposed in the centre of the pit. However, localized blocks of diorite are exposed in the northeast wall – northwest segment and the east wall, while plagioclase porphyry is exposed along the southeast wall.

The mineralized hydrothermal breccia in the Springer Pit occurs along a north-northwest–south-southeast trend. To the west, the mineralized breccia zone is bounded by a “mix” of breccia and intrusive rocks, which are then bounded by monzonite rocks. Monzonite rocks are the dominant rock type along the south side of the Springer Pit. Intrusive diorite rocks bound the mineralized breccia to the north and northeast. Finally, a series of younger north–south trending augite porphyry dykes are interpreted to occur throughout the proposed pit area. These dykes are often chlorite and calcite-altered and commonly faulted. These younger dykes intersect the different rock types and the major faults.

For further discussion of the site geology and major geological structures at the Mount Polley Mine, refer to the 2016 Cariboo and Springer Pit design report (Golder 2016a).

The dyke and fault models for the Springer and Cariboo Pits are shown in Figures 2 and 3, together with the October 2019 topography. At the time of the 2021 review, the topography had not changed since LiDAR collection in October 2019; therefore, all figures within this report use the 2019 topography.

3.0 MOUNT POLLEY CURRENT MINE STATUS

A plan of the Mount Polley Mine and the locations of the existing pits and waste rock dumps at the time of the October 2021 review are shown in Figure 1. The review photographs are presented in Appendix A. The following sections provide an overview of the status of the pits and waste rock dumps at the Mount Polley Mine at the time of the 2021 review.

3.1 Open Pit Development and Status

3.1.1 Cariboo Pit

The status of the Cariboo Pit at the time of the 2021 review is shown in Figures 1 and 4. The Cariboo Pit is located between 2,800 N and 3,550 N, and 1,160 E and 1,990 E, to the southeast of the Springer Pit. Mining operations in the Cariboo Pit were carried out from 1996 to 2001 and, upon completion, the pit was backfilled with waste rock from other pits. Mining activities in the Cariboo Pit resumed in 2015, until the mine went into care and maintenance in May 2019. At the time of the 2021 review, the Cariboo Pit was flooded to approximately elev. 1,020 m.

Four walls have been excavated in the Cariboo Pit. These walls are labelled in Figure 4 and in Appendix A, Photograph A-2. A haul ramp enters the pit from the south, descends along the southeast wall, and wraps around the east, northeast, and west walls to the pit bottom on the east side (Figure 4). Six benches have been excavated on either side of the haul ramp that enters the pit from the south. The Cariboo Pit crest at its highest point is at approximately elev. 1,181 m on the east wall, and the pit floor was at elev. 921 m; however, the pit bottom was flooded and was not visible at the time of the review.

The northeast wall of the Cariboo Pit is an approximately 900 m long southwest-facing wall that includes three segments: the northwest, central, and southeast wall segments (Figure 4). The northwest segment includes about seven single benches that have been excavated to the elev. 1,894 m platform between the Cariboo and Springer Pits. The central segment of the northeast wall includes a waste rock rehandle slope and has a large catch-bench area at elev. 988 m (not visible at the time of the 2021 review). There are about six single benches excavated in the rehandle slope. On the southeast segment there is a nose that notches into the east wall. The crest of the northeast wall is at approximately elev. 1,168 m, and at the base of the wall is a haul road ramp at elev. 952 m. From the crest of the rehandle slope to the catch-bench area below the northwest segment of the northeast wall is about 180 m high, and the overall slope height from the crest to the pit bottom is 247 m.

The east wall experienced deep-seated toppling instability in April 2017 and unloading of the area was completed in 2018. The wall is currently stable. The crest of the unload zone is located at elev. 1,181 m. The wall is approximately 247 m high.

On the southeast side of the pit, the east wall curves and changes orientation from southwest-facing (east wall), through west-facing, and becomes northwest-facing (southeast wall). The southeast wall is approximately 380 m long. The crest of the southeast wall is located at elev. 1,146 m, and the toe of the wall was at the pit bottom (elev. 921 m). There are three double benches below the haul road ramp into the pit on the southeast wall and one single bench. The southeast wall is approximately 225 m high.

A saddle exists between the Springer and Cariboo Pits, and its elevation has remained unchanged since the 2019 review; the south side of the saddle is at elev. 1,096 m and at elev. 1,084 m on the north side. The saddle on the southwest side forms the west wall in the Cariboo Pit. The wall is approximately 163 m high.

3.1.2 WX Pit

The WX Pit is an east-facing alcove that was excavated into a ridge located to the south of the Springer Pit (Figures 1 and 4). The crest of the ridge is located at approximately elev. 1,156 m, and the floor of the WX Pit is located at elev. 1,053 m. Three double benches were excavated to form a maximum wall height in the alcove of approximately 80 m. Three single benches have been mined beneath the WX Pit to elev. 1,030 m as a continuation of the west wall on the west side of the haul ramp. The WX Pit has been excavated to its ultimate configuration.

3.1.3 C2 Pit

The C2 Pit is a west-facing alcove that is located at the southwest end of the Cariboo Pit (Figures 1 and 4). The crest of the wall is at elev. 1,159 m, and the pit floor is located at elev. 1,062 m. Three to four double benches have been excavated in the C2 Pit, to form a maximum wall height in the alcove of approximately 90 m. The C2 Pit has been excavated to its ultimate configuration.

3.1.4 Springer Pit

The Springer Pit is located to the northwest of the Cariboo Pit and to the southwest of the mined-out and backfilled Bell Pit (Figures 1 and 4). The Springer Pit is pear shaped and is approximately 1,000 m long and approximately 600 m wide. The pit floor at the south end of the pit is excavated to approximately elev. 940 m. In 2015 and 2016 tailings were discharged as slurry into Springer Pit from the saddle between the Cariboo and Springer Pits. Approximately ⅓ of the tailings have been dredged from Springer Pit and pumped as slurry to the tailings storage facility between March 2016 and October 2019. Approximately 3.5 Mt of tailings remain in the Springer Pit. The tailings had a free water cover (approximately elev. 986 m) at the time of the 2021 review and the water was actively being pumped. The long-term mine plan includes continued dewatering, removal of the tailings, and an expansion of the Springer Pit to merge with the Cariboo Pit.

3.1.5 Wight Pit

The Wight Pit is located at the northeast end of the mine property along the northwest shore of Polley Lake between 5,150 N and 5,820 N, and 2,380 E and 3,025 E (Figure 1). Mining of the open pit was completed in 2009 and underground operations were carried out via an adit that was driven into the base of the northwest wall of the pit. Underground operations ceased in 2018.

The Wight Pit trends northwest–southeast, and the entrance is located at the south end of the pit. The pit floor was initially mined down to elev. 804 m and was backfilled by 2016 to approximately elev. 875 m at the north end of the pit and approximately elev. 911 m at the south end of the pit. The west wall of the pit has a maximum crest of elev. 1,020 m, and approximately seven double benches have been excavated on this wall, of which six were visible above the backfill during the 2021 review. The west wall is approximately 146 m high. The east wall has a maximum crest of elev. 964 m and an approximate maximum wall height of 116 m. Approximately five double benches have been excavated on the east wall. The north wall has a maximum crest of elev. 996 m and a wall height of approximately 120 m. Approximately seven double benches have been excavated on the north wall, of which six were visible above the backfill during the 2021 review.

The south end of the Wight Pit was backfilled with waste rock in 2009 and used to access the underground portal located at the bottom of the north wall. The waste rock backfill extends approximately 140 m north from the mined-out south wall, and the top of the fill has a maximum elevation of elev. 911 m.

3.2 Waste Rock Dump Development and Status

3.2.1 Northwest Potentially Acid Generating Dump

The Northwest PAG Dump is located at the northwest end of the mine property to the west of the Springer Pit between 3,600 N and 4,630 N, and 470 E and 1,150 E (Figure 1). A layer of NAG rock was placed on the bottom lift, and PAG rock was end-dumped on top of the NAG lift in four lifts from the bottom up. No activities were occurring on the Northwest PAG Dump at the time of the 2021 review and there was no change in the dump configuration since the 2020 review. The dump at the north end of the upper platform is at elev. 1,140 m. The toe of the dump is located at approximately elev. 1,020 m, and the dump is approximately 120 m high.

Ultimately, the PAG material will be transferred into the open pits during mine closure.

3.2.2 Southeast Rock Disposal Site

The SERDS, previously referred to as the Southeast NAG Dump (Golder 2021) and the Life of Mine NAG Dump (Golder 2016b), is located at the southeast end of the mine property and covers the old Sandwich Dump, the Southeast Zone Pit, and the Pond Zone Pit (Figure 1). The SERDS is located between approximately 1,300 N and 2,500 N, and 3,100 E and 4,420 E. It is a southward extension of the existing Northeast NAG Dump. The top lift of the SERDS is at elev. 1,110 m and no additional dumping has occurred since the 2020 review.

3.2.3 Northeast Non-acid Generating Dump

The Northeast NAG Dump is located to the north of the SERDS and to the northeast of the East Waste Dump between 2,500 N and 4,200 N, along the west side of Polley Lake (Figure 1). Waste rock from the Wight Pit was consigned to the dump, and this dump has been inactive for several years.

4.0 REVIEW OF OPEN PIT SLOPE STABILITY PERFORMANCE

The following sections summarize open pit slope stability performance observations that were made during the 2021 review.

4.1 Cariboo Pit Slope Stability Performance

With the exception of localized zones within and adjacent to the Polley Fault causing bench-scale planar failure, overall rock mass quality in the Cariboo Pit is generally good. Slope stability continues to be favourable, and the pit walls have not exhibited any signs of large, multi-bench instability since the 2020 review. Bench-scale stability continues to be favourable and, in general, there is adequate catchment on the slopes. An overview of the Cariboo Pit is shown in Appendix A, Photograph A-2. The Cariboo Pit walls are labelled in Figure 4. The slope stability performance exhibited by the walls is presented in the following sections.

4.1.1 Northeast Wall – Northwest Segment

An overview of the northeast wall of the Cariboo Pit is shown in Figure 4 and in Appendix A, Photograph A-2. The northwest segment of the northeast wall is adjacent to the Springer Pit Phase 3 pushback. The two pit areas are separated by the Polley Fault (Appendix A, Photograph A-3). This area has not changed since the 2020 review.

Approximately seven single benches have been excavated along the northwest segment of the northeast wall of the Cariboo Pit. The wall was in good condition with no signs of overall wall instability at the time of the 2021 review. The majority of the major geological structures are favourably oriented with respect to the northwest segment of the northeast wall (Figure 2), and the benches were exhibiting good stability performance. North–south trending augite porphyry dykes are exposed in the wall and dip favourably to the east at steep angles (Appendix A, Photograph A-3). Moderately dipping features are evident on the northwest side of this segment where benches have broken back to these features (Appendix A, Photograph A-3). Catchment is still adequate in these areas where localized back-break has occurred.

The Polley Fault and adjacent faults trend at approximately 350 degrees and dip to the east-northeast at approximately 70 degrees (Figure 3 and Appendix A, Photograph A-3). The north-northwest–south-southeast striking regional trend intersects the northeast wall at an oblique angle. Ravel debris continues to accumulate at the base of fault traces on individual benches; however, adequate catchment has been maintained on the wall.

4.1.2 Northeast Wall – Central Segment

An overview of the central segment of the northeast wall of the Cariboo Pit is shown in Figure 4 and in Appendix A, Photograph A-4. A rehandle slope excavated in waste rock is located in the upper central portion of the northeast wall of the Cariboo Pit. Approximately six single benches have been excavated in the waste rock rehandle slope. The lower benches in the rehandle material have been re-sloped to reduce the bench face angles. This area has not changed since the 2020 review. The rehandle slope is exhibiting good overall slope stability with no signs of bulging or instability in the face of the slope and no cracking behind the crest of the slope.

Seven single benches have been excavated in rock down to elev. 998 m, below the waste rock rehandle slope. South-southeasterly dipping structures strike sub-parallel to the central segment of the northeast wall, and the bench faces are breaking back to these moderately dipping structures (Appendix A, Photograph A-4). These structures exhibit a dip on the order of 55 to 65 degrees, and a dip direction of 200 degrees true azimuth. The catch-benches range from 8 to 11 m in width. They currently have adequate catchment to contain the ongoing ravel material.

4.1.3 Northeast Wall – Southeast Segment

An overview of the southeast segment of the northeast wall of the Cariboo Pit is shown in Figure 4 and in Appendix A, Photograph A-5. This area has not changed since the 2020 review and was exhibiting good stability performance at the time of the 2021 review. The double bench faces on the wall are breaking back to moderately to steeply south-southeasterly dipping joints, and some localized raveling has occurred (Appendix A, Photograph A-5). The ravel debris was confined to localized areas of the benches, and adequate catchment is being maintained on the overall slope. There are some fault exposures on the northwest side of the wall segment around about mid-wall height (Appendix A, Photograph A-5). Minor ongoing raveling appears to be occurring along these faults; however, the overall wall catchment is adequate. The East Cariboo Fault is exposed in the upper northeast corner of the southeast wall segment (Appendix A, Photograph A-5).

4.1.4 East Wall

An overview of the east wall is shown in Figure 4 and Appendix A, Photograph A-6. The East Cariboo Fault intersects the southeast segment of the northeast wall (Figure 3) and forms the boundary between the southeast segment of the northeast wall and the east wall. The East Cariboo Fault generally follows an orientation trend similar to the Polley Fault; it strikes northwest–southeast and dips steeply to the northeast at approximately 60 degrees.

In previous years, multi-bench-scale toppling instability developed in the hangingwall of the East Cariboo Fault, at the top of the slope between approximately elev. 1,108 and 1,160 m and was being monitored with geotechnical visual reviews and prism monitoring. Toppling displacement began to accelerate in the spring of 2017, and the upper three to four benches failed on 7 April 2017. The slope was well monitored prior to the instability. A rockfall berm was constructed below the failure zone, based on the results of rockfall and runout analyses. The rockfall berm contained the failure debris. It was recommended that the crest of the east wall be mined down to elev. 1,120 m to remove failure debris that could continue to ravel. The crest of the east wall was unloaded by mining five single benches to elev. 1,120 m and this was completed in 2018 (Golder 2019). At the time of the 2021 review, the unload area and single benches were exhibiting good stability performance (Appendix A, Photograph A-6).

Appropriate ditching has been implemented around the unload zone to intercept and conduct water away from the east wall on the south side of the unload area. There is one area of wall seepage that was noted during the 2019 review on the unload area north of the interception ditch and was again observed during the 2021 review (Appendix A, Photographs A-6 and A-7). The source of the water could be due to a geologic structure in the wall that extends to higher ground to the northeast. The water is infiltrating into the fill material on the unload zone. The benches below the seepage zone are dry and there are no signs of increased raveling or instability (Appendix A, Photograph A-6). At the time of the 2021 review there were no concerns related to slope stability due to the seepage area. The unloaded area should continue to be inspected during routine visual inspections for excess seepage and raveling.

The benches below the unload zone are partially infilled with failure debris; however, there is adequate catchment below the two benches that are filled (Appendix A, Photograph A-6). A wide bench was excavated at the toe of the east wall beside the haul road ramp into the pit; however, at the time of the 2021 review, the wide bench was under water.

4.1.5 Southeast Wall

The status of the Cariboo Pit southeast wall at the time of the 2021 review is shown in Figure 4 and in Appendix A, Photograph A-8. One single bench and nine double benches (six double benches above the haul ramp and three double benches below the ramp) have been excavated in the southeast wall. The in-pit reservoir was at elev. 1,020 m at the time of the 2021 review; therefore, the lower southeast wall was not visible (Appendix A, Photograph A-8). The southeast wall continues to exhibit adequate slope stability performance. There are bench-scale wedge failures that continue to ravel on the north side of the southeast wall (Appendix A, Photograph A-8). The areas should be monitored for increased ravel debris. Once access is required into Cariboo Pit along the haul ramp on this wall as water is removed, maintain the rock rollout berm along the haul ramp to contain potential rockfall and to protect light vehicles or equipment that may need to enter the pit to access the pit lake or pumping equipment. Benches on the south end of the southeast wall have bench faces breaking back to moderate dipping, planar, continuous joints that dip toward the northwest (Appendix A, Photograph A-8).

Overall, the southeast wall is exhibiting adequate stability performance. Adequate catchment remains along the majority of the wall, and the benches have not been significantly infilled by ravel debris. The degree of available catchment along this wall should continue to be monitored, particularly if access is required to the in-pit reservoir as pumping continues.

4.1.6 West Wall

A saddle has been developed between the southeast side of the Springer Pit and the west side of the Cariboo Pit (Appendix A, Photograph A-9). The crest of the saddle is located at elev. 1,084 m, and the west wall of the Cariboo Pit has been mined down to elev. 921 m. At the time of the 2021 review, the bottom of the west wall was not visible due to the in-pit reservoir (Appendix A, Photograph A-9).

The Polley Fault is a broad zone of deformation 60 to 80 m wide that is exposed in the west wall. The fault zone strikes approximately north-northwest–south-southeast and dips steeply to the east. Bench-scale planar failure continues to be observed along a shallow easterly dipping fault within the Polley Fault Zone and in the immediate hangingwall. The degree of catchment and bench infilling along the portion of the west wall where the Polley Fault is exposed should continue to be monitored (Appendix A, Photograph A-9). If the in-pit reservoir is lowered and mining resumes, it may be necessary to increase catch-bench widths or construct rollout berms along the working bench along the west wall if rockfall hazards become a concern.

Bench stability performance is better outside of the Polley Fault Zone in the west wall. The rock along the upper south side of the wall and on the lower north side of the wall below the Polley Fault Zone exhibits good rock quality and favourable geological structure orientations.

4.1.7 Haul Ramp

The haul ramp into Cariboo Pit enters from the south heading north then wraps around the pit from the southeast, east, northeast, and west walls to the pit bottom (Figure 1). The haul ramp has pumping infrastructure that is located on the east side of the ramp to the in-pit reservoir's edge at elev. 1,020 m. There is a wedge instability that has continued to ravel over the years on the east side of the haul ramp entrance before the C2 Pit (Appendix A, Photograph A-10). Material has accumulated at the toe of the instability. There is a risk of rock rollout that could damage the pipe infrastructure for dewatering, and the ramp is going to be used for long-term access into the Springer Pit once mining activities reach this elevation. A berm should be constructed in front of the instability area. The ravel material could be used to cover the pipe for protection and a rock rollout berm should be constructed at the toe of the wedge instability. The berm should be inspected and cleaned annually while the haul ramp is actively being used by light and heavy traffic.

4.2 C2 Pit Slope Stability Performance

The C2 Pit is a small pit that was mined out immediately southeast of the Cariboo Pit (Appendix A, Photograph A-11). The C2 Pit has an in-pit reservoir (elev. 1,077 m) and only two double benches were visible above the water level. The benches appear to be in adequate condition and exhibiting good stability performance. There are five benches below the C2 Pit above the haul ramp in and out of the Cariboo Pit. The catch-benches are infilled and there is limited catchment available. A rock rollout berm should be established and maintained along the haul ramp to protect operations as well as the pumping infrastructure along the haul ramp (Appendix A, Photograph A-12).

4.3 WX Pit Slope Stability Performance

The WX Pit is a small pit that was mined out immediately west of the C2 Pit and southwest of the Cariboo Pit. The WX Pit has three double benches excavated. The benches in the west wall of the WX Pit have limited catchment available and the benches to the south appear to have more catchment available. As mining resumes on the saddle between the Springer and Cariboo Pits, overspill could infill these benches and potentially cause a rockfall risk to traffic along the haul ramp into Cariboo Pit. Limit the amount of overspill onto the catch-benches from new mining activities at the crest of the wall. If the catch-benches continue to become infilled, install a rockfall rollout berm at the base of wall to reduce the risk of rockfall to light vehicles and personnel (Appendix A, Photograph A-13).

4.4 Springer Pit Slope Stability Performance

The status of the Springer Pit at the time of the 2021 review is shown in Appendix A, Photograph A-14, and the pit walls are labelled in Figure 4. The pit has been partially backfilled with tailings and water, and mining has not been carried out in the Springer Pit for a few years. The inundation of the Springer Pit has not adversely impacted the overall slope stability performance of the pit slopes. Slope stability analyses to assess the impact of dewatering the Springer Pit slopes as the tailings are dredged from the pit have been carried out, and the results are presented in a separate document (Golder 2017). The analyses assessed a scenario where the backfill materials in the pit are removed and where high water tables remain in the pit slopes. The stability analyses indicated factors of safety between 1.7 and 2.0 for the southwest and northeast walls of the Springer Pit, respectively. Consequently, the removal of the tailings and water from the Springer Pit is not expected to adversely impact the overall pit slope stability of the Springer Pit. When mining resumes in the Springer Pit the walls should be monitored for seepage, particularly in the east and south walls where seepage has been noted previously (Golder 2016b). No dredging activities have been carried out in the Springer Pit since 2019 and dewatering was ongoing. The water level in the pit was at approximately elev. 986 m (Appendix A, Photograph A-14).

The overall rock mass quality in the Springer Pit is good, and the slopes continue to exhibit favourable overall and bench-scale slope stability. The slope stability performance exhibited by the walls at the time of the 2021 review is presented in the following sections.

4.4.1 North Wall

The north wall is continuing to exhibit favourable stability performance and there has been very little change to the wall since the 2020 review (Appendix A, Photograph A-14). Large-scale geological structures are favourably oriented with respect to the north wall (Figure 3). The catch-benches have some ravel infilling in areas where the Springer and Wishbone Faults are exposed in the wall (Appendix A, Photograph A-15).

4.4.2 East Wall

The east wall has not changed significantly over the last few years. The benches are infilled with old mining overspill (Appendix A, Photographs A-16). There is too much material on the elev. 1,000 m bench to safely clean and re-establish the catch-bench. Depending on the mine plan there are two options to proceed with mining (Figure 5 and Appendix A, Photograph A-16):

1) If MPMC plan to only mine along the saddle between the Springer and Cariboo Pits, there are no concerns with leaving the elev. 1,000 m bench as is.

2) If MPMC plan to mine concurrently at the Springer Pit bottom and along the saddle between the Springer and Cariboo Pits, additional catchment may be required below the current Springer Pit bottom. Once the Springer Pit is dewatered, the available catchment on the benches below the elev. 1,000 m catch-bench should be inspected. If adequate catchment is not available, a wider catch-bench will be required with a rock rollout berm.

4.4.3 South Wall

The south wall is exhibiting adequate stability performance, and some benches have broken back to moderately dipping joints over about three single benches mid-wall (Appendix A, Photograph A-17). There are some steeply dipping dykes in the south wall that are causing minor bench-scale raveling (Appendix A, Photograph A-17). Adequate catchment remains along the wider geotechnical bench at elev. 1,000 m to contain any ravel debris.

Preparations for mining activities were underway at the time of the 2021 review (Appendix A, Photograph A-18). When mining resumes, every effort should be made to limit overspill into the WX, Cariboo, and Springer Pits. Depending on the amount of overspill from mining activities a rock rollout berm may be required on the west side of the access ramp into Cariboo Pit (Appendix A, Photograph A-13).

4.4.4 West Wall

The west wall is continuing to exhibit favourable slope stability performance and there has been very little change to the wall since the 2020 review (Appendix A, Photograph A-19). Some large geological structures are visible in the west wall, and they are favourably oriented with no large-scale instability apparent (Figure 4). The catch-benches have some ravel infilling in localized areas, but there continues to be adequate catchment along the majority of the west wall. At the time of the 2021 review there had been a minor rock rollout on the ramp to the pumping equipment in the Springer Pit along the west wall (Appendix A, Photograph A-20). The boulders should be removed, and the area should be monitored. A rock rollout berm should be constructed in the area where the overhanging material is still visible since vehicles continue to utilize the ramp.

During the 2020 review, reduced catchment was identified on the north side of the west wall below the north nose where equipment was being stored. A rock rollout berm was established along the toe of the wall (Appendix A, Photographs A-21 and A-22). Continue to keep equipment and personnel at least 10 m from the wall to reduce the risk of rockfall.

4.5 Wight Pit Slope Stability Performance

The status of the Wight Pit at the time of the 2021 review is shown in Figure 1 and in Appendix A, Photograph A-23. With the exception of the rock within the Rusty Fault on the northeast side of the pit, and within the Green Dykes that bound the south side of the west wall toppling zone, overall rock mass quality in the Wight Pit is generally good. The slope stability performance exhibited by the various walls at the time of the 2021 review is presented in the following sections.

4.5.1 West Wall

An overview of the west wall of the Wight Pit is shown in Appendix A, Photographs A-23 and A-24. In 2007, toppling instability developed in the middle of west wall along the steeply dipping, north–south striking joints and faults. A steep west-northwest–east-southeast striking dyke swarm that intersects the middle of the west wall formed release structures for the south side of the toppling zone. The highest deformation rates occurred immediately adjacent to the north side of the dyke swarm, and deformation rates decrease toward the north and away from the dyke swarm. Ongoing monitoring data and visual observations have indicated that the portion of the west wall on the south side of the dyke swarm has not exhibited any deformation.

The toppling deformation to the north of the dykes decelerated after unloading of the crest was carried out and mining of the pit was completed. The toe of the south side of the west wall toppling zone has been buttressed with waste rockfill (Appendix A, Photograph A-24). The crest of the west wall was inspected during the 2021 review. The unloaded area appears to be in similar condition to what was observed in 2020 review, with some ongoing displacement and raveling caused by deformation and creep from within toppling zone (Appendix A, Photograph A-25). The cracks behind the crest of the west wall were in similar condition to the 2020 review, with some ongoing year-over-year displacement (Appendix A, Photograph A-26). This displacement trend is also indicated by the prism monitoring data and discussed further in Section 4.6.3.1. Prism monitoring and visual review of the cracks should continue to assess areas that exhibit ongoing creep displacements and to monitor for any sudden accelerations in the toppling zone.

The rockfill buttress in the bottom of the pit provides a very large catch-bench for the majority of rockfall from the toppling zone (Appendix A, Photograph A-27). To the north of the backfill, a rockfall ditch and berm was constructed several years ago along the toe of the west wall to keep the pit floor free of raveling rocks from the north side of the topple zone. This ditch and berm have been effective, as rockfalls have not been observed beyond the berm. An inactive wellhouse is located near the base of the north side of the west wall, and there was limited catchment on the bench immediately above (Appendix A, Photograph A-27). If the wellhouse is reactivated, the condition of the berm should be reviewed and, if required, cleaned out to provide sufficient catchment and rockfall protection to personnel accessing the wellhouse. Catchment along the west wall should continue to be monitored. There is sufficient room to expand the size and height of the catchment berm at the base of the north end of the west wall, if required.

4.5.2 North Wall

The status of the north wall at the time of the review is shown in Appendix A, Photograph A-28. The slopes along the northwest and north sides of the pit continue to remain stable and have only exhibited raveling along fault intersections, particularly in the northwest and northeast corners of the wall. This ravel material is infilling the catch-benches; however, there is adequate rockfall protection below the slope at the pit bottom (Appendix A, Photograph A-28).

4.5.3 East Wall

The status of the east wall at the time of the 2021 review is shown in Appendix A, Photograph A-29. The benches on the east wall are infilled with ravel debris. As well, ongoing raveling is occurring along the Rusty Fault in the northeast corner of the east wall (Appendix A, Photograph A-29). A talus slope has developed at the toe of the Rusty Fault, and ravel debris is continuing to accumulate at the base of the wall. A rockfall catch ditch and berm have been constructed along the toe of the east wall, and there is adequate rockfall protection on the pit floor (Appendix A, Photograph A-29). If access to the bottom of the pit is required, the degree of available catchment in the ditch should be inspected at least twice a year and, if the ditch becomes filled, it should be cleaned out with an excavator so that personnel working at the base of the wall remain protected from rockfall.

There is a potential undaylighted wedge developing at the north end of the east wall that was first observed in 2018 and has been inspected annually since (Appendix A, Photograph A-29). The undaylighted wedge is formed by the intersection of the Rusty Fault and a fault that dips toward the north-northwest. The line of intersection of the Rusty Fault and the fault that dips toward the north-northwest does not appear to be daylighted, but displacement could be occurring along the wedge between the two faults. Additional prisms were installed in 2019 and 2020. The prism monitoring data and locations are discussed further in Section 4.6.3.3.

Toppling deformation has previously occurred along the crest of the east wall; however, the toppling slowed and stopped after mining of the pit was completed. The cracks associated with the toppling deformation in the till at the crest of the east wall were inspected during the 2021 review (Appendix A, Photograph A-30). The cracks in the till behind the east wall are rounded and it appears that there has been little to no movement on the east wall.

A perimeter ditch was re-established around the north and east wall of the Wight Pit in 2021 (Appendix A, Photograph A-31). After the large storm event that occurred in 2020, the perimeter ditch was re-established to convey water around the Wight Pit. At the time of the 2021 review, the ditch was in good condition. The ditch should be inspected at least twice per year (in the fall and after freshet) and if any repairs are required, they should be completed.

4.6 Review of Pit Slope Stability Monitoring Data

Prisms are an integral part of the monitoring system for walls of the open pits at Mount Polley Mine. Long-term deformations can be detected in the prism data, and displacement vectors can be calculated to assist in determining failure mechanisms. Diligence and care should continue to be applied to the monitoring accuracy and frequency. The MPMC survey staff achieve a good level of accuracy in the prism monitoring surveys.

Monitoring data up to 31 October 2021 for the Cariboo, Springer, and Wight Pits have been provided by MPMC. The locations of the monitoring prisms in the Cariboo, Springer, and Wight Pits are presented in Appendix B, Figures B-1, B-11, and B-18. Monitoring prism plots are presented in Appendix B. All of the prisms were not read between December 2020 and May 2021 due to winter conditions.

Slope distance is not being recorded in the monitoring data spreadsheets. Every effort should be made to record slope distance as this is an integral component of the data review to understand apparent movement of the prisms relative to the base station.

As prisms are reset or moved, the prism maps should be updated. The inactive prisms should be clearly marked in the data collection spreadsheets.

Continue to measure the prisms in all the pits on a monthly basis (excluding winter months between December and May) and review the data for changes in the magnitude and rate of displacement.

4.6.1 Monitoring Prism Data – Cariboo Pit

Several prisms area located in the Cariboo Pit (Appendix B, Figure B-1). Since mining ceased in 2019, the trends in the prism data have been steady, with little indication of movement with the exception of ongoing slow-moving relaxation of the pit walls. The following sections provide a review of the prism readings from October 2019 to October 2020 for the Cariboo Pit. Due to the in-pit water reservoir increasing in elevation from elev. 1,000 m to elev. 1,020 m throughout 2021, several of the prisms on the lower benches of the pit were not read during the reporting period.

4.6.1.1 Northeast Wall – Northwest Segment

The Cariboo Pit northeast wall – northwest segment has five 700 series and seven 800 series prisms installed (Appendix B, Figure B-1). The prisms are showing small displacements that are within the accuracy of the system. A typical 700 series prism plot is shown in Appendix B, Figure B-2, and a typical 800 series prism plot is shown in Appendix B, Figure B-3.

The 700 series prisms show little movement, with total displacements of 10 mm or less over the reporting period. The 700 series prisms indicate a small upward vertical displacement within the accuracy of the system (unlikely that the base station is settling) and the horizontal displacement is generally to the south-southeast (out of the pit wall). The 700 series prisms are exhibiting low velocities and no indication of acceleration.

The 800 series prism show about 20 mm or less of total displacement over the reporting period. The prisms indicate downward vertical displacement and movement out of the pit wall to the south-southwest. The 800 series prisms are exhibiting very low velocities and no indication of acceleration.

Overall, the monitoring prism data indicate the wall appears to be stable, and there is no indication of large incremental velocities or acceleration in the prism readings.

4.6.1.2 Northeast Wall – Central Segment

There are 10 prisms installed on the northeast wall – central segment (Appendix B, Figure B-1). Four of these prisms are on the waste rock rehandle slope (two on the upper benches, two on the lower benches) and six on the bedrock below the rehandle slope.

All the prisms on the rehandle slope show similar movement out of the slope into the Cariboo Pit (south-southeast). Prisms 814 and 815 on the upper benches of the waste rock rehandle slope indicate between 7 and 15 mm of total displacement over the reporting period. A typical prism plot on the upper slopes of the waste rock rehandle slope is presented in Appendix B, Figure B-4. These prisms are exhibiting very low velocities and no indication of acceleration. These displacements are typical for long-term settlement of a waste rock slope and are not a concern.

Prisms 828 and 829 are on the lower benches of the waste rock rehandle slope. A typical prism plot on the lower slopes of the waste rock rehandle slope is presented in Appendix B, Figure B-5. The prisms indicate less than 15 mm of total displacement over the reporting period. Prism 828 is moving to the northeast whereas Prism 829 is moving to the west. Both prisms are exhibiting very low velocities with no indication of acceleration. Again, these trends are typical for long-term settlement of a waste rock slope and are not a concern.

The prisms on the bedrock benches below the waste rock rehandle slope that were visible during the 2021 reporting period are showing total displacements of less than 15 mm over the reporting period. A typical plot for the bedrock below the waste rock rehandle slope is shown in Appendix B, Figure B-6. All prisms are showing movement out of the pit wall.

Overall, the wall appears to be stable and there is no indication of large incremental velocities or acceleration in the prism readings.

4.6.1.3 Northeast Wall – Southeast Segment

There are 10 prisms installed on the Cariboo Pit northeast wall – southeast segment (Appendix B, Figure B-1). A typical plot of a prism on the upper benches of the northeast wall – southeast segment is presented in Appendix B, Figure B-7. The prisms located on the upper benches of the wall are all moving out of the pit wall to the south-southwest and exhibit total displacements of less than 7 mm over the reporting period.
The displacements are within the accuracy of the system and there is no indication of acceleration.

A typical plot of a prism on the lower benches of the northeast wall – southeast segment is presented in Appendix B, Figure B-8. The prisms on the lower benches of the wall are all moving out of the pit wall to the south-southwest and indicate total displacements of less than 5 mm (very little movement) over the reporting period.

Overall, the wall appears to be stable and there is no indication of large incremental velocities or acceleration in the prism readings.

4.6.1.4 East Wall

There are 10 prisms installed on the east wall of the Cariboo Pit (Appendix B, Figure B-1). The majority of the prisms were moved in 2017 due to the April 2017 toppling failure and subsequent unloading in the area.
The prisms installed on the single benches above the unload zone are all showing total displacements of less than 15 mm over the reporting period. The movement is out of the pit wall to the west. There is no indication of acceleration or large incremental velocities. A typical plot of a prism on the east wall on the benches above the unload zone is presented in Appendix B, Figure B-9.

Prism 844 is on the elev. 1,084 m bench below the unload zone. The prism is also moving out of the pit wall towards the southwest and the total displacement is about 5 mm over the reporting period.

Three additional prisms should be installed along the crest of the east wall unload zone and recommended locations for the additional prisms are shown in Figure 6. The prisms on the east wall continue to freeze and break over the winter months. Covers could be manufactured for these specific prisms to protect the prisms from the elements and water infiltration. The covers could be made of plywood or metal.

Overall, the wall appears to be stable and there is no indication or large incremental velocities or acceleration in the prism readings.

4.6.1.5 Southeast Wall

The southeast wall of the Cariboo Pit has 11 prisms installed. Prisms 821 and 823 are no longer reading. The prisms that are being monitored on the southeast wall exhibit total displacements between 2 and 10 mm over the reporting period. The prisms are all generally moving to the west-northwest out of the pit wall. There is no indication of acceleration or large incremental velocities. A typical prism plot for the southeast wall is shown in Appendix B, Figure B-10.

Overall, the wall appears to be stable and there is no indication of large incremental velocities or acceleration in the prism readings.

4.6.1.6 Elevation 1,013 m Bench (All Pit Walls)

There are eight prisms installed on the elev. 1,013 m bench in the Cariboo Pit from the north wall notch to the haul ramp into the pit. The prisms have been read since May 2018; however, readings ceased in 2021 due to the in-pit reservoir elevation increasing above this bench height. When Cariboo Pit is dewatered, the prisms on the elev. 1,013 m bench should be re-shot and re-established if safe to do so.

4.6.2 Monitoring Prism Data – Springer Pit

The Springer Pit monitoring prism locations are shown in Appendix B, Figure B-11. Since mining ceased in 2014, the trends in the Springer Pit prism data have been steady, with ongoing relaxation of the pit walls occurring. MPMC began reading the majority of the prisms in the Springer Pit in 2010 in the upper benches, with a select few in 2011 and 2012 in the lower benches. The following sections provide a review of the prism readings from October 2020 to October 2021 for the Springer Pit.

4.6.2.1 East Wall

The prisms on north end of the east wall indicate between 2 and 10 mm of total displacement over the reporting period. The wander plots generally indicate movement out of the pit wall to the southwest. There is no increase in incremental velocity or indication of acceleration. Representative plots are shown in Appendix B, Figures B-12 and B-13.

4.6.2.2 North Wall / North Nose Area

The prisms on the north wall / north nose area are exhibiting small total displacements between 0 and 15 mm over the reporting period. Wander plots generally indicate the movement is out of the pit wall to the south. There is no increase in incremental velocity or indication of acceleration. Typical plots for the north wall / north nose area are shown in Appendix B, Figure B-14 and B-15.

4.6.2.3 West Wall

The prisms on the west wall indicate small total displacements between 2 and 10 mm over the reporting period. The wander plots generally indicate the movement is out of the pit wall to the south-southeast. There is no increase in incremental velocity or indication of acceleration. Representative plots are presented in Appendix B, Figures B-16 and B-17.

4.6.3 Monitoring Prism Data – Wight Pit

The Wight Pit monitoring prism locations are shown in Appendix B, Figure B-18. Since mining ceased in 2009 and the pit was backfilled, the movement within the pit walls has continued to exhibit similar displacement trends to previous years, indicating ongoing relaxation of the pit walls as well as ongoing toppling in the west wall.

The base station was reset in June 2020; therefore, the majority of the prisms in the Wight Pit show a jump in total displacement of approximately 50 mm at this time. The base station on the east wall (at Prism 587) is located on the south side of the east wall within about a metre of the wall crest, and evidence of erosion was visible on the slope below in 2020 (Golder 2021). It was recommended that the survey base station be re-installed farther back from the crest of the east wall to reduce the risk to survey personnel. Rather than move the base station, MPMC installed a new station (WP13) that monitors movement of the existing base station. The station indicates less than 10 mm of total displacement between October 2020 and June 2021. No further readings were available for

the station. Continue to collect readings at WP13 and Prism 587 at the same frequency that readings are taken in the Wight Pit to monitor movement of the base station. Use caution when working near the edge of the east wall.

The following sections provide a review of the prism readings from October 2020 to October 2021 for the Wight Pit.

4.6.3.1 West Wall

The prisms located at the crest of the west wall toppling instability have indicated a steady trend of toppling displacements over the years and prisms in this area continue to show ongoing displacements. Visual observations of the tension cracks were made during the 2021 review and there appears to be little change visually. The prisms above the unload area indicate, on average, 40 mm of total displacement over the reporting period downward in the vertical component and out of the pit wall to the northeast. There is no increase in incremental velocity or indication of acceleration. A representative plot of the prisms above the unload area is shown in Appendix B, Figure B-19. Prisms 530 and 523 show similar trends in total displacement; however, the movement is in the downward vertical component and to the southwest. The direction of movement is isolated to these two prisms and appears to have begun after the base station was reset. Prism 528 stopped being read in 2020.

The prisms at the crest of the unloaded area indicate between 30 and 80 mm of total displacement during the reporting period. The movement trend indicates ongoing settlement on the unload crest towards the north-northeast. There is no increase in incremental velocity or indication of acceleration. This movement is indicative that the cracks in the unload area are continuing to develop and that the wall continues to gradually deform. Representative plots for the west wall unload are shown in Appendix B, Figures B-20 to B-21. Prisms 594 and 595 were installed in September 2020 on the unload area crest. If prisms are lost on the unload area, replace these prisms when safe to do so and with good sightlines to the base station.

The prisms on the north end of the west wall (outside of the unload area) indicate between 30 and 90 mm of total displacement over the reporting period in the downward vertical component and out of the pit wall to the east-southeast. There is no increase in incremental velocity or indication of acceleration. A representative plot of the prisms north of the unload area on the west wall is shown in Appendix B, Figure B-22.

4.6.3.2 North Wall

The prisms on the north wall indicate between 27 and 41 mm of total displacement over the reporting period in the downward vertical component and movement out to the southeast. There is no increase in incremental velocity or indication of acceleration. Typical plots for the north wall are shown in Appendix B, Figures B-23 and B-24.

4.6.3.3 East Wall

As recommended by Golder in 2019 (Golder 2020), prisms have been installed on the east wall, and during the 2020 review, three additional prisms were installed along the crest of the east wall. The prisms on the east wall indicate between 90 and 192 mm of total displacements (120 mm average total displacement) over the reporting period with movement generally in the downward vertical component and towards the southeast to southwest. There is no increase in incremental velocity or indication of acceleration. A typical plot for the east wall is shown in Appendix B, Figure B-25. During the 2021 review it was observed that some of the prisms get knocked over by wildlife (Appendix A, Photograph A-30). These prisms need to be reset and re-shot by the base station as soon as damage is discovered, and these prism resets reduce the accuracy of the long-term monitoring data that are being collected along the east wall. It would be beneficial to determine a more permanent prism installation that cannot be knocked over by wildlife.

5.0 STABILITY CONSIDERATIONS FOR CARIBOO AND SPRINGER PITS

5.1 Slope Stability Considerations for Cariboo Pit

The Cariboo Pit continues to exhibit overall good slope stability performance with the exception of minor localized areas of displacement. The current pit slope design recommendations are still considered to be appropriate based on the current performance of the Cariboo Pit. The existing pit slope design criteria for the Cariboo Pit are presented in Table 1.

Table 1: Summary of Cariboo Pit Recommended Pit Slope Design Criteria

Wall Dip Direction Azimuth (degrees)	Pit Design Sector Azimuth (degrees)	Bench Height (m)	Bench Face Angle (degrees)	Inter-ramp Angle (degrees)	Bench Width (m)	Rationale
000	180	24	65	46	12	Use a double bench configuration with a 65 degree BFA.
030	210	24/12	65/70	46/43	12/8.5	Use a single bench configuration with a 70 degree BFA in the Polley Fault. Otherwise, use a double bench configuration with a 65 degree BFA.
060 to 090	240 to 270	24/12	70	49/43	12/8.5	Use a single bench configuration with a 70 degree BFA in the Polley Fault. Otherwise, use a double bench configuration with a 65 degree BFA.
120	300	24/12	65/70	46/43	12/8.5	Use a single bench configuration with a 70 degree BFA in the Polley Fault. Otherwise, use a double bench configuration with a 65 degree BFA
150	330	24	65	46	12	No slope stability controls.
180 to 240	000 to 060	24	70	49	12.13	No slope stability controls.
270	090	12	70	43	8.5	Current design is a single bench configuration due to toppling along East Cariboo Fault.
300	120	24	70	49	12.13	No slope stability controls.
330	150	24	65	46	12	Use a double bench configuration with a 65 degree BFA.

Source: Golder 2016a.

BFA = bench face angle.

The catch-bench widths for the double benches range from 11.5 to 12 m. The effective catch-bench width is likely to exceed the regulatory 8 m minimum requirement, after accounting for bench crest back-break and the accumulation of ravel debris on the benches. There is little concern over the availability of catchment on the double benched slopes. The design catch-bench width for single benches is 8.5 m. After bench crest back-break and the accumulation of ravel debris on the benches, the effective catch-bench widths may be less than 8 m on walls where single benches are recommended. Effective catch-bench widths can be maximized by ensuring that benches are scaled and cleaned prior to drilling and blasting the next bench. Standard Operating Procedures related to slope stability performance monitoring can be used to identify areas where available catchment is insufficient and where rockfall is creating a hazard to mining operations. A single wide catch-bench or a series of slightly wider catch-benches can be used in areas where rockfall becomes a safety issue.

With the exception of localized areas where the available catch-bench width has been lost due to failures or overspill from mining activities above, the majority of the pit slopes in the Cariboo Pit are achieving the intended design objectives.

If mining resumes, the following potential remedial measures should be considered in the Cariboo Pit:

- When the Cariboo Pit is dewatered, the area below the east wall unload zone should be visually inspected and a rollout berm in the east corner of the haul ramp switchback should be built and maintained to capture any potential ravel debris from the east wall toppling area.
- When the Cariboo Pit is dewatered, the west wall below the Polley Fault should be visually inspected. A rollout berm may be required below the west wall where planar failure is occurring within the Polley Fault Zone and the immediate hangingwall. If catchment decreases along the wall, a wider geotechnical catch-bench may be required when mining proceeds.

5.2 Slope Stability Considerations for Springer Pit

The Springer Pit is currently being used as temporary storage for tailings. During 2015 and 2016 tailings were discharged as slurry into Springer Pit from the saddle between the Cariboo and Springer Pits. Approximately ⅓ of the tailings were dredged from Springer Pit and pumped as slurry to the tailings storage facility between March 2016 and October 2019. Approximately 3.5 Mt of tailings remain in the Springer Pit. The tailings had a free water cover (approximately elev. 986 m) at the time of the 2021 review and the water was actively being pumped. The long-term mine plan includes continued dewatering, removal of the tailings, and an expansion of the Springer Pit to merge with the Cariboo Pit.

Overall, the walls are performing adequately, with the exception of overspill on the east wall. The current pit slope design recommendations are still considered to be appropriate based on the current performance of the Springer Pit. When mining resumes in the Springer Pit, the elev. 1,000 m bench should be cleaned or, alternatively, a new 12 m catch-bench should be excavated below the elev. 1,000 m bench (Figure 5). The existing pit slope design recommendations for the Springer Pit are presented in Table 2.

Table 2: Summary of Springer Pit Recommended Pit Slope Design Criteria

	Pit Design Sector Azimuth (degrees)	Bench Height (m)	Bench Face Angle (degrees)	Inter-ramp Angle (degrees)	Bench Width (m)	Rationale
000	180	12	70	43	8.5	Single bench due to the shallowest dipping structures within Set 3 in the south wall, which dip at angles that are less than the design bench face angle and undercut the current benches. These structures are shown in Appendix A, Photograph A-17.
030	210	24	70	50	11.5	No slope stability controls.
060 to 180	240 to 000	24	65	46.5	11.5	No slope stability controls.
210 to 240	030 to 060	12	70	43	8.5	Single bench through Polley and Springer Faults.
270	090	12	70	43	8.5	Single bench through Polley and Springer Faults. Single bench due to shallow, westerly dipping structures at the bottom of east wall.
300 to 330	120 to 150	12	70	43	8.5	Single bench due to the shallowest dipping structures within Set 3 in the south wall, which dip at angles that are less than the design bench face angle and undercut the current benches. These structures are shown in Appendix A, Photograph A-17.

Source: Golder 2016a.

6.0 REVIEW OF WASTE ROCK DUMP STABILITY PERFORMANCE

The waste rock dumps status at the time of the 2021 review is shown in Figure 1 and the photographs of the waste rock dumps taken during the review are presented in Appendix A. The following sections summarize the waste rock dump slope stability performance observations that were made during the 2021 review.

6.1 Northwest Potentially Acid Generating Dump Stability Performance

The Northwest PAG Dump was exhibiting good stability performance at the time of the 2021 review and there had been little change since the 2020 review (Appendix A, Photograph A-32). The upper PAG lifts were not exhibiting any signs of overall instability or deep-seated instability (Appendix A, Photograph A-33). No signs of dump face bulging or deformation were observed. There was no evidence of ponding or significant cracking on the dump platform (Appendix A, Photograph A-33). Continue to monitor any settlement cracks that could develop, and doze to mitigate the infiltration of water into the dump.

The haul road along the north end of the Northwest PAG Dump has previously shown evidence of water erosion. At the time of the 2021 review, the haul road was in adequate condition and ditching was controlling the flow of water (Appendix A, Photograph A-34).

The lower lifts of the Northwest PAG Dump are exhibiting good overall stability performance. All of the dump faces are at angle of repose and the lifts consist of good, coarse material (Appendix A, Photograph A-35). The berm at the toe of the lower lifts on the inside of the light vehicle road is performing adequately and no rock rollout was visible on the road. There is evidence of ponding in some areas on the lower lifts (Appendix A, Photograph A-36). The ponding water on the lower lifts should be drained, filled, and graded such that water will no longer pool on the lift (particularly near the crest edge) (Appendix A, Photograph A-37). There is also evidence of water ponding below one of the ramps to the lower lifts and fine-grained material has accumulated in this area (Appendix A, Photograph A-37). Water should be diverted away from the area and controlled down the haul ramp.

At the toe of the Northwest PAG Dump there are no signs of foundation failure or deformation observed along the toe of the dump (Appendix A, Photograph A-38). Future construction will progress the dump to the west and north. Construction of the expansion will be bottom-up starting with NAG material at the base and PAG material on top. The thickness of NAG material required in this area should be confirmed with the MPMC environmental team. The foundation soils for areas of the expansion that are on original ground are colluvium and till with localized depressions of saturated soils (Golder 2013). As previously recommended, the foundation materials should be loaded slowly with the initial NAG lift to preload the foundation. This has been achieved to date with the previous initial construction of the Northwest PAG Dump and can continue to be achieved by preloading the foundation with the NAG lift. Once the remaining foundation of the dump has been preloaded with NAG material, the PAG lifts can be advanced from south to north over the NAG material (Golder 2013).

6.2 Southeast Rock Disposal Site Stability Performance

Since the 2020 review, there has been no change to the SERDS (Appendix A, Photograph A-39). The dump platform is properly graded, no ponding was visible, and there were very few settlement cracks observed on the platform (Appendix A, Photograph A-40). The upper and lower dump faces are at angle of repose, with no signs of deformation or bulging in the face or in the foundation soils (Appendix A, Photographs A-41 to A-43). The dump height is relatively low, and the dump is continuing to exhibit adequate stability performance.

6.3 Northeast Non-acid Generating Rock Dump

The Northeast NAG Dump has been inactive for several years. The areas of the dump that were visible during the 2021 review were exhibiting good stability performance and there was no indication of deformation of the waste dump or the foundation (Appendix A, Photograph A-44). The platform has lots of vegetation growing and the berms in place around the perimeter of the platform are not showing any signs of deformation. As well, the lower slopes have good vegetation growth and there is no indication of foundation deformation (Appendix A, Photograph A-45).

6.4 Tailings Road

A minor instability of the Tailings Road occurred prior to the 2019 review. The instability and runout was likely due to flowing water over the road caused by runoff and the water infiltrating the fill material. This subsequently led to the instability.

The instability area was inspected by Golder during the 2021 review and has remained relatively unchanged since the instability occurred (Appendix A, Photograph A-46). The crest area is bermed off and there is no access at the toe of the slope. There is evidence of ponding water on the platform of the Tailings Road (Appendix A, Photograph A-47). Water needs to be redirected using appropriate ditching above the Tailings Road such that water doesn't flow past the berm at the entrance and onto the platform. If water continues to pond on the platform after appropriate ditching has been implemented above the Tailings Road, the platform may need to be regraded. Visual reviews should be carried out of the instability to check for changes to the instability area, backscarp, and toe of the slope.

When the Tailings Road construction restarts, it is possible that the road may be constructed over fine-grained foundation materials. The road may need to be constructed from south to north with smaller lift heights to control pore pressures in the foundation materials and loading rates. Using a dozer to pre-load the foundation materials, the Tailings Road construction could begin off the S-curve in the current road to the east with a lower lift height. The lower lift could be advanced north and south from this access road along the alignment of the proposed Tailings Road (Figure 10). Once the lower lift is advanced to the toe of the current Tailings Road fill, it would be tied into the failed area. The instability area should be remediated with good-quality, coarse-grained material that is dumped short and pushed into the instability area by a dozer to help tie the Tailings Road together.

6.5 Review of Waste Rock Dump Stability Monitoring Data

Prisms are an integral part of the monitoring system for the waste rock dumps at Mount Polley Mine. Long-term deformations and settlement of the dumps can be detected in the prism data, and displacement vectors can be calculated to assist in determining failure mechanisms. Diligence and care should continue to be applied to the monitoring accuracy and frequency. The MPMC survey staff achieve a good level of accuracy in the prism monitoring surveys.

The Northwest PAG Dump is the only dump on site that is currently being monitored by prisms. The location of the monitoring prisms on the Northwest PAG Dump are shown in Appendix B, Figure B-26. Monitoring prism plots are presented in Appendix B.

6.5.1 Northeast Potentially Acid Generating Dump Monitoring Prism Data

There are 27 prisms that were actively monitored on the Northwest PAG Dump through the reporting period (Appendix B, Figure B-26). The 100 series prisms were read six times between October 2020 and October 2021, and the 700 series prisms, Prisms 776 through 779, were read 14 times within the data review period.

The 100 series prisms are located on various lifts of the Northeast PAG Dump. On the north end of the dump, the 100 series prisms show approximately 0 to 20 mm of total displacement over the reporting period with both a vertical and horizontal component, which is consistent with ongoing settlement. The wander plots show that the movement is generally to the northwest, which is out of the dump slope. The incremental velocity is low and there is no indication of acceleration for any of the 100 series prisms on the north end of the dump. Typical prism plots for the 100 series on the north end of the Northwest PAG Dump are shown in Appendix B, Figures B-27 and B-28. Prism 106 on the lower lift of the north end of the dump shows 170 mm of total displacement in readings between June and July 2021. The majority of the movement is in the horizontal component with about 40 mm in the vertical component downward. The wander plot indicates that the movement is to the south. The readings after July 2021 are constant and there is little indication of movement. It is possible that the prism was knocked over. The area should be inspected after freshet and the prism monitoring data that are collected after freshet should be reviewed to understand if the movement is the dump or potentially the prism being knocked over. The prism plot for Prism 106 is shown in Appendix B, Figure B-29.

The 100 series prisms located on the south end of the dump show between 0 and 25 mm of total displacement over the reporting period with both a vertical and horizontal component, which is consistent with ongoing settlement. The wander plots show that the movement is generally to the southeast with some variability between prisms. The incremental velocity is low and there is no indication of acceleration for any of the 100 series prisms on the south end of the dump. A typical prism plot for the south end of the dump is shown in Appendix B, Figures B-30 and B-31. Prisms 103, 119, 120, 121, and 122 all have a sudden increase or decrease in total displacement (movement is in the horizontal and vertical components) that appears to revert back to normal readings between May and June 2021. Prism 119 is shown in Appendix B, Figure B-32. It is possible that there was an issue with the reading taken in June 2021 or that a backsight was not corrected for properly. Readings after June 2021 appear to follow the typical trend of a waste dump settling.

The 700 series prisms are all located on the southwest access road crest edge to the Northwest PAG Dump. The prisms all show approximately 30 mm to 65 mm of total displacement over the reporting period with both a vertical and horizontal component, which is consistent with ongoing settlement. The wander plots show that the movement is to the southwest, which is out of the dump at an angle approximately perpendicular to the crest. The incremental velocity is low and there is no indication of acceleration for any of the 700 series prisms. A representative prism plot for the 700 series is shown in Appendix B, Figure B-33.

7.0 WASTE ROCK DUMP DESIGN CONSIDERATIONS

The proposed ultimate design of the Northwest PAG Dump has been updated since the slope stability review in 2020 and will include an expansion to increase the lift height of the northern portion of the dump to elev. 1,150 m and extend the dump to the west and north (Figure 7). Overall, the dump will be approximately 140 m high.

During the 2021 review, Golder discussed with MPMC staff how the extension should be progressed from the lower lifts of the Northwest PAG Dump towards the west then to the north (Appendix A, Photograph A-38). Future construction will progress the dump to the west and north. Construction of the expansion will be bottom-up, starting with NAG material at the base and PAG material on top. The thickness of NAG material required in this area should be confirmed with the MPMC environmental team. The foundation soils for areas of the expansion that are on original ground are colluvium and till with localized depressions of saturated soils (Golder 2013). As previously recommended (Golder 2013), the foundation materials should be loaded slowly with the initial NAG lift to preload the foundation. This has been achieved to date with the previous initial construction of the Northwest PAG Dump and can continue to be achieved by preloading the foundation with the NAG lift. Once the remaining foundation of the dump has been preloaded with NAG material, the PAG lifts can be advanced from south to north over the NAG material (Golder 2013).

The proposed ultimate design of the SERDS is currently under review as a co-disposal site. The detailed design will be complete in 2022.

8.0 SUMMARY OF GEOTECHNICAL CONSIDERATIONS

Slope stability monitoring and surface water management will be key to maintaining the stability of the existing pit slopes and waste rock dump slopes. The following sections describe the recommended actions.

8.1 Pit Slope Stability Performance Monitoring

The stability of the pit slopes is being monitored by survey prisms that are installed on benches in the Cariboo, Springer, and Wight Pits as well as by visual inspections. The prisms should be measured by the MPMC survey team on approximately a monthly basis. Readings are not required in winter when the prisms are covered in snow and the slopes are frozen. Survey personnel should continue to ensure consistency in readings and use the same setup and monitoring procedures for each set of measurements. This will improve the ability to detect localized and short-term displacements, as well as develop more accurate interpretations of long-term settlement trends. If any significant storm events occur that exceed a five-year return period or daily maximum precipitation, the prisms should be read. Daily temperature and barometric pressure corrections should be applied to the monitoring data, as rapid changes in temperature or barometric pressure can have a significant impact on the day-to-day accuracy of the data. The current system is functioning adequately and is being used to monitor pit slope displacements. The following general guidelines should be used in collecting and interpreting the monitoring data:

- Slope distance should be recorded in the prism monitoring spreadsheets.
  - Slope distance data should be used with caution. It is possible for a portion of the slope to move a significant distance perpendicular to the line of sight with very little change in the slope distance measurement. Therefore, the 3D displacements must also be reviewed for signs of long-term displacement.
- Velocity threshold criteria have been established for pit walls based on previous experience. However, these data must also be reviewed for signs of acceleration. If a prism is showing acceleration—regardless of the measured velocity—personnel should be told to avoid the area and the source of the displacement should be investigated. Displacement trend guidelines for the pit wall prisms are illustrated in Figure 8.
- If prisms are moved or reset, the prism should be renamed and a new data collection sheet should be completed. The old prism should become inactive in the data collection sheet.

A major part of the slope stability monitoring program will be the regular visual inspections of the bench faces and crest areas for early evidence of slope instability. Regular pit inspections should be carried out quarterly, and areas of instability should be inspected monthly. After a major rainfall event, an inspection of the pit walls should be completed to check for any adverse conditions after the event. These inspections should ideally be carried out by the same individual to maintain continuity of the observations. The observations should be recorded in a diary so that a record of the stability performance is available should it be required in the event of instability.

8.2 Waste Rock Dump Stability Performance Monitoring

Similar to the pit slopes, the stability of the waste rock dump slopes is being monitored by survey prisms and visual inspections. The prisms should be measured by the MPMC survey team on approximately a quarterly basis when the dumps are not active. Readings are not required in winter when the prisms are covered in snow and the slopes are frozen. Survey personnel should continue to ensure consistency in readings and use the same setup and monitoring procedures for each set of measurements. This will improve the ability to detect localized and short-term displacements as well as develop more accurate interpretations of long-term settlement trends. If any significant storm events occur that exceeds a five-year return period or daily maximum precipitation, the prisms should be read. Daily temperature and barometric pressure corrections should be applied to the monitoring data, as rapid changes in temperature or barometric pressure can have a significant impact on the day-to-day accuracy of the data. The current system is functioning adequately and is being used to monitor waste rock dump slope displacements. The following general guidelines should be used in collecting and interpreting the monitoring data:

- Slope distance should be recorded in the waste rock dump monitoring spreadsheets.
  - Slope distance data should be used with caution. It is possible for a portion of the slope to move a significant distance perpendicular to the line of sight with very little change in the slope distance measurement. Therefore, the 3D displacements must also be reviewed for signs of long-term displacement.
- Velocity threshold criteria have been established for the waste rock dumps based on previous experience. However, these data must also be reviewed for signs of acceleration. If a prism is showing acceleration—regardless of the measured velocity—personnel should be told to avoid the area and the source of the displacement should be investigated (Figure 9).
- If prisms are moved or reset, the prism should be renamed and a new data collection sheet should be completed. The old prism should become inactive in the data collection sheet.

A major part of the slope stability monitoring program will be the regular visual inspections of the waste rock dump crests, platforms, and slope faces for early evidence of slope instability. The waste rock dumps should be inspected once per quarter and during periods of high precipitation that may cause additional infiltration into the dump or additional erosion. These regular inspections should ideally be carried out by the same individual to maintain continuity of the observations. The observations should be recorded so that a record of the stability performance is available should it be required in the event of instability.

The visual reviews should include the following:

- inspecting the crests for signs of cracking and localized settlement and ponding water
- inspecting the faces of the waste rock dumps for signs of over-steepening, bulging in the middle or at the toe of the face, seepage, and erosion
- inspecting the foundation, or toe of the waste rock dump, for signs of deformation

Visual observations should be documented on inspection forms.

8.3 Surface Water Management

Surface water management around the pits and waste rock dump areas is a key component of maintaining the stability of the slopes. The following areas should continue to be monitored and managed:

- The seepage area noted on the unload area of the east wall of the Cariboo Pit in 2019 should continue to be monitored as well as the benches below the seepage area within the unload zone.
- The Wight Pit perimeter ditch should be maintained to convey water around the pit.
- The platforms should be regraded to promote water draining away from the face of the dump if any ponding water is noted on the waste rock dumps.
- Appropriate ditching and/or water bars around the area of the Tailings Road failure should be maintained to promote water flowing away from the dump faces.

9.0 SUMMARY OF 2021 REVIEW RECOMMENDATIONS

The recommendations following the 2021 review are summarized in Table 3. The ID column has a unique number for each recommendation, prefixed with the year the recommendation was originally made. New recommendations and comments from 2021 are marked with *italic text.* Recommendations that were marked as complete in previous years are not included in the summary table.

Table 3: Summary of Recommendations for 2021 Review

Area	ID	Recommendation	Timeline
Cariboo Pit	2019-03	If access is needed below the east wall on the haul road switchback or mining resumes, a rock rollout berm should be built and maintained below the east wall unload zone.	If access is needed or mining resumes, immediately.
	2020-01	Install three new prisms on the unload zone.	*Completed in fall 2020; however, the new prisms failed over the winter. These prisms should be replaced in Q2 2022 before monitoring resumes.*
		Replace broken head on existing prism.	*Completed in 2021; however, the prism head broke again. Replace in Q2 2022 and install a cover to protect the prisms on the east wall from the elements. The cover could be made of plywood or metal.*
	2021-01	*Rock rollout berm in front of wedge instability along haul ramp and below C2 Pit due to limited catchment available.*	*Q2 2022 – personnel enter the Cariboo Pit to access the pumping infrastructure and a rollout berm should be in place to protect the pump equipment and personnel.*
Springer Pit	*2021-01*	*Remove boulders from haul ramp on west wall and establish a rock rollout berm in front of overhang in bench.*	*Q2 2022 – personnel enter the Springer Pit to access the pumping infrastructure.*
Wight Pit	2018-02	Clean catch ditch along east wall below Rusty Fault.	Once per year or as required.
	2020-02	Install two to four additional prisms along the west wall between Prisms 595 and 543.	*Complete – two prisms were installed on the west wall in early 2021.*
	2020-03	Move the location of the monitoring base station farther back from the crest of the east wall.	*Incomplete – a new station was installed that monitors the existing base station for movement.*
Tailings Road	2019-06	Remediate failure scarp area.	*Incomplete in 2020 and 2021. Divert water away from the Tailings Road to limit ponding in the area of the scarp area until it is remediated.*
All areas – prism monitoring data	2019-07	Collect slope distance measurements.	*Incomplete – Q2 2022*

10.0 CLOSURE

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this report.

PROJECT
MOUNT POLLEY MINE
2021 ANNUAL PIT SLOPE AND WASTE DUMP STABILITY REVIEW

TITLE
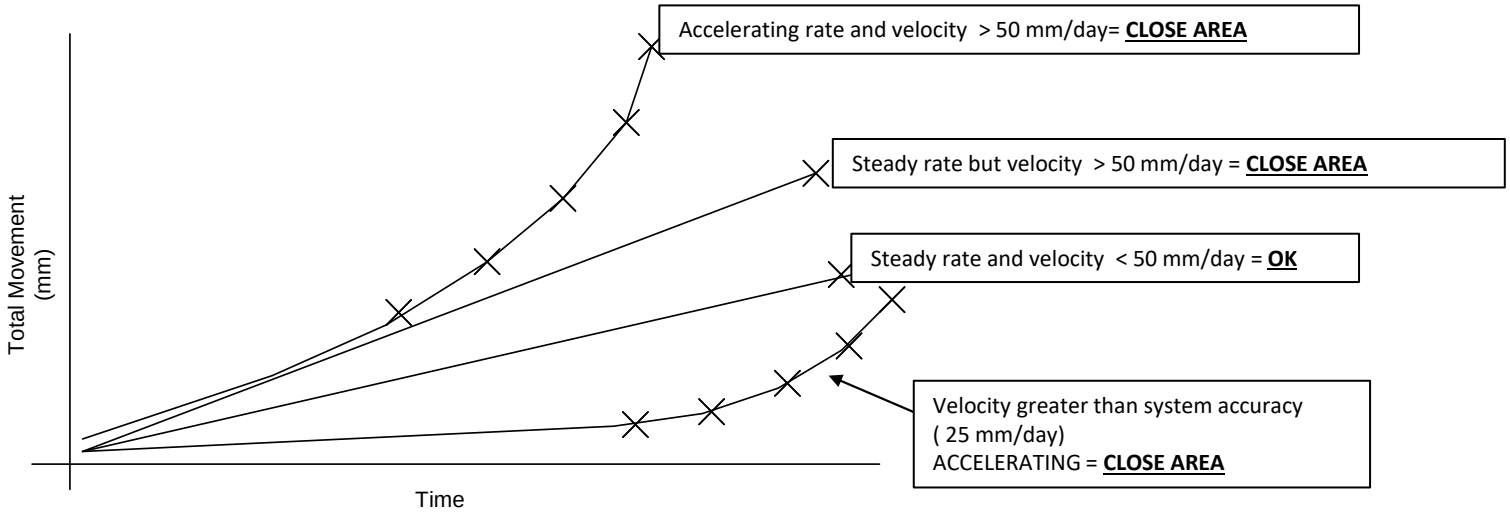
NORTHWEST POTENTIALLY ACID GENERATING DUMP PROPOSED ULTIMATE DESIGN CONFIGURATION

PROJECT NO.	PHASE	REV.	FIGURE
21452039	**73100**	**0**	**7**

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM: ANSI A
0 25 mm

Prism Data Interpretation Procedures



A) Daily displacement (mm)
(How many millimetres did it move? Was this less than or more than the monitoring system accuracy?)

B) Daily velocity (mm/day)
(How fast is it moving?)

C) Direction of movement (azimuth)
(Does the direction of movement make sense? Is it moving away from the wall, parallel to the wall, or into the wall?)

D) Direction of movement (vertical)
(Are all of the prisms moving upward? If so, is it possible that the base station or back-sight is settling?)

E) Total displacement graph
(Is it accelerating?)

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM ANSI A
0 25 mm

OVERSPILL HAS INFILLED BENCHES ON THE EAST WALL. LITTLE CHANGE SINCE THE 2020 REVIEW DUE TO NO MINING ACTIVITIES.

THERE IS TOO MUCH OVERSPILL TO SAFELY CLEAN THE ELEV. 1,000 M BENCH. ONCE THE SPRINGER PIT IS DEWATERED, THE BENCHES SHOULD BE ASSESSED AS TO WHETHER OR NOT THERE IS ADEQUATE CATCHMENT AVAILABLE IF MINING ACTIVITIES ARE TO OCCUR CONCURRENTLY ON THE SADDLE AND AT THE PIT BOTTOM. A NEW 12 M WIDE BENCH BELOW THE OVERSPILL MAY BE REQUIRED.

FUTURE CONSTRUCTION WILL PROGRESS THE DUMP TO THE WEST THEN NORTH. AREAS TO THE WEST ARE DAMP. CONSTRUCTION OF THE EXPANSION WILL BE BOTTOM-UP CONSTRUCTION STARTING WITH NAG MATERIAL AT THE BASE WITH PAG MATERIAL ON TOP. THE NAG LIFT FOR SHOULD BE PROGRESSED FROM SOUTH TO NORTH AT A LOW LIFT HEIGHT (SIMILAR TO WHAT HAS BEEN DONE PREVIOUSLY FOR THE CONSTRUCTION OF THIS DUMP) TO PRELOAD THE DAMP AREAS.

MINOR INSTABILITY OF THE TAILINGS ROAD OCCURRED IN 2019. WATER IS STILL PONDING ON THE CREST OF THE TAILINGS ROAD (SEE PHOTOGRAPH A-47).

WHEN CONSTRUCTION OF THE TAILINGS ROAD IS RESTARTED, REMEDIATE THE FAILURE BY ADDING GOOD QUALITY, COARSE-GRAINED MATERIAL, AND DUMPING SHORT AND PUSHING TO FILL THE SCARP. DO NOT END DUMP MATERIAL DIRECTLY OVER THE SCARP.

PRELIMINARY PREDICTIONS OF GROUNDWATER SEEPAGE FOR THE WIGHT OPEN PIT AT CLOSURE – MOUNT POLLEY MINE

1.0 INTRODUCTION

This technical memorandum presents preliminary predictions of groundwater seepage for the Wight Pit Lake at closure at the Mount Polley Mine that is operated by the Mount Polley Mining Corporation (MPMC). These predictions were made in support of the Reclamation and Closure Plan that is currently being prepared for the site. This Plan assumes that the Wight Pit will be allowed to flood to a spillover elevation of approximately 926 m.

This memorandum documents preliminary predictions of groundwater seepage from the Wight Pit Lake at closure. It is understood that the Wight Pit Lake hydrology, quality of pit lake water and resulting seepage quality is assessed by the concurrent studies conducted by MPMC and Golder.

2.0 BACKGROUND

Surface mining of the Wight Pit occurred between 1999 and 2009. The pit floor reached an elevation of approximately 804 m; however, since the mining stopped the pit has been partially filled with waste rock with the pit bottom presently at an elevation of approximately 875 m in the northwest and approximately 912 m in the southeast, as presented on Figure 1. In the northwest, the pit crest is located at a distance of approximately 200 m from the Polley Lake shore and in the southeast this distance is about 80 m. At both locations the pit bottom is below the average level of Polley Lake of approximately 920 m.

Similar to the nearby Springer Pit, the majority of the Wight Pit walls were excavated in monzonite bedrock that was intruded by hydrothermal breccias. Three northwest-southeast striking faults intersect the pit, and these faults have been intruded by thick and presently weathered mafic dykes. In 2014, groundwater seepage was observed in the southeast corner of the pit along the east-west striking dyke that is exposed in the pit wall (Golder, 2014a).

The southeast corner of the pit also intersected a relatively thick sequence of overburden deposits of glacio-lacustrine and glacio-fluvial origin. In 2004, Golder conducted hydrogeological investigations in these deposits that included installation and testing of two pumping wells (Golder, 2004) and in 2005 Golder assisted in the installation and testing of two dewatering wells that became part of pit wall dewatering/depressurization system (Golder, 2005). The location of these wells is presented in Attachment 1. Interpretation of hydrogeological data collected during these investigations suggested that the overburden southeast from the pit is highly variable, ranging in texture from silt/clay to sand/gravel, with coarser sediments present at depth and directly overlying bedrock.

Golder, Golder Associates and the GA globe design are trademarks of Golder Associates Corporation.

MPMC provided information on the historical dewatering rates for the Wight Pit. In 2008, when the majority of the pit was mined out, MPMC estimated groundwater inflow to this pit to range between 950 m^3/day (175 USgpm) in winter and 1600 m^3/day (300 USgpm) during spring/summer. MPMC also indicated that in 2008 only one overburden dewatering well was operational; however, the dewatering records for this well are not available. In 2014, MPMC estimated that, during summer months, the groundwater inflow to the Wight Pit was approximately 1300 m^3/day (240 USgpm), and indicated that the dewatering wells were not active at this time.

3.0 PRELIMINARY ESTIMATES OF SEEPAGE AT CLOSURE

At present the hydrogeological data from the area of the Wight Pit is not sufficient for the development of a detailed hydrogeological model that could be used to estimate seepage near this pit during closure. Most importantly, current hydraulic head data from the overburden sediments and bedrock surrounding the dewatered pit are not available. However, the available information was considered sufficient for providing preliminary estimates of this seepage based primarily on the historical groundwater inflows to this pit and information from the nearby Springer Pit. These preliminary estimates relied on a simplified analytical model of groundwater seepage near the Wight Pit that was based on the following assumptions:

- Seepage in bedrock near the Wight Pit can be represented using the Thiem equation that describes radial flow of groundwater towards a circular sink under steady-state conditions. The portion of this seepage originating from the topographic high west of the pit was based on the effective radius to the inferred groundwater divide of approximately 700 m and hydraulic head near this divide of 1080 m elevation. The portion of this seepage originating from the east (i.e. from Polley Lake) was based on the effective radius to Polley Lake of 325 m and the Polley Lake level of 920 m;
- Seepage in the overburden along the southeast wall of the Wight Pit can be represented using Darcy's Law. The cross-sectional area for this seepage was estimated to be approximately 2000 m^2 based on Golder (2006) interpretation, and the effective distance between the seepage face along the pit wall and Polley Lake was assumed to be 80 m;
- Estimates of groundwater seepage to the Wight Pit in 2008 and 2014 ranging between 950 m^3/day (175 USgpm) and 1600 m^3/day (300 USgpm) were assumed to consist of 50% of inflow from bedrock and 50% inflow from the overburden, under the assumption that in 2008 only one dewatering well was operational (as indicated by MPMC) and that in 2014 the dewatering system was off. For the base case estimates of groundwater seepage, inflow to the dewatered pit originating from bedrock alone was thus assumed to be equal to 650 m^3/day (120 USgpm) or 50% of average inflow estimated in 2008 and 2014;
- Groundwater seepage from the overburden to the Wight Pit under dewatered conditions was assumed to be equivalent to the pumping rate of 1900 m^3/day (350 USgpm) that was utilized during testing of TW05-1 in 2005 (Golder, 2006).

The simplified analytical model was calibrated to the estimates of groundwater inflow during mining by adjusting hydraulic conductivity assigned to the overburden and bedrock. When these parameters for overburden and bedrock were set to 6×10^{-5} m/s and 2×10^{-7} m/s, respectively, the model calculated total inflow was 2,600 m^3/day (470 USgpm) and matched 700 m^3/day (120 USgpm) estimated to originate from bedrock and 1,900 m^3/day (350 USgpm) assumed to enter the pit from the overburden. The values of hydraulic conductivity adopted in the calibrated model are in good agreement with bulk hydraulic conductivity of bedrock estimated for the mine site (Golder, 2014b) and with results of overburden testing near the Wight Pit discussed in Golder (2004, 2006).

Following calibration, the simplified analytical model was used to predict groundwater seepage near the Wight Pit for the pit lake level ranging between 880 m (i.e. current pit bottom) to 926 m (i.e. spillover elevation). The results of these calculations are presented in Table 1. Groundwater inflow to the pit lake was predicted to gradually decrease as the pit lake level increases from approximately 2,600 m^3/day (470 USgpm) when the pit lake level is at 880 m elevation to about 600 m^3/day (100 USgpm) when the lake is at a spillover elevation of 926 m. Groundwater outflow from the pit lake was predicted to occur once the pit lake level is above the water level elevation of Polley Lake (i.e. approximately 920 m) and was calculated to reach approximately 500 m^3/day (90 USgpm) when the pit lake is at the spillover elevation. The majority of this outflow was calculated to occur via the overburden materials that are present in the southeast between the pit wall and Polley Lake.

Table 1: Predicted Groundwater Flows for Wight Pit Lake

Pit Lake Elevation (m)	Groundwater Flow (m^3/day)	
	Into the Lake	Out of the Lake
Base Case		
880	2600	0
900	2500	0
910	2100	0
920	800	0
926	600	500
Lower Reasonable Bound		
926	400	300
Upper Reasonable Bound		
926	700	800

Table 1 also presents a range of potential groundwater inflow and outflow from the Wight Pit Lake that could be expected considering the uncertainty in the understanding of hydrogeological conditions near the facility. This range was calculated by considering the estimated range of historical pit inflows and the results of testing conducted previously in the overburden. The analysis indicated that, for the pit lake level at spillover elevation, the groundwater inflow to the pit could range from 400 m^3/day to 700 m^3/day: whereas, the outflow from the pit towards Polley Lake could vary from 300 m^3/day to 800 m^3/day.

4.0 SUMMARY AND RECOMMENDATIONS

The simplified hydrogeological analysis that was carried out for the Wight Pit Lake indicates that groundwater inflow to this lake could range between approximately 2600 m^3/day (470 USgpm) when the pit lake level is at 880 m elevation and 600 m^3/day (110 USgpm) when the spillover elevation of 926 m is reached. Once the pit lake level is above the average water level in Polley Lake of 920 m, groundwater seepage from the pit lake towards Polley Lake would occur. When the Wight Pit Lake is at spillover elevation this outflow was calculated to be approximately 500 m^3/day (90 USgpm).

Due to limited hydrogeological data available for the Wight Pit, the above predictions should be considered only as preliminary estimates of actual groundwater fluxes that could occur at closure. At present there is lack of understanding of groundwater levels in the area surrounding the Wight Pit and the hydrogeological significance of faults intersecting the east pit wall. In the absence of this information more accurate predictions of these fluxes cannot be made. The following activities are recommended to address these data gaps so that the estimates of groundwater seepage could be refined:

- Borehole survey: During the 2004 and 2005 investigations, several boreholes and wells were completed between the crest of the Wight Pit and Polley Lake (Attachment 1). It is recommended that the condition of these boreholes be assessed for their suitability for hydraulic head monitoring and water quality sampling;
- Installation of monitoring wells: If the borehole survey finds that wells installed in 2004-2005 are no longer accessible and/or suitable for groundwater monitoring, two multi-level monitoring wells should be installed between the Wight Pit and Polley Lake. At each location the shallow piezometer should target the more permeable portion of the overburden and the deep piezometer should be completed in bedrock. One of the deeper installations should target the fault/dike structure that is present in the southeast corner of the pit;
- Seepage survey: A seepage survey, focusing on major structure identified along the pit walls, should be conducted. If practicable, quantitative measurements of groundwater seepage from the fault/dyke structure in the southeast corner of the pit (and other visible seepage) should be made to facilitate estimates of hydrogeological properties of this feature;
- Groundwater monitoring: Monitoring wells near the Wight Pit should be included in the groundwater monitoring program for the site. Hydraulic heads at these installations should be measured at least weekly and groundwater quality should be assessed on a quarterly basis. After one year of monitoring, the groundwater quality data should be assessed for seasonal variability and the monitoring frequency should be adjusted appropriately;
- The existing hydrogeological model should be expanded to include the Wight Pit and its calibration should be updated to include new data sources described above. The expanded model should be used to refine the predictions of groundwater seepage that could occur at closure.

5.0 CLOSURE

We trust that the above information is sufficient for your needs at this time. Should you have any questions or require clarification, please do not hesitate contact the undersigned at 604-296-4200.

STUDY LIMITATIONS

Study Limitations

This document has been prepared for the exclusive use of Mount Polley. The factual information, descriptions, interpretations, and comments contained herein are specific to the project described in this document and do not apply to any other project or site. Under no circumstances may this information be used for any other purposes than those specified in the scope of work unless explicitly stipulated in the text of this document or formally authorized by Golder. This document must be read in its entirety as some sections could be falsely interpreted when taken individually or out-of-context. As well, the final version of this document and its content supersedes any other text, opinion or preliminary version produced by Golder.

Golder shall not be held responsible for damages resulting from unpredictable or unknown underground conditions, from erroneous information provided by and/or obtained from other sources than Golder, and from ulterior changes in the site conditions unless Golder has been notified by Mount Polley of any occurrence, activity, information or discovery, past or future, susceptible of modifying the underground conditions described herein, and have had the opportunity of revising its interpretations, comments and recommendations. Furthermore, Golder shall not be held responsible for damages resulting from any future modification to the applicable regulations, standards and criteria, for any use of this document and its content by a third party, and/or for its use for other purposes than those intended. Golder shall not be held responsible for any decrease, real or perceived, of a property's value or any failure to complete a transaction, as a consequence of this document.

Hydrogeologic/hydrologic investigations and groundwater modelling are dynamic and inexact sciences. They are dynamic in the sense that the state of any hydrological system is changing with time, and in the sense that the science is continually developing new techniques to evaluate these systems. They are inexact in the sense that groundwater systems are complicated beyond human capability to evaluate them comprehensively in detail, and we invariably do not have sufficient data to do so. A groundwater model uses the laws of science and mathematics to draw together the available data into a mathematical or computer-based representation of the essential features of an existing hydrogeologic system. While the model itself obviously lacks the detailed reality of the existing hydrogeologic system, the behaviour of a valid groundwater model reasonably approximates that of the real system. The validity and accuracy of the model depends on the amount of data available relative to the degree of complexity of the geologic formations, the site geochemistry, the fate and transport of the dissolved compounds, and on the quality and degree of accuracy of the data entered. Therefore, every groundwater model is a simplification of a reality and the models described herein are not an exception.

The professional groundwater modelling services performed as described in this document were conducted in a manner consistent with that level of care and skill normally exercised by other members of the engineering and science professions currently practising under similar conditions, subject to the quantity and quality of available data, the time limits and financial and physical constraints applicable to the services. Unless otherwise specified, the results of previous or simultaneous work provided by sources other than Golder and quoted and/or used herein are considered as having been obtained according to recognised and accepted professional rules and practices, and therefore deemed valid. This model provides a predictive scientific tool to evaluate the impacts on a real groundwater system of specified hydrological stresses and/or to compare various scenarios in a decision-making process. However and despite the professional care taken during the construction of the model and in conducting the simulations, its accuracy is bound to the normal uncertainty associated to groundwater modelling and no warranty, expressed or implied, is made.

PRELIMINARY PREDICTIONS OF GROUNDWATER SEEPAGE FOR THE BOUNDARY PIT – MOUNT POLLEY MINE

1.0 INTRODUCTION

This technical memorandum presents preliminary predictions of groundwater seepage for the Boundary Pit Lake at closure at the Mount Polley Mine, which is operated by the Mount Polley Mining Corporation (MPMC). These predictions were made in support of water balance studies for the site. It is understood that the Boundary Pit hydrology and resulting seepage quality is assessed by the concurrent studies conducted by MPMC and Golder Associates Ltd.

2.0 BACKGROUND

Surface mining of the Boundary Pit started in 2008. The pit floor reached an elevation of approximately 1,068 m, or about 14 m below the original ground surface at the northwest pit crest. Similar to the adjacent Wight Pit, most of mining at the Boundary Pit occurred in monzonite bedrock that was intruded by hydrothermal breccias and intersected by northeast striking faults.

At present, hydrogeological data specific to the Boundary Pit are not available. However, MPMC indicated that during mining seepage was not observed along the pit walls. This lack of seepage is considered reasonable due to the relatively shallow depth of this pit and depth to water table measured at monitoring wells that were installed near other mine facilities. It is thus considered likely that the water table was located near or below the floor of the Boundary Pit before mining at this location commenced.

Although seepage to the Boundary Pit from the surrounding rock mass is not expected, seepage out of this pit could occur due to water entering the pit via surface water run-off and direct precipitation. An estimate of these potential seepage rates out of the pit was made to provide input to the pit water balance and to characterize a potential seepage pathway originating from the Boundary Pit.

3.0 PRELIMINARY ESTIMATES OF SEEPAGE

The preliminary estimates of seepage from the Boundary Pit were based on the following assumptions:

- The pit bottom is located at an elevation of 1,068 m, or approximately 14 m below the ground surface at the northeast pit crest, and approximately 5 m below the lowest point along the pit crest (towards northeast). It is likely that the pit bottom does not extend to a significant depth below the water table.

CANADA'S BEST MANAGED COMPANIES Platinum member

Golder, Golder Associates and the GA globe design are trademarks of Golder Associates Corporation.

- If the Boundary Pit is flooded, seepage from this pit would be directed northeast towards the Wight Pit and discharge to that pit. This could occur not only during operation, when the Wight Pit is dewatered, but also during closure due to water table depression that would develop southwest of the Wight Pit after it is flooded to an elevation of 926 m (Golder 2015).
- Seepage from the Boundary Pit would occur via the upper bedrock zone, as incorporated in the groundwater model for the Springer and Cariboo pits (Golder 2014). This zone is assumed to extend 40 m below the surface with a bulk hydraulic conductivity of 1×10^{-6} m/s (lower bound of 6×10^{-7} m/s, upper bound of 3×10^{-6} m/s). Due to a decrease in permeability with depth, potential seepage via deeper bedrock is assumed to be negligible.
- Seepage would occur under an average hydraulic gradient of 0.1 m/m, which corresponds to the approximate slope in ground surface between the crest of the Boundary Pit and the crest of the Wight Pit.
- The maximum depth of flooding could be approximately 5 m, considering pit wall height northeast from the pit bottom (approximately 1,073 m elevation).

Based on the above assumption and a Darcy's Law calculation that considers changes in the dimensions of the seepage area as the pit is being flooded, the seepage rate from the Boundary Pit when the pit lake level is 5 m above its base is estimated at approximately 60 m^3/d, and could range between 40 m^3/d and 180 m^3/d due to uncertainty in bedrock permeability. Seepage is estimated to decrease as the height of water column above the pit bottom decreases (Table 1).

Table 1: Predicted Seepage Quantities from the Boundary Pit

Water Level above Boundary Pit Bottom (m)	Estimated Groundwater Seepage (m^3/d)		
	Lower Bound	Base Case	Upper Bound
0	2	3	10
1	6	10	29
2	12	20	61
3	16	26	79
4	32	53	159
5	35	59	177

4.0 CLOSURE

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this memorandum.

We trust that the above information is sufficient for your needs at this time. Should you have any questions or require clarification, please do not hesitate contact the undersigned at 604-296-4200.

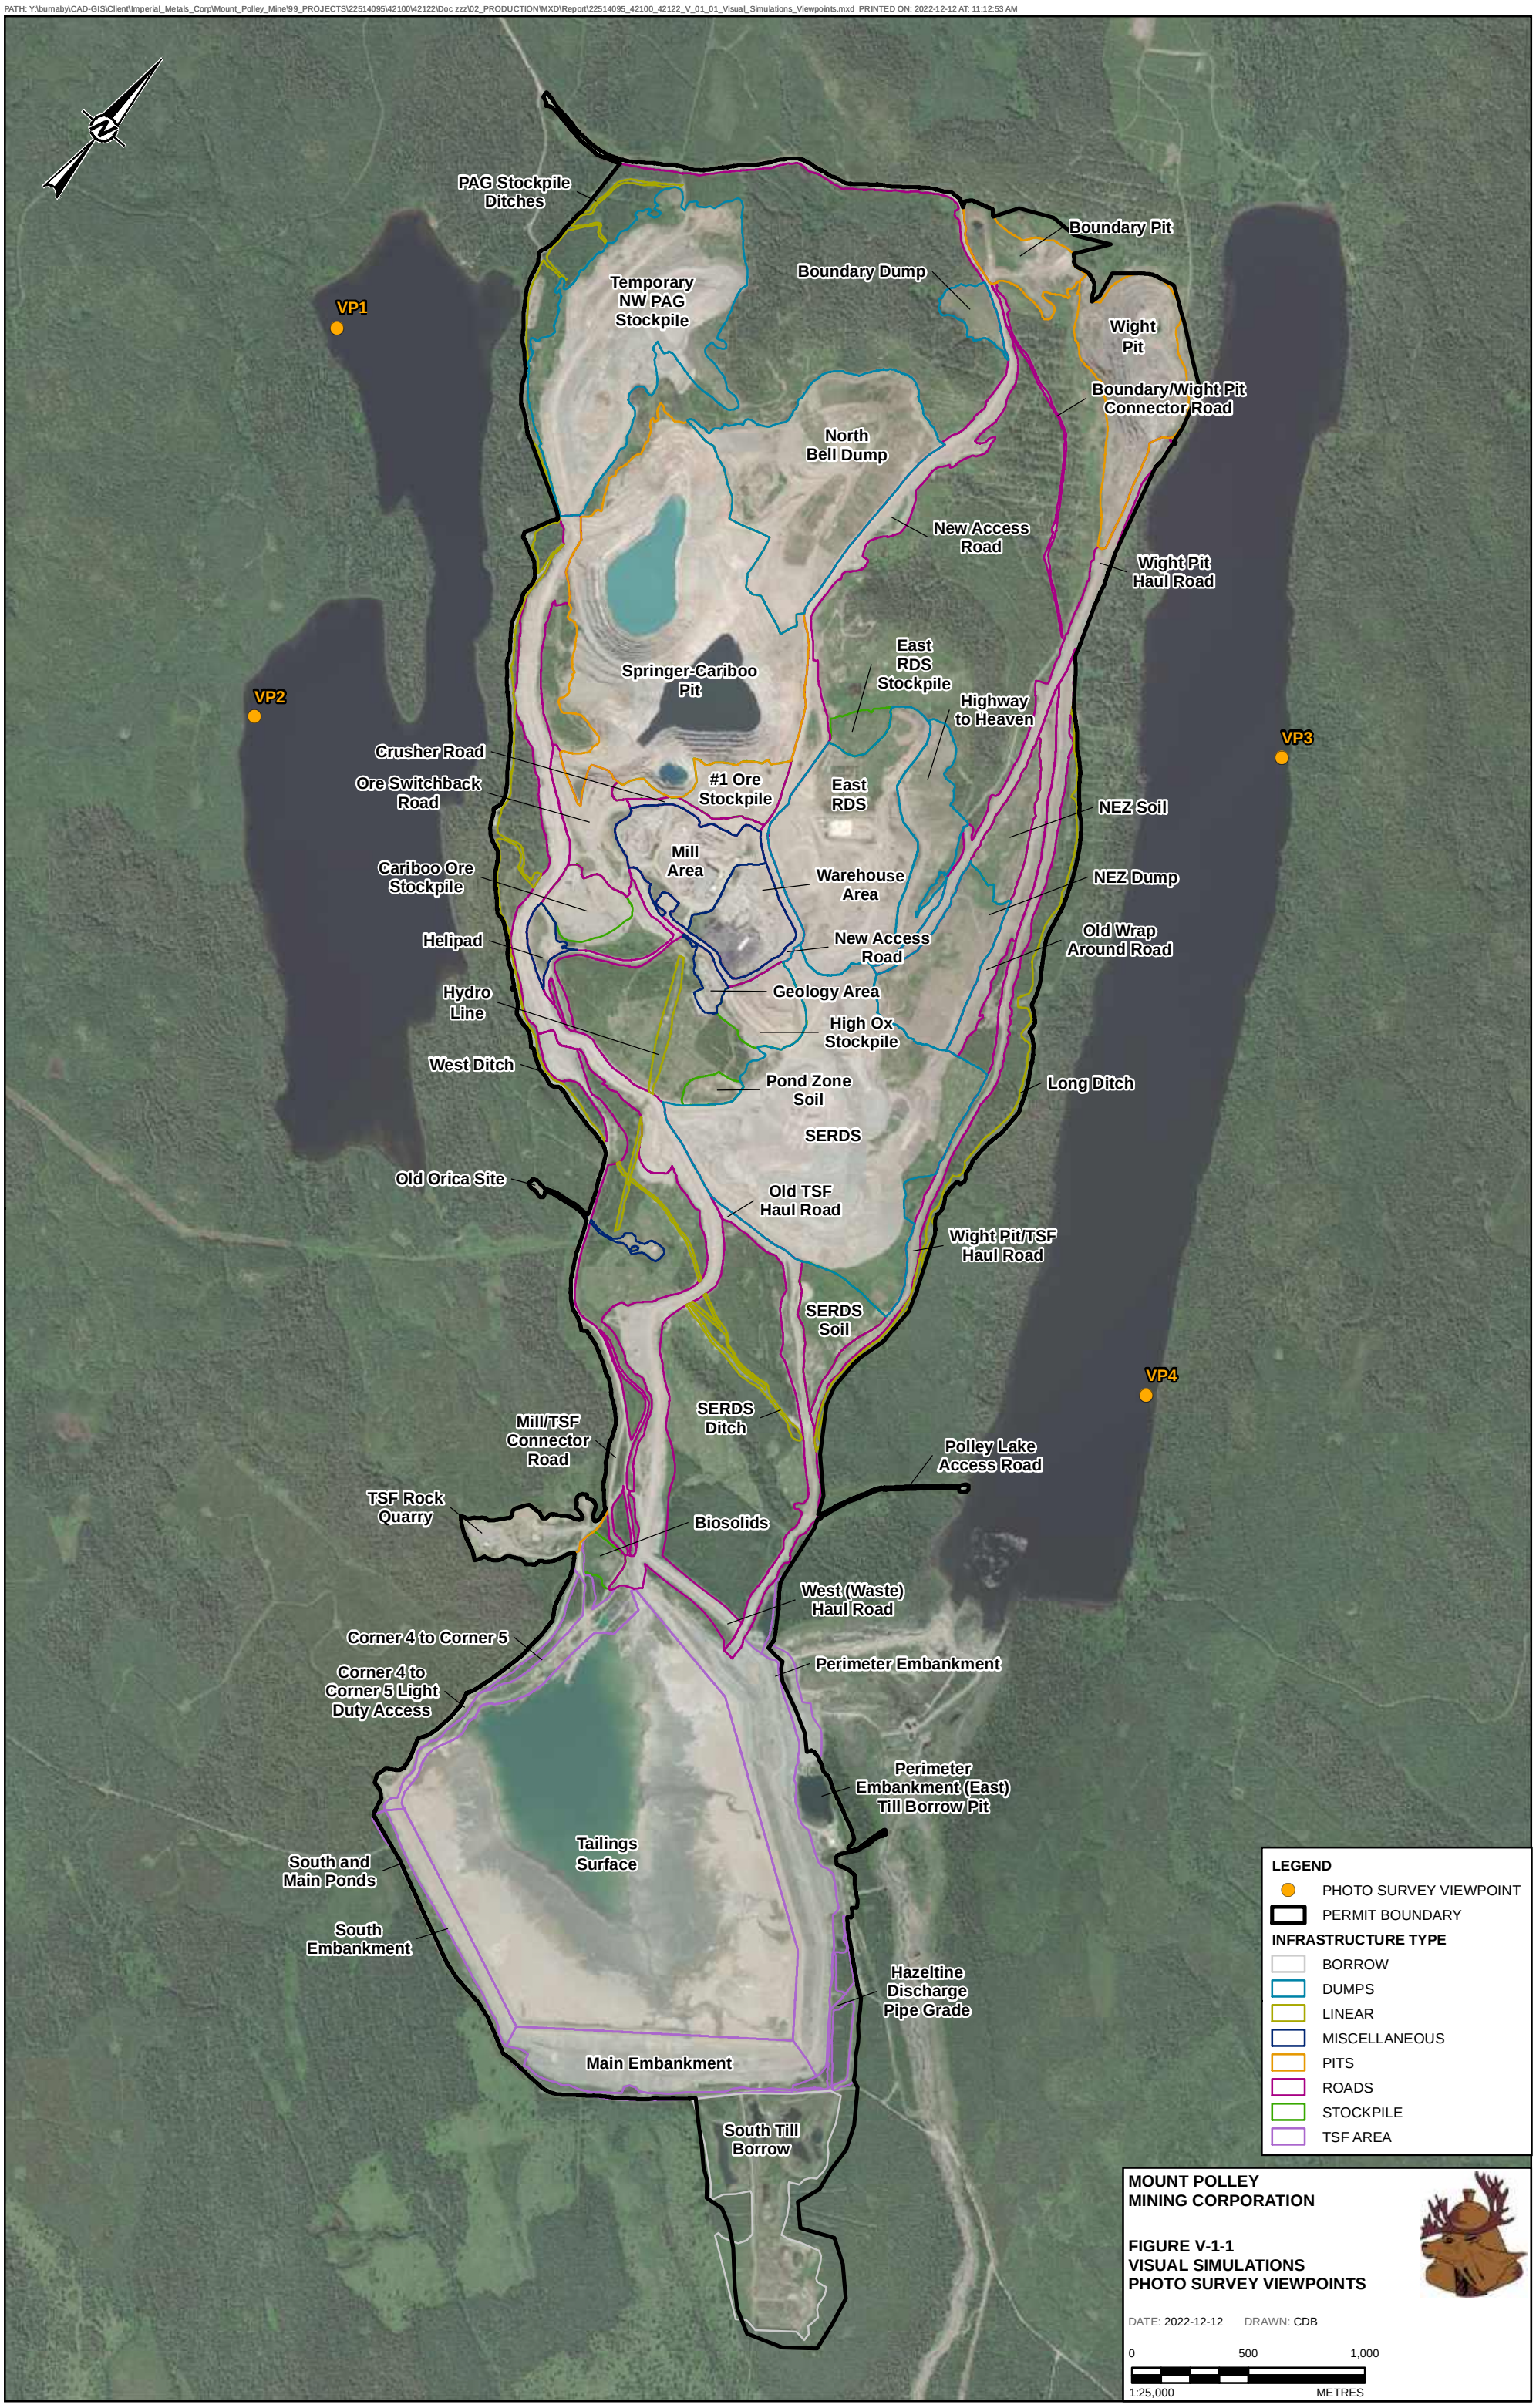
STUDY LIMITATIONS

This document has been prepared for the exclusive use of Mount Polley. The factual information, descriptions, interpretations, and comments contained herein are specific to the project described in this document and do not apply to any other project or site. Under no circumstances may this information be used for any other purposes than those specified in the scope of work unless explicitly stipulated in the text of this document or formally authorized by Golder. This document must be read in its entirety as some sections could be falsely interpreted when taken individually or out-of-context. As well, the final version of this document and its content supersedes any other text, opinion or preliminary version produced by Golder.



Golder shall not be held responsible for damages resulting from unpredictable or unknown underground conditions, from erroneous information provided by and/or obtained from other sources than Golder, and from ulterior changes in the site conditions unless Golder has been notified by Mount Polley of any occurrence, activity, information or discovery, past or future, susceptible of modifying the underground conditions described herein, and have had the opportunity of revising its interpretations, comments and recommendations. Furthermore, Golder shall not be held responsible for damages resulting from any future modification to the applicable regulations, standards and criteria, for any use of this document and its content by a third party, and/or for its use for other purposes than those intended. Golder shall not be held responsible for any decrease, real or perceived, of a property's value or any failure to complete a transaction, as a consequence of this document.

Hydrogeologic/hydrologic investigations and groundwater modelling are dynamic and inexact sciences. They are dynamic in the sense that the state of any hydrological system is changing with time, and in the sense that the science is continually developing new techniques to evaluate these systems. They are inexact in the sense that groundwater systems are complicated beyond human capability to evaluate them comprehensively in detail, and we invariably do not have sufficient data to do so. A groundwater model uses the laws of science and mathematics to draw together the available data into a mathematical or computer-based representation of the essential features of an existing hydrogeologic system. While the model itself obviously lacks the detailed reality of the existing hydrogeologic system, the behaviour of a valid groundwater model reasonably approximates that of the real system. The validity and accuracy of the model depends on the amount of data available relative to the degree of complexity of the geologic formations, the site geochemistry, the fate and transport of the dissolved compounds, and on the quality and degree of accuracy of the data entered. Therefore, every groundwater model is a simplification of a reality and the models described herein are not an exception.

The professional groundwater modelling services performed as described in this document were conducted in a manner consistent with that level of care and skill normally exercised by other members of the engineering and science professions currently practising under similar conditions, subject to the quantity and quality of available data, the time limits and financial and physical constraints applicable to the services. Unless otherwise specified, the results of previous or simultaneous work provided by sources other than Golder and quoted and/or used herein are considered as having been obtained according to recognised and accepted professional rules and practices, and therefore deemed valid. This model provides a predictive scientific tool to evaluate the impacts on a real groundwater system of specified hydrological stresses and/or to compare various scenarios in a decision-making process. However and despite the professional care taken during the construction of the model and in conducting the simulations, its accuracy is bound to the normal uncertainty associated to groundwater modelling and no warranty, expressed or implied, is made.

TAILINGS STORAGE FACILITY

OPERATION, MAINTENANCE AND SURVEILLANCE MANUAL

1.0 OBJECTIVE

This Operation, Maintenance and Surveillance Manual (OMS) is intended to fully describe and outline the personnel, infrastructure, and procedures for the Tailings Storage Facility (TSF) and related water management structures at the Mount Polley Mine.

Within this Manual are:

- Descriptions of the roles and responsibilities of the various personnel involved with the TSF and water management at Mount Polley, including their identities and contact information.
- Site Description, both the natural geography/geology and the mine infrastructure and access.
- Description of the TSF and water management infrastructure and their design.
- Operations procedures for all elements of the TSF and water management, including design and operating limitations and Quantitative Performance Objectives (QPOs).
- Maintenance procedures for the TSF and water management infrastructure.
- Surveillance activities for the TSF and water management infrastructure and systems.
- Record keeping and document control processes.
- Emergency procedures for tailings and water management.
- Incident Reporting

The main body of text is intended to form the background of the information and systems in place, with much of the detailed information contained within the appendices for ease of understanding and accessibility. In practical terms, not all information can be contained within a single source document such as this Manual. Certain, more detailed documents will be outlined and referenced by this Manual.

2.0 ROLES AND RESPONSIBILITIES

Personnel involved in the safe operation, maintenance, surveillance and supervision of the TSF and water management infrastructure are not limited to those employed by Mount Polley Mining Corporation (MPMC). According to the Health, Safety and Reclamation Code for Mines in British Columbia (*Mines Act*), the Mine Manager (General Manager [GM] in MPMC organization) shall be responsible for ensuring that the *Mines Act* is followed with respect to all aspects of the performance and management of tailings and water management structures.

Corporate responsibility for tailings management falls to the Chief Operating Officer (COO) of Imperial Metals Corporation. The COO is required to put in place the appropriate management structure and provide assurance to all parties concerned with the operation of MPMC tailings and water management facilities through proper stewardship. In addition to the MPMC employees interacting with the facilities on a first-hand basis, there is an extensive group of design professionals and regulatory representatives involved in the successful implementation of this Manual. The following text will outline the key personnel and a short description of their Roles & Responsibilities.

A full list of personnel and their roles and responsibilities can be found in Table 2-1. The reporting and communications structure can be found in

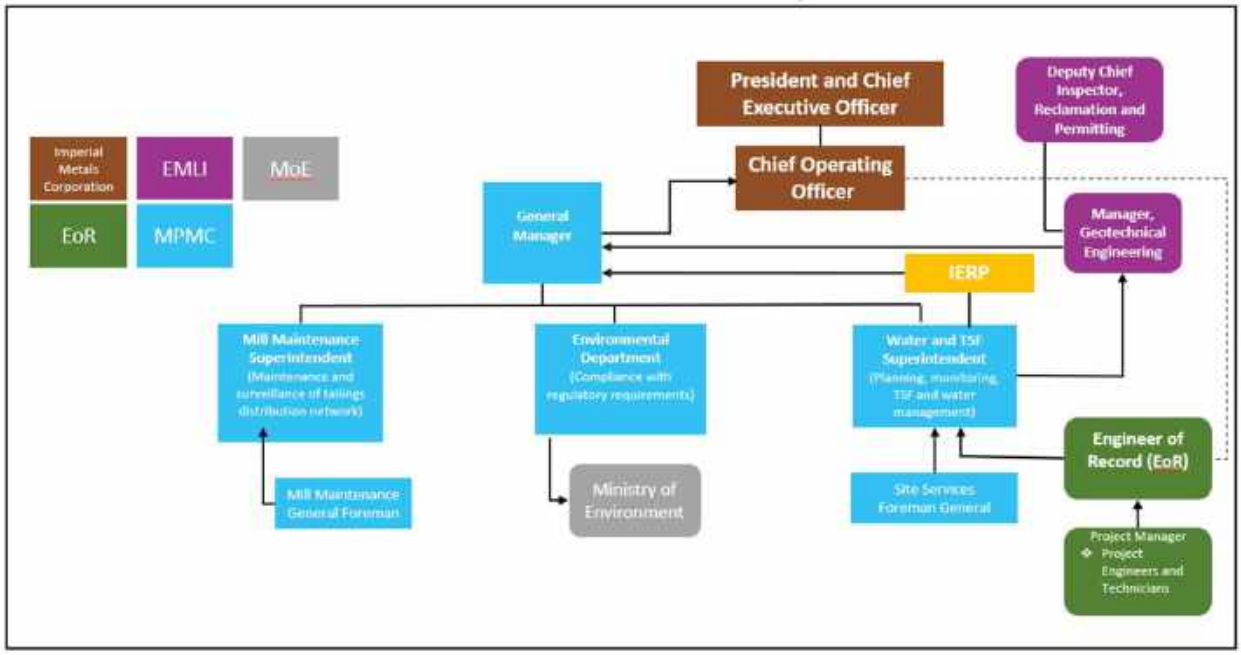

Figure 2.1.

Table 2-1 Key OMS Personnel Contact Information and Responsibilities

Title	Name	Contact Information				Responsibilities
General Manager	Kelly Parker	Home:		Cell:	250-423-8537	Responsible for the overall activities of the Mount Polley Mine, inclusive of the TSF.
		Office:	(236) 800-4771	Radio:	Channel 5	
		E-mail:	Kelly.Parker@mountpolley.com			
Water and TSF Superintendent	Matt O'Leary	Home:		Cell:	(250) 274-0658	Responsible for the planning, coordination and daily management of TSF monitoring and water management activities. Coordinates activities of the EoR, and plans for and submits required permit amendments. Responsible for updating the EPRP. Responsible for Environmental Permitting and Compliance
		Office:	(236) 317-4938	Radio:	Channel 5

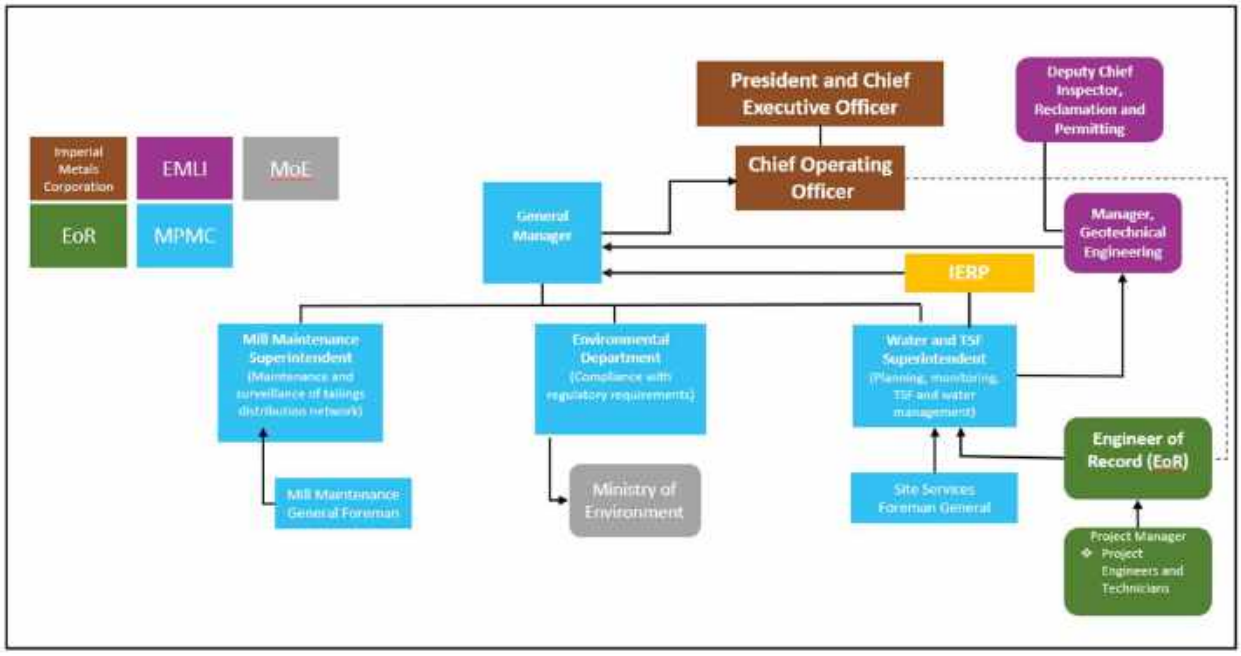

Figure 2.1 Organizational Structure

2.1 Imperial Metals Corporation

President and CEO:

- Ensures that MPMC is provided with all appropriate resources necessary to maintain conformance with all regulatory requirements and guidelines. Is also responsible for reporting to the Board of Directors regarding tailings stewardship.

Chief Operating Officer:

- Facilitates the proper allocation of personnel and financial resources in order to ensure tailings stewardship is in conformance with all regulatory requirements and guidelines. Reports to the President and CEO.

2.2 MPMC

Mine Manager (General Manager [GM]):

- Responsible for all activities occurring at the Mount Polley Mine site, inclusive of the TSF and all water management facilities, under the Mines Act. Reports to the COO.
    - Manager is ultimately responsible for the mine as per Act/Code
    - Designated under Section 21 of the Mines Act
    - Accountable for all aspects of the performance and management of Tailings and Water Retaining Structures.

- Responsible for compliance with regulatory requirements and relevant guidelines.
- Responsible to submit all compliance reports to the required regulatory agencies by the due dates.
- Defines site roles and responsibilities, authority and accountability.
- Allocates required human and financial resources.
- Reports Reportable Incidents including significant TSF or dam safety incidents to the Chief Inspector.

- In order to fulfill the Mines Act requirement of having a General Manager onsite every day, Water and TSF Superintendenta designate will be assigned when the GM is absent. The Water and TSF Superintendentdesignate will be responsible for communication directly with the General Manager and bringing them into the process as quickly as possible during an emergency or incident occurring.

Tailings Qualified Person Water and TSF Superintendent(Water and TSF Superintendent in MPMC organization):

> *"designate a TSF qualified person for safe management of the MPMC Tailings Storage Facility."*

- This includes, but is not limited to:
  - Develops and implements the tailings and water management plans for the TSFs under their supervision.
  - Coordinates the design, construction and overall management of tailings storage facilities on the site with the EoR as well as internal and external resources.
  - Develops succession plan for EoR.
  - Implements training programs for tailings and water management activities.
  - Implements the Operations, Maintenance and Surveillance Manual (OMS).
  - Provides QPOs for operational and maintenance activities for inclusion in the OMS. (Appendix I)
  - Reports to the General Manager regarding the status and performance of the Tailings Management System.

Site Services General Foreman/Supervisor

- Responsible for site maintenance activities including surveillance on dewatering/tailings pipelines as well as Water treatment plant operators and pump watch. Site Services General Foreman and Supervisor reports to Water and TSF Superintendent.

Mill Maintenance Superintendent / Mill Maintenance General Foreman

- Mill maintenance department, which deals with aspects of the operation and surveillance of the tailings distribution network to corner 5. Reports to the General Manager.

-

Environmental Department

- All activities involved in ensuring that MPMC activities remain compliant with all regulatory requirements as they pertain to the receiving environment. Reports to the General Manager or Designate.

2.3 WSP

Engineer of Record (EoR): Germán Pizarro, P. Eng

> *"The engineer of record, as a qualified professional, has professional responsibility for assuring that a tailings storage facility or dam has been designed and constructed in accordance with the applicable guidelines, standards and regulations"*

- Is employed by WSP, a consulting company capable of providing a variety of professional engineering services regarding TSF and water management operations and surveillance.
- EoR is referenced throughout this manual, referring both to the specific individual and the organization (WSP). All communication dictated by this manual shall include the specific individual serving as EoR (Germán Pizarro, P.Eng.).
    - Is a qualified and competent engineer with experience commensurate with the consequence classification and complexity of the facility.
    - The responsibilities of the EoR must be assigned to an individual and not a firm.
    - Hold the professional responsibility for the facility design, and is responsible for evaluating the adequacy of the as-built facility relative to the design as well as applicable standards, criteria, and guidelines.
    - Report on annual Dam Safety Inspections.
    - Participates in Dam Safety Reviews.
    - Participates in risk assessments.
    - Provides Quantitative Performance Objectives and monitoring frequencies required to ensure the facility is functioning as designed for inclusion in the OMS.
    - In the event of a change of the EoR, participates in implementing the succession plan, including understanding the risks and liabilities associated with such changes and employing appropriate change management procedures.

EoR's Representatives

WSP employees who provide support in all manner of TSF design, construction, operations, maintenance and surveillance. Operate under the responsibility and authority of the EoR.

2.4 Governing Bodies

Ministry of Energy, Mines and Low Carbon Innovation (EMLI)

- Serves as the primary regulatory body for the mining industry in BC. Provides inspection services and issues the necessary operating permits on behalf of the Province regarding TSF and water management activities. Receives and coordinates the review of all designs, construction, operations and surveillance reports submitted to them.

Ministry of Environment and Climate Change (BC-ENV)

- The provincial ministry responsible for issuing effluent management permits and setting environmental standards with respect to the mining activities that have the potential to affect the receiving environment around the mine site. Provides inspection and oversight services to ensure and enforce compliance.

2.5 Independent Engineering Review Panel (IERP)

- The IERP is currently comprised of three (3) qualified experts and shall meet at a minimum annually.The objectives of the IERP are to confirm that the design and operation of the TSF is consistent with industry standards of best practice, to identify areas where risk reduction measures may be required and to provide advice that may add value to the safe operation, closure and long-term maintenance of the TSF.
    - Made up of independent subject matter experts not currently involved in or responsible for the design, operation or construction of the facility.
    - Provides an independent assessment to senior mine management and regulators whether the tailings storage facility is designed, constructed and operated appropriately, safely and effectively.
    - Provides the site team with practical guidance, perspective, experiences and standard/best practices from other operations.
    - Reviews and comments on the planning and design process, monitoring programs, data analysis methodology and work performed by site team and/or contract consultants.
    - Provides non-binding advice and guidance, but does not direct the work or perform the role of the Engineer of Record.
    - Size and make-up of the ITRB based on complexity of the tailings system, in terms of risk, consequence and disciplines of substance.

- The IERP acts only to advise MPMC and has no actual decision-making capability or responsibilities other than those listed within the Terms of Reference document (Appendix G). The IERP submits all formal communication to the GM.

3.0 COMPETENCY AND TRAINING

At the corporate level, the COO is responsible for ensuring that all individuals described within this Manual have the appropriate level of training and experience to perform their roles effectively. This is accomplished through the site GM, who is responsible under the *Mines Act* for all activities that occur at the mine site, inclusive of the TSF and water management systems.

On site, it is the responsibility of the supervisory personnel involved in the operation, maintenance and surveillance of the TSF to train individuals falling under their respective management. Competency in the various roles is provided through existing orientation and training programs and is to be administered in correspondence with the procedures existing at MPMC. Review of the applicable portions of this Manual with individual workers is the responsibility of each supervisor to whom the worker reports.

Each training session must be documented, and a record kept within the TSF partition on the mine server. The records will contain a detailed list of site activities for which the trainee was trained and be signed by the person who provided/supervised the training. The primary example of this will be the distribution of and orientation to this Manual. All individuals involved in the procedures within this Manual shall be introduced to the appropriate sections and appendices of this Manual and provided access to the relevant source documents.

4.0 MANAGING CHANGE

Over time, the physical and regulatory environment is almost certainly going to change. The embankments and water control structures will continue to be developed and the application of ever-improving Best Practices will require updates to this Manual.

Changes to the design or operating plan for the TSF and related pipelines and structures must be reviewed, approved and documented by the Water and TSF Superintendent. TSF design changes will be conducted by the EoR as required for operational or regulatory changes and submitted to MPMC for review. Changes requiring authorization under the *Mines Act* shall be submitted to EMLI by MPMC. Operational changes will be reviewed and approved by the General Manager. In all cases, documentation of the change, including as-built records, are required.

At a minimum, this Manual will be fully reviewed, updated, and distributed once per year. This shall ensure that the procedures contained within shall follow Good Practices in tailings management, are up to date and apply to the most current conditions regarding the facilities and the regulatory environment. The Manual will also be updated to reflect minor changes such as to

personnel and operating conditions. Though this may not result in a full re-issue of the Manual, all affected personnel will be updated as required.

It is the responsibility of the Water and TSF Superintendent to keep this Manual up to date, ensure it is properly distributed and accessible, and that the proper training is conducted and documented.

5.0 FACILITY DESCRIPTION

The Mount Polley Mine, operated by MPMC (a wholly owned subsidiary of Imperial Metals Corporation), is an open pit/underground copper/gold mine that is permitted to process up to 8.2M tonnes per year of ore. The mine is located in central British Columbia, 8 km southwest of the town of Likely, and 56 km (100 km by road) northeast of Williams Lake. Access to and from the mine is via road by turning east off the Cariboo Highway (97) onto the Likely Road at 150 Mile House, BC and following it for approximately 75 km to the Bootjack Forest Service Road (FSR). The Bootjack FSR leads directly to the mine parking lot after 14 km. The physical location of the mine is at 52º 33' North by 121º 38' West. See Figure 5.1.

Ore concentrates from the mine are trucked to facilities at the Port of Vancouver and then shipped to overseas smelters or transported by rail to smelters in North America. MPMC was formed in 1996, and mining activities commenced in May, 1997.

The current mine site infrastructure consists of the Mill Site, Springer Pit as the active mining area, Wight Pit for temporary storage of mine contact water and two (2) rock disposal sites (RDSs): The Southeast Rock Disposal Site (SERDS); and the Temporary Northwest (NW) Potentially-Acid Generating (PAG) Stockpile, as well as the access roads, power lines, a tailings pipeline, drainage collection systems, and sediment/seepage control ponds. The Underground, Boundary Zone Pit, the Pond Zone Pit, the Southeast Zone (SEZ) Pit, the Bell Pit, the Cariboo are not active. Back-filling of the Bell Pit and Pond Zone Pit with waste rock was completed in 2012, and the SEZ Pit was backfilled in 2013. On January 7, 2019 Imperial Metals announced the suspension of operations at MPMC commencing May 31, 2019. MPMC has entered into Care and Maintenance from May 31, 2019 to Sept 2021 and restarted operation in November 2021. Deposition of tailings into the TSF commenced on June 1, 2022 with limited mill feed during commissioning. Full mill throughput has been achieved in January 2023.

There is a magnetite processing facility on the mine site owned by MPMC. The facility uses tailings to filter and screen magnetite for resale. The facility will be operating as needed.

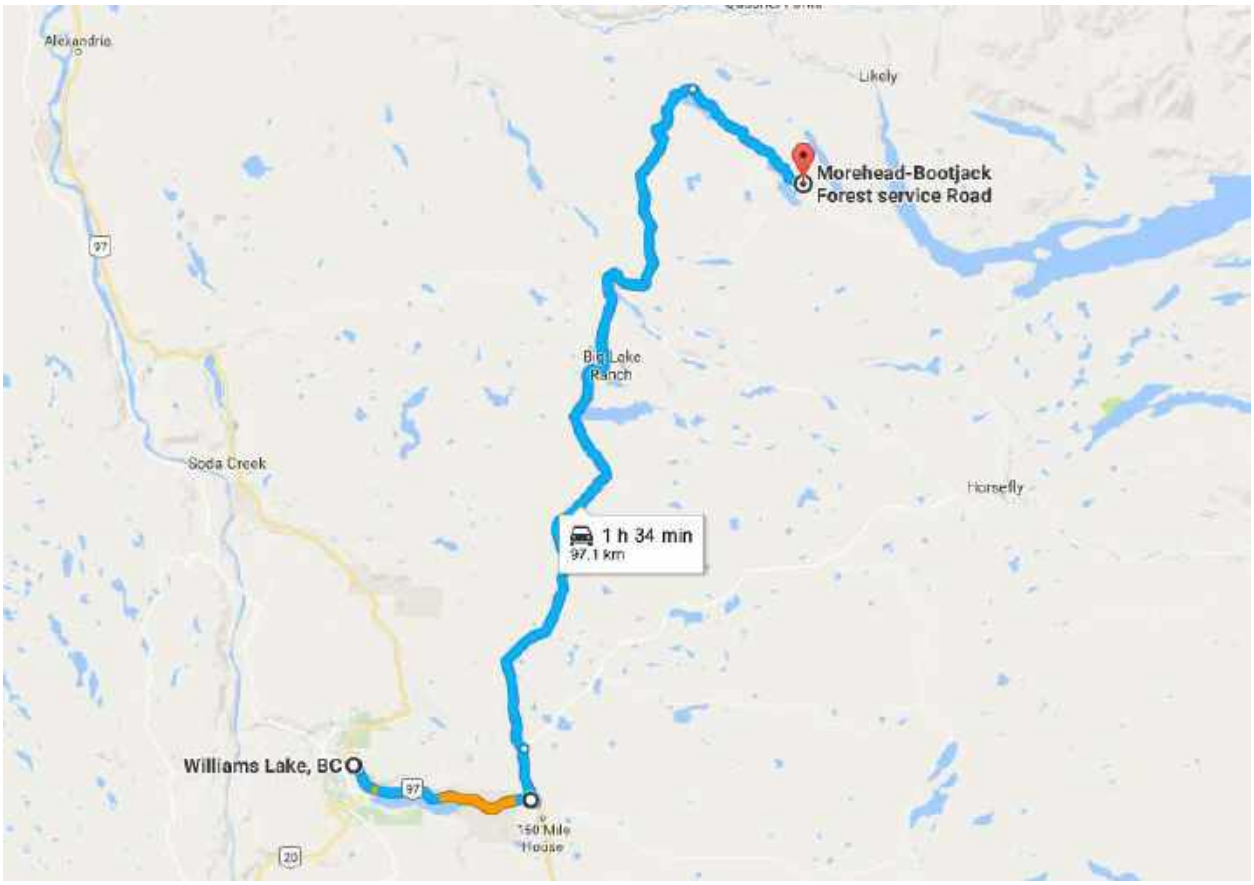

Figure 5.1 Site location and road access from Williams Lake

The TSF lies to the southeast of the mining and concentrator facilities. The Springer Pit has been partially filled with tailings and is being mined with conventional Truck/Shovel operation. Springer Pit tailings are being deposited in the SERDS Co-Disposal Tailings Facility authorized by EMLI. This facility is located on the top of the SERDS. A site aerial photograph taken in 2022 and indicating major mine components is included as Figure 5.2.

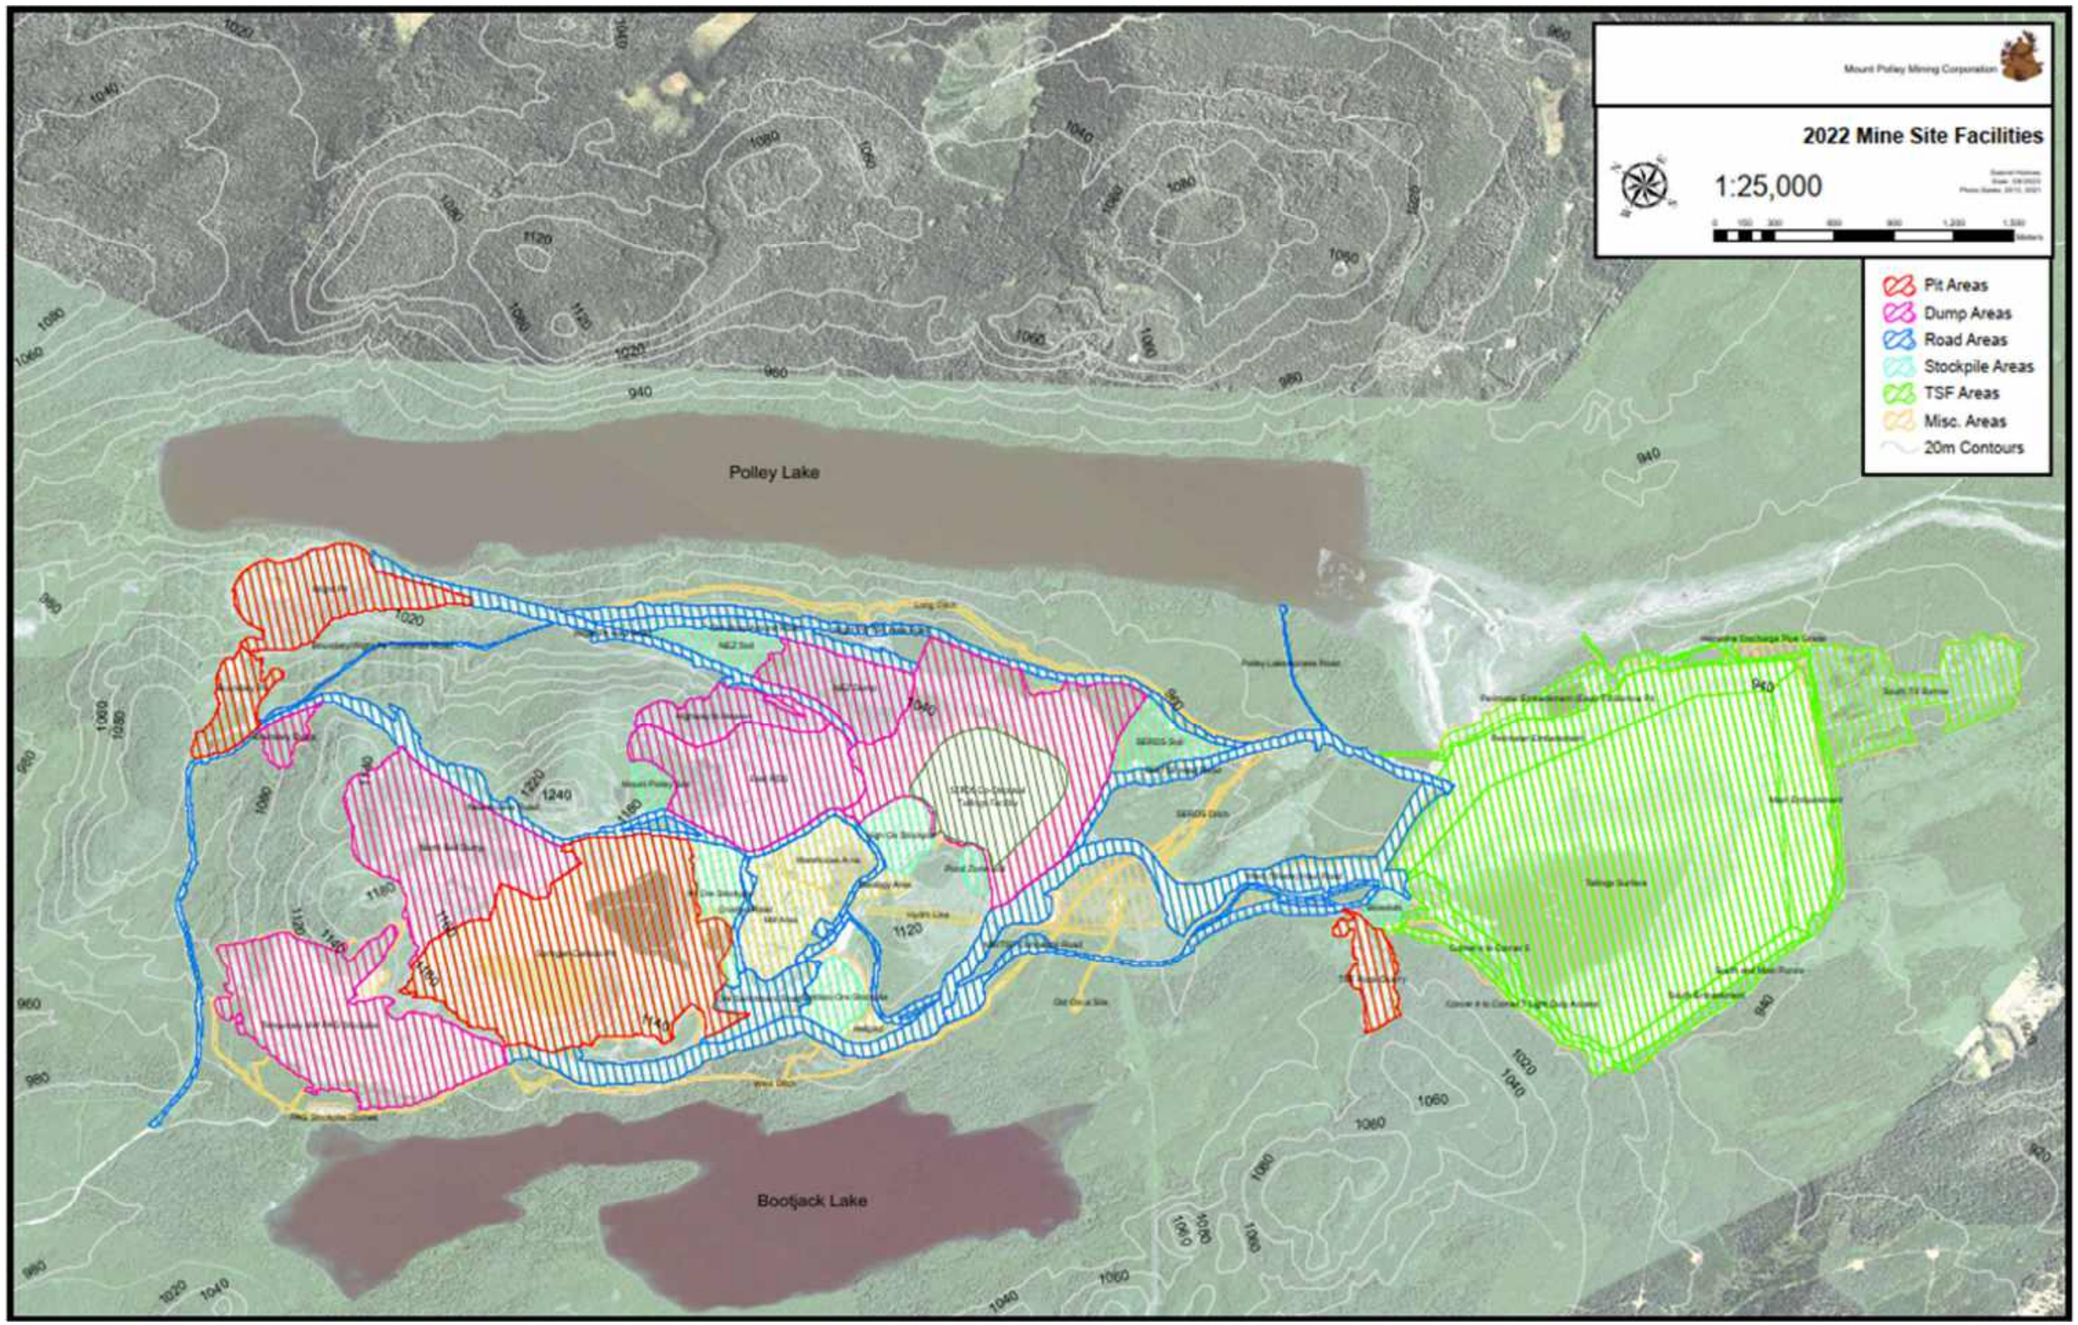

Figure 5.2 Mine Site Infrastructure

6.0 KEY TSF AND WATER MANAGEMENT COMPONENTS

All water management structures are designed in accordance with the environmental parameters as set out in the BC-ENV -issued *Environmental Management Act* (*EMA*) Permit 11678 and the EMLI-issued *Mines Act* Permit M-200.

As per clause 2.4.5 of *EMA* Permit 11678:

"Surface water control works must be provided for all areas disturbed by roads, open pits, rock disposal/storage sites, the mill site and ore storage sites. The surface water control works must be designed to convey all flows up to a 1 in 10 year 24-hour storm event and must be designed to withstand all flows up to a 1 in 200 year 24-hour storm event, without significant damage"

A formal Water Management System Review was completed in 2016, as required by condition C.2.(b) of a *Mines Act* Permit M-200 amendment from July 9, 2016 (entitled: Approving Return to Restricted Restart of Operations). The latest Water Management Plan was issued to EMLI and ENV for 2021. The Water Management System Review provides: an overview of water management planning for the Mount Polley Mine Site; an update on completed and ongoing site works; the review (and associated outcomes) of the design criteria and operational requirements of the water management system, and an outline of planned work.

The discussion is broken into the following parts:

- TSF
- West Ditch System
- Long Ditch System
- CCS, PETBP, and WTP
- Mill Site and Pit Dewatering
- Non-contact Water Ditch Systems
- Pumping and Piping

Lastly, in this section will be a sub-section referencing the various appendices and external documents which describe the tailings and water management systems in much greater detail.

6.1 TSF

The Tailings Storage Facility (TSF) at the Mount Polley Mine is located to the southeast and at lower elevation to the pits and mill site. The TSF is a constructed, (mostly) centerline embankment, currently built to a minimum crest elevation of approximately 969.6 m. At that elevation, the embankment constrains about 270^{o} of the stored tailings, with natural ground to the west-northwest

completing the containment. Utilization of the TSF began in 1997 and served as the sole destination for mill process discharge until August 2014, when a breach of the embankment occurred. The breached embankment has since been repaired to a crest elevation of being built to the 970m in 2023.The TSF system consists of a constructed embankment, the core of which defines the boundary between the upstream and downstream elements of the facility. Upstream are the stored tailings and supernatant water, as well as the infrastructure to deposit the tailings slurry and return the supernatant water to the mill (reclaim system). Downstream are the additional structural elements including the buttress, seepage collection and pumping system to manage the seepage flows. The following subsections describe in detail the various elements of the TSF.

6.1.1 Construction History

The design and construction monitoring of the TSF embankments through 2010 was completed under the direction of Knight Piésold Ltd. (KP). AMEC Environment & Infrastructure (AMEC), now John Wood Group, assumed the role of EoR for the TSF on January 28, 2011. WSP assumed the role in November 2014, with Terry Eldridge, P.Eng. and on February 4, 2019, with Germán Pizarro, P.Eng.

The overall embankment has incorporated a staged expansion design utilizing a modified centerline construction methodology up to elevation 963.5 m, at which point it became centreline construction. The embankments were approaching elevation of 970 m when the Perimeter Embankment breach occurred.

The breach of the Perimeter Embankment occurred on August 4, 2014. The width of the breach was about 100 m, and overall damage occurred to about 400 m of the Perimeter Embankment.

The 2015 Freshet Embankment was built across the breach to manage the 2015 spring freshet and prevent any further uncontrolled release of water and/or tailings from the TSF. The 2015 Freshet Embankment consists of cement-soil-bentonite cut-off wall constructed within a granular core and supported by a wide rockfill embankment.

Significant buttressing of the Main Embankment and Perimeter Embankment was also completed to increase the factor of safety of the existing facility. The buttressing has been incorporated into the current design.

On June 23, 2016, MPMC received an amendment to *Mines Act* Permit M-200 authorizing the continued repair and construction of the TSF to elevation 970 m, as well as the return to use of the TSF facility for tailings and water management. The permitted works are based on the design report: *Mount Polley Mine Tailings Storage Facility Detailed Design to Elevation 970 m* as issued by WSP on November 3, 2015.

Construction of the Corner 1 buttress was completed in 2019 prior to Care and Maintenance. The 2022 construction consisted consists of:

- Testing filter and transition material on all embankments to ensure spec is achieved. Replace material as needed.
- Removing the rockfill material at corner 1
- Raise all embankments to 970m elevation as per design

The construction season of 2023construction was a continuous of 2022 by raising all zones to the 970m elevation

6.1.2 Embankment

The TSF comprises one (1) overall embankment that is approximately 4.5 km long. The embankment, based upon original, separate embankments, is subdivided into three (3) sections: The Perimeter, Main, and South Embankments, going clockwise starting from the NW abutment. Heights vary along the embankment and are approximately 40 m, 58 m, and 32 m respectively (based upon the Perimeter, Main and South nomenclature). Crest elevations of the embankment are between 969.6 m and 970 m.

Structurally, the embankments generally follow that of a typical low permeability core centerline dam. A till core provides the low permeability structure, with downstream filter and transition zones meant to protect the core from internal erosion and conduct any seepage water quickly to the toe of the embankment. Downstream of the filter and transition zones is the rockfill portion of the embankment and buttress. Upstream of the core is the upstream structural component, which varies from rockfill, discharged tailings, and constructed sand cell tailings along the embankment.

6.1.3 Breach

On August 4, 2014, a breach of the Perimeter Embankment occurred near station 4+300, releasing tailings, embankment material, and water. Subsequent investigative works determined that the primary cause was structural failure of the foundation along a Glaciolacustrine Unit (GLU). The large volume of water impounded in the TSF at the time exacerbated the resulting embankment damage and release of stored materials.

The width of the breach was about 100 m and overall damage occurred to about 400 m of the Perimeter Embankment. Soon after the breach, the Temporary Upstream Rockfill Berm was constructed within the TSF to contain any further release of water and mine waste. Once this berm was constructed, the investigation as to the cause of the breach and subsequent cleanup and repair work commenced.

Repair began in November 2014 with the construction of the Freshet Embankment. After the breach area investigation and footprint cleanup work was completed, an engineered rockfill was emplaced to completely replace the missing portion of the embankment to elevation 950 m. Once this was completed, a specialized, rig-based tool system (a cutter-soil mixer) was brought in that systematically reworked a portion of the fill into a low permeability plastic concrete barrier. This effectively reconnected the low permeability element of the embankment (till core) across the breach area and facilitated the storage of water in the TSF.

The next stage of repair involved the planning and design of a full reconstruction of the breach area, followed by submission to the EMLI for an amendment to *Mines Act* Permit M-200 allowing the return to the TSF for ongoing tailings storage. The amendment was granted in June, 2016. Construction activities in this area resumed soon after. Construction has been carried out in stages.

As a part of reconstruction, a rock drain was installed upstream of the breach repair at approx. elevation of 950m. This drain is connected to a system of pipes, which run across the core of the

embankment and connect to a single discharge pipe, which conveys the water to the ditch system upstream of the PETBP. This is intended to promote consolidation of the tailings and unsaturated tailings conditions in the beach above and around the drain and reduce the hydraulic head applied to the cut-off wall and core in this area.

6.1.4 Buttresses

The investigations within the breach area and along the extents of the Main and Perimeter Embankments identified glaciolacustrine soil layers in some areas that control the stability of the embankments. The foundation failure at Corner 1 was primarily due to units of this material, with the path of failure going through this material. To fully repair the embankment and return the otherwise unaffected portions of the embankment to use, buttressing was determined to be necessary.

Buttresses have been installed along the Perimeter and Main Embankments. Construction of these buttresses was completed in 2016 to provide stability for the final 970 m elevation configuration of the TSF.

The buttress at Corner 1 was completed for the 970 m TSF configuration in 2019.

6.1.5 Downstream

All mine-influenced (contact) water at the Mount Polley Mine must be collected and directed to the appropriate location. Over time, the TSF will convey contact water to the downstream area by way of seepage through the embankment and upstream drains and via precipitation falling directly onto the embankment downstream of the core. To intercept and collect this water, MPMC has constructed ditching systems and collection ponds at the base of the embankment.

The Main Embankment Seepage Collection Pond (MESCP) and South Embankment Seepage Collection Pond (SESCP) are located at the downstream toe of the Main Embankment and South Embankment, respectively. The ponds collect water from the toe and foundation embankment drains as well as local runoff. The SESCP is dewatered by a single 8.8 hp Grindex pump (run off a generator), pumping through 6” pipe into an open gravity-flow ditch reporting to the MESCP. The MESCP is dewatered by two (2) 200 hp 3-stage Peerless pumps (run off grid power), pumping through a single12” HDPE pipe to the TSF. There is an additional 12” HDPE pipe at the MESCP as contingency if the primary HPDE is plugged with ice. Additional pumps are on standby in case of emergency such as high precipitation or snowmelt event.

Based on site water management objectives, the MESCP is used as feed water for TSF dust control sprinklers.

Downstream of the Perimeter Embankment, from west to east, are the Central Collection Sump (CCS), and the Perimeter Embankment Till Borrow Pond (PETBP). In addition to collecting seepage water directly from the embankment, these ponds are also an integral part of the overall

site water management strategy. They will be further described later in this section after the description of the two main ditching systems.

6.1.6 Upstream

The settled tailings and reclaim pond, the tailings discharge piping system and the reclaim pumping and piping systems are located upstream of the embankment core. During operation, tailings slurry is discharged onto the TSF from 24" lines at locations based on the beach development plan. The coarsest fraction settles out of the slurry first, forming the beach, and the remaining water and finer material report to the reclaim pond for further settling and clarification.

The reclaim pond contains the reclaim barge and the beginning of the reclaim piping system. Water from the pond is pumped to the PETBP (via the Booster Station) and water treatment plant for discharge off site.

Clean water upstream and to the west of the TSF is directed away from the facility by the TSF clean water diversion ditch into a small wetland below the South Embankment, which discharges to the natural environment.

6.2 West Ditch System

The West Ditch System collects water between the west side of the Mount Polley Mine Site and Bootjack Lake. The West Ditch System spans from the Temporary Northwest (NW) PAG Stockpile to the SERDS Sump. Mine site geometry does not allow for a continuous, open-flow ditch through this distance, so the system comprises a series of ditches and sumps, which are progressively pumped into one another progressing downstream. The system consists of the following components, described from upstream to downstream:

6.2.1 Junction Zone Ditch and Junction Zone Seepage Sump

The Junction Zone Ditch has two (2) branches; one (1) of which is now partially buried by the Temporary NW PAG Stockpile and one (1) that remains out of the Temporary NW PAG Stockpile footprint. Of the 'buried' branch, 200 m of ditch remains exposed. For the second, 'exposed', branch, the ditch is 680 m in length with an average grade of 4%. Flows from the Junction Zone Ditch report to the 9K Sump by open-ditch gravity flow.

The Junction Zone Ditch also conveys water from the Junction Zone Seepage Sump. The Junction Zone Seepage Sump has two (2) 120V, pumps (running off grid power) installed and pumping into a double 2" line to the Junction Ditch.

6.2.2 9K Sump and Ditch System

The 9K Sump collects water from the Junction Zone Ditch and localized runoff from the west side of the Temporary NW PAG Stockpile through open-ditch gravity flow in the 9K Sump Ditch. The

9K Sump Ditch is 290 m long with an average grade of 5%. The 9K Sump has two (2) 50 hp low head, high volume, Flygt pumps (running off grid power) installed and pumping into a single 12" line, 480 m in length, to the NW PAG Sump.

6.2.3 NW PAG Sump and Ditch System

Two (2) open-flow ditches run parallel to the toe of the Temporary NW PAG Stockpile dump at an (approximate) 50 m offset. The upper ditch, flowing southwest, is partially buried, with 725 m of ditch remaining exposed at an average grade of 7%, and this flows into the NW Sump.

There are 2 pumping options for the NW PAG Sump utilizing two (2) 75 hp 2-stage Peerless pumps which running off grid power. The primary option is to pump from the NW PAG Sump to the gravity feed portion of the north branch of Mine Drainage Creek Ditch (an additional 150 m through existing 12" line), The second option is to pump into a 12" line, 850 m in length, to the Springer Pit.

6.2.4 Mine Drainage Creek Sump and Ditch System

The Mine Drainage Creek Ditch System runs along the west side of the West Haul Road and collects water through open-ditch gravity flow as well as, at times, pumped flow from the NW Sump. The north (flowing southeast) and south (flowing northwest) branches of the Mine Drainage Creek Ditch collect in Mine Drainage Creek Sump, which is situated in the low topography between the two (2) ditches. Water captured in the Mine Drainage Creek Sump is pumped up the south branch of the Mine Drainage Creek Ditch and into the gravity feed portion of the Lower West Ditch.

The north reach of Mine Drainage Creek Ditch is 1,160 m in length with an average grade of 4%. The south reach of Mine Drainage Creek Ditch is 400 m in length with an average grade of 5%. The Mine Drainage Creek Sump has two (2) 140 hp high head Flygt pumps installed (running off grid power). One (1) 140 hp low head, high volume, Flygt pump installed has the capability of pumping through a 16" line, 568 m in length, to the Lower West Ditch and a second 16" backup line, to the Lower West Ditch, 630 m in length, is also installed.

6.2.5 Lower West Ditch

The Lower West Ditch is a 575 m long open-flow rock-armored gravity ditch, which collects water along the south side of the West Haul Road. It has an average grade of 4%, and feeds into four (4) 24" HDPE pipes that convey water under the TSF light vehicle road and into the SERDS Ditch. An overflow structure has also been constructed at this location such that, if the four (4) 24" HDPE pipes were to be overwhelmed, overflowing water would be conveyed over the TSF light vehicle road and into the SERDS Ditch.

6.2.6 Orica Ditch

The Orica Ditch runs west-east and collects water flowing below (south) of the old Orica explosive storage site. Water is conveyed to the SERDS Ditch via open-ditch gravity flow (and French drain under the heavy-duty Tailings Access Road). The ditch is a 725 m long open-flow gravity ditch with an average grade of 1%.

6.2.7 Bootjack Creek Sump

Bootjack Creek Sump collects water from the east side of the Tailings Access Road and pumps it via pipeline to the SERDS Ditch. The sump has one (1) 50 hp high head Flygt pump installed (running off grid power) and pumping into a 10" line, 120 m in length, to the SERDS Ditch.

6.2.8 SERDS Ditch

The Lower West Ditch, Orica Ditch and Bootjack Creek Sump all feed into the SERDS Ditch. The SERDS Ditch is a 1,475m long open-flow rock-armored gravity ditch with an average grade of 3.5% that feeds into the SERDS Sump. The SERDS Ditch is conveyed under the heavy-duty Tailings Access Road by three (3) 24" HDPE pipes. An overflow structure has also been constructed at this location such that, if the three (3) 24" HDPE pipes were to be overwhelmed, an overflow structure is constructed such that additional water would be conveyed to the Orica Ditch.

6.2.9 SERDS Sump

The SERDS Sump is located adjacent (across the haul road) from the Long Ditch Sump. The sump is 25 m wide by 60 m long and averages 1 m deep, collecting water at the terminus of the SERDS Ditch (also the terminus of the West Ditch System). 590 m of 30" HDPE pipe with an overall grade of 2.2% carries water over Bootjack Creek and into the CCS. An overflow system consisting of a 24" HDPE pipe is installed that reports to the Lower Long Ditch Sump. An overflow structure has also been constructed at this location such that, if the 30" HDPE pipe and 24" HDPE pipe were to be overwhelmed, overflowing water would be conveyed over the road to the Upper Long Ditch Sump.

The general layout of the West Ditch System can be seen in Figure 6.1. Additional information is contained in the *Water Management Inspection Manual* (Appendix C).

6.3 Long Ditch System

The Long Ditch system collects water between the east side of the Mount Polley Mine Site and Polley Lake. The Long Ditch spans from below the site access (Bootjack) road to the Long Ditch Sump. As with the West Ditch System, the Long Ditch System is composed of a series of open ditches and pumped out sumps that progressively convey the water it collects to the CCS. The system consists of the following components:

6.3.1 Joe's Creek Coffer Dam and Pipe

Joe's Creek collects seepage from the North Bell Dump and consists of a sump and dam system with a secondary overflow sump constructed and fed by a buried culvert from the first sump to the second. Both sumps feed into a 1,400 m 12" HDPE pipe that carries the water to the start of the Long Ditch and can also be directed to the Wight Pit based on site water management objective.

6.3.2 Wight Pit Dewatering

Wight Pit is ultizaed as temporary mine contact water storage and has a capacity of 3.5M m^3. Water is pumped by a barge into a Booster Tank containing two (2) 140hp Flygt 2400MT pumps. From Booster water is pumped by a 12" HDPE/steel pipe to the Long Ditch. There is also a valve located to convey water into the NEZ Booster tank to pump Wight Pit water to the mill for processing.

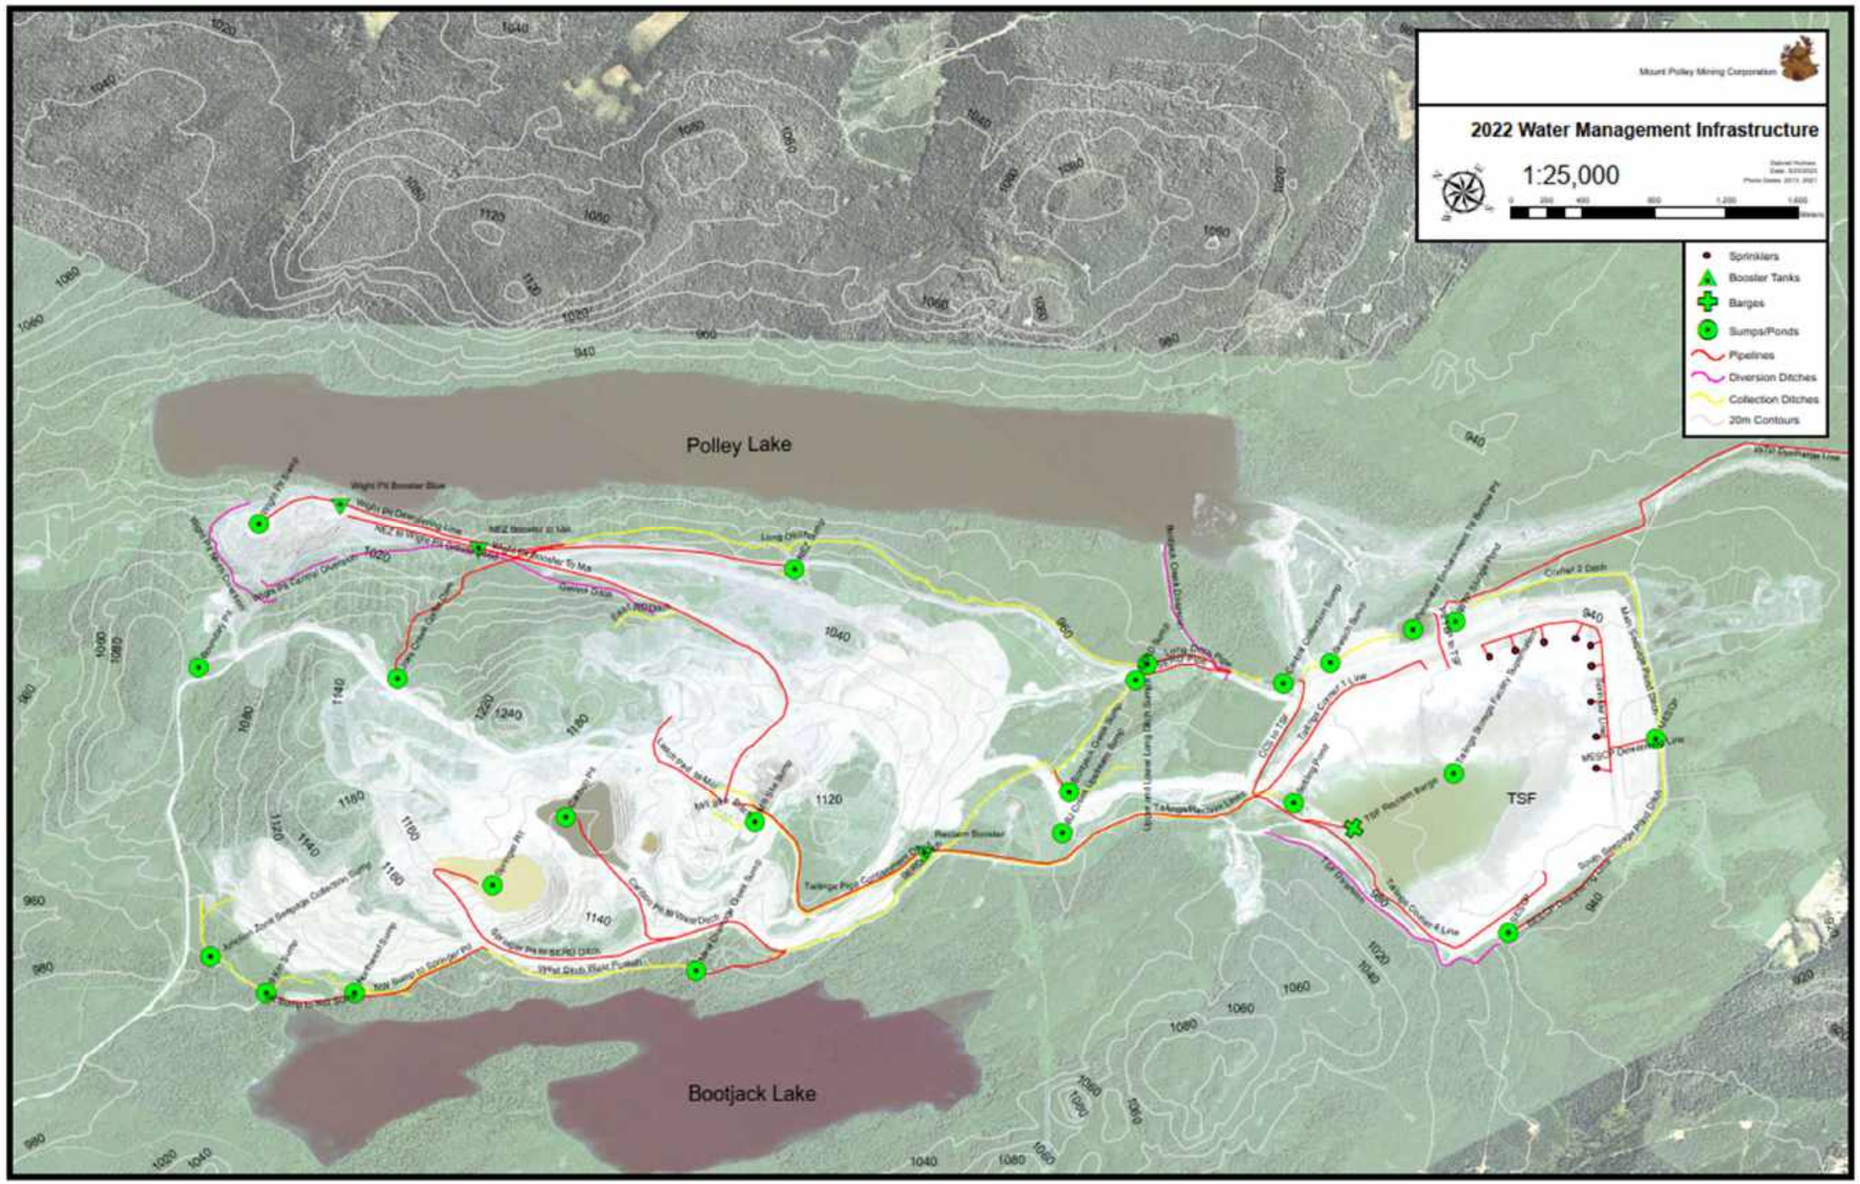

Figure 6.1 – 2022 Site Water Management Infrastructure*Fixed Water Management Infrastructure*

6.3.3 The Long Ditch

The Long Ditch is an open-ditch gravity flow system that runs along the east side of the Mount Polley Mine Site between the disturbance footprint and Polley Lake. The Long Ditch itself runs from the Wight Pit Haul Road to the Upper Long Ditch Sump. After receiving water from Joe's Creek Pipe and the Wight Pit (if directed there), the Long Ditch intercepts various surface and rock disposal sites runoff via an open-ditch gravity flow system before being collected in the Upper Long Ditch Sump.

The ditch is 3,650 m in length with an average grade of 0.9%.

6.3.4 NEZ Sump

The Northeast zone (NEZ) sump (which is located near seep 2) collects mine contact water from NEZ Seep 1 and NEZ Seep 2. These seeps have been identified as having high levels of dissolved copper levels. The seeps collect into a 24" gravity feed pipeline that conveys the water to the a booster station located on the Wight Pit ramp. From this location, the NEZ seeps water can be pumped to the mill for treatment or gravity flow to the Wight Pit sump via an open ditch along the highwall of the ramp. Water from the Wight Pit booster can also be directed into this tank as needed.

6.3.5 The Upper Long Ditch Sump

The Upper Long Ditch Sump collects water from the Long Ditch. At the end of the Long Ditch, prior to entering the sump, water is directed into a 610 m long 30" gravity-flow pipe conveying water to the CCS (over Bootjack Creek). Average pipe grade is 1.3%. An overflow structure is installed in the Upper Long Ditch Sump such that any overflow will report to the Lower Long Ditch Sump.

6.3.6 The Lower Long Ditch Sump

The Lower Long Ditch Sump is designed to convey overflow from the SERDS Sump and the Upper Long Ditch Sump. This back-up system consists of a gravity-fed 500 m, 22" HDPE pipe with an average grade of 2.1% reporting to the CCS (over Bootjack Creek) and also provides infrastructure for tie-in for mechanical pumping assistance (to supplement gravity-flow systems).

The components of the Long Ditch System can be seen in Figure 6.1. Additional information is contained in the *Water Management Inspection Manual*.

6.4 CCS, PETBP and WTP

6.4.1 The Central Collection Sump (CCS):

The CCS is at the confluence of the West Ditch and Long Ditch systems and receives water from these two systems as well as local runoff that reports directly to it. The CCS serves as a distribution

facility for the waters that report to it. Depending on water management needs, water from the CCS may be pumped into the TSF via diesel pump or allowed to overflow into the PETBP (via culvert under the Postage stamp) for discharge through the WTP.

6.4.2 Perimeter Embankment Till Borrow Pond (PETBP)

The PETBP is immediately downstream of the Perimeter Embankment and receives direct flow from the immediate area through precipitation and seepage. It serves primarily as a storage area for the various ditching systems, with overflow coming from the CCS. Total available volume within the PETBP is approximately 190,000 m^3. The PETBP also serves as the sump for the WTP.

Two electrical pumps are in place using levels to pump from the PETBP to the TSF as contingency if:

1. Water level in the PETBP increases due to large inflow of water (rain events, etc)
2. WTP is shutdown

6.4.3 Water Treatment Plant (WTP)

The WTP consists of a Veolia Actiflo® ACP-650 unit and associated infrastructure. The plant receives mine-influenced water, treats it, and discharges the treated water through a 7 km 24'' HDPE pipeline into Quesnel Lake. 'Sludge' from the WTP reports to settling ponds and is pumped to the TSF. Overflow reports to the PETBP. The primary source of input water for the WTP is the PETBP.

The WTP may be passively operated should water meet full discharge requirements and written authorization is given from the ministry. Such water would flow through the plant without the addition of reagents or operation of the mechanical components of the facility.

Additional information is contained in the *Water Management Inspection Manual*.

The WTP will be operated to maintain the TSF pond size within the normal operating range as defined by the QPOs (Appendix I). Careful planning is required to ensure volume does not exceed the QPO. This may include using the Wight Pit to temporarily hold surplus water.

6.5 Mill Site Dewatering

The mill site and shops are situated in a local low area, with associated runoff and drainage reporting to the Mill Site Ditch system. The 270 m long Mill Site Ditch runs around the northeast side of the Mill Site starting at the wash bay and flows into the Mill site sump. Water from the Mill Site Sump is pumped into the tailings deposition line. Drainage on the west side of the mill is directed into the Mill basement and pumped into the tailings box then conveyed into the tailings deposition line.

6.6 Clean Water Ditch and Sump Systems

Wherever possible, clean (non-mine-influenced) water is kept separate from mine-influenced water and conveyed to the receiving environment surrounding the mine site.

6.6.1 Site Access Road

Clean water to the north and east of the Mount Polley Mine Site is controlled by a series of under-road culverts and roadside ditching along the Site Access Road to ensure that water reports to natural receiving environments.

6.6.2 Joe's Creek (Clean Water) aka North Dump Creek

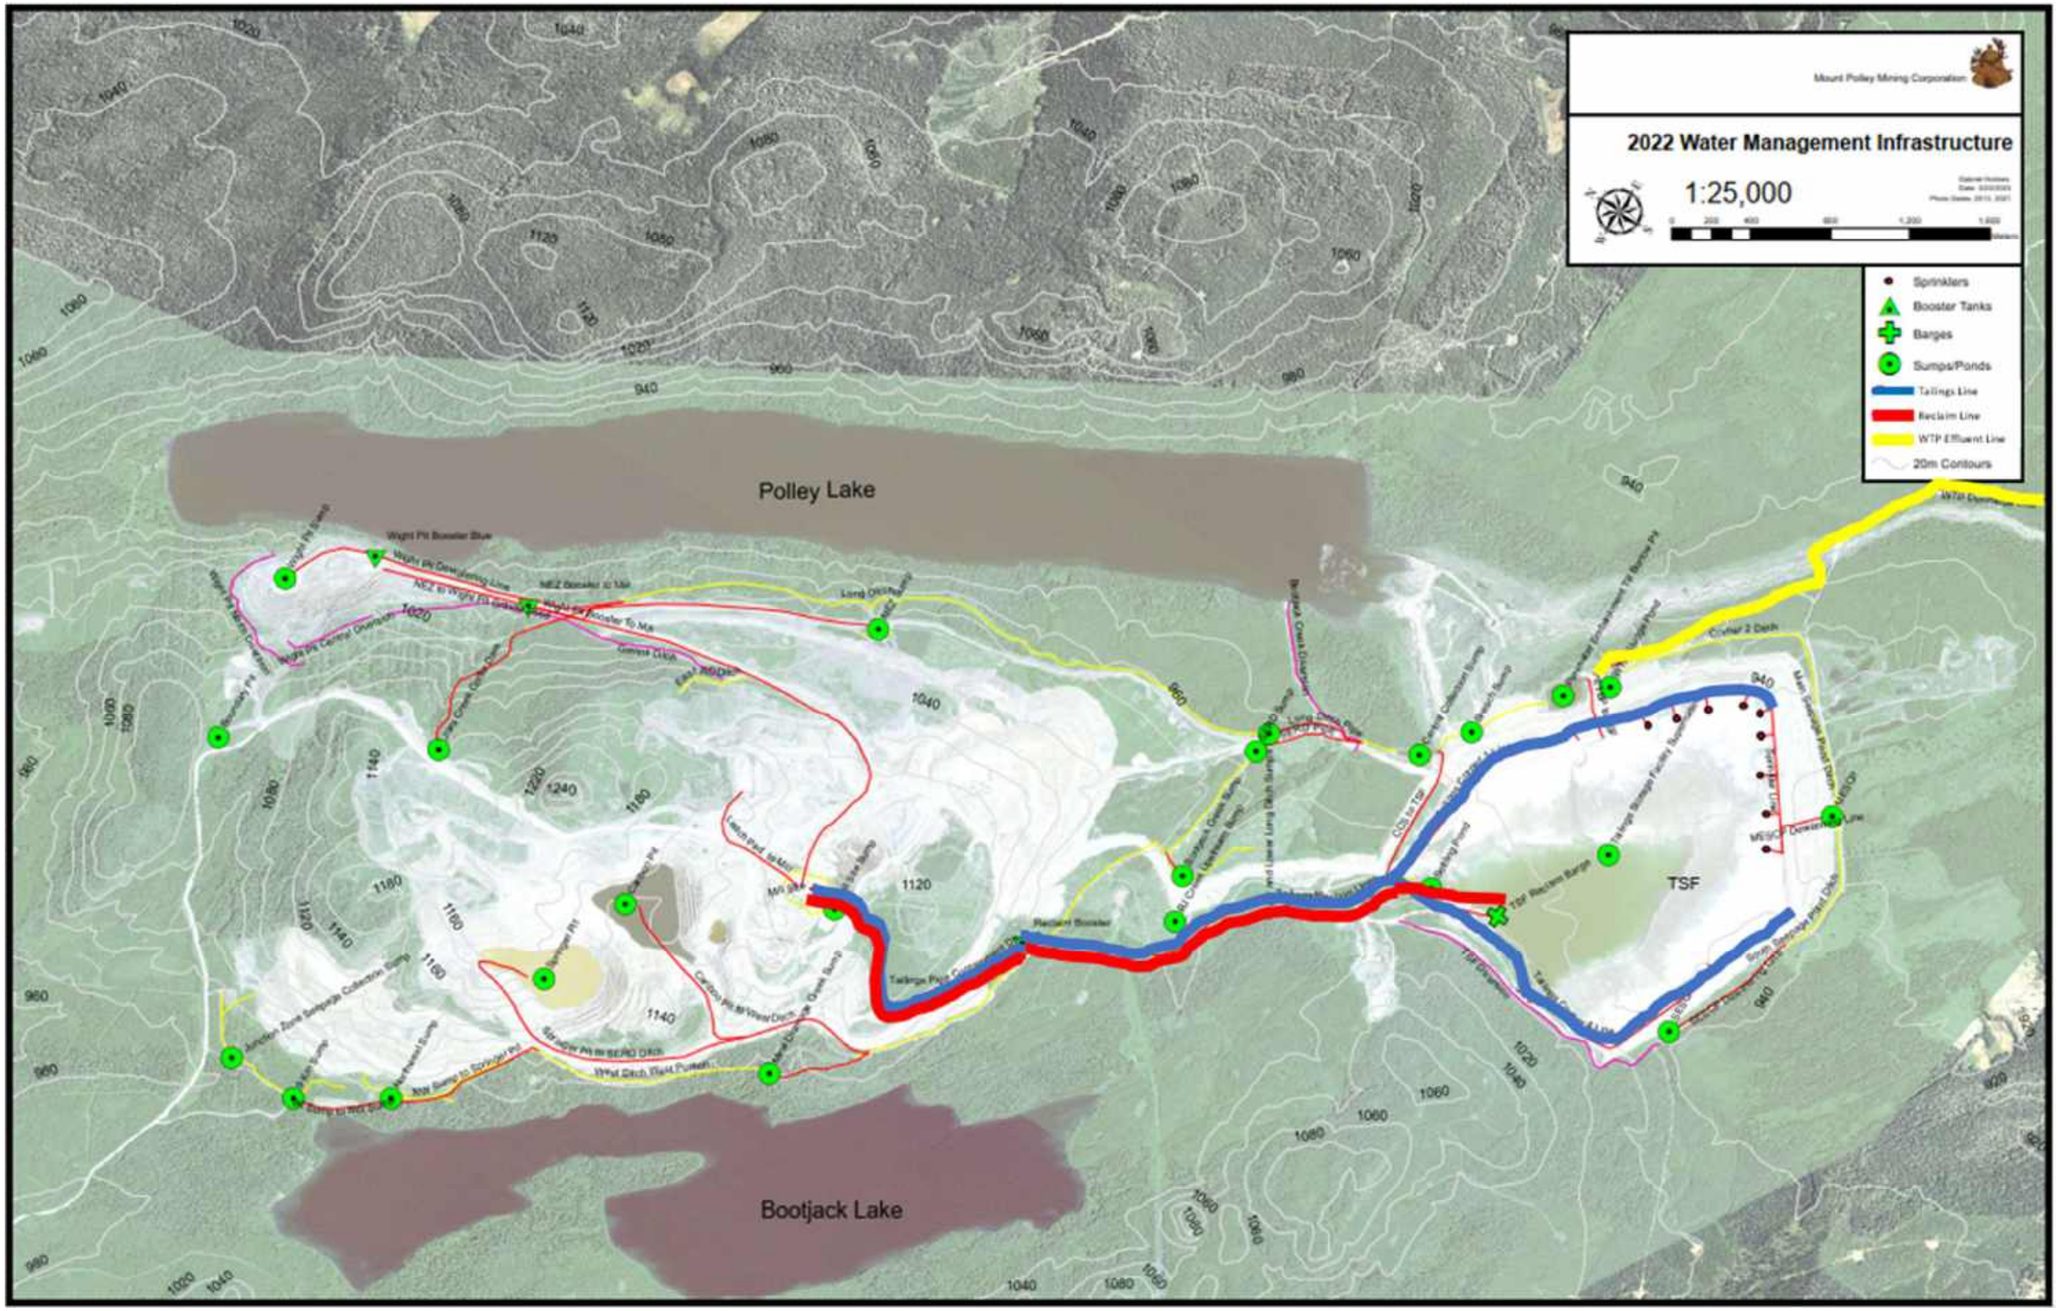
Mine-influenced water in this system is collected through the aforementioned dam and buried pipe system at Joe's Creek (Section 6.3.1). Clean water collected below this point flows through an existing drainage towards Polley Lake (North Dump Creek); a culvert carrying it under the Wight Pit Haul Road.

6.6.3 TSF Clean Water Ditch (Corner 5 to Corner 4)

Clean water upstream and to the west of the TSF is directed away from the facility and into a small wetland below the South Embankment.

6.6.4 Bootjack Creek

Bootjack Creek is a natural creek running west-to-east along the southern half of the Mount Polley Mine Site. Bootjack Lake previously flowed into Bootjack Creek, but no longer does due to the construction of a dam (prior to work by MPMC). Bootjack Creek is crossed by mine infrastructure at three (3) locations: the TSF light vehicle road, the heavy-duty Tailings Access Road, and a heavy-duty access along the old TSF haul road. Bootjack Creek flows into Polley Lake.



6.6.5 Gavin's Ditch and Sump System

A ditch and sump system to stop water from entering the Wight Pit Haul Road and direct it into natural receiving environments via the North Dump Creek capture clean water to the north and northwest of the Wight Pit Haul Road, from the Highway to Heaven Dump to North Dump Creek.

6.7 Major Piping and Pumping Systems

There are numerous piping and pumping systems at the Mount Polley Mine, which are utilized to meet water management goals. Many of them are quite simple, involving small pumps and small diameter HDPE pipe conveying water from one small sump to another location. These small systems are sufficiently described under their respective area titles in previous sections. This section will focus on the major pumping and piping systems, namely the Tailings Distribution

Lines and the Reclaim Pumps and Line. See Figure 6.2 for a layout of the major pumping and piping systems; TSF Discharge and Reclaim.

6.7.1 Tailings Distribution Line

The Mill Tailings Distribution line is approximately 7,000m, 24" HDPE line sits within a containment ditch until just before entering onto the TSF. This ditch is meant to contain any potential spill. At the access onto the TSF, the CCS acts as the receiving structure should the tailings line develop a leak. On the embankment, the tailings line will be positioned just upstream of the core so as to deliver tailings to the areas that require beach development according to the deposition planning.

6.7.2 Reclaim Pumping and Piping System

Primary pumping occurs from a floating barge situated within the TSF Reclaim Pond, which outflows into a 24" HDPE pipe that extends to the Booster Station. Water pumped from the reclaim pond is deposited into a sump at the Booster Station. From the booster station, the reclaim water can be pumped to the mill for operations.

The reclaim line route follows that of the tailings distribution line from just above the TSF until the Booster Station. Any potential leakage of the reclaim line from the TSF to the Booster Station will be contained within the ditching systems or flow back into the TSF.

The pumping systems at the Reclaim Barge and Booster Station have been built-for-purpose by an offsite manufacturer. The Reclaim Barge system consists of four 250 hp vertical turbine Peerless pumps, and the Booster Station consists of five 250 hp vertical turbine pumps. More specific detail into both systems can be found in the information packages provided by the manufacturer, which are kept with the Mill Maintenance Superintendent and the Electrical Superintendent. Both pumping systems are connected to grid power and under the direct operational control of the mill, which monitors their operation in the Mill Control Room.

6.8 Reference Materials

There exists a great deal of documentation on the various TSF and water management systems described in this Manual. These documents can describe the design, operations, and regulatory permitting in much more detail than can be practically included in this Manual. Table 6.1 lists a few of the more frequently referenced documents in this Manual. Hard copies of these and additional reports are kept onsite in the Technical Services area of the main office on site at the Mount Polley Mine. Permit amendments are kept in digital format and distribution is limited due to some material being of a confidential nature. Finally, the procedural manuals are kept onsite and used regularly by Mine Technical Services department personnel. A copy of the *Water Management Inspection Manual* is included in this manual as Appendix C.

PE 11678 Amendment (Hazeltine Creek Discharge)	February 1, 2020	MOE Permit amendment authorizing the tailings and water management activities into the Springer Pit.
PE 11678 Amendment (Hazeltine Creek Discharge)	December 31, 2020	Incorporates Sept 2020 consent order into 11678 permit
PE 11678 Amendment (Hazeltine Creek Discharge)	December 1, 2022	Interim Extension of Quesnel Lake Discharge

7.0 OPERATIONS

This section is meant to outline and describe the operational protocols for the TSF and water management systems. All systems are designed to handle the tailings and site water management conditions that MPMC will expect to see throughout the remaining mine life as well as to adhere to the most up to date regulatory permits from EMLI and BC-ENV.

It should be expected that the systems would evolve over time to accommodate additional information, site knowledge, the pursuit of Good Practices, and all regulatory changes that may occur. Necessary updates, including the annual review, shall be performed to keep this section current.

The following operations description will be presented in three sub-sections:

- Tailings Deposition and TSF Operations
- Site Water Management
- Flood Management

7.1 Tailings Deposition and TSF Operations

The TSF serves MPMC as the facility for storing tailings and supernatant water, as well as the temporary storage of site water pumped into it and rainfall that reports directly to it. Care must be taken to ensure that safe operations are maintained, and that the following primary storage conditions are met: QPO's were updated in Sept 2023 and TSF Water Management summarized below in Figure 7.1.

Normal Operating Pond Storage Volume	Inspection frequency	Once per week	Estimated based on storage curve determined from most recent topographic and bathymetric surveys. Surveys are to be completed a minimum of two times per year (spring and fall). The majority of water inflows to the TSF are pumped and therefore the pond volume is in the direct control of the operator; however, temporary detention of large runoff volumes in the TSF is required and the pond volume can increase above 1.7 million m³ during large freshet events (e.g., about 2.1 million m³ during a 1 in 10 year freshet event; about 3.5 million m³ during a 1 in 200 year freshet event [Golder 2015]).
	Minimum	1.5 million m³	Target provided by MPMC to allow reclaiming water for operation of the mill. Aimed to allow for an approximate 4 m deep pond at the barge location.
	Maximum	1.7 million m³	To limit storage of water in the TSF.
Freeboard	Inspection frequency	Once per week	Difference in elevation between the pond and the lowest completed section along the crest of the embankment.
	Normal Operating Zone	≥ 1.1 m	Inflow design flood (IDF) based on the probable maximum precipitation (PMP) 72-hour event. Golder (2017).
	Concern Zone	1.0 to 1.1 m	Stop all pumps pumping water into the TSF. Increase monitoring frequency of freeboard and beach width, particularly in areas of reduced beach width. If reduced freeboard is unrelated to freshet, construct emergency spillway at Corner 5, or as directed by the EoR, and increase pumping from TSF to other facilities.
	Buffer Zone	0.8 to 1.0 m	Stop all pumps pumping water into the TSF. Increase monitoring frequency of freeboard, beach width, piezometers and seepage rate/turbidity, particularly in areas of reduced beach width. If reduced freeboard is unrelated to freshet, construct emergency spillway at Corner 5, or as directed by the EoR, and maximize pumping from TSF to other facilities.
	Unsafe or Out of Compliance Operating Zone	< 0.8 m	Stop all pumps pumping water into the TSF. Stop slurry deposition into the TSF. Increase monitoring frequency of freeboard, beach width, piezometers and seepage rate/turbidity, particularly in areas of reduced beach width. If reduced freeboard is unrelated to freshet, construct emergency spillway at Corner 5, or as directed by the EoR, maximize pumping from TSF to other facilities.

Figure 7.1 2023 QPO – TSF Water Management

Adhering to these conditions will require the careful planning of the transfer of waters into and out of the TSF.

7.1.1 Construction

Construction of the TSF occurs under the authority granted by the EMLI and must meet all conditions outlined in *Mines Act* Permit M-200 and its' amendments. All construction activities will occur under the surveillance of the EoR or designate and follow the designs outlined in the design report *Tailings Storage Facility Detailed Design to Elevation 970 m* as well as any updates received from the EoR. Regular communication between the EoR and MPMC will occur throughout the construction period to ensure that the intent of the design is met and any changes occur only with the appropriate engineering work to guide it.

At the end of the construction period, a Construction Record report shall be prepared by the EoR and submitted to EMLI by MPMC by March 31st of the following year. Any additional reporting stated in *Mines Act* Permit M-200 amendments shall be adhered to as well. Figure 7.2 indicates a typical cross section of the dam at Corner 1.

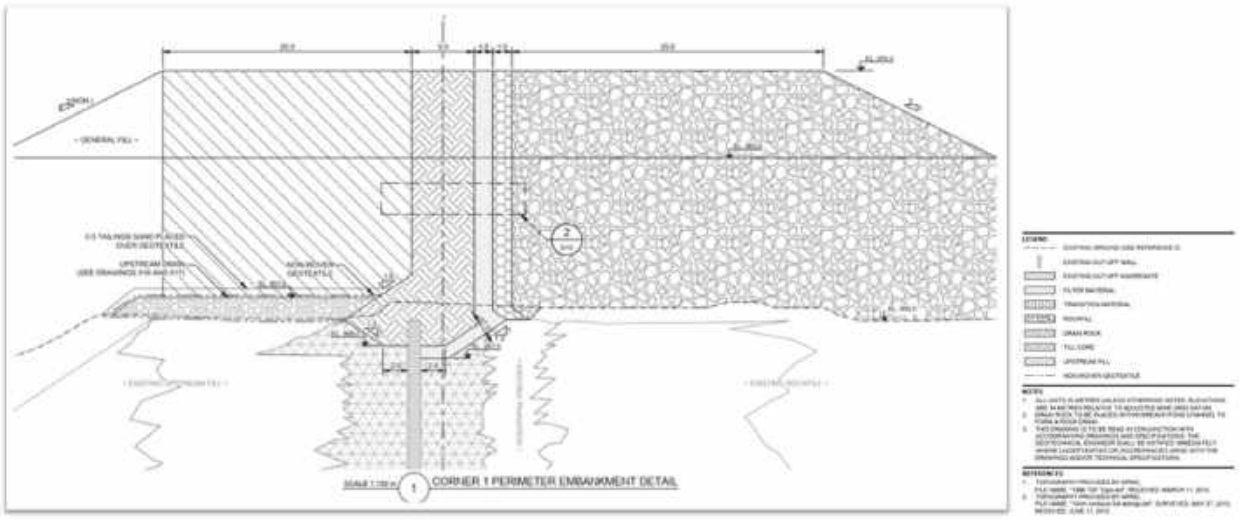

Figure 7.2 – Typical TSF Cross-section at Corner 1

Construction activities may begin or end at any time, so long as the conditions stated above are adhered to and QA/QC protocols are met. The primary intent of construction is to provide ongoing tailings and water storage as the TSF continues to fill, which will require planning and setting construction goals which ensure the appropriate amount of storage is available at all times.

7.1.2 Tailings Deposition and Beach Management

Tailings shall be delivered to the TSF from the Mill Tailings Distribution line when the mill is operating. Within the TSF, the line shall be situated in such a way to be upstream of the embankment core and emplaced in a way that, should a breach of the line occur, any unmanaged flow would not flow over the crest of the embankment. Discharge may occur via spigot or through the full pipe. A deposition plan will be updated on a regular basis using the latest bathymetric survey and mining plan available.

Figure 7.3 shows the zones of operation for the Beach Width from the QPO document.

Beach Width			
Normal Operating Beach Width	Inspection frequency	Daily	Portion of beach above pond level. The pond is to be maintained within the centre of the facility against the western boundary of the TSF against the natural topography. Temporary detention of large runoff volumes in the TSF is required and the beach widths are expected to decrease below 100 m during large freshet events.
	Normal Operating Zone	> 100 m	Minimum during normal operating conditions.
	Concern Zone	60 to 100 m	Regain 100 m beach along all the facility within 1 month (pumping to other facilities may be required [e.g., open pits]). Adjust tailings deposition to build tailings beach in area of reduced beach width. Increase pumping from TSF to the water treatment plant. Increase monitoring frequency of beach width, freeboard, piezometers, and seepage rate and turbidity, particularly in area of reduced beach width
	Buffer Zone	20 to 60 m	Regain 100 m beach along all the facility within 2 months (pumping to other facilities may be required [e.g., open pits]). Adjust tailings deposition to build tailings beach in area of reduced beach width. Maximize pumping from TSF to the water treatment plant. Increase monitoring frequency of beach width, freeboard, piezometers, and seepage rate and turbidity, particularly in area of reduced beach width

Figure 7.3 – QPO Beach Width Zones of operation

The area of discharge shall change according to beach development requirements, as determined by visual inspection. Water and TSF Superintendent is responsible for tailings deposition through written authorization on the weekly dewatering meeting. Site Services will be contacted to perform the necessary valve and line work to move the discharge. Occasionally, deposition will be controlled by line maintenance needs, but shall return to normal configuration once maintenance work is completed.

The objective of beach development will be to provide an adequate buffer between the free water within the reclaim pond and the embankment core throughout all foreseeable flood events. This will normally allow beaches of 300 m length or more around the entire facility, depending on elevation. Maintaining beaches of minimum 100 m width during normal operations ("normal" being defined as a pond volume between 1.5M m^3 to 1.7M m^3 after freshet and 3.5 million m^3 following a 1 in 200 year freshet event, respectively – see Pond Management sub section) is the minimum target. Of necessity, beaches will be constructed much greater than 100 m wide before

moving discharge to another location so that the loss of beach while discharging elsewhere does not reduce the beach to less than 100 m.

Beach width will be determined primarily by visual estimation based on the minimum distance from the TSF pond to the embankment. Drone flyover and Online resources (Figure 7.4) can also be used to determine beach width.

Sentinel Playground | Sentinel Hub (sentinel-hub.com)

Website:https://apps.sentinel-hub.com/sentinel-playground/?source=S2&lat=52.51458338709581&lng=-121.60340022935998&zoom=15&preset=1-NATURAL-COLOR&layers=B01,B02,B03&maxcc=64&gain=1.0&gamma=1.0&time=2022-11-01%7C2023-05-15&atmFilter=&showDates=false

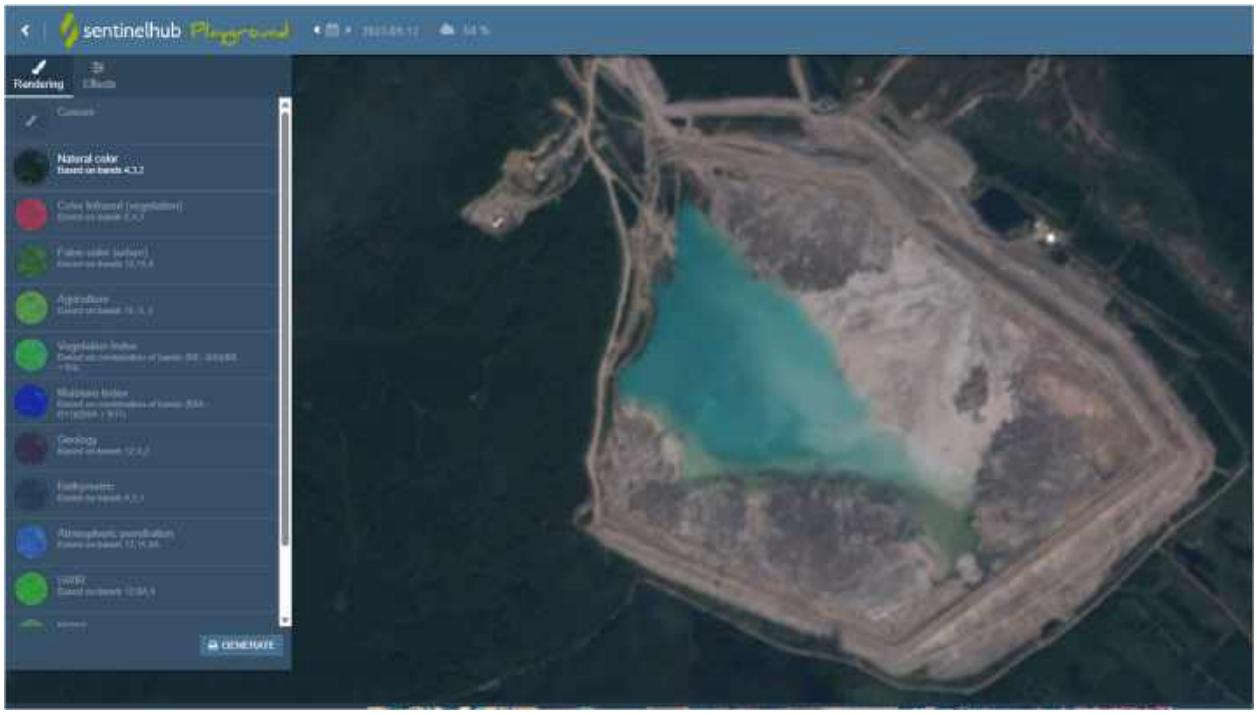

Figure 7.4 Sentinelhub – MPMC TSF location

Small ponds will occasionally form on the beaches themselves. If they are not connected to the main pond, they will not impact beach length consideration. Effort will be made to 'push' out these ponds via tailings deposition management.

Tailings Distribution lines which are in operation will be visually inspected every shift by Mill Maintenance personnel (Mill to corner 5) and Site Services personnel (Corner 5 to discharge). The person performing the inspection has the authority to stop tailings flow to the TSF by contacting the Mill Manager/Water and TSF Superintendent or designate. Changes to tailings deposition shall be communicated to the Water and TSF Superintendent.

The beaches are formally inspected weekly by Water and TSF personnel and informally by operations and supervisory personnel as a part of their daily routine. There are also many informal inspections performed by other individuals on the embankment performing their regular duties.

7.1.3 Reclaim Pond Management

Under normal operating conditions and average meteorological conditions, including freshet, the reclaim pond within the TSF shall contain between 1.5 and 1.7 million m^3 of water. The TSF is used for temporary detention and attenuation of flow rates; therefore, for example, the reclaim pond size could increase to 3.5 million m^3 during a 1 in 200 year freshet event. The fundamental basis of the water management on site is to ensure that water does not accumulate in the TSF, specifically to the point of increasing the onsite water reserve year-over-year. Exceeding the estimated reclaim pond volumes for average and 1 in 200 year freshet events does not necessarily compromise embankment safety but is not consistent with Best Practice.

The key parameters further restricting the allowable pond volume are freeboard, beach length and flood storage capacity. The site water balance does not predict the pond to contain more than 3.5million m^3 of free water except as the result of an event larger than a 1 in 200 year freshet event. Planning for freshet management is based upon being able to safely manage this scenario.

However, if an event or events lead to this happening, there are certain factors that must be checked. The primary factor will be freeboard and beach width, specifically any expectation of beach width going below 20 m. MPMC must engage all practical effort to prevent this from happening and the excess water would have to quickly be brought down to acceptable levels afterward.

Pond volume will be regularly tracked by the Water and TSF Superintendent on a spreadsheet utilizing pond elevation pickups and mass balance calculations based on flyover survey and communicated to the EoR weekly in the TSF Weekly Report. A pond sounding is conducted on an as needed basis to calibrate and confirm the accuracy of the water balance. Snow and beach ice do not contribute to the free water pond volume calculation, nor does pond ice. If determinable, snow and ice do count as impounded materials and will cause the lowering of total storage, and will be tracked, though likely by estimation.

7.1.4 Reclaim Barge

The reclaim barge shall be operated by an automated system controlled by Mill Operations. Water will be pumped through the reclaim piping system (i.e., via the Booster Station) back to the Mill on an as-needed basis. Instrumentation installed on the operating systems within the barge and Booster Station pumps monitor the systems' operation on a continual basis. Mill Operations shall formally inspect the reclaim line and supporting infrastructure at least once per shift.

Reclaim barge raises will be required at the elevation of the tailings deposition increase. Planning will be discussed in the weekly dewatering meetings. Execution will be carried out as quickly as possible to avoid interrupting the flow of reclaim water out of the TSF.

7.2 Site Water Management

This sub-section shall describe the operations of the various water management structures and systems (exclusive of the TSF reclaim). Some of the systems are described in much detail within the *Water Management Inspection Manual* (Appendix C), and will be referenced as such within this section.

In general, water management at the Mount Polley Mine is intended to ensure that the utmost care is given to manage the site water in a socially responsible way, adhering to all permits and making efficient use of the water resource utilized. The systems are designed to be robust and easily understood and implemented. Redundancy or overdesign is included wherever practical and MPMC will continue to improve upon these systems as water management experience continues to develop. MPMC also has a strong commitment to including the local community groups in the planning and implementation of the activities on site that affect the local receiving environment.

The site water management operations' section will be broken into the following topics:

- Cariboo Pit Sump
- Wight Pit Temporary water storage and dewatering
- West and Long Ditch Systems
- TSF Seepage
- CCS and PETBP
- Other Water Management Facilities

7.2.1 Springer and Cariboo Pit Storage and Dewatering

Cariboo Pit Sump

The Cariboo pit is an active dewatering sump for the Springer Pit. Water from the Springer pit is pumped into the Cariboo Pit Sump. Water from this sump is pumped into a booster station, from

there the water can be pumped to the mill process tank or to the West Ditch. This is shown in Figure 7.5 below.

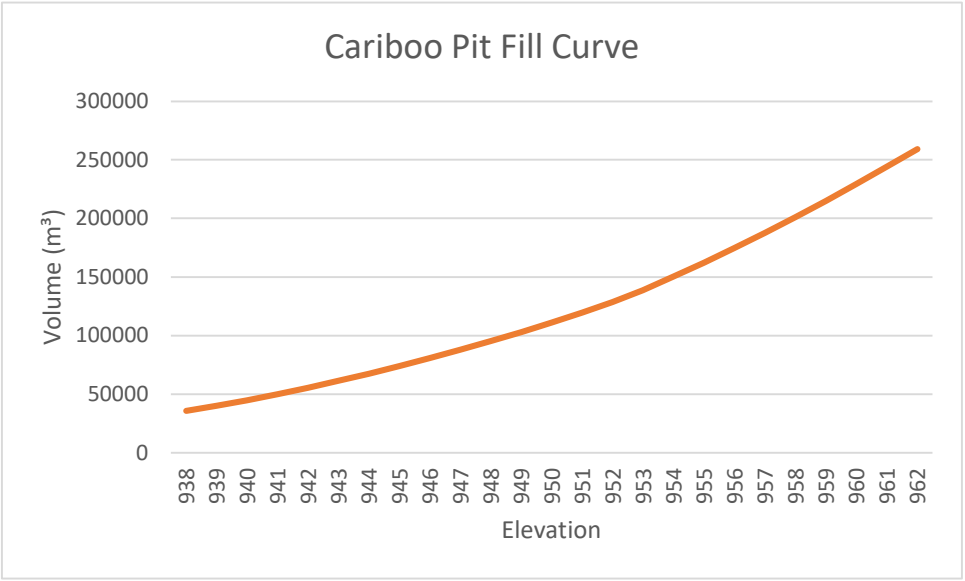

Figure 7.5 Cariboo Pit Sump Storage Curve 2023

Springer Pit

The Springer pit is the main mining location for Phase 4 and future mining once permitted. Temporary sumps are established as needed and the water is pumped to the Cariboo Pit Sump. It's noted that the maximum water elevation is permitted to 1025 masl (EMA 11678 section 1.3.1)

7.2.2 (1025m elevation) including the deposited tailings. This is shown in Figure 65. belowWest and Long Ditch Systems

A majority of the West Ditch and Long Ditch sub-systems performs automatically and do not require operational input, instead relying upon regular inspections and maintenance to ensure they continue to function properly. There are a few small components that do require manual interaction, and this is generally performed by the individuals performing the inspections according to the *Water Management Inspection Manual* (Appendix C).

As mentioned above, the seepage collection ponds and recycle pumps typically operate without requiring any external adjustments; however, the following special circumstances will require specific actions:

- In the event of an emergency that may compromise a water storage facility, all diversion ditches that feed the facility may need to be directed away. In addition, if water quality and permits allow, discharge of water to natural receiving environments may be possible. Many of the structures already include overflow devices or structures within them, and other bypasses

may need to be installed, if safe to do so at the time. See the *Water Management Inspection Manual* for detail.

- During freezing conditions, pumps may be operated on a timed pumping cycle (based on site conditions) to prevent conveyance pipes from freezing. Pumps may be turned on and off based on cycle time rather than water level (the latter representing the more standard level setting). Once temperatures return to those suitable, pumps can operate under normal conditions.

The West and Long Ditch systems are required to handle the following precipitation events:

- Safely contain and convey a 1 in 10 year 24-hour storm event.
- Be capable of withstanding all flows resulting from up to a 1 in 200-year 24-hour storm event without significant damage.

It is therefore expected that the system shall effectively manage all normal meteorological events, with environmental discharge being a distinct possibility in extreme weather events, but accommodation for this is included in the design. As it is not possible to determine the magnitude of an event in real time, the assumption shall be to contain and convey all flows until it is observed impractical under the guidance of the *Water Management Inspection Manual*. Trust in the design and ensuring the system is properly maintained are therefore necessary to ensure the systems operate as intended.

7.2.3 TSF Seepage

All waters that report through the TSF shall be considered contact water and must be managed accordingly. Seepage through the embankment (including the upstream drain), and precipitation that falls on the embankment, but downstream of the core will report to one of the seepage control structures and make its way to one of the seepage ponds. All collection ponds described below have permanently installed, color coded water level indicators. The appropriate response for a given water level is described within the *Water Management Inspection Manual*. The general goal will be to maintain as little water in any of these systems as is practical, reserving storage for times of high flow.

Seepage management for the Main and South Embankments is primarily automated. Flows report through a ditching system to one of the seepage ponds, which are then conveyed by pumping to the TSF. There are periods of time when the pumping systems are not on automatic, specifically the summer months, with pumping controlled by the individuals performing the inspection duties. Maintenance and surveillance following the *Water Management Inspection Manual* is essential for proper operability of this system.

Seepage at the Perimeter Embankment eventually reports to either the CCS, or PETBP. It is essentially a gravity driven system, and is therefore automated, and kept functional through the surveillance and maintenance protocols. The CCS and PETBP also serve other functions beyond that of purely TSF seepage control and are described in the following sub-section.

The MESCP and SESCP serve as the supply source for dust control waters on the TSF beaches as well as the utilization of water cannons (if setup) to optimize evaporation of excess water. Excess water in the MESCP may also be pumped back into the TSF via the same line that conveys water to the dust control sprinklers.

7.2.4 CCS and PETBP

As with the other water management systems, operational guidance for both the CCS and PETBP is contained within the *Water Management Inspection Manual*.

Overflow from the CCS reports to the PETBP. The PETBP is the central water management control structure for site waters outside of the TSF. Water level in the PETBP is controlled by the WTP discharge and 2 electric pumps in the PETBP on automatic floats to pump to the TSF. During the times of low site flow, the excess water in the TSF will be conveyed to the PETBP for eventual discharge through the WTP. This water transfer will occur by overflowing the Booster Stations allowing the water to flow into the west ditch. These systems are capable of meeting the design criteria to manage the 1 in 10 year 24-hour storm event (PETBP to TSF) and 0.3 m^3/s for the TSF to PETBP system to maximize site discharge through the WTP.

7.2.5 Other Water Management Facilities

Non-Contact Water Ditches

The non-contact water system is composed of fully self-functioning ditches and sumps. The key to ensuring this system remains operable lies in the regular inspection and maintenance of these structures, following the *Water Management Inspection Manual*.

Dust Control Systems

The primary method of dust control on site is to wet down the mine roads system. A fill station is setup at the crest of the Cariboo Pit and is supplied by water from the Cariboo Pit Sump. Temporary stations may also be utilized at other locations as needed, so long as any necessary protections are installed.

Secondarily, there is need to control dust on the large, dry surface within the TSF. There is a non-fixed system to supply water to large sprinklers, which are placed in various locations within the TSF. The system typically sources its water from the MESCP, but any location will suffice to get water to the appropriate locations. Mine Operations operated the fill stations and Site Services is responsible for the TSF sprinklers.

7.3 Water Management Meeting

To effectively manage the site water system and infrastructure, a water management meeting facilitated by the Water and TSF SuperintendentWater and TSF Superintendent shall be held at regular intervals. During periods of high water management activity, such as freshet, these meetings will occur weekly or bi-weekly, and occur monthly during times of little activity, such as winter and late summer.

The meetings will address all site water related matters such as pumping requirements, pit dewatering, projects, WTP, tailings discharge, water discharge, ponds, sumps and ditches. Representatives from the following Departments will attend the meeting:

1. Mill Maintenance / Electrical
2. Mine Operations
3. Environmental
4. Procurement (optional)

7.4 Emergency Flood Management

A great deal of effort has been undertaken to study, design, and implement the water management systems in place at MPMC to ensure that water is controlled and conveyed in an appropriate way without undue harm to the systems or the receiving environment. Each system is designed according to its own set of criteria, which is not common everywhere on site. When an unusually large precipitation or flood event occurs, it is essential to know how to deal with it.

First, it needs to be understood that, although there are definitions such as “1 in 10-year 24-hour storm event’ or “1 in 200-year freshet” there is no practical way of determining this while it is occurring. During such occurrence, the first priorities shall be the safety of the TSF, which will be guided by the TSF Operations Parameters, QPOs and the Water Management Inspection Manual. Facilities may need to be prioritized, and it may become necessary to abandon action for a lower priority facility to ensure that higher priority infrastructure is protected.

It will also be crucial to maintain the appropriate level of communication, through normal operating parameters or by way of the EPRP protocols, with the EoR and Regulators. Extreme events will present MPMC with a wide variety of potential problems, and decision making amongst the various stakeholders may become necessary. However, the responsibility to protect the facilities and the receiving environment is MPMC’s and it may become necessary to react without the consent of regulators or the EoR. Planning (and proper implementation of the plan) will be the corrective action to this type of action having to occur.

7.4.1 Systems Priority

The highest priority will be given to the health and welfare of personnel and, following this, the receiving environment. Stating the priority level for the various water management components will be based upon these two overarching goals.

The TSF is the most potentially hazardous component. The TSF is designed to a much higher standard than the other facilities on site as it is expected to handle a much greater flood event than any other (non-pit) component. Though the standard procedure for excess site water reporting to the CCS and PETBP will be to pump it into the TSF, this will need to cease if the water level increases too rapidly or freeboard requirements are approached. Conditions within the TSF at the time will form the basis of decision making regarding potential danger. Site Management and the EoR will have to be involved in the action planning surrounding any type of event that may cause an unsafe condition in the TSF.

Below is a list of possible actions to limit damage in an extreme run-off or precipitation event:

- Cease tailings delivery.
- Cease all water pump-back into the TSF.
- Maximize WTP throughput without compromising permit criteria
- Maximize reclaim and facilitate an alternative storage location.
- Re-direct into the Cariboo Pit from the Mill Process Water Tank.
- Re-direct into the Wight Pit from the Mill Process Water Tank.
- Cease all pit dewatering.
- Install additional pumps in a facility at risk. United Rental has pumps available for MPMC
- Direct as much water into the pits as possible. They are, practically speaking, unfillable by a single event.
- Engage the EoR to aid in evaluating the situation and formulating the appropriate action plan, which may include construction of a Spillway.
- Facilitate offsite discharge.
- Stop concentration of flows by shutting off pumping systems that pump from one sump to another and allowing individual sumps and ditches to overflow, ideally into a pre-existing channel.
- Install pumps in the TSF and pump water downstream.

Ideally, communication with the EoR, regulators and the directly affected communities will have been initiated. No assumption of permission being granted should be made. MPMC and/or the EoR may have to make the determination themselves, but it is preferable to have advanced notice to all affected groups.

The Water Management Inspection Manual (Appendix C) and the EPRP both contain pre-arranged information meant to aid in emergency level event decision making (cheat sheets).

7.4.2 Emergency Spillway

The emergency Spillway has been designed by WSP and the liner material has been procured and is available on site. The liner (ENVIRO 6000) material is approved by the EoR and is located in

the instrumentation seacan near the quarry. The Mine Operation Superintendent (or designate) holds the keys to this locked seacan. The design is referenced in Appendix F of this document.

8.0 MAINTENANCE

As outlined in this Manual, water management on site comprises multiple components and associated facilities. These components and facilities must be inspected and maintained regularly to ensure that any changes to their condition, performance, or a potentially hazardous condition can be identified and promptly addressed.

Maintenance will be broken into two groups: Equipment maintenance and Facility maintenance. Both types will be heavily dependent on proper surveillance of the associated systems.

8.1 Equipment Maintenance

Equipment maintenance refers to maintenance of the pumping and piping systems and their associated structures and power systems. Equipment maintenance is generally performed by certified tradespeople following common maintenance practices. The maintenance they perform will be that associated with regular operations, at regular intervals, as well as reactive maintenance as the result of an observed substandard condition. Equipment maintenance will follow the recommendations of the manufacturer or site specific Standard Operating Procedures (SOPs.)

Mill Maintenance Superintendent or designate

- 24" and larger pipes, valves, and gates for the reclaim and discharge lines from the Mill building, through the Booster Station, and down to the Corner 5 "Y" (discharge line) or the TSF Barge (reclaim line).

- Mechanical components of all fixed pumping systems, including:
    - Reclaim Barge, pumps and associated non-electrical equipment
    - Booster Station pumps and associated non-electrical equipment.
    - PETBP-TSF pump-back system.

- All water and tailings distribution equipment within the mill complex
- All fixed power distribution equipment – poles, lines, and transformers, all protective devices
- Installation and maintenance of electric motors and other components
- Instrumentation installation and maintenance. This does not refer to TSF performance monitoring instrumentation, rather instrumentation on the mechanical and electrical pumping systems.

Water and TSF Superintendent or designate

- All pumps, pipelines and associated equipment throughout the mine site not under the responsibility of the Mill department, including:
    - All discharge pipeline downstream of the Corner 5 “Y”, and all other components of the discharge system on the TSF.
    - All non-electrical components of the ditch systems’ dewatering infrastructure.

8.2 Facility Maintenance

Facility maintenance is maintenance on the TSF embankments, buttresses, seepage collection ponds, ditches, geotechnical instrumentation and groundwater wells. It is generally the maintenance of any structure made of earth materials. These structures do not move, and so typically only degrade because of outside forces, such as running water, gravity, and equipment activity. Following the proper surveillance protocols is crucial to ensure that facility maintenance items are properly identified in a timely fashion.

All facility maintenance is done under the Water and TSF Superintendent’s authority through MPMC personnel and contractors. It can be the result of either an automatic response to an obvious deficiency, through instrumentation readings and analysis or indirect observations, such as seepage increases. The extent of the maintenance may need to be determined by the EoR and effective communication is essential for this to occur.

8.2.1 Embankments

The embankments will be subject to gravity, weather and equipment activity. The crests of the embankment shall be kept in such a way as to facilitate traffic and avoid water ponding. Ponded water should not be allowed to flow over the crest of the embankment as that could result in erosion of the downstream slope, rather it should be encouraged to flow through the coarse downstream shell or pumped into the TSF. Trenching across the core is not permitted.

Settlement of the embankment may result in cracking along the crest. Any crack(s) shall be documented and communicated with the EoR, who will determine the course of action to be taken.

8.2.2 Ditches and Sumps

Ditches and sumps will be kept clear of built up material and obstructions and shall be repaired after any damage that may occur to them is observed. Damaged areas should be built up beyond their original condition so as not to repeat the damage for a similar event. Culverts will be kept open and weirs will be kept free of debris and maintained such that they perform as required. The Site Services group will perform maintenance. There will also be the occasional need to clear plants and trees that may grow in the ditches and sumps.

8.2.3 Access

Roads, trails, ladders and all other means of accessing the various facilities need to be kept usable to ensure their proper functionality. The majority of this work is the plowing of roads (year round), but also includes snow shoveling, ice removal, and other types of access related maintenance issues. This is typically reaction-based maintenance and requires proper communication from the impacted individuals to Mine Operations.

8.2.4 Geotechnical Instrumentation

Generally, the instruments do not require regular maintenance, but may require occasional maintenance as follows:

- The piezometer wires may need to be cut and re-attached if the readout box is unable to acquire any data.
- Piezometer wires that are exposed may become corroded and may need to be trimmed until a fresh surface is exposed to allow readings to be taken.
- Extension of Slope Inclinometer casings to facilitate embankment buttress construction.
- Power systems for instrumentation, such as the SAA's, in-place inclinometer (IPI) and dataloggers.

The TSF Instrumentation Technician will facilitate the repairs of any of the Geotechnical Instrumentation with guidance from the Water and TSF Superintendent and EoR when necessary.

8.2.5 Groundwater Wells

Decommissioning and replacement of existing groundwater wells and construction of groundwater wells at new monitoring locations are addressed by a third party Qualified Professional in an assessment of the monitoring program and possible impacts for groundwater every three (3) years, as per *EMA* Permit 11678.

Well development is completed as soon as possible after installation of new wells and is completed on any wells where water being purged contains significant amounts of sediment (the presence of sediment is noted in sampling observations).

During bi-annual sampling, any wells missing PVC J-plugs, casing protector lids, or locks are noted and fixed. Additional maintenance items are noted during bi-annual sampling, based on observations of the physical state of the well and/or properties of the water.

9.0 SURVEILLANCE

As outlined in this Manual, water management on site comprises multiple components and associated facilities. These components and facilities must be inspected regularly to ensure that any changes to their condition, performance, or a potentially hazardous condition can be identified and promptly addressed.

The Mill Maintenance Superintendent and Water and TSF Water and TSF Superintendent are responsible for ensuring that surveillance is carried out regularly. The Water and TSF Superintendent is responsible for daily management of the TSF water management systems and ensures crew carries out routine activities. The Water and TSF Superintendent is also responsible for directing and coordinating all TSF surveillance and facility maintenance to the specifications of the EoR.

The Water and TSF Superintendent will conduct and document an embankment surveillance walkover at least once per quarter. Weekly Embankment surveillance reports, completed by the MPMC Instrumentation Technician, shall be reviewed by the Water and TSF SuperintendentWater and TSF Superintendent and filed at the Mount Polley Mine Site. Additional (non-routine), documented "drive-bys" of the TSF and associated facilities will be required following extreme or unusual events. The Water and TSF Superintendent must be made aware of any unusual events or observations and shall contact the EoR as required. Typical examples of unusual events and observations to be made during such walkovers are outlined in the "Unusual Event or Observation" section included in the *Water Management Inspection Manual*.

Guidance documents are included in the *Water Management Inspection Manual* (provided in Appendix C) to help guide the observation and surveillance process. The documents cover major items related to the TSF and associated facilities. Additional details are provided in the following sections.

9.1 Water Management Systems

Site Services personnel in accordance with the Water Management Inspection Manual, which includes water management checklists, shall inspect the seepage collection ponds and recycle pumps. Typical observations to be made during surveillance are as follows:

- Water levels in ditches, sumps, ponds and within the TSF;
- Pump back flow rates from pumps;
- Evidence indicating seepage from the ditches, sumps and/or ponds;
- Evidence indicating erosion or instability on the slopes of ditches, sumps and/or ponds;
- The overflow culverts and pipelines between sumps and/or ponds are free of any obstructions; and
- Ensuring that the discharge end of pipelines, culverts and spillways are not obstructed
- Ensuring that ditches are not obstructed/blocked.

Additional observations will also be required under special circumstances as follows:

- Monitor the pumping from sumps and/or ponds during freezing conditions to ensure that the pumping cycle is adequate at keeping the pipes from freezing and in keeping the pond level constant; and

- Monitor the water quality in the sumps and/or ponds during spring freshet to ensure that the seepage water is at acceptable levels if water permits allow for discharge.

The Unusual Event or Observation document identifies additional events and circumstances that may require increased observations and documentation.

Environmental Department personnel will also be indirectly inspecting the various facilities as they perform their required materials sampling.

9.2 Tailings Impoundment and Pond

The TSF is operated according to the protocols outlined in the Operations Section of this manual. Daily measurements of the pond level shall be carried out and instrumented flows into and out of the TSF will be measured. Increasing the number of measurements of, and improving upon the measurement of, flows into and out of the TSF will continue and provide for a more accurate TSF mass balance. This information will be utilized to form a materials balance for the TSF impoundment. This balance will be regularly checked against actual conditions and modified as information is gained and understanding of the facility improves. Topographic and bathymetric surveys will be carried out after freshet and during fall each year to confirm the pond size.

Visual inspection, specifically for beach condition and deposition line condition will also be performed daily. However, winter conditions will likely preclude proper beach inspection, and beaches may have to be determined indirectly via survey data.

The weekly TSF Field Inspection conducted by Instrumentation Technicians according to the *Water Management Inspection Manual* includes some areas of pond inspection. Freeboard and beach width are to be checked against the QPO triggers and any QPO dictated actions are to be followed. Pond depth is operational only. There are no directly related QPO dictated actions, and pond depth is not practical to determine for much of the year.

9.3 Tailings Embankment

Weekly surveillance of the embankments and associated structures should follow the Field Inspection Report (included in the *Water Management Inspection Manual*). Typical observations to be made during surveillance include:

- Evidence indicating embankment structure deformation (e.g. slope bulging, tension cracks on the crest or crest settlement);
- Evidence indicating seepage, runoff or erosion;
- Clarity and quantity (visual estimate) of seepage water entering the seepage collection sumps;
- Other unusual conditions in the TSF area.
-

The embankment and associated earthwork structures do not require regular maintenance; however, specific maintenance items may be identified as a result of regular observations and surveillance of the embankment.

The Unusual Event or Observation document outlines additional observations that may need to be documented after any unusual event.

In addition to regular inspections of the TSF by site personnel, the EoR will conduct an annual Dam Safety Inspection (DSI) and will include all elements of the TSF (Pond, Embankments, Buttresses, Seepage, and Operations). Recommendations from this inspection will be delivered to MPMC for review and implementation. The inspection report shall be completed and submitted to EMLI by March 31 of the year following the inspection. Additionally, the IERP may conduct a review of any structure or process at their discretion, followed up with a written report submitted to the Mount Polley General Manager.

9.4 Tailings Discharge Pipelines

The tailings discharge pipelines will be inspected each shift and maintained regularly to ensure that the system operates properly. The *Water Management Inspection Manual* includes a Daily (each shift) Tailings Line Inspection Checklist for regular surveillance of the pipelines. Typical observations to be made during surveillance include:

- Evidence indicating leakage from the pipelines;
- Evidence indicating grade variations and/or blockages;
- Confirmation that conveyance ditch lining (where appropriate) is continuous;
- Evidence of overhanging rock or objects that could fall and damage the pipelines

The Unusual Event or Observation document outlines additional observations that will need to be documented after any unusual event. Repairs to the discharge pipeline, and/or discharge sections may be required after any such unusual event.

Noted deficiencies shall be communicated to the Mill Maintenance Superintendentand the Water and TSF Superintendent. The individual performing the inspection has the authority to stop the tailings flow through communication with the Mill Manager or Mill Maintenance Superintendentand Water and TSF Superintendent if he or she feels a line deficiency has the potential to cause significant damage to a structure or the environment.

9.5 Beaches

MPMC Technical Service staff shall formally inspect and document the beaches weekly according to the protocols in the *Water Management Inspection Manual*. Daily, informal inspections shall also occur by the various operations and supervisory personnel. Beach maintenance will occur through proper deposition management, which will be done through the Water and TSF

Superintendent. Deposition will be moved according to beach development needs. A model of the tailings deposition is included in the TSF design report (*Tailings Storage Facility Detailed Design to Elevation 970 m*, Nov. 3, 2015) as Appendix D of that report. The latest deposition model was completed in March 2019 (reference number 1894924-073-PP-Rev0-51141). There are some assumptions within the model that may have to be modified as actual deposition conditions are observed.

Within the QPO's (Appendix I), beach width monitoring has trigger levels indicating the various response actions based upon the reading or change in reading. MPMC is responsible for implementing the QPO actions based upon the recorded data or through direction of the EoR. The EoR must be notified of any anomalous trends. Additional readings and inspections may also be required after any *Unusual Event or Observation*, at the direction of the EoR or at the direction of the Water and TSF Superintendent.

9.6 Drain Pipes/ditches and Seepage Pipes.

Measurements of the Seepage Turbidity and Seepage rates will be conducted by Environmental Technicians. Figure 9.1 summarizes the QPO zones and monitoring frequency

Quantitative Performance Objective		Value	Source/Comment/Action
Seepage turbidity (Field test)	Data gathering frequency	Once every two weeks.	South Embankment drain, Main Embankment east drain, Main Embankment west drain, Corner 1 cutoff wall seepage drain, Corner 1 upstream drain, South diversion ditch and North diversion ditch. Probe is highly sensitive to sampling quality. Re-test turbidity immediately if reading exceeds 1.5 NTU.
	Normal Operating Zone	Turbidity < 1.5 NTU	A copy of the figures reported in the 2022 annual dam safety inspection presenting the historical turbidity readings is attached.
	Concern Zone	Turbidity < 2.0 NTU	Increase monitoring frequency of seepage rate/turbidity and piezometers around the area of concern. Complete inspection of tailings beach, embankment, buttress, downstream toe and seepage collection ditch/pond near the area of concern.
	Buffer Zone	Turbidity < 3.0 NTU	Same actions as for Concern Zone and collect and submit seepage water samples for expedited laboratory testing.
	Unsafe or Out of Compliance Operating Zone	Turbidity > 3.0 NTU	Same actions as for Buffer Zone. If laboratory test results confirm the turbidity levels measured in the field: - increase pumping from TSF to other facilities. - adjust tailings deposition to build tailings beach upstream of the embankment. - stop all other pumps pumping water into the TSF.
Seepage rate	Data gathering frequency	Once every two weeks.	If the seepage rate from the South Embankment drain, Main Embankment east drain, Main Embankment west drain, or Corner 1 upstream drain increase or decrease significantly (e.g., more than 50% between readings), notify the Engineer-of-Record (EoR) and the TSF Qualified Person within 24 hours.
	Normal Operating Zone	Corner 1 cutoff wall seepage drain: < 1.0 l/s	Maximum rate expected during normal operating conditions (i.e., beach width > 100 m, pond size < 1.5 million m³) based on readings since 2015. Higher rates can be expected during freshet or large precipitation events. A copy of the figures reported in the 2022 annual dam safety inspection presenting the historical seepage rates are attached.
	Concern Zone	Corner 1 cutoff wall seepage drain: < 3.0 l/s	Increase monitoring frequency of seepage rate/turbidity, piezometers and beach width around the area of concern. Complete inspection of tailings beach, embankment, buttress, downstream toe and seepage collection ditch/pond near the area of concern.
	Buffer Zone	Corner 1 cutoff wall seepage drain: < 6.0 l/s	Same actions as for Concern Zone. Increase pumping from TSF to the water treatment plant.
	Unsafe or Out of Compliance Operating Zone	Corner 1 cutoff wall seepage drain: > 6.0 l/s	Same actions as for Buffer Zone. Maximize pumping from TSF to the water treatment plant and increase pumping to other facilities (e.g., open pits). Adjust tailings deposition to build tailings beach upstream of the embankment. Stop all other pumps pumping water into the TSF.

Figure 9.1 – QPO Turbidity and Seepage Zones and monitoring frequency

- Bi-Weekly measurement of flow and field parameters (temp, pH, Specific conductivity, turbidity) at:
  - Upstream Drain (Turbidity & Seepage Rate)
  - South Diversion Ditch (Turbidity)
  - North Diversion Ditch (Turbidity)
  - Cut-off-Wall (COW) Drain (Turbidity)
  - East Main Toe Drain (MTD) (Turbidity & Seepage Rate)

- West MTD (Turbidity & Seepage Rate)
- South Toe Drain (STD) (Turbidity & Seepage Rate)

9.7 Reclaim System

The reclaim pipeline, Reclaim Barge (including pumps), and Booster Station are inspected each shift as a part of the shift inspection performed by Mill Operations staff or Site Services which also inspects the discharge line. The mechanical systems are constantly monitored by instrumentation, which reports to the Mill Operations Control Room.

Typical areas to inspect during visual surveillance of the reclaim pipeline include:

- Locations of excessive wear of the pipeline (filed with Mill Maintenance Department); and,
- Evidence indicating leakage from the pipeline.
- Evidence of leakage or improper operation of a pump, header, or distribution tank.

Additional inspections are required after any unusual event. The Unusual Event or Observation document outlines additional observations that will need to be documented. Repairs to the reclaim pipeline, reclaim barge and/or Booster Station may be required after any such unusual event.

9.8 Instrumentation

All instrumentation components must be read regularly by the Instrumentation Technician. The monitoring frequency for the geotechnical instrumentation is determined by the EoR and specifies the schedule by which data must be collected, plotted and reported. The readings are to be collected, reviewed and forwarded to the EoR according to his prescribed schedule. Within the QPO's (Appendix I), all instruments have trigger levels indicating the various response actions based upon the reading or change in reading. MPMC is responsible for implementing the QPO actions based upon the recorded data or through direction of the EoR. The EoR must be notified of any anomalous trends. Additional readings and inspections may also be required after any *Unusual Event or Observation*, at the direction of the EoR or at the direction of the Water and TSF Superintendent.

9.8.1 Geotechnical Instrumentation

MPMC personnel in accordance with the frequencies determined by the EoR gather Geotechnical instrumentation data.

Existing instrumentation locations are presented in Figure 9.2 and Figure 9.3 and a summary is provided in the sections below.

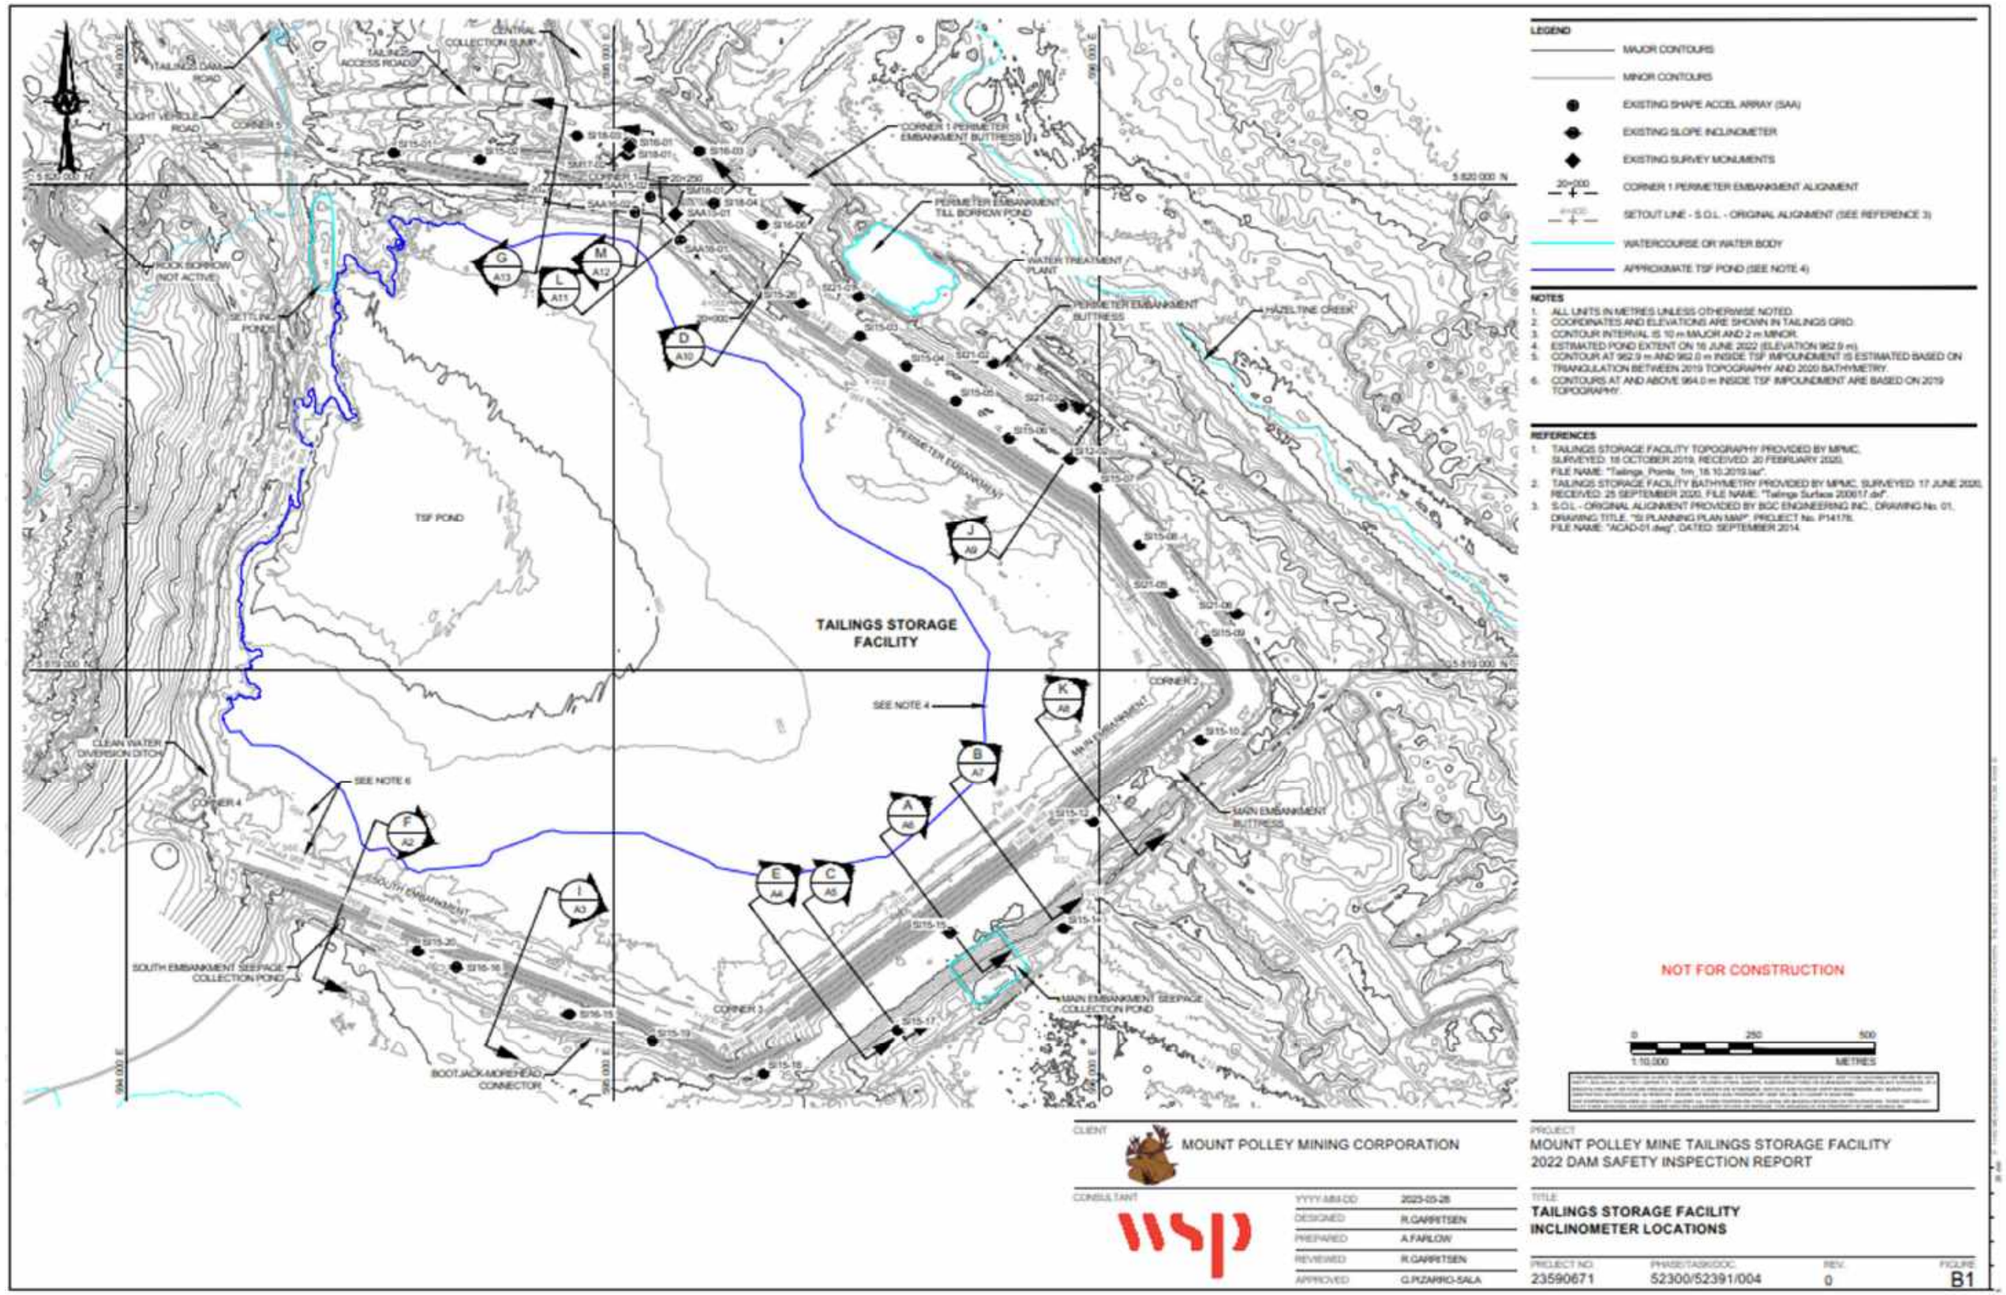

Figure 9.2 Slope Inclinometer and SAA locations

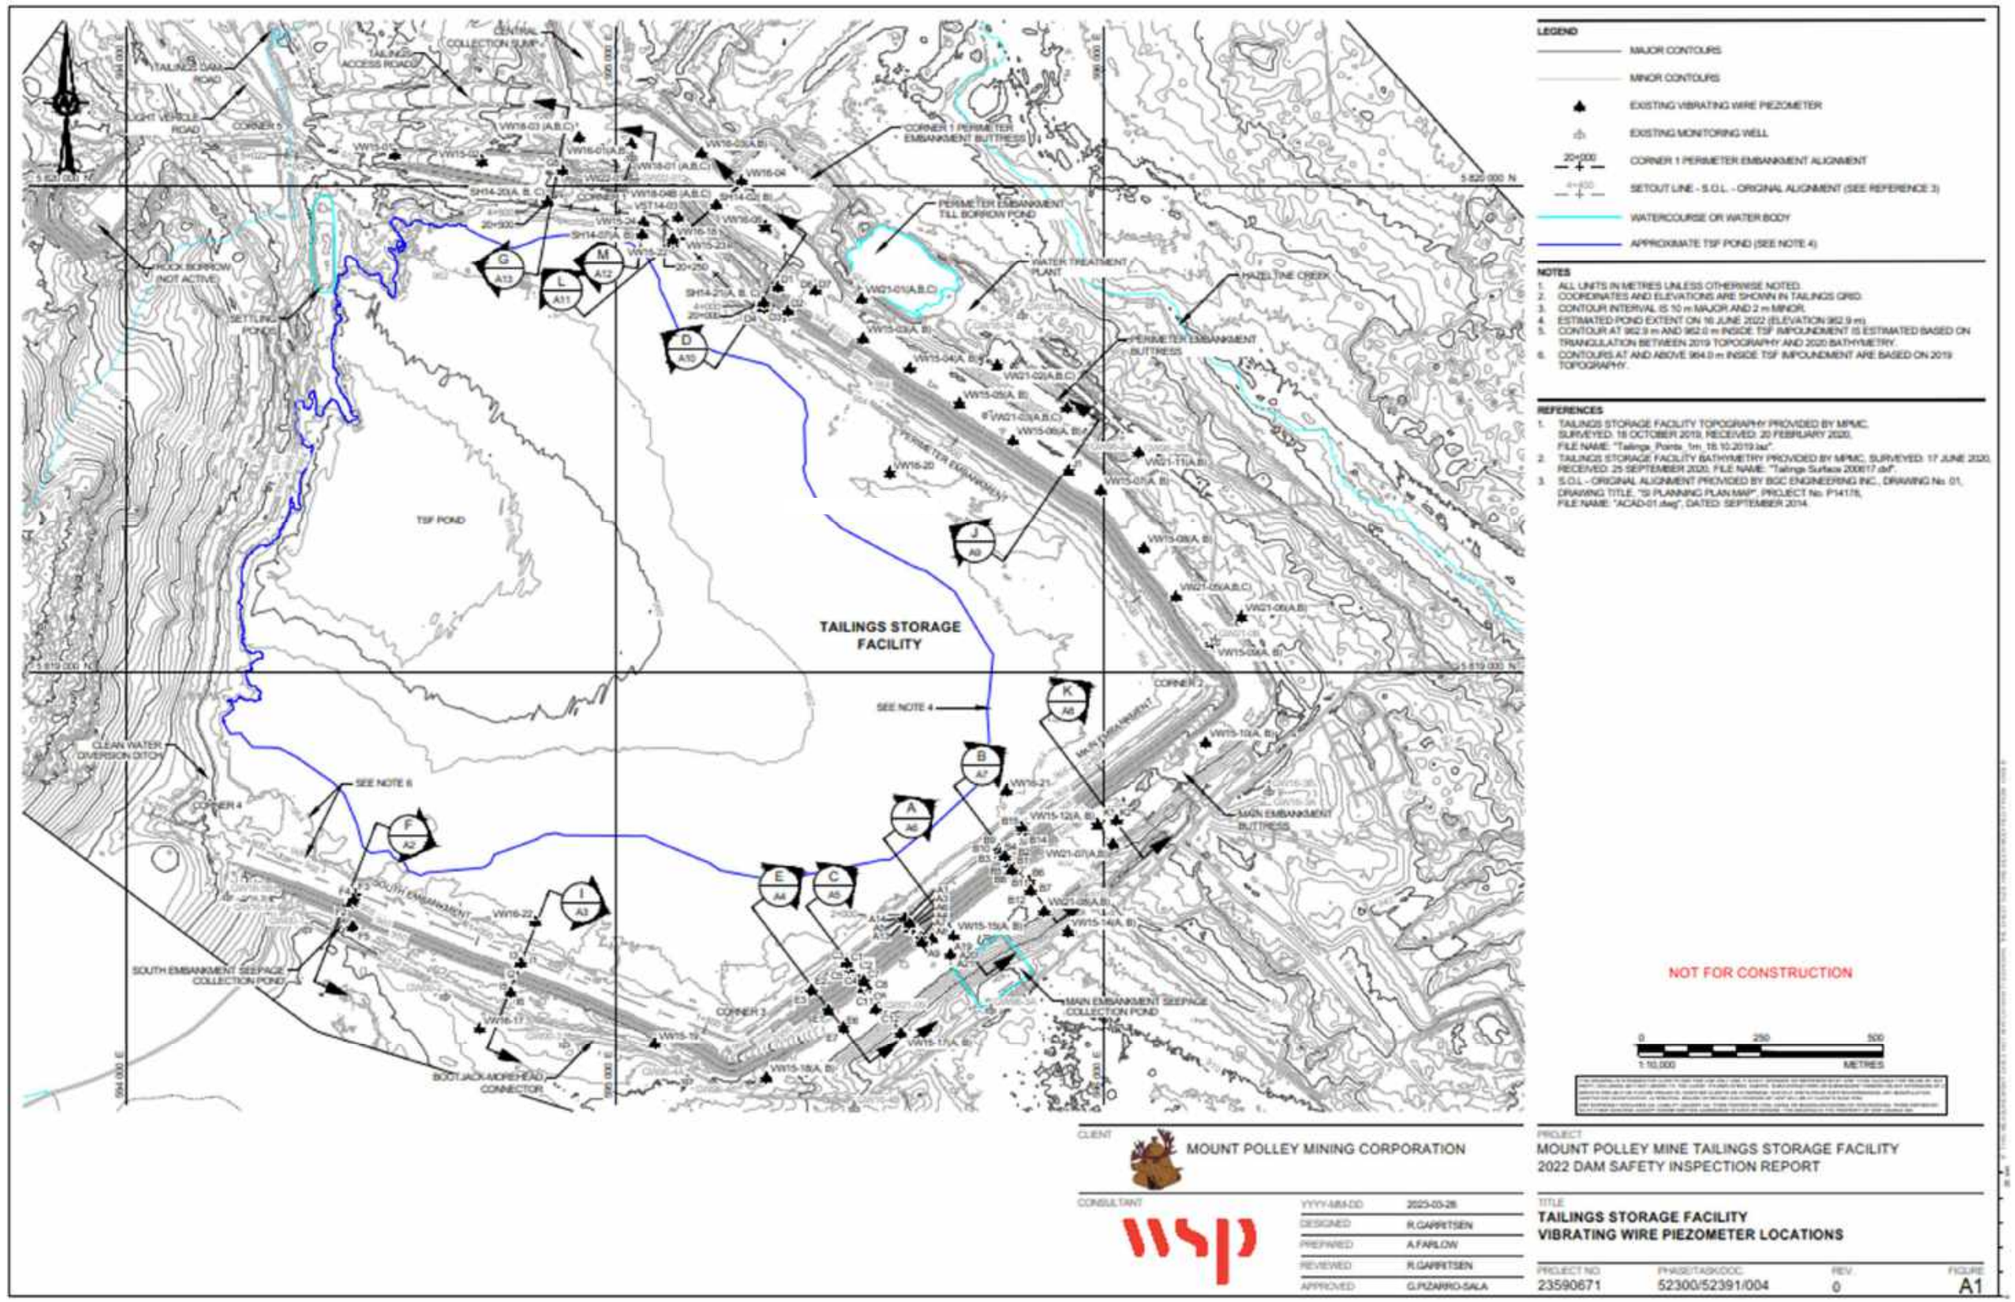

Figure 9.3Vibrating Wire Piezometer Locations

See the QPO (Appendix I) for specific triggers and response actions for geotechnical instrumentation, beach width and freeboard. The trigger values define four (4) operating zones: Normal Operating Zone, Concern Zone, Buffer Zone, and Unsafe or Out of Compliance Operating Zone. If the trigger levels are exceeded, the instruments are to be re-read immediately. If the initial readings are proven accurate, the EoR is to be contacted. If a change below the trigger level is recorded in multiple instruments in a similar location, the EoR is to be notified immediately. Interpretation of the instrumentation data is performed by the EoR, so the EoR will initiate communication with site related to interpretation of dam performance issues based on the instrumentation data. Communication related to any other issues related to dam performance that are identified on site will be initiated by site personnel to the EoR. If the instrumentation readings are within the Buffer Zone, the EoR and Water and TSF Superintendent are to be contacted immediately.

If the instrumentation readings are within the Unsafe or Out of Compliance Zone, the EoR, Water and TSF Superintendent, and onsite General Manager are to be contacted immediately, and the emergency response actions and notification under the EPRP (and section 11.0 of this document) are to be followed.

9.8.2 Inclinometers

A list of active inclinometers installed is included in Appendix B.

The slope inclinometers are to be read, and the data downloaded, reviewed and submitted to the EoR, once every two weeks. The tops of the inclinometer casings are to be surveyed quarterly, and the survey data supplied to the EoR with the inclinometer readings. The Water and TSF Superintendent is responsible for checking the readings against the QPOs and implementing the associated actions listed in Appendix I when the recorded instrumentation readings exceed the normal operating zone. The EoR shall be responsible for interpreting the data collected. Based on TSF performance, the reading frequency may be increased or decreased and installation of the in-place inclinometer may be required at the sole discretion of the EoR.

See the QPO table (Appendix I) for specific triggers and response actions for inclinometers. Inclinometer instrumentation is operated in accordance with the *Inclinometer Operation Manual* (attached in Appendix C.2).

Inclinometer instrumentation is operated in accordance with the *In-Place Inclinometer Manual* (attached in Appendix C.3).

9.8.3 Vibrating Wire Piezometers

The list of vibrating wire piezometers installed in the foundation can be found in Appendix B.

The piezometers are to be read, recorded, reviewed and submitted to the EoR once every two weeks. The Water and TSF Superintendent is responsible for checking the readings against the

QPOs and implementing the associated actions listed in Appendix I when the recorded instrumentation readings exceed the normal operating zone. The EoR shall be responsible for interpreting the data collected. Based on TSF performance, the reading frequency may be increased or decreased at the sole discretion of the EoR.

Trigger levels and the required follow-up actions for vibrating wire piezometers are listed in the QPO's (Appendix I). The embankment piezometers will fluctuate based on the pond level within the TSF, and will be interpreted by the EoR once every two weeks. Piezometer instrumentation is operated in accordance with the *Piezometer Operation Manual* (attached in Appendix C.4).

9.8.4 Shape Acceleration Arrays (SAA)

The four (4) SAAs installed in the 2015 Freshet Embankment are listed in Appendix B.

The SAAs are to be read by the data-logger daily and the data downloaded, reviewed and submitted to the EoR once every two weeks. The Water and TSF Superintendent is responsible for checking the readings against the QPOs and implementing the associated actions listed in Appendix I when the recorded instrumentation readings exceed the normal operating zone. The EoR shall be responsible for interpreting the data collected. Based on TSF performance, the reading frequency may be increased or decreased at the sole discretion of the EoR.

SAA instrumentation is operated in accordance with the *SAA Operation Manual* (attached in Appendix C.5).

9.8.5 Groundwater Wells

MPMC has a *QA/QC Manual* (Appendix H), which is required under *EMA* Permit 11678. This manual was last updated in November 2020 for the annual review. This manual includes a Groundwater Well Standard Operating Procedure and Groundwater Well Work Method for the operation of groundwater wells at Mount Polley Mine; both are included for reference in Appendix H.

Wells are used to collect information for both environmental and embankment performance monitoring. Any wells sampled for environmental reasons shall do so under their respective requirements and procedures. Information gathered for the purposes of embankment performance monitoring will be sent to the EoR for analysis.

10.0 DOCUMENTATION

10.1 Annual Dam Safety Inspection (DSI)

Annual inspections of the TSF and associated facilities are required to evaluate the current performance of the TSF and to observe potential deficiencies in its condition, performance and/or operation. The Water and TSF Superintendent is responsible for arranging the inspections. This

level of dam safety evaluation should be based on detailed observations made by the EoR on site and the relevant information on the TSF operations collected by site personnel. Additional reviews may be required also as a follow up to the report of an unusual event or observation.

The EoR will evaluate the safety of the TSF and incorporate a routine review of the following:

- The consequence classification of the dam;
- The OMS Manual;
- The availability of all documents pertaining to dam safety on site;
- The site surveillance practice; and
- Changes in relevant regulatory requirements since the last inspection.

The EoR will issue an annual inspection report after completing the review. The report will be prepared in accordance with the EMLI *Guidelines for Annual Dam Safety Inspection Reports*. The report will include the following:

- Conclusions on the status of the TSF;
- Statements indicating completion of recommendations from previous inspections and reviews; and

Recommendations, setting priorities and a timeline for completion, if necessary.The Mount Polley General Manager and the EMLI should review each annual inspection report. The report shall be submitted to the EMLI Chief Inspector by March 31 of the following year. Copies of the reports should be made available on site and are available in the office of the EoR. The Mount Polley General Manager will ensure that an appropriate action plan is prepared and executed to ensure that all recommendations made in the annual inspection report are followed. This action plan shall be documented within the General Managers Summary Report which is submitted to EMLI before March 31 annually.

10.2 Independent Engineering Review Panel (IERP)

An independent engineering review panel (IERP) has been established to provide expert technical guidance related to all aspects of the design, construction, operation and closure planning for the TSF.

The IERP comprises at least three (3) qualified experts, and shall meet at a minimum annually. The objectives of the IERP are to confirm that the design and operation of the TSF is consistent with industry standards of best practice, to identify areas where risk reduction measures may be required and to provide advice that may add value to the safe operation, closure and long-term maintenance of the TSF.

A report prepared by the IERP shall be submitted to the Mount Polley General Manager within one (1) month of completion of a review meeting. The Mount Polley General Manager shall

provide a summary of IERP activities and recommendations to the EMLI Chief Inspector on an annual basis.

10.3 Dam Safety Review

The principle objective of a Dam Safety Review (DSR) is to ascertain that a dam has an adequate margin of safety, based on the current engineering practice and updated design input data. A DSR may also be carried out to address a specific problem. The 2022 DSR was finalized and recommendations and action plans are tracked.

A qualified engineer will be responsible for conducting each DSR at the TSF. The engineer conducting the DSR must be qualified to conduct safety evaluations and be familiar with the designs and other site-specific conditions and requirements pertaining to operations of the impoundment and associated facilities; but ideally should not have been involved in the design, construction or operation of the TSF.

Routine DSRs at the TSF will be scheduled, confirmed or revised at the time of each annual inspection. As required under the *Mines Act* Permit M-200; a DSR for the TSF was completed in April, 2017 and 2022.

A detailed scope of work for each DSR will be defined by the engineer prior to conducting the review and will be consistent with current engineering practice at the time it is conducted. Each DSR will evaluate the safety of the TSF and incorporate a detailed review of the following:

- The consequences classification of the dam;
- The adequacy of past annual inspection practice, the annual inspection recommendations, and their implementation;
- The OMS Manual; and
- Timing for the next regular DSR.

Each DSR report should include conclusions and, if necessary, recommendations pertaining to the safety of the TSF. Copies of the DSR will be sent to the Mount Polley Mine General Manager and the EMLI for review. Similar to the annual inspection report, an action plan should be prepared by the Mount Polley General Manager to address any DSR recommendations. A copy of each DSR will be sent to the EMLI and will also be available at the site and at the office of the EoR.

10.4 Construction Records (As-built) Report

At the end of each year's construction activities, the EoR shall prepare a construction record report of the activities. The report will document the extent of the construction activities, QA/QC results, and modifications to the design, which have occurred. It will also comment on whether construction was completed to the nature of the design, and, if not, detail all required works to

ensure that embankment safety shall be maintained. The report is due by March 31 of the year following construction.

11.0 EMERGENCY PROCEDURES

All operation of water management structures as outlined in this OMS Manual, including that relating to emergency procedures, is completed in accordance with regulatory requirements, company policies and sound operating practices, encompassing all significant aspects of, and activities for, the economical, safe and environmentally responsible storage of tailings and management of water. Additionally, there are two (2) documents, independent to the OMS Manual that specifically address emergency response: the TSF-specific *Emergency Preparedness and Response Plan* (EPRP) and the Mount Polley Mine Site *Emergency Response Plan* (ERP). The TSF *EPRP* is included in Appendix E for reference.

The *EPRP* enables MPMC to identify emergency and hazardous conditions threatening the TSF, expedite effective response actions to prevent failure, and reduce loss of life and property damage should failure occur. The *EPRP* provides TSF-specific guidance to complement the Mount Polley Mine Site *ERP*.

EMLI has outlined the definition of a Reportable Incident shown below in **Error! Reference source not found.**. Section 1.7.1 (2)(c) of the HSRC is specific to the Tailings Dam Facilities.

Reportable Incidents

Reportable Incidents

1.7.1 (1) The following incidents are classified as dangerous occurrences and must be reported in accordance with section 1.7.2:

(a) an incident that causes serious injury or loss of life;

(b) an incident that had the potential to cause serious injury or loss of life.

(2) In addition to an incident referred to in subsection (1), the following incidents are classified as dangerous occurrences and must be reported in accordance with section 1.7.2:

(a) unexpected major groundfall, slope failure or subsidence;

(b) unexpected structural failure or collapse of any part of the mine;

(c) for dams or dikes:

(i) unexpected cracking, subsidence, seepage, springs;

(ii) loss of freeboard;

(iii) washout, structural erosion, or any other deficiency that may adversely affect the integrity of the structure.

Figure 11.1 – 2022 HSRC Reportable Incidents

In the event of a Reportable Incident, the TSF QP or designate will notify EMLI. HSRC Section 1.7.2 outlines the requirements of this notification

Notification of a Reportable Incident

1.7.2 (1) In the event of a reportable incident, the manager must

(a) in the case of a reportable incident referred to in section 1.7.1. (1) (a), within 4 hours of the reportable incident, provide a verbal notification of the incident to an inspector, the management co-chair and the worker co-chair of the OHS committee or their designates and the local union,

(b) within 16 hours of a reportable incident, provide a written notice of the incident to an inspector, the management co-chair and the worker co-chair of the OHS committee or their designates and the local union, and

(c) within 60 days of a reportable incident, or within any longer time that may be specified by the chief inspector, submit the investigation report required under section 1.7.4 (2) to the chief inspector.

(2) The manager must engage with First Nations that may be affected by reportable incidents to determine which reportable incidents must be reported to the First Nations.

Figure 11.2 2022 HSRC Reportable Incident Notification

In the event that MPMC is unable to comply with any of the terms and conditions of the *Mines Act* Permit M-200 regarding the TSF, due to any cause, MPMC will:

- Immediately notify the EMLI of the failure to comply;
- Immediately take action to stop, contain, and/or clean up unauthorized discharges or otherwise stop the non-compliance, correct the problem, and if applicable, repeat sampling and analysis of any non-compliance immediately; and,
- The report will contain a description of the non-compliance, including dates and times, if the non-compliance has not been corrected, the anticipated time it is expected to continue, and the steps taken or planned to reduce, eliminate, and prevent reoccurrence of the non-compliance.

11.1 Warning Signs

There are three status levels (or warning signs) which can be assigned to observations or conditions noted with respect to the TSF and other water management facilities. Certain triggers for the TSF, as listed within the QPO tables, (Appendix I), already contain stated actions, which shall be the

default reaction to such an occurrence since they refer to very specific criteria. However, the responses listed in the QPO's are very specific, and these and other observations and conditions should also be incorporated into the site EPRP, which defines and describes the general response to varying degrees of emergency condition, as follows:

Level 1 - Condition

Unusual conditions that do not yet represent a potential emergency, but do require prompt investigation and resolution.

The action in the event of a Level 1 Condition will typically involve an investigation, intensified monitoring, inspecting and/or testing, and defining and implementing possible corrective measures. The trigger levels, which elicit a description of "Concern Zone" within the QPO table, would be described as Level 1 within the EPRP guidelines.

Construction equipment will be available at the Mount Polley Mine Site and include, but not be limited to: excavator(s), grader(s), haul truck(s) and bulldozer(s). Construction materials will be available at the TSF and around the Mine Site for use in repairing or remediation of any damaged areas.

The notification procedures are as follows:

- The person first noticing a Level 1 Condition shall notify the Mine Operations Superintendent and the Water and TSF Superintendent and initiate corrective actions and intensified monitoring.
- The Water and TSF Superintendent shall notify the General Manager and the EoR as appropriate.

Level 2 – Condition

Conditions that represent a potential emergency, if sustained or allowed to progress, but no emergency is imminent.

The first action in the event of a Level 2 Condition is to discuss and define an action plan, at the site, under the direction of the Water and TSF Superintendent. The trigger levels which elicit a description of "Buffer Zone" or "Unsafe or Out of Compliance Operating Zone" within the QPO table would be described as Level 2 within the EPRP guidelines. A more complete understanding of the full condition and consultation with the EoR may upgrade any of these triggers to Level 3.

In many cases, this will also involve contacting, and discussing the event with the EoR. After such a plan is prepared, it must be presented to the Mount Polley General Manager for approval. Construction equipment should be made available, if required, at short notice.

The notification procedures are as follows:

- The person first noticing a Level 2 Condition shall notify the Mine Operations Superintendent and the Water and TSF Superintendent. Initiate corrective actions and/or intensified monitoring as appropriate.
- The Water and TSF Superintendent shall notify the Mount Polley General Manager and the EoR as appropriate.
- Buffer Zone and Unsafe or Out of Compliance Operating Zone will trigger a Reportable Incident Notification to EMLI

Level 3 - Condition

An emergency defined by either failure of a significant component of the TSF and/or associated facility or a significant failure of the performance of a component of the TSF. Such failure may have already occurred, or be imminent.

The first actions in the event of any Level 3 (Emergency) Condition are:

- Check that all persons who could possibly be affected are safe; and
- Initiate the appropriate chain of communications.
- If not done so already, a Reportable Incident Notification must be submitted to EMLI

The person who initiated the communication should then stand by at a safe location near the problem area and await further instructions or decisions. All those involved in emergency response, after first having communicated with the appropriate parties, should consider two (2) types of actions as first steps in the emergency response, with respect to the protection of human life and health, environment and property:

- What can be done to prevent the situation from worsening?
- What can be done to reduce the consequences of the impending or actual failure?

Any such action must be presented to the Water and TSF Superintendent, who will refer the action to the Mount Polley General Manager and the EoR, who collectively will decide on its implementation in consultation with the EMLI.

The notification procedure for a Level 3 (Emergency) Condition is as follows:

- The person noticing a Level 3 (Emergency) Condition shall notify the Mine Operations Superintendent, who will inform the Water and TSF Superintendent and the Mount Polley

General Manager. Corrective actions and/or intensified monitoring are to be initiated, as appropriate.

- The Water and TSF Superintendent will contact the EoR.
- The Mount Polley General Manager shall notify the Corporate (Vancouver) office and the EMLI.

In the event of an emergency that will result in an actual or potentially imminent embankment failure, or unplanned release of water to the environment, the Mount Polley Mine General Manager shall also notify the BC-ENV, and Emergency Management BC.

Names and telephone numbers for the key contacts are given in Table 2-1..

Certification of This Manual

This manual was produced onsite and is intended to provide full guidance with respect to the Operation, Maintenance, and Surveillance of the TSF as well as the Site Water Management Infrastructure. It is a live document in the sense that it shall be kept up to date to reflect the most current conditions and shall be re-distributed in part or whole if it deemed necessary to maintain a safe, operable site.

The Master Hardcopy shall be kept onsite in the Water and TSF Superintendent's Office. Digital Copies of this Manual, in its entirety, shall be kept in the Environmental partition of the Mount Polley Server. Digital copies of the reference documents listed in Table 6.1 shall also be kept in the same folder.

The Water and TSF Superintendent as well as the General Manager shall sign the Master Hardcopy. All other copies are reproductions only.

The Manual is valid until March, 2022

APPENDIX 4-1B: Geochemistry of Tailings from the Mount Polley Mine, British Columbia

Geochemistry of tailings from the Mount Polley Mine, British Columbia

C.B. Kennedy & S.J. Day
SRK Consulting (Canada) Inc., Vancouver, BC, Canada

C.D. Anglin
Imperial Metals Corp., Vancouver, BC, Canada

To support remedial decisions for the Tailings Storage Facility breach at the Mount Polley Mine (MPM), a geochemical characterization program assessing the metal leaching and acid rock drainage potential of the tailings and other materials released into Polley Lake, Hazeltine Creek, and Quesnel Lake was performed. Because the tailings and other materials settled under subaerial conditions along the banks of Hazeltine Creek and in subaqueous conditions in Polley and Quesnel Lakes, the geochemical characterization assessed reactivity in both terrestrial and aquatic environments. Tailings and other materials deposited in these areas were found to be consistently non-acid generating indicating that weathering conditions are expected to be pH-basic under all depositional conditions. Leaching potential of tailings in subaerial environments was low and the potential for oxidative and reductive dissolution under deep water conditions was found to be negligible. Sub-aerial copper leaching is likely controlled by mineral solubility, which will limit loadings to the environment and can be used to inform remedial decisions.

1 INTRODUCTION

A failure of a glacial lacustrine layer beneath the Perimeter Embankment of the Tailings Storage Facility at the Mount Polley Mine (MPM), British Columbia caused a breach of the embankment tailings dam on August 4, 2014 (IEEIRP, 2015). The dam breach resulted in a release of tailings and other materials into Polley Lake, Hazeltine Creek, and Quesnel Lake. As part of remediation planning, a geochemical characterization program assessed the metal leaching and acid rock drainage (ML/ARD) potential of the spilled tailings and other materials and this paper presents the key findings from the investigation.

2 BACKGROUND

2.1 *Geological Setting*

The Mount Polley deposit is classified as an alkalic porphyry copper gold deposit (BC MINFILE No. 093A 008). The host rocks for porphyry mineralization are intrusions into the Nicola Volcanics varying in composition from diorite to syenite. Alteration is potassic (secondary biotite and pink orthoclase) and propylitic (calcite-epidote-chlorite-pyrite). Sulphide mineralization consists mainly of chalcopyrite ($CuFeS_2$) and pyrite (FeS_2), with lesser bornite (Cu_5FeS_4), covellite (CuS), and digenite (Cu_9S_5). Carbonate mineralization is principally calcite, with occurrences of malachite ($Cu_2CO_3(OH)_2$); iron carbonates have not been reported.

A significant portion of the copper at the MPM is not associated with sulphides (upwards of

50% in the upper portions of each pit) and has been historically been termed copper-oxide, although this includes both silicate hosted copper (e.g., chlorite) and copper carbonates like malachite (Taplin 2002).

2.2 *Ore Processing and Tailings Deposition*

Processing of ore mined from the Mount Polley yields a copper sulphide concentrate. In general terms, the concentrate is produced by blasting the ore and then hauling it to the processing plant, where it undergoes three stages of crushing, and three stages of grinding, followed by rougher and cleaner flotation to produce a copper concentrate. The flotation circuit concentrates sulphide minerals as they are hydrophobic. Following the removal of the copper sulphide minerals by flotation, the remainder of the slurry is disposed of as tailings. The tailings are lower in sulphide mineral content compared to the ore as majority of the copper sulphides have been removed.

Mill process reagents, with the exception of lime, are not expected to be present with the tailings and other materials deposited as they would either have remained with the concentrate (chemically bound to mineral surfaces) or degraded quickly in the environment. Life-of-mine processing changes were minimal and not expected to affect the geochemical reactivity of the tailings. As a result, the tailings geochemistry can be considered in aggregate.

Tailings slurry produced in the mill is gravity-fed to the TSF with deposition by single-point discharge. The single point discharge was often directed to cells, where bulldozers and weirs were used to separate the coarser fraction of the tailing from the finer fractions and build up sand adjacent to the embankments. The discharge point was sequentially rotated along the entire length of the three embankments (i.e. the Perimeter, Main, and South Embankments). The tailings produced during operations would have been well mixed and there appears to have been limited potential to create anomalous geochemistry zones that could have spilled after the dam breach.

3 CONCEPTUAL MODEL AND STUDY DESIGN

An initial geochemical conceptual model (IGCM) was formulated to guide the design of the characterization approach for the tailings and other materials deposited, which effectively represents hypotheses about tailings characteristics and reactivity that are subsequently evaluated through observations, sampling, testwork, and interpretation.

Complete details of the IGCM are provided in SRK (2015) and indicated that two main configurations of the tailings and other materials deposited needed to be evaluated. First, subaerial tailings along the banks of Hazeltine Creek would be susceptible to oxidation of sulphides due to exposure to atmospheric oxygen. Second, subaqueous tailings on the bottom of Polley Lake and Quesnel Lake would be much less reactive in terms of sulphide oxidation due low or oxygen free water but could facilitate dissolution of secondary minerals (i.e. iron hydroxides).

4 CHARACTERIZATION METHODS

4.1 *Overview*

Geochemical characterization of the tailings and other materials deposited consisted of field sampling along Hazeltine Creek and a series of geochemical tests to understand the composition, mineralogy and leaching characteristics under various storage configurations. SRK focused on the tailings and other materials deposited along Hazeltine Creek because weathering under sub-aerial conditions should represent the most likely scenario for leaching based on the IGCM. In addition, sampling by another consulting group (Minnow Environmental) included tailings and other materials deposited that settled in Polley and Quesnel Lakes. Between the historical data for the site, and two independent sampling campaigns, the assumption was that geochemical variability would be characterized. Complete details of field sampling and analytical

methods are provided in SRK (2015) and the following section provides key aspects of the methods used as part of the ML/ARD characterization program.

4.2 *Hazeltine Creek Sampling*

Samples of exposed tailings and other materials deposited in Hazeltine Creek were collected along 18 parallel transects, oriented roughly perpendicular to the course of Hazeltine Creek. The transects were spaced approximately 500 m apart beginning with transect ST17/18 in the area of the dam breach and ending with transect ST01 near the mouth of Hazeltine Creek at Quesnel Lake (Figure 4-1).

At each transect, major physical/depositional features were sampled, with up to five samples per transect. Physical/depositional features were determined in the field based on particle size (fine grained versus coarse), colour, or depositional area (e.g. high on a bank or shoulder versus adjacent to the creek). In total, 68 samples containing tailings and other materials deposited were collected. Approximately 10% of samples were collected as field duplicates and silica sand samples were included as field blanks.

Figure 4-1: Location of Hazeltine Creek Sampling Locations (SNC-Lavalin, 2015).

A total of 78 additional samples were collected from the study area for sequential extraction analyses by Minnow Environmental between August 13 and October 24, 2014. Specific details of the sample collection procedures and locations are provided in Minnow (2015). Of the samples collected, 18 were from the profundal zone in Quesnel Lake (6 lake sediment samples and 12 tailings and other materials deposited), 18 were from the littoral zone in Quesnel Lake (2 lake sediment samples and 16 tailings and other materials deposited), and 15 were tailings and other materials deposited from along Hazeltine Creek. Fifteen samples from the bottom of Polley Lake were also collected.

4.3 *Laboratory Analyses*

4.3.1 *Acid-Base Accounting and Trace Element Composition*

A two-phase testing approach was used for geochemical characterization in order to constrain composition variability and understand specific acid-base accounting (ABA) and mineralogical characteristics of the Hazeltine Creek samples.

Phase one testing included moisture content, multi-element analysis, including sulphur content by aqua regia digestion with an inductively coupled plasma mass spectrometry (ICP-MS) finish, total inorganic carbon (TIC), and particle size distribution by sieving.

Phase two testing was conducted on 25% of the samples, which were selected to capture the range of sulphur, TIC, copper, and selenium content in the Hazeltine Creek samples based on the results of the phase 1 analyses. Testing included paste pH and conductivity, modified Sobek Neutralization Potential determination (MEND 1991), total sulphur (by LECO furnace) and sulphate sulphur (by hydrochloric acid (HCl) leach). A non-sulphide copper analysis was also conducted by leaching sampled using 2.5% sulphuric acid with the filtered leachate submitted for ICP-MS multi-element scans.

4.3.2 *Mineralogical Characterization*

Mineralogical characterization using Quantitative Evaluation of Minerals by Scanning Electron Microscopy (QEMSCAN) was conducted on splits from all of the kinetic test program samples (see Section 4.3.4). Rietveld X-ray diffraction (XRD) and electron microprobe were selectively used to refine and confirm modal abundances, mineral form (e.g. the different iron oxides present) and element deportment for low concentrations that could not be resolved by QEMSCAN.

4.3.3 *Sequential Extractions*

Sequential extractions involve a progressive series of chemical extractions applied to the same sample in order to partition the total element content into geochemical 'fractions'. The sequential extractions conducted for the tailings were designed and directed by Minnow Environmental (Minnow 2015) and based on Tessier et al.'s (1979) procedure with modifications. However, the procedure is designed for soils, and as a result, some of the reagents used would likely target different mineral fractions in tailings than they would in soils. The most significant deviation included the 'organically bound' elements as there are expected to be limited amounts of organic materials in the tailings and the reagents (nitric acid, hydrogen peroxide) and temperatures (85°C) used likely oxidized some of the sulphide and may also leach more resistant oxide minerals. Tessier et al. (1979) also noted some alteration of the minerals smectite, chlorite and mica in this digestion step and these minerals are present in the MPM tailings.

4.3.4 *Kinetic Testing*

The kinetic testing program consists of six standard laboratory humidity cells (MEND, 1991) (labelled HCs 1 - 6), three column leach tests (COLS 1 – 3), two blanks (a HC and a column), and one HC duplicate. The intent of the kinetic testing program was to establish weathering rates under oxygen unlimited conditions using humidity cell testing and then use column tests to evaluate the effect of longer flow paths and lower water to solids ratios that were more similar to the field than dilute HC tests.

A range of tailings samples containing mean and upper 95th percentile materials for copper, selenium and sulphur were selected. Columns tests consisted of between 1.5 and 4.5 kg of material that were splits from the humidity cells (i.e. HC-1 = COL-1) and were leached with between 150 and 500 mL of water in a week, respectively. All kinetic tests were flushed weekly with leachate analysed for anions, major cations and trace elements needed for the province of British Columbia water quality assessments.

5 RESULTS

5.1 *Hazeltine Creek Field Sampling*

Two types of tailings-bearing samples were observed along Hazeltine Creek. They were classified in the field as 'grey tailings' and 'magnetite sands' based on physical and mineralogical characteristics. The grey tailings were silty-sand sized particles, and reacted strongly to HCl fizz test in the field. The magnetite sands samples were pinkish-orange, had a moderate to weak fizz reaction and were strongly magnetic.

The grey tailings tended to be most abundant along the embankments and upper benches of the creek, whereas the magnetite sands were commonly present in low-lying areas near the creek. With the exception of the area near the tailings dam breach and Polley Lake, the tailings were deposited in relatively thin 'skiffs' (e.g. 10 to 20 cm deep). The thickest observed subaerial tailings deposits (e.g. 1 to 1.5 m deep) were in the immediate vicinity of the tailings dam breach and Polley Lake (SNC-Lavalin 2015).

5.2 *Laboratory Analyses*

5.2.1 *Acid Base Accounting*

The form of sulphur was found to be sulphide, with sulphate typically below detection. Sulphide sulphur from ICP-MS was used for calculating acid-potential (AP). Neutralization potential (NP) by titration was found to be overestimated and carbonate by TIC was used to estimated NP for acid-base account calculations (SRK 2015). Iron carbonates, which can also overestimate carbonate NP, have not been identified at MPM.

Consistent with expectations from operational sampling (data provided by MPMC to BC Ministry of Environment (MoE) http://www.env.gov.bc.ca/eemp/incidents/ 2014/mount-polley.htm), the tailings and other materials deposited were found to all be non-ARD generating (Figure 5-1).

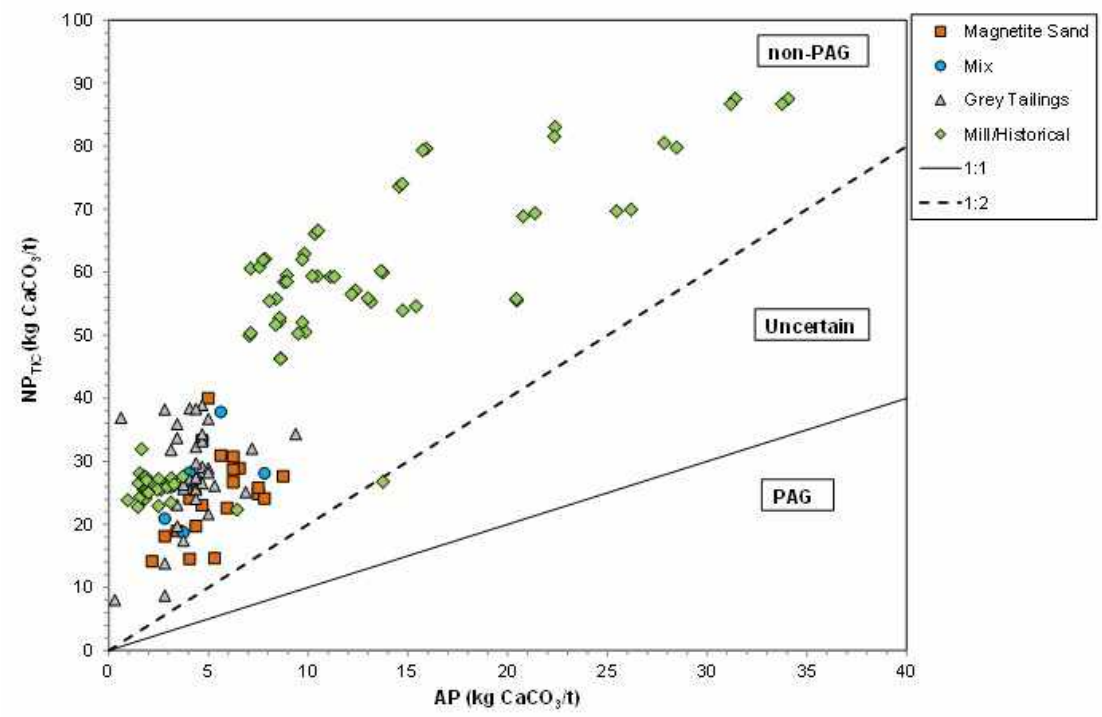

Figure 5-1: Comparison of tailings and other materials deposited and MPM mill/historical tailings.

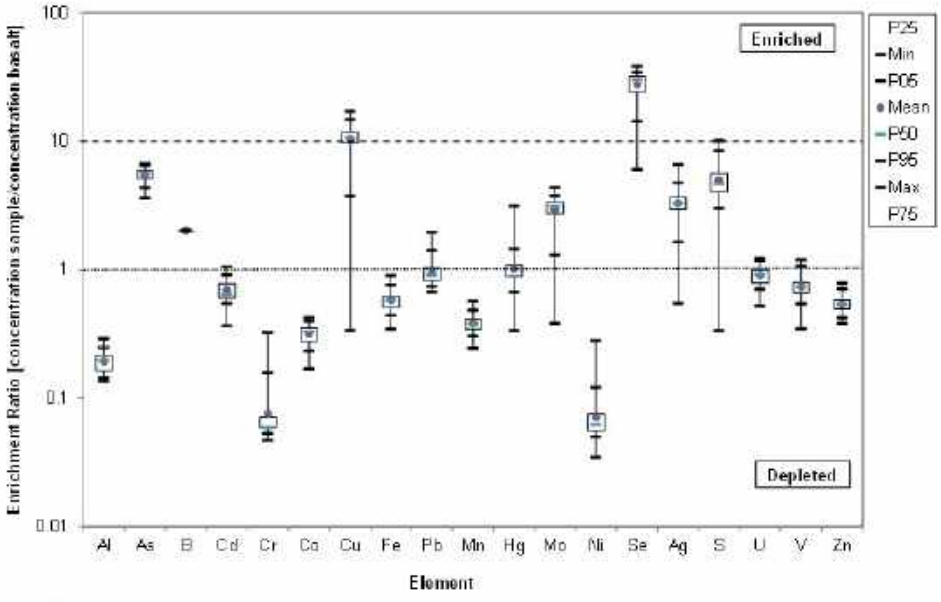
5.2.2 *Trace Element Occurrence*

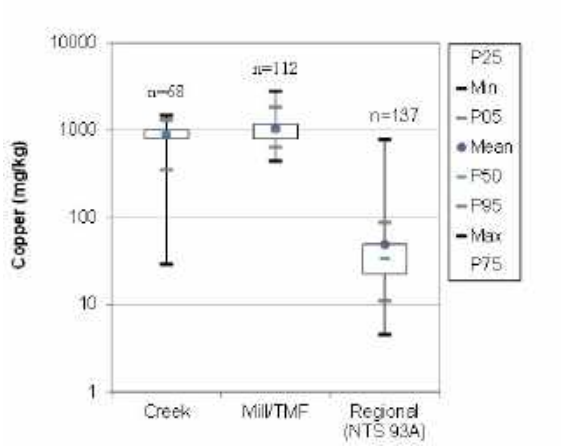
Complete analytical composition results for all samples from a 35 element scan are provided in SRK (2015). A statistical summary and shortened list of element concentrations that have guidelines for the protection of freshwater aquatic life in British Columbia is provided in (Table 5-1).

Table 5-1: Statistical summary of selected trace elements in MP tailings and other materials deposited.

Statistic	As mg/kg	Cu mg/kg	Pb mg/kg	Hg mg/kg	Mo mg/kg	Se mg/kg	V mg/kg	Zn mg/kg
Min	7.2	29	4.0	0.03	0.57	0.3	86	40
P5	8.7	360	4.4	0.06	1.9	0.74	120	45
P25	10	800	4.9	0.08	3.9	1.2	160	52
Mean	11	880	5.7	0.091	4.3	1.4	180	57
Median	11	910	5.4	0.08	4.6	1.5	180	56
P75	12	990	6.0	0.10	5.0	1.6	200	61
P95	13	1300	8.5	0.13	5.5	1.8	250	74
Max	13	1500	12	0.28	6.5	1.9	300	82

To provide an indication of trace element enrichment in the tailings and other materials deposited samples, concentrations were compared to typical global average concentrations for basalt (Price 1997). This comparison approach is a standard element leaching screening practice as outlined by MEND (2009). Concentrations present at more than an order-of-magnitude above global average values were considered enriched for the purpose of screening and enrichment ratios are shown in Figure 5-2. The ratios were calculated by dividing the concentration of copper (for example) in the sample by the typical concentration of copper in basalt. Ratios greater than 10 are considered enriched. Ratios less than one indicate lower concentrations in the Hazeltine Creek samples than in average basalt. 'Box and whisker' plots were used to illustrate the results, with the boxes representing the 25th to 75th percentile ranges. The solid horizontal line represents equivalence with typical basalt, whereas the dashed line represents ten times the concentration of basalt.





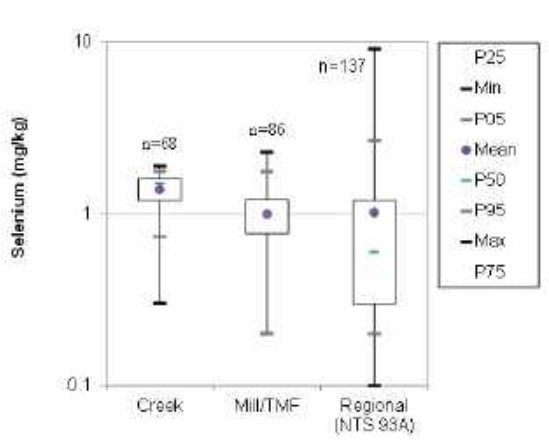


Figure 5-2: Element enrichment assessment for Hazeltine Creek tailings samples.

Based on the enrichment screening method of MEND (2009), copper and selenium are considered to be enriched in the tailings. However, the average concentration of selenium in operational tailings from within the TSF is lower (1.1 mg/kg) than the spilled materials and similar to the average of 137 regional stream sediment samples from the region surrounding Mount Polley (average 1.0 ppm, range 0.1 to 9.1 ppm)(GSC 1981; Jackman 2008)(Figure 5-3).

(A)

(B)

Figure 5-3: Comparison of copper (A) and selenium (B) concentrations in Hazeltine Creek tailings and other materials deposited, operational mill tailings and regional sediments.

5.2.3 *Mineralogy*

The samples are dominated by silicates, including feldspars, chlorite and quartz. Iron oxides (mainly magnetite) were frequently the next most abundant minerals after the silicates, followed by carbonates and the minor amounts of sulphides. The presence of quartz at concentrations greater than 1% is a good indication that the tailings are intermixed with native sediments as the deposit is syenitic to monzonitic and the tailings should contain very little to no quartz (BC MINFILE No. 093A 008).

Sulphide mineralogy is consistent with the ore mineralogy previously described for the project, including pyrite and chalcopyrite as the two main sulphide minerals in approximately equal proportions (approximately 0.2% for each mineral), followed by bornite (less than 0.1%) and other copper sulphides (likely covellite).

The main carbonate present was calcite, ranging from 0.7% to 4.5%. Dolomite was also present, although typically less than 0.1% with the exception of one sample (HC-4) at 0.4%. Malachite was also present, although at near detection levels.

Copper and selenium deportment was investigated, however, the concentration of selenium was too low to be detected by QEMSCAN or electron microprobe and only copper results are available. Chalcopyrite contained approximately half of the copper when total copper concentrations were above 0.05%. Chlorite was the next most abundant mineral to host copper, followed by bornite and covellite/chalcocite.

The deportment in chlorite was unexpected as previous investigations have indicated that chrysocolla was the non-sulphide mineral phase hosting copper. However, other studies have also noted the same finding (Chanquıa et al, 2010) and the overall implication is likely insignificant in terms of reactivity as previous work by MPMC has shown copper in the non-sulphide phase extremely resistant to leaching by acidic solutions (Taplin 2002; Henry 2009). Results from the non-sulphide copper leach also support these findings with an average of 50% of the copper in a non-sulphide phase. Given the recalcitrant nature of this copper mineral phase, it is also considered a much less reactive phase compared to copper sulphides.

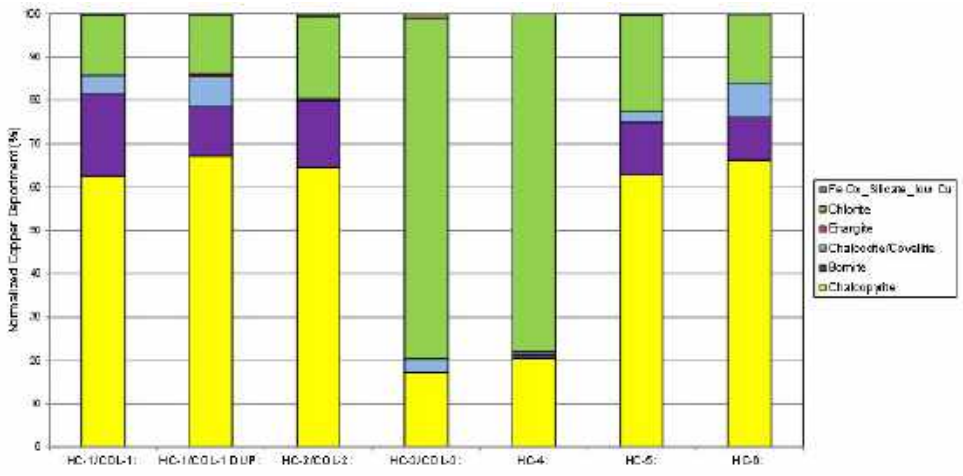

Figure 5-4: Mineral deportment of copper in Hazeltine Creek tailings and other materials deposited samples.

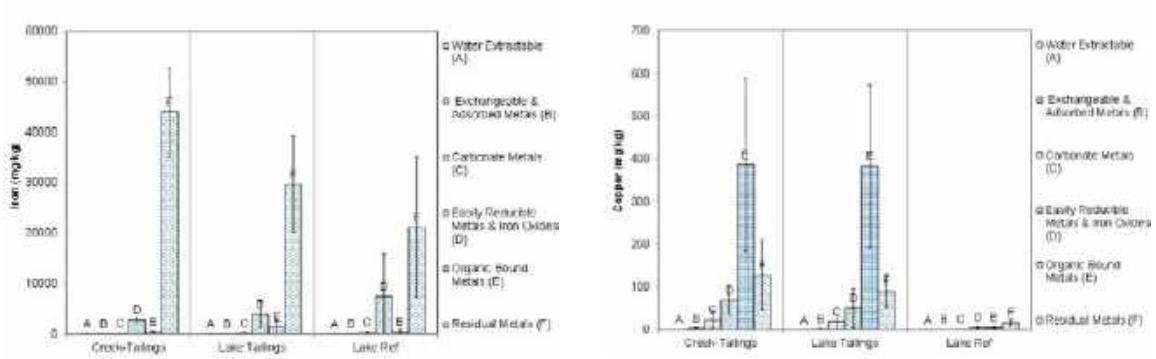
5.2.4 *Sequential Extraction Results*



Results from the extractions were grouped together to represent tailings and other materials deposited from Hazeltine Creek, from the bottom of Quesnel and Polley Lake, and also lake sediments that were not impacted by the tailings discharge (i.e. a background lake reference). Iron and copper are shown in

Figure 5-5. Iron is not considered enriched the tailings, but is often associated with minerals that are susceptible to dissolution under sub-oxic conditions.

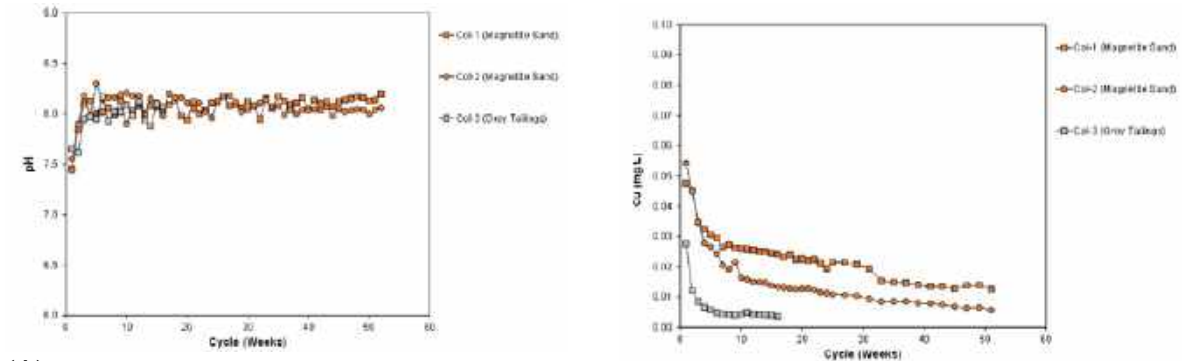
Iron was predominantly associated with the 'residual metals' fraction (e.g. 85% of total iron extracted in lake tailings) in all samples tested, which is likely comprised of mainly sulphides due to the use of an aqua regia digest as the final step. Magnetite was not likely dissolved in any of the sequential extraction steps. Only a small portion of the iron was present in the reducible fraction (~ 12%) and at lower concentrations than the background lake reference samples.

Copper was mainly associated with the 'organic bound' fraction, although as previously discussed in Section 4.3.3, this is likely partially associated with sulphide minerals and also chlorite due to the reagents and temperatures used in the extraction step (Tessier 1979). Mineralogy results also support this with the deportment of copper partially in chlorite. The 'residual' fraction contained the next highest amount, but also notable for copper was the presence of 4% in the 'carbonate metal', likely reflecting the presence of malachite.

Selenium results (not shown) were predominantly below detection (0.2 mg/kg based on aqueous concentrations in the extractions), with only the 'organic bound' and residual fraction slightly above detection limits.

(A) (B)

Figure 5-5: Sequential extraction results for iron (A) and copper (B).



5.2.5 *Kinetic Testing*

Complete results for all elements regulated by the province of British Columbia are provided in SRK (2015) for both humidity cells and columns. Approximately one year of testing has been completed for this investigation, with testing on-going.

Copper is the focus of results presented below as copper is one of the two elements identified as enriched in the tailings. Sampling by the British Columbia Ministry of Environment (BC MOE) at the Mount Polley Mine has also identified copper as the main element of concern. Copper leaching is strongly pH dependent and therefore pH is also included for discussing long term copper behavior.

Humidity cell results (data not shown) have shown steadily declining rates of copper leaching under pH neutral conditions (pH of 8). Copper is leaching at a rate of 0.002 mg/kg/week, with concentrations around 0.005 mg/L. The columns (which are splits from HC composites) are also pH slightly basic (pH of 8) with a copper leaching rate slightly lower than the humidity cells at 0.001 mg/kg/week with concentrations now around 0.01 mg/L (Figure 5-6). The higher concentrations and lower leaching rate in the columns are interpreted here to reflect a solubility limit being reached, which is discussed in Section 6.1.1.

The lower pH and higher copper concentrations during the start of the kinetic tests are likely a result of the samples being stored in the laboratory for several months before testing began. During this time, the sulphide minerals would still have been oxidizing but the acidity formed could not be neutralized by the available carbonate minerals as there was no flow of water through the sample. As the column test started and water was passed through the tailings, pH increased and copper concentrations decreased.

6 DISCUSSION

6.1 *Leaching Mechanisms*

6.1.1 *Subaerial Weathering of Tailings*

Tailings and other materials deposited are expected to weather under neutral pH conditions. ARD has not been identified as a concern for Mount Polley tailings historically and the results of this program confirm the previous findings that weathering and trace element release will be under neutral pH.

The tailings and other materials deposited and mixed-in sediment materials deposited along the banks of Hazeltine Creek and any other subaerial setting will weather in the presence of oxygen. However, leaching is expected to be slow because sulphides leach at relatively slow rates under neutral to basic pH conditions when compared to acidic conditions, which is typically orders-of-magnitude faster. On-going geochemical testing is supporting this assessment and showing slowly declining copper release rates. Silicates will also weather, but at even slower rates that are dependent on mildly acidic rainwater (the dissolved carbon dioxide equilibrium pH of rainwater is ~5.5). Given the carbonates present in the MPM tailings, mildly acidic rainwater will be neutralized upon contact and leaching of silicates would be slower than could occur by rainwater.

Thermodynamic first principles and the equilibrium modelling software package PHREEQC (version 2.17.4137) (Parkhurst and Appelo, 1999) predicts low solubility of copper at neutral pH as compared to concentrations that are associated with copper porphyry deposits under acidic pH (Day and Rees, 2006). This is because secondary copper oxide minerals (i.e. malachite, tenorite) that would form after oxidative dissolution from a copper sulphide are only sparingly soluble. The prediction of contact water (i.e. tailings seepage) by PHREEQC under aerobic conditions and pH 8 carbonate buffered rainwater is an upper limit of 0.02 mg/L due to copper oxide solubility limits. This is consistent with other copper concentrations measured under neutral pH at the MPM and other copper porphyry sites (Day and Rees, 2006).

Copper concentrations were used to evaluate copper solubility control in water samples from the laboratory and field. The sites included a sampling site in upper Hazeltine Creek downstream of a one kilometre stretch of deposited sub-aerial tailings (referred to as HAC-13), from the column test containing tailings with 95th percentile copper content, and from a ditch collecting seepage from subaerial tailings and other materials deposited after two years since the tailings spill (provided by the BC MOE and MPM). The ditch water is from an area referred to as the Polley Flats, which is just below Polley Lake and one kilometer downstream of where the width of the area of tailings and other materials deposited is narrow (Figure 4-1). Results were plotted against solubility curves generated using PHREEQC for malachite ($Cu_2CO_3(OH)_2$), tenorite (CuO), and copper hydroxides ($Cu(OH)_2$). A saturation index of zero was used for all three secondary copper minerals, but a saturation index of 0.5 was also used for malachite as activation energy barriers often need to be overcome before a mineral can precipitate and this requires a higher degree of saturation. Malachite (as opposed to tenorite or copper hydroxides) was chosen to evaluate the saturation index range as it is the most likely secondary mineral control based on it being commonly identified on site and in the tailings.

The outcome of the comparison is shown in Figure 6-1. There is a good fit of the dissolved copper concentration results to the predicted concentrations based on pH and mineral solubility, especially to malachite with an SI of 0.5. Lower pH values were associated with spring freshet were similar to the initial flush of material in the laboratory kinetic testing program. During the winter (or prolonged dry periods), the majority of tailings are no longer receiving infiltration due to snow and ice cover allowing oxidation products and acidity to accumulate around the sulphide grains in tailings that do not freeze in the winter. Once freshet begins, these oxidation products and acidity will be neutralized and get flushed from the tailings, with pH increasing while copper concentrations decrease.

Selenium was shown to be correlated with copper (SRK 2015) and likely is present as an accessory element in the copper sulphides as this element often replaces sulphur owing to similar

geochemical properties (Ralston et al, 2008; MEND 2015). However, the methods used in this study could not detect selenium co-precipitated with silicate minerals and so selenium release should be conservatively assumed to be associated only with oxidative dissolution of sulphides.

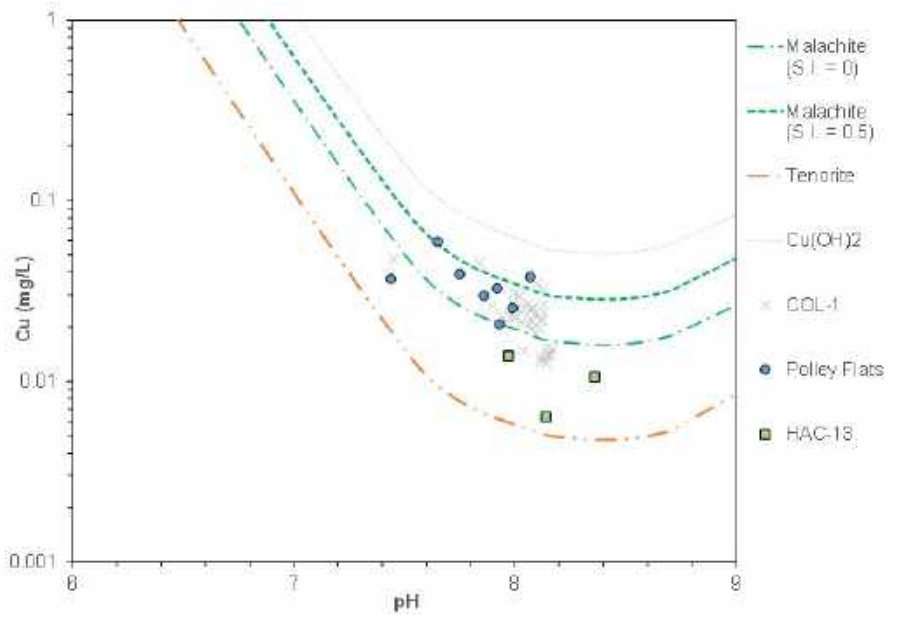

Figure 6-1: Secondary copper mineral solubility curves and monitoring results.

6.1.2 *Subaqueous Dissolution of Tailings*

For any of the tailings and other materials deposited that ended up in Quesnel or Polley Lake, water saturation is the best way to inhibit oxidation of sulphides (INAP 2010). Therefore, leaching of any elements hosted in sulphides (i.e. copper and selenium) that would be released by oxidation is effectively inhibited for tailings present in Quesnel and Polley Lakes.

Based on the results of the mineralogical characterization work and sequential extractions, the risk for mobilization of elements under reducing conditions was found to be low. Easily reducible iron oxides were minor components of the tailings samples tested and neither copper nor selenium were associated with a mineral phase that would be susceptible to reductive dissolution.

It should also be noted that selenium behaves quite differently under reducing conditions and will either sorb to mineral surfaces if it is present as selenite, or precipitate as elemental selenium (Ralston et al, 2008; MEND 2015). In either event, even if selenium was released from reductive dissolution processes, its geochemical behaviour under reducing conditions would result in it being removed from the water column and it is not considered a water quality risk under subaqueous reducing conditions.

6.2 *Reclamation Considerations*

The presence of a secondary mineral control on copper concentrations is an important finding for reclamation planning. This is because any efforts to encourage precipitation run-off and discourage infiltration into the tailings, through either grading or evapotranspiration through soil covers and vegetation growth, will likely result in a decreased loading of copper to the receiving environment. Mineral solubility control will maintain concentrations at a fixed level, so despite unchanging copper concentrations, with less water moving through the tailings, less copper can be transported. The establishment of vegetation on the top of the tailings may also help slow

down oxygen diffusion into the tailings and probably result in lower rates of sulphide oxidation and therefore primary copper leaching rates.

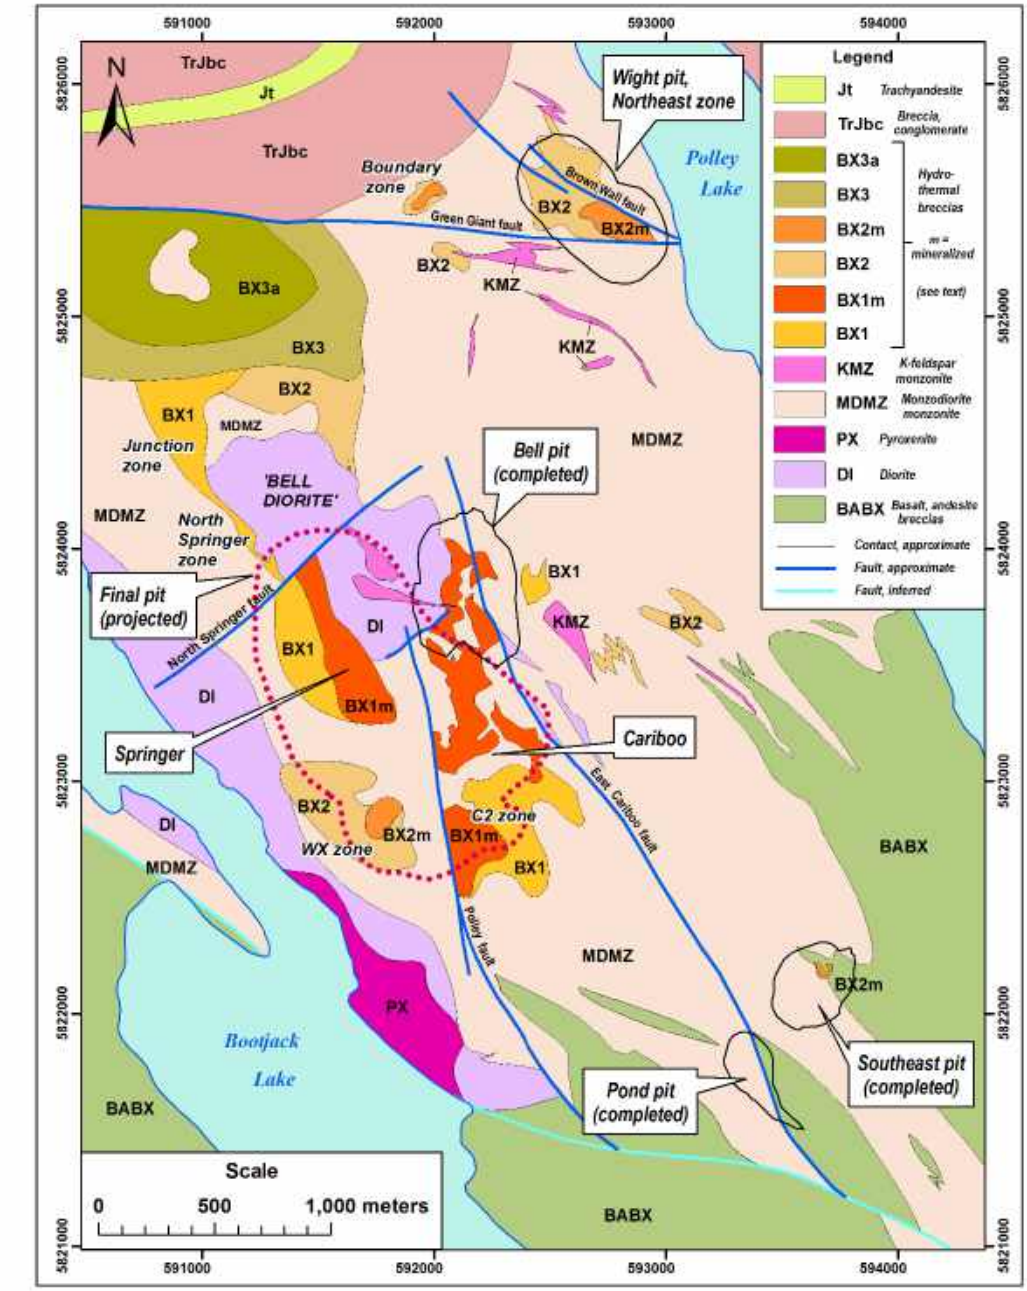
ABA	Acid-Base Accounting
AP	Acid Potential; expressed in units of kg $CaCO_3$/t
ARD	Acid Rock Drainage
HCT	Humidity Cell Test
ML	Metal Leaching
MPM	Mount Polley Mine
MPMC	Mount Polley Mining Company
Non-PAG	Non-Potentially Acid-Generating
PAG	Potentially Acid-Generating
SERDS	Southeast Rock Disposal Site
TIC	Total inorganic carbon or carbonate. Expressed in units of %C.
TIC-NP	Neutralization Potential calculated from total inorganic carbon or carbonate; expressed in units of kg $CaCO_3$/t
TIC-NP/AP_{crit}	Critical ratio of TIC-NP to AP that is used to segregate waste rock at the mine for ARD potential.

1 Introduction

Mount Polley Mining Corporation (MPMC) operates the Mount Polley Mine (MPM) to produce gold and copper concentrates. Waste rock produced by mining has varying degrees of acid rock drainage (ARD) potential which is managed by MPMC to limit the potential for development of ARD in the future. The metric used to date to classify waste rock is the total inorganic carbon neutralization potential (TIC-NP) to acid potential (AP) ratio (TIC-NP/AP) with TIC-NP/AP≤2 defining potentially ARD generating (PAG) materials. SRK Consulting (SRK) has been working with MPMC to refine acid-base accounting procedures and understand the specific factors controlling ARD potential at MPM to support mining of the Springer Deep and WX zones. This work has resulted in development of site-specific acid-base accounting procedures for these specific geological zones that will be mined consistent with theoretical considerations and similar approaches used at other mining operations in BC.

This report provides a summary of the methods and factors considered in the development of the site-specific acid-base accounting procedures and evaluation of a site-specific TIC-NP/AP criterion for waste rock from the Springer Deep and WX Zones at MPM.

2 Background



2.1 Geology

The Mount Polley deposit is classified as an alkalic porphyry copper gold deposit (BC MINFILE No. 093A 008) and has been mined from several mineralized zones. With the exception of the distinctive small Pond Zone, common features of these zones are:

- The host rock for porphyry mineralization is the Mount Polley Intrusive Complex (MPIC) which intruded into Nicola Group Volcanics (Figure 2-1). The intrusion is primarily monzonite to monzo-diorite in composition. Smaller phases vary in composition from diorite to syenite.
- Mineralization is associated with magmatic-hydrothermal breccias. Alteration and mineralization occur in the matrix of the breccias, and in veins and swarms distributed around the breccias. BX1 is the main host for the bulk of the mineralization at MPM which is mined in the Cariboo and Springer Pits (Figure 2-1) and is planned to be mined from the Springer Deep and WX Zones. BX1 is characterized by alteration which resulted in the strongest destruction of both primary and breccia textures.
- Alteration at MPM is classified as potassic (sodic and calcic) with salmon-pink potassium feldspar as the main alteration mineral. Biotite is less common. Sodic alteration is defined by albite and calcic alteration is defined by actinolite, diopside, epidote, clinozoisite, and sporadic andraditic garnet. Calcite is pervasive. Alteration is zoned with the strongest calcic-potassic alteration in the core associated with BX1. Nicola Group rocks and fringing MPIC rocks have propylitic alteration.
- Like other alkalic porphyry deposits (e.g., Copper Mountain, Brenda), MPM lacks the strong hydrothermal alteration zoning that is commonly observed in calc-alkalic porphyry deposits (e.g., Highland Valley Copper, Island Copper, Gibraltar). In particular, phyllic alteration is absent at MPM. A common feature of calc-alkalic porphyry deposits is often a pronounced pyritic halo that surrounds the copper mineralization and is associated with phyllic and propylitic alteration. At MPM, discontinuous pyritic zones are present but do not appear to be mineralization halos. MPM geological staff identified a pyritic zone in the south wall of the Springer Pit which extends into the adjacent Cariboo Pit. Samples from Bell Pit blast holes collected in the early years of operations were identified as being from a Pyrite Zone but the location of this feature is not known.
- Sulphide mineralization consists mainly of chalcopyrite ($CuFeS_2$) and pyrite (FeS_2), with lesser bornite (Cu_5FeS_4), covellite (CuS), and digenite (Cu_9S_5).
- Carbonate mineralization is principally calcite, with occurrences of malachite ($Cu_2CO_3(OH)_2$) formed as a natural weathering product of copper sulphides. Iron carbonates have not been reported.
- A significant portion of the copper at the MPM is not associated with sulphides (upwards of 50% in the upper portions of each pit). This fraction has been termed ‘copper oxide’ by MPM personnel and is associated primarily with chrysocolla ($(Cu,Al)_2H_2Si_2O_5(OH)_4 \cdot nH_2O$) and malachite ($Cu_2CO_3(OH)_2$) in equal proportions (Henry 2009). SRK (2015) showed that chlorite is a significant host for copper.

The WX and Springer Deep zones share these characteristics with copper-gold mineralization that is hosted by the BX1 magmatic-hydrothermal breccia that crosscuts monzonite and monzodiorite intrusive units of the MPIC.

Figure 2-1: Geological Map of the Mount Polley Mine

2.2 Site Location, Layout, and Mine Plan

MPMC has been operating MPM, located approximately 56 km northeast of Williams Lake and approximately 15 km southwest of the community of Likely in British Columbia, Canada, since 1996. MPMC recovers copper and gold from porphyry-style mineralization by open pit and underground mining. The plant is capable of processing 22,000 tonnes of ore per day using standard mineral flotation technology.

Full scale mining began in the Cariboo Pit by mining high grade oxide and gold parts of the ore body prior to transitioning to the Bell Pit in 1999. Mining was suspended in 2001 due to unfavorable market conditions. The mine re-opened in 2005 after a three- and half-year care-and-maintenance period. The following zones have been mined since 2005:

- Completed mining and backfilling of the Bell Pit.
- Completed mining and backfilling of the small Southeast Zone and Pond Zone Pits.
- Completed mining and flooding of the Wight Pit (Northeast Zone).
- Completed mining of the Boundary Pit.
- Completed mining and flooding of Northeast Zone underground (access from the Wight Pit).

In May 2019, mining was again suspended due to unfavourable market conditions. Mining operations restarted in November 2021 and milling operations resumed in June 2022.

The current approved mine plan includes mining from the Springer Pit until year 2025. Non-PAG waste rock is currently being placed in the southeast rock disposal site (SERDS) and used as construction material, with PAG waste rock placed in the temporary NW PAG stockpile until being re-handled to the Springer Pit at closure.

MPMC is in the process of preparing a joint Mines and Environmental Management Act (MEMA) permit amendment application package to cover the Springer Pit Expansion which would include mining of the Springer Deep and WX Zones from years 2024 to 2031. The mine plan within the amendment calls for non-PAG rock to similarly be placed in the SERDS and used as construction material, with PAG waste rock placed in the temporary NW PAG stockpile until being backfilled to the open pit at closure.

2.3 Regulatory Framework

The Mount Polley Mine development project received a BC Environmental Assessment certificate in 1992 and the Mines Act Permit *M-200* in 1995. Mining at the site has been carried out under the *M-200* permit since commercial production began in 1997.

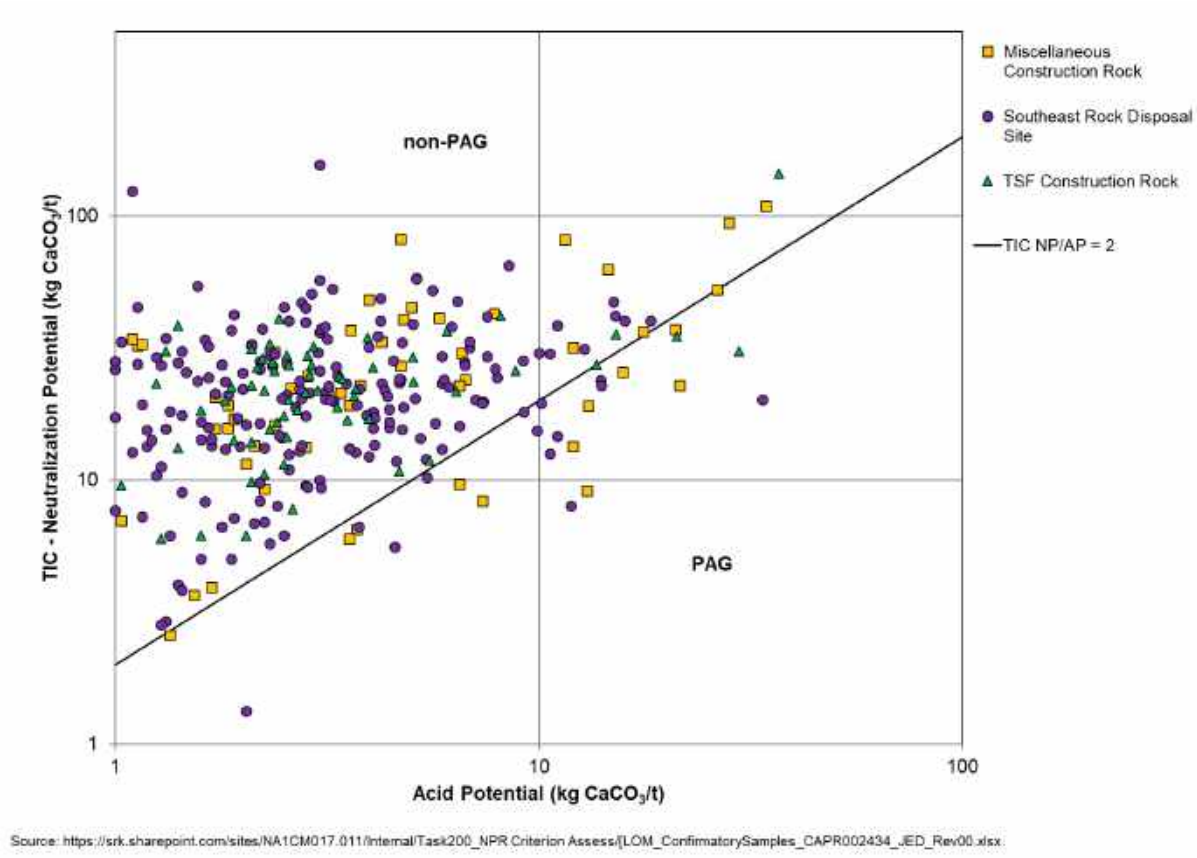
The *M-200* permit governs how mine wastes are managed to minimize the impacts of metal leaching and acid rock drainage (ML/ARD). Within the *M-200* Permit, waste rock is required to be segregated for ARD potential and the ARD potential of waste rock is defined using an NP/AP (or NPR) criterion of 2, where NP is calculated using total inorganic carbon (termed TIC-NP) and AP is calculated using total sulfur.

The *M-200* Permit Section 3 (c) stipulates that:

- PAG waste rock can only be disposed in the Cariboo, combined Cariboo/Springer, Wight, and Southeast Zone pits, where it will be submerged permanently beneath a water cover.
- A maximum of 62 million tonnes of PAG waste rock can be stored in the Temporary NW PAG Stockpile until being re-handled to one of the approved pits at closure for permanent submergence.
- Isolated pockets of PAG materials (less than 1,000 tonnes) may be blended with non-PAG materials within the waste rock dumps, at a minimum non-PAG:PAG ratio of 20:1.

Within the framework of evaluating a site-specific TIC-NP/AP criterion for incorporation to the *M-200* Permit, Federal guidance (MEND 2009) outlines that materials with NP/AP within the range of 1 to 2 are considered to have uncertain potential for ARD. Site-specific NP/AP criteria can be developed provided that “acid potential generates acid identical to pyrite and neutralization potential reacts like calcite” (MEND 2009).

2.4 Waste Rock Segregation and Confirmatory Sampling



Waste rock is segregated during mining at MPM using procedures outlined in MPMC (2022). To summarize, waste rock and ore domains are modelled within an ore control and ABA block model prior to mining to support mine planning. Modelled ore control and ABA values are then confirmed by analysis of blasthole cuttings to confirm ore/waste boundaries and PAG/non-PAG boundaries on the pit bench prior to mining.

The success of operational segregation is confirmed through yearly collection of samples from segregated non-PAG rock, results of which are reported in annual ML/ARD reports (i.e. SRK, 2023).

Since 2009, 351 samples have been collected from non-PAG waste rock which has been segregated and placed in the SERDS, used as construction rock for various roads around the site, or used for tailings facility construction. The total dataset of confirmatory samples from 2009 to 2022 (n = 351) is plotted in Figure 2-2 as a function of TIC-NP/AP, which shows that operational segregation is effective with 9% of the samples collected to date thus far having been classified as PAG.

The samples identified as PAG had an average TIC-NP/AP of 1.3, relative to the average TIC-NP/AP of all non-PAG samples of 14. These results indicate successful operational waste rock segregation which results in a mass balance TIC-NP/AP that far exceeds 2 for NAG waste rock.

Figure 2-2: ARD Classification for NAG Waste Rock Confirmatory Samples

3 Conceptual Geochemical Model for Site-Specific NP/AP Criterion

3.1 Mineralogical Considerations

Implementation of a site-specific or the generic TIC-NP/AP criterion stipulated by the Permit relies on analytical methods appropriately quantifying NP and AP within the bulk rock mass. At MPM, the mineralogical data have shown that calcite is the dominant carbonate mineral and that calcite abundance can accurately be quantified by total inorganic carbon or total carbon from the onsite laboratory (SRK 2023). Pyrite is the dominant sulfide mineral and other sulfur forms (including sulfate) are not common. Acid potential is therefore appropriately calculated from total sulfur.

Since waste segregation is based on analysis of drill core or blast hole cuttings which represent the bulk size fraction, an additional consideration is the degree to which carbonate and sulphur minerals partition during blasting. If the minerals segregate equivalently, the TIC-NP/AP criterion (TIC-NP/AP_{crit}) can be applied directly to the drill samples but if fractionation occurs it may be necessary to correct for the effect. Methods and results used to evaluate the effects of mineral partitioning are further outlined in Section 4.2 and Section 6.2 respectively.

3.2 Acid Neutralization Reactions

The TIC-NP/AP_{crit} reflects the ratio at which carbonate minerals are consumed relative to the rate of sulphide oxidation. For example, a TIC-NP/AP criterion of 2 assumes 2 moles of carbonate are needed to buffer the acid generated by oxidizing each mole of sulphide. The criterion is intended to ensure sufficient carbonates are available within the material to buffer acid produced by the total amount of sulphide to prevent formation of ARD.

The following processes affect the rate of carbonate utilization.

Pyrite oxidation and the generation of acidity (as H^+ equivalent) are summarized by reaction (1) below, where oxidation of one mole of pyritic sulphur generates two moles of H^+:

$$FeS_2 + 15/4O_2 + 7/2H_2O \rightarrow Fe(OH)_3 + 2SO_4^{2-} + 4H^+ \quad (1)$$

Carbonate in solution at near neutral pH values is speciated between dissolved carbon dioxide ($H_2CO_3^0$) and bicarbonate (HCO_3^-) as follows:

$$CaCO_3 + 2H^+ \rightarrow Ca^{2+} + H_2CO_3^0 \quad (2)$$

$$CaCO_3 + H^+ \rightarrow Ca^{2+} + HCO_3^- \quad (3)$$

If reaction (2), which is thermodynamically favored at lower pH, dominates the TIC-NP/AP_{crit} would be 1 given that the two protons produced per mole of sulphur (Equation 1) are neutralized by one mole of calcium carbonate equivalent. Reaction (3), which prevails at higher pHs, indicates a criterion of 2. Kinetic test data for samples from numerous other porphyry mines in BC show a similar outcome and yield the conclusion that the TIC-NP/AP_{crit} lies between 1 and 2.

A generic (not site-specific) TIC-NP/AP_{crit} assumes that reaction (3) is dominant and that a ratio of 2 would be required to prevent onset of acid generation. However, once the kinetics of the acid generation and neutralization reactions and the mineralogy of the materials are better understood (i.e., through static and kinetic laboratory geochemical testing), a site-specific TIC-NP/AP_{crit} can be evaluated.

4 Methods

4.1 Confirmation of Total Carbon and Total Sulfur as Analytical Proxies for Pyrite and Calcite

Previous work reported in SRK (2016) confirmed that total carbon can act as a proxy for calcium and magnesium carbonate content and that total sulfur can act as a proxy for pyrite. These conclusions were tested by mineralogical characterization of the drill core samples collected for humidity cell testing of representative samples from the Springer Deep and WX zones (Section 4.3.1) and of twenty of the bulk samples of blasted Springer Deep and WX zone waste rock collected to evaluate blast fractionation (Section 4.2) to confirm the existing ABA procedures apply to these new zones to be mined.

The blasted samples were shipped to the University of British Columbia Department of Earth, Ocean, and Atmospheric Sciences laboratory with the humidity cell samples tested at the SGS laboratory in Burnaby, BC. At both labs, the mineralogy was analyzed using quantitative x-ray diffraction (qXRD) by Rietveld refinement.

4.2 Blast Fractionation

Mineral partitioning during blasting can have an effect on the classification of waste rock ARD potential since fines tend to be more reactive. If carbonate minerals preferentially partition into the blast fines, the use of a bulk TIC-NP/AP classification factor can lead to misclassification of rock that will probably not generate acid as PAG. The reverse can also occur if sulphide minerals preferentially partition to the fines. SRK (2016) showed that both carbonate and sulphide minerals partitioned into the fine fractions for samples from the Bell and Cariboo Pits, but that this effect was much stronger for carbonate resulting in ARD potential classifications based on the bulk fraction leading to misclassification of some of some non-PAG rock as PAG.

To confirm the blast fractionation behavior of Springer and WX Zone rock, MPMC environmental technicians collected forty-four samples of blasted Springer and WX Zone Waste rock. Sample collection involved:

- Identification of two locations where Springer waste rock was being blasted and two locations where WX zone waste rock was being blasted through liaison with site mine geologists (i.e. four locations total);
- Location of each site in the open pit using coordinates supplied from the mine geologists. At the active digging face which was being excavated following blasting at each location, 10 samples and 1 field duplicate were collected of the bulk blasted size fraction on a 5 x 2 m grid yielding 44 samples total. Samples were collected with a shovel and placed in new plastic buckets.

Buckets were labelled, sealed, and shipped to Global ARD Testing in Burnaby, BC. At Global ARD, all forty-four samples were sieved into coarse (+10 mm), medium (-10 mm +2 mm), and fine fractions (-2 mm). Each fraction was weighed and analyzed for total sulfur, sulphate sulphur by hydrochloric acid leach, Modified Sobek NP using the MEND (1991) method, and total inorganic carbon (TIC) by hydrochloric acid leach and measurement of the evolved gas by coulometer.

4.3 Determination of NP/AP_{crit} for Springer Deep and WX Zones

4.3.1 Kinetic Testing Program

Humidity Cell Tests Initiated from 2004 to 2009

Humidity cell tests were performed on fifteen samples in support of geochemical characterization for permitting of mining of the Wight Pit (Northeast Zone), Southeast Zone, Boundary Zone, Pond Zone, and expansion of the Springer Pit. Results have been reported annually as part of Permit M-200 requirements. The samples were selected to evaluate oxidation rates for typical and elevated sulphide concentrations within waste rock. Results from testing of nine samples of monzonite, breccia, and diorite samples were used as part of the assessment owing to having similar lithology to the Springer Deep and WX Zones. Two samples from the Pond Zone which has distinctive skarn type mineralization and four samples of unknown lithology from the Springer and SE Zones were not considered relevant and were not used (HC-8 to HC-13).

Humidity Cell Tests Initiated in 2022

In 2022, four humidity cells samples were specifically selected to represent future waste rock that would be generated by mining the Springer Deep and WX Zones, which represent the source of waste rock for the remaining mine life. Samples were selected by SRK from the drill hole database to represent upper range sulphur content for the dominant rock types in both zones.

All four humidity cell tests and a method blank test are in operation at the SGS Laboratory in Burnaby, BC and were initiated on August 5, 2022. HCT leachate analysis is as follows:

- Weekly pH and conductivity to 12 weeks, then bi-weekly.
- Anions (sulfate, acidity, alkalinity, fluoride, chloride) bi-weekly for week 0 to 8 and then every 4 weeks.
- Multi-element analysis (Al, Sb, As, Ba, Be, Bi, B, Cs, Cd, Ca, Cr, Co, Cu, La, Fe, Pb, Li, Mg, Mn, Hg, P, Mo, Ni, K, Rb, Se, Si, Ag, Na, Sr, S, Te, Tl, Th, Sn, Ti, W, U, V, Zn, Zr) bi-weekly for week 0 to 8 and then every 4 weeks

4.3.2 Interpretation of Kinetic Test Data

A site-specific TIC-NP/AP_{crit} can be developed by assessing relative rates of acid generation and carbonate mineral utilization under the high weathering conditions of the humidity cell tests. The method used has been used at several other porphyry mines and projects in BC for the same purpose (i.e., SRK 2014; 2020b) and is summarized here. The main inputs for determining a TIC-NP/AP_{crit} are stable sulphate release rates under non-acidic conditions, and the combined release rates of Ca, Mg, Na and K [(Ca+Mg+0.5Na+0.5K)/SO_4] expressed in moles. Sulphate release rates are proxy for acid generation, while the combined major cations are proxy for acid neutralization. The release of Ca, Mg, Na and K reflects the dissolution of carbonate minerals by the combined effects of sulphuric acid (from pyrite oxidation) and carbonic acid (formed by atmospheric CO_2 dissolved in the deionized water). The consideration of Na and K release reflects the potential for Ca and Mg liberated by carbonate

dissolution to exchange with Na and K on the surface of phyllosilicates due to their greater affinity for exchange sites. The release rate for Na and K are halved to account for their lower charge (univalent) compared to calcium and magnesium (divalent). Inclusion of Na and K assures that utilization of carbonate for acid neutralization is not underestimated due to cation exchange effects.

Only stable release rates calculated after the initial flush from each HCT are used to base the assessment on the release of ions resulting from both acid generation and neutralization reactions as opposed to flushing of small amounts of soluble minerals that will not reflect longer term effects. At low oxidation rates (lower sulphate release), the dominant process in the test is dissolution of carbonates by carbonic acid in deionized water under high water-to-solid ratios. As the influence of sulphide oxidation increases (shown by increase in sulphate release), the ratio better reflects the interaction of sulphuric acid with carbonates.

Under site conditions, buffering of infiltrating waters containing dissolved CO_2 by carbonate mineral dissolution occurs within a short distance within the waste rock pile and tailings profile so that the apparent flushing of carbonate minerals by carbonic acid observed in the HCT does not occur in a full-scale dump. A stabilizing [$(Ca+Mg+0.5Na+0.5K)/SO_4$] trend at higher sulphate release therefore shows how the waste rock responds to generation of sulphuric acid which is the dominant process controlling NP depletion under field conditions. This information can thus be used to determine the TIC-NP/AP_{crit} for the materials tested based on the ratio at which the materials being tested stabilize.

5 Quality Control

5.1 Quality Control Methods

QA/QC procedures for static testing programs conducted by MPM which involve analysis of total sulfur and total carbon at the onsite laboratory are reported in the annual ML/ARD reports for the mine (i.e., SRK 2023) and are not detailed herein.

QA/QC of humidity cells initiated from 2004 to 2009 has been conducted previously and is reported in several humidity cell assessments (i.e., SRK 2008, 2009, and 2010).

For static and kinetic testing programs initiated as part of this assessment, SRK followed internal QA/QC procedures as outlined in the SRK Expectations for Laboratory Geochemical Data Quality (2022) which have been agreed upon with the laboratories that SRK uses. The procedures included the following QA/QC components in addition to lab QA/QC procedures:

- Static characterization
  - A duplicate sample (split following sample pulverization) underwent static testing for every twenty samples.
  - SRK monitored static results from duplicates, in addition to checking lab-initiated QC samples (duplicates, blanks and certified reference materials) against expected values.
  - Internal consistency of the data set was checked by monitoring sulfur balance (i.e., four-acid sulfur vs total sulfur, sulfate sulfur less than total sulfur etc.), NP compared to fizz rating (based on the MEND (1991) method, paste pH (to ensure consistency with NP and TIC), and TIC (to ensure consistency with NP).
  - Results from samples that were outside of SRKs criteria were subject to further evaluation. A recheck request was issued to the lab where deemed necessary by the SRK geochemist. The lab may be asked to comment, to investigate further, or to re-run a sample to confirm a result.
- Humidity Cell Testing
  - A blank waste rock HCT was operated to test for contamination within the de-ionized water used or from the testing apparatus.
  - SRK monitored leachate data for indications of contamination, for ion balance, to ensure detection limits stay consistent, and for trend analysis to identify data spikes which could indicate analytical errors.
  - Results from blanks or samples that were outside SRK's criteria were subject to further evaluation. A re-check request was issued to the lab where deemed necessary. The lab would have been asked to comment, investigate further, or re-run a sample to confirm the result.

5.2 Quality Control Results

Results of SRK's QA/QC assessment are provided in Appendix A, with results summarized as follows:

- The static data reported herein passed SRK's QA/QC criteria and no re-check requests were issued.
- Re-check requests issued for the humidity cell data were limited to one-off data spikes, irregular detection limits resulting from dilution, and anomalously high concentrations in method blank tests. As of the time of reporting, there were no outstanding re-check requests, and the results were considered acceptable for the study.

6 Evaluation of Site-Specific ABA Procedures and NP/AP Criterion for Springer Deep and WX Zone Waste Rock

6.1 Confirmation of Total Carbon and Total Sulfur as Analytical Proxies for Pyrite and Calcite

Full results of mineralogical analysis of the HCT samples and bulk samples of blasted Springer Deep and WX zone waste rock are provided in Appendix B, with a summary of the sulfide and carbonate mineralogy results provided in Table 6-1.

The results show that calcite is the only detectable carbonate mineral, and that pyrite is the only sulfur mineral detected. This confirms that total carbon can act as a proxy for calcium and magnesium carbonate content and that sulfur can act as a proxy for pyrite for samples the WX and Springer Deep Zones.

Table 6-1: Summary of Springer Deep and WX Zone Sulfide and Carbonate Mineralogy Data

Zone	Statistic	Pyrite	Calcite
		wt%	wt%
WX	min	<DL	0.6
	median	0.5	1.7
	max	3.4	4.0
	count	12	12
SD	min	0.9	0.6
	median	1.9	1.4
	max	2.8	2.9
	count	12	12

6.2 Blast Fractionation

Results of blasted WX and Springer Zone waste rock samples sieved to coarse (+10 mm), medium (-10 mm +2 mm), and fine fractions (-2 mm) are shown as box and whisker plots for total sulphur and total inorganic carbon in Figure 6-1 and Figure 6-2, which also include the bulk fraction results calculated as weighted averages using the fraction weights for each sample. Full analytical results by size fraction are provided in Appendix C. Review of the results showed:

- Total sulphur showed a higher mean in the fine fraction (mean = 0.41%) relative to the medium, coarse, and bulk size fractions which had means of 0.26%; however, all fractions had similar medians in the range of 0.15% and 0.17%. Using a t-test, there was not a statistically significant

difference between levels of total sulphur in the fine and bulk fractions using a 95% confidence level.

- TIC-NP was notably enriched in the fine fraction (median of 21 kg $CaCO_3$/t) relative to the coarse and bulk fractions which had medians of 5.4 and 7.3 kg $CaCO_3$/t respectively. Using a t-test, the fine fraction had statistically significant higher TIC-NP values compared to the coarse and bulk fractions fraction using a 95% confidence interval.

Figure 6-3 shows the size fraction relationship for the fine and bulk fractions for TIC-NP/AP. The relationship shows that TIC-NP/AP is higher in the fine fraction for the full range of measured TIC-NP/AP.

The regression line for the TIC-NP/AP relationship in (Figure 6-3) is:

$$\text{Log (TIC-NP/AP, -2 mm)} = 0.90 \text{ Log (TIC-NP/AP, bulk)} + 0.29$$

Given that the reactivity of the fine fraction dominates the reactivity of the bulk material, the equation can also be used to calculate NPR thresholds in the fines equivalent to the bulk rock mass which is tested during mining for classification purposes. Table 6-2 compares the equivalent fine and bulk fraction equivalent TIC-NP/AP ratios calculated using the regression.

The approved TIC-NP/AP_{crit} of 2 has a fine fraction equivalent of 3.6 indicating that the effects of mineral partitioning during blast fractionation within Springer Deep and WX Zone rock will lead ARD classifications based on bulk TIC-NP/AP ratios to be overly conservative leading to misclassification of non-PAG waste rock as PAG. TIC-NP/AP_{crit} of 2.0 for the fine size fraction has a bulk size fraction equivalent of 0.9.

Table 6-2: Fine to Bulk Fraction Equivalents Calculated from Regression

TIC/AP Bulk Size Fraction	TIC/AP -2 mm Size Fraction
0.7	1.6
0.9	2.0
1.0	2.3
1.5	3.1
2.0	3.8
3.0	5.2

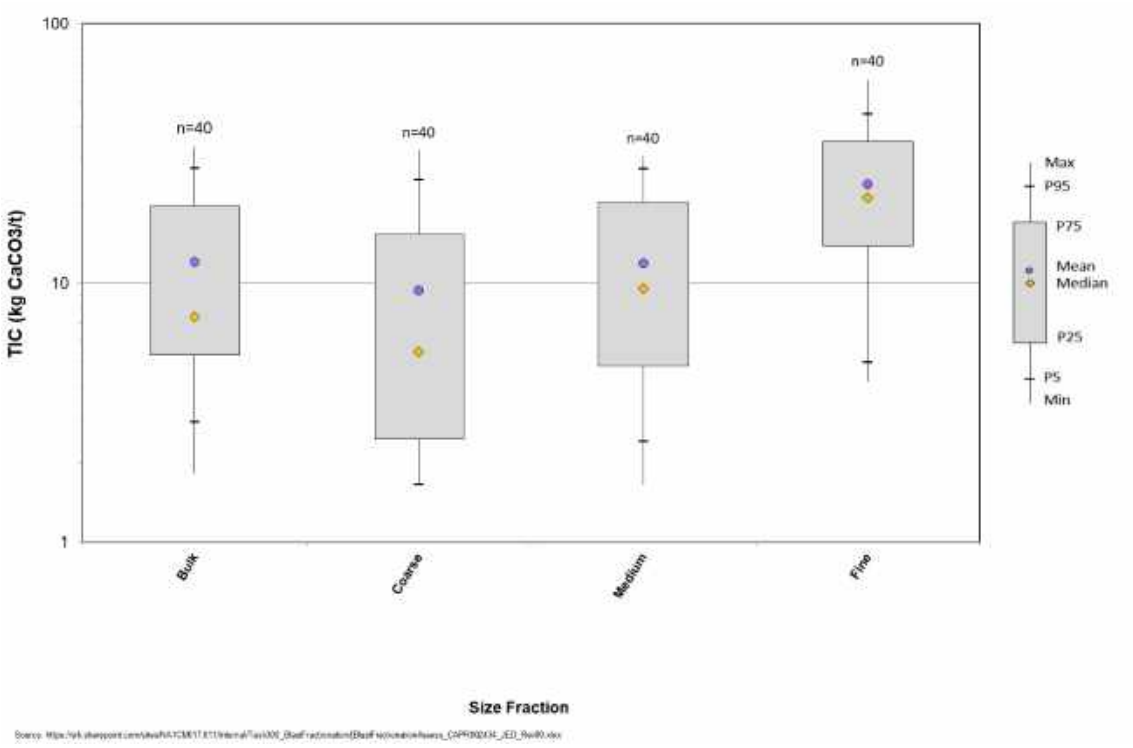

Figure 6-3: Measured TIC/AP for the -2mm versus calculated TIC/AP for the Bulk Fraction

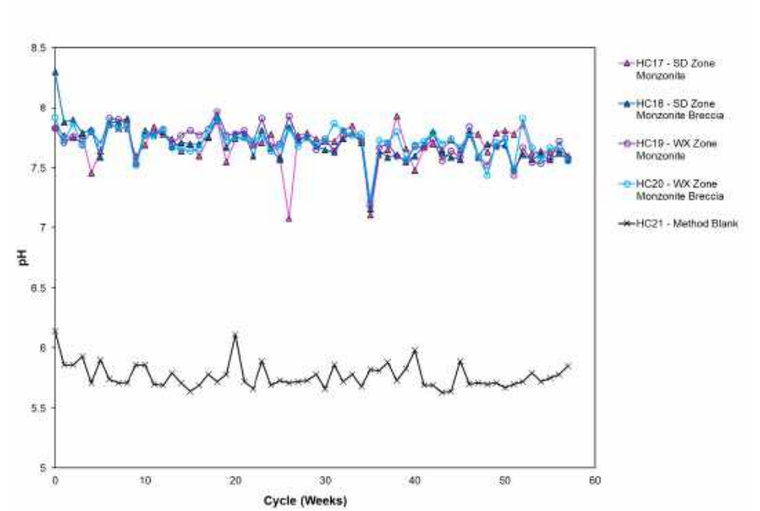
6.3 Kinetic Characteristics

6.3.1 Trend Description

Humidity cell leachate concentration timeseries charts for the 2022 HCTs up to September 2023 are provided in Appendix B, with kinetic stable rates summarized in Table 6-3. All four tests yielded non-acidic leachate (pH 7.1 to 8.3) from weeks 0 to 57 (Figure 6-4) and showed stabilizing weathering rates after 16 to 24 weeks for most major and trace elements following an initial flush of accumulated weathering products (Figure 6-4 and Appendix B). Based on the mineralogical results (Section 6.1 and Appendix B), leaching trends following the initial flush were interpreted to represent the primary oxidation of pyrite with acid neutralization by calcium and magnesium carbonate minerals.



Stable HCT concentrations for major cations (Ca, Mg, Na, and K) and sulphate, the major proxy for acid generation (Figure 6-4 and Appendix B), indicated release rates had stabilized for development of the site-specific TIC-NP/AP classification threshold. Figure 6-4F showed that the ratio of major ions to sulphate was showing slight variability but was varying within the expected range, further confirming release rates had sufficiently stabilized for development of the site-specific TIC-NP/AP for the Springer Deep and WX Zone samples.

6.3.2 Interpretation

Given the stability of major ion release rates, the data were evaluated to develop a site-specific TIC-NP*/AP_{crit}.

Figure 6-5 shows the rate of sulphate release (i.e., the approximate sulphide oxidation and acid generation rate) compared to the relative rate of acid neutralization by calcium and magnesium carbonate minerals in addition to sodium and potassium to account for cation exchange processes. As expected, the plot shows that at low sulphate release rates (e.g. <8 mg SO_4/kg/week), carbonate dissolution is primarily controlled by interaction with the de-ionized water used in the humidity cell test procedure which has a slightly acidic pH of 5.5 to 6.1 due to equilibration with atmospheric carbon dioxide (Figure 6-4).

At higher oxidation rates (e.g., >10 mg SO_4/kg/week) where release ratios are indicative of the material responding to sulphuric acid generated by sulphide oxidation, the data shows there is a tendency toward consumption of approximately 1.6 moles of calcium, magnesium, sodium, and potassium per mole of sulphate released. The data therefore indicate that a site-specific NP*/AP_{crit} of 1.6 is supported by the kinetic data.

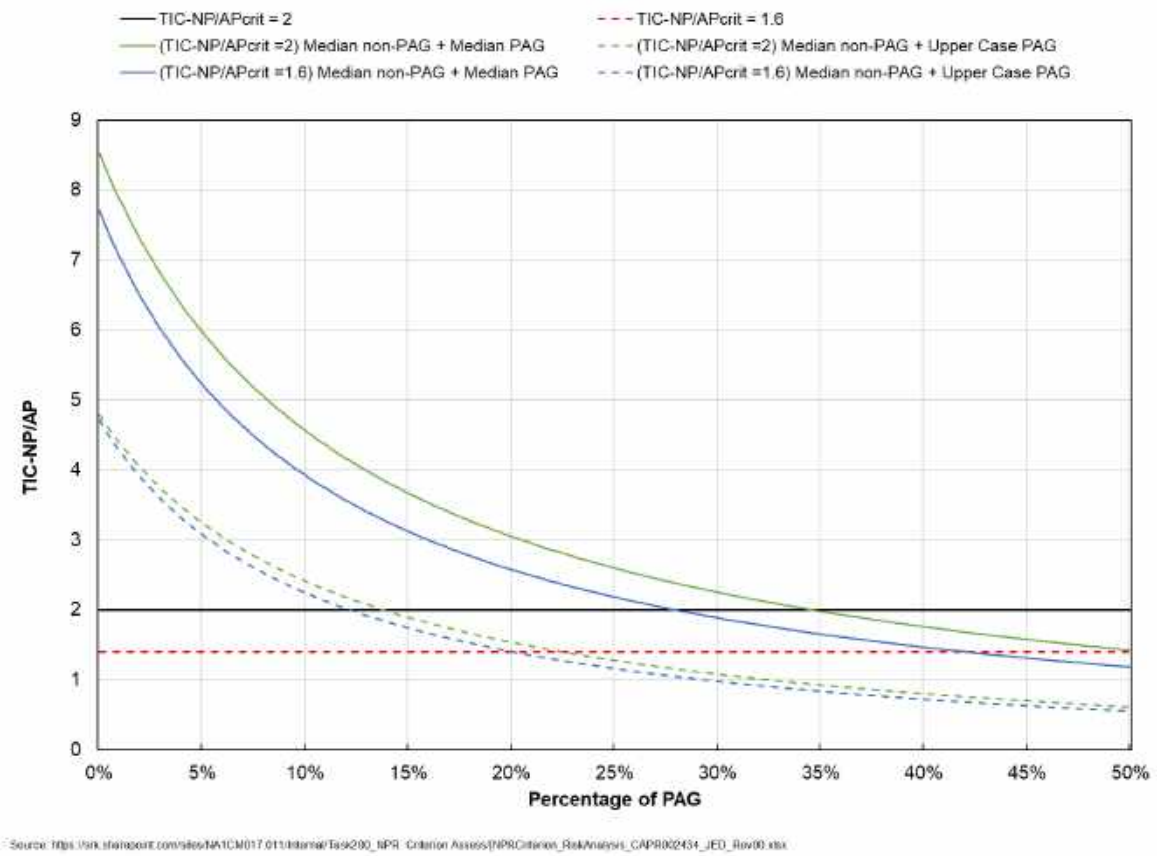
Figure 6-5: Average Stable Molar Ratio of Calcium, Magnesium, Sodium and Potassium Relative to Sulphate, Compared to Average Stable Sulphate Release Rates for all Waste Rock HCTs Assessed

6.4 Risk Assessment for Implementation of Site-Specific TIC-NP/AP_{crit}

In order to assess the risk of implementing the TIC-NP/APcrit as an operational criterion for classifying acid generation potential of waste rock, SRK has considered risk factors related to the potential for localized acidification due to PAG materials being incorporated with non-PAG waste rock and potential neutral pH leaching effects due to use of a lower NPR.

The main risk factors considered in this evaluation are:

- The effect of the PAG rock on overall mass balance TIC-NP/AP of the segregated non-PAG rock. As the proportion of PAG rock increases, the mass balance TIC-NP/AP will decrease, and the risk of acidification progressing beyond the PAG rock to the surrounding non-PAG rock increases.
- The degree to which changing the TIC-NP/AP_{crit} will change the neutral pH metal leaching potential of the segregated non-PAG rock.



6.4.1 Effect of PAG Rock Included with non-PAG Rock

Assuming the ML/ARD management plan continues to be properly implemented, the main reason for PAG rock to be used in construction or placed in the SERDS non-PAG rock are operational upsets whereby waste rock with TIC-NP/AP below the criterion is deposited.

Mass balance calculations were used to assess the effect of increasing the PAG content within construction rock or the SERDS using blast hole ABA data, which provides an indication of the range of TIC-NP and AP values observed in non-PAG and PAG material at the site. The calculations aimed to model mixing of non-PAG material that had median ABA characteristics (median TIC-NP and AP based on the total dataset of blast hole samples) with PAG material that had a range of TIC-NP and AP values. Non-PAG and PAG statistics were calculated separately using a TIC-AP/AP_{crit} of 2.0 and 1.6 to classify waste rock ARD potential to assess the influence of the TIC-NP/AP criteria on mass balance TIC-NP/AP.

The simulated PAG rock used in the mixing calculations consisted of: median TIC-NP and AP values (median TIC-NP/AP; solid lines in Figure 6-6) and 25th percentile TIC-NP and 75th percentile AP (upper case PAG; dashed lines in Figure 6-6).

Figure 6-6: Mass Balance Calculations Simulating the Effects of Mixing non-PAG and PAG Waste Rock

The results from the mass balance calculations shown in Figure 6-6 indicate that the change of the TIC-NP/AP_{crit} from 2.0 to 1.6 does not result in a large downward shift in mass balance ARD potential of non-PAG rock across a range of incorporated PAG content. Based on the observation that 9% of the confirmatory non-PAG samples collected to date were classified as PAG (defined as bulk TIC-NP/AP>2) (Section 2.4), these results indicate that lowering the TIC-NP/AP_{crit} does not pose a risk to mass balance TIC-NP/AP. The mix modelling indicates that a typical mix of segregated non-PAG which incorporates 9% PAG would have a TIC-NP/AP ratio of 4.1 in the bulk fraction which is in excess of 2 (Figure 6-6). This is equivalent to a TIC-NP/AP ratio of 6.7 in the blast rock fines.

6.4.2 Implications for Neutral pH Leaching in non-PAG Rock

The use of waste rock segregation addresses the potential for pH depression to levels at which sulphide oxidation accelerates and the solubility of metals increases exponentially. However, a lower TIC-NP/AP criterion could lead to higher sulphide content in segregated non-PAG which in turn could lead to higher sulphide oxidation rates and metal(oid) release rates.

For the Springer Deep and WX zones, decreasing the TIC-NP/AP criterion from 2.0 to 1.6 would increase the mean bulk size fraction sulphur content of non-PAG rock from 0.15 to 0.17 %S (medians of 0.091 and 0.099 %S respectively).

Given the negligible change in the sulphide sulphur content of non-PAG rock, the use of the site-specific TIC-NP/AP criterion is not expected to increase the neutral pH metal leaching potential of non-PAG rock for constituents released from oxidation of sulphide minerals including sulphate, copper, selenium, and zinc and the source term for non-PAG rock would remain unchanged.

7 Conclusion and Recommendations for TIC-NP/AP_{crit}

Based on the results of the assessment of site-specific ABA procedures and a TIC-NP/AP_{crit} for the Springer Deep and WX Zones, SRK recommends the following:

1. MPM can segregate waste rock for the Springer Deep and WX Zones according to the site-specific TIC-NP/AP criterion of 1.6 established herein.
2. MPM should account for blast fractionation prior to segregation of waste rock on the pit bench to ensure that non-PAG waste rock is not misclassified as PAG as follows:
    a. For the fine fraction (<2mm), PAG rock is defined as TIC-NP/AP ≤ 1.6;
    b. For the bulk fraction (i.e., samples of blast hole cuttings or drill core), PAG rock is defined as TIC-NP/AP ≤ 0.7. This accounts for preferential enrichment of carbonate minerals in blast fines.

SRK recommends that the regression to account for the effects of blast fractionation be tested and updated each year during mining of these zones to ensure that the samples collected are represented by the larger zones to be mined.

Closure

This report, Evaluation of Acid-Base Accounting Procedures and the Criterion for Classifying ARD Potential of Waste Rock – Springer Deep and WX Zones, was prepared by:

EXPERIMENTAL METHOD

The 20 samples of **Project #: 2221 (B1)** were reduced to the optimum grain-size range for quantitative X-ray analysis (<10 μm) by grinding under ethanol in a vibratory McCrone XRD Mill (Retsch GmbH, Germany) for 10 minutes. Continuous-scan X-ray powder-diffraction data were collected over a range of 3-80°2θ with CoKα radiation on a Bruker D8 Advance Bragg-Brentano diffractometer equipped with an Fe filter foil, 0.6 mm (0.3°) divergence slit, incident- and diffracted-beam Soller slits and a LynxEye-XE detector. The long fine-focus Co X-ray tube was operated at 35 kV and 40 mA, using a take-off angle of 6°.

RESULTS

The X-ray diffractograms were analyzed using the International Centre for Diffraction Database PDF-4 and Search-Match software by Bruker. X-ray powder-diffraction data of the samples were refined with Rietveld program Topas 4.2 (Bruker AXS). The results of quantitative phase analysis by Rietveld refinements are given in Table 1 (separate file, ***Global ARD Testing Services Inc Revised Results May 31 2023 - Project 2221 (B1) PO GL22-1707 - 20 samples.xlsx***). These amounts represent the relative amounts of crystalline phases normalized to 100%. The Rietveld refinement plots are shown in Figures 1-20. Ideal formulae of the mineral phases present are shown in Table 2.

Note that the X-ray diffraction patterns in many of the samples are affected by the presence of some unknown clays which could not be analyzed (see hump fitted with calculated peak at ~7°2θ in Figures 1-15). Therefore, the results should be considered approximate.

Table 2. Ideal formulae for phases present; proj: 2221(B1)

Mineral	**Ideal Formula**
Actinolite	$Ca_2(Mg,Fe^{2+})_5Si_8O_{22}(OH)_2$
Analcime	$Na[AlSi_2O_6]\cdot H_2O$
Calcite	$CaCO_3$
Chabazite	$(Ca,K_2,Na_2)_2[Al_2Si_4O_{12}]_2\cdot 12H_2O$
Clinochlore	$(Mg,Fe^{2+})_5Al(Si_3Al)O_{10}(OH)_8$
Clinozoisite	$Ca_2Al_3(SiO_4)_3(OH)$
Diopside	$CaMgSi_2O_6$
Grossular	$Ca_3Al_2(SiO_4)_3$
Hematite	α-Fe_2O_3
Illite-Muscovite 1M & 2M	$K_{0.65}Al_{2.0}Al_{0.65}Si_{3.35}O_{10}(OH)_2$-$KAl_2AlSi_3O_{10}(OH)_2$
Kaolinite	$Al_2Si_2O_5(OH)_4$
K-feldspar (microcline, orthoclase)	$KAlSi_3O_8$
Magnetite	$Fe^{2+}Fe^{3+}{}_2O_4$
Plagioclase (albite; albite, calcian)	$NaAlSi_3O_8$-$CaAl_2Si_2O_8$
Prehnite	$Ca_2Al_2Si_3O_{10}(OH)_2$
Pyrite	FeS_2
Quartz	SiO_2
Stilbite	$NaCa_4(Si_{27}Al_9)O_{72}\cdot 28H_2O$
Talc	$Mg_3Si_4O_{10}(OH)_2$
Titanite	$CaTiSiO_5$

NOTES:
Acceptance criteria at Global ARD Testing for all CRMs is ±10 % of certified value.
Job No: YVR2210450

Date of Analysis (24 h): May 3-5, 2022
pH of DI water (pH Units): 5.69
EC of DI water (µS/cm): 1.21

METHODS:
Total sulphur by Leco.
Total Inorganic Carbon (TIC): HCl leach, evolved CO_2 analysed by CO_2 Coulometer.

ABBREVIATIONS:
R = Rep = Replicate (is a sub-sample scooped from a single pulp sample bag produced per client sample)
D = Dup = Duplicate (is 2nd sub-pulp sample bag produced by processing a 2nd split of the head sample received. A duplicate pulp sample is prepared only at client request)
EC = Electric Conductivity
ORP = Oxidation Reduction Potential
NP = Neutralization Potential
Calc. = Calculation
IND = Indeterminate
NR = Not Requested

CALCULATIONS:
- *1 CaCO3 Equivalents: based on TIC
- *2 Sulphide-Sulphur: Total-sulphur - sulphate-sulphur
- *3 AP (Acid Potential): Sulphide-Sulphur x 31.25
- *4 NNP (Net Neutralization Potential): NP - AP
- *5 NPR (Neutralization Potential Ratio): NP/AP

REFERENCES:
Sample Preparation: ASTM E877-08; MEND Report 1.20.1, Version 0 (2009)
ABA: Dried below 40°C (as requested by client), jaw-crushed if necessary, split by riffling and pulverized to 85% passing 200 mesh (75 µm).
Modified ABA (Sobek) NP: MEND Acid Rock Drainage Prediction Manual, MEND Project 1.16.1b (pages 6.2-11 to 17), March 1991.
Paste pH / Fizz Rating: Sobek, A.A., Schuller, W.A., Freeman, J.R. and Smith, R.M.; US EPA-600/2-78-054 (1978).
Sulphate Sulphur: Based on MEND method. The S extracted is determined by analysing the extract for SO4 using UV-Vis Spectrophotometer (STD Method 4500-SO42- E).

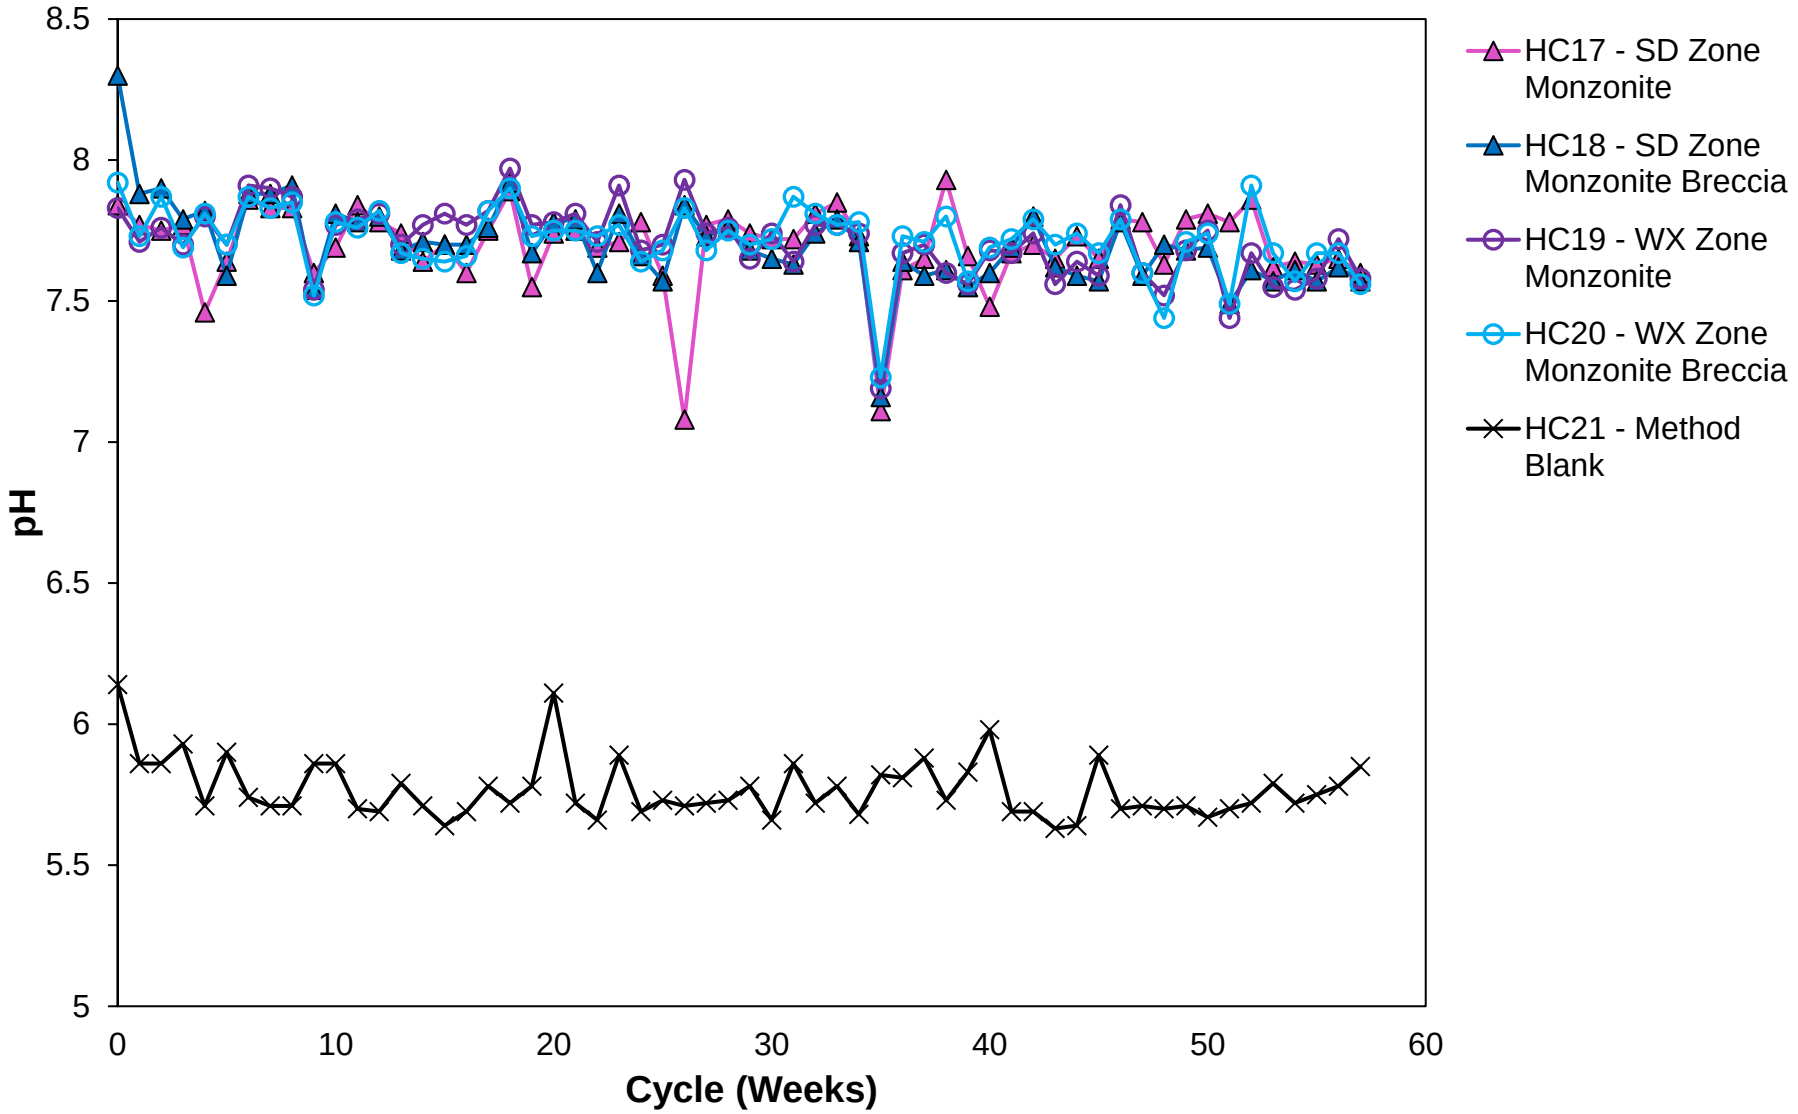
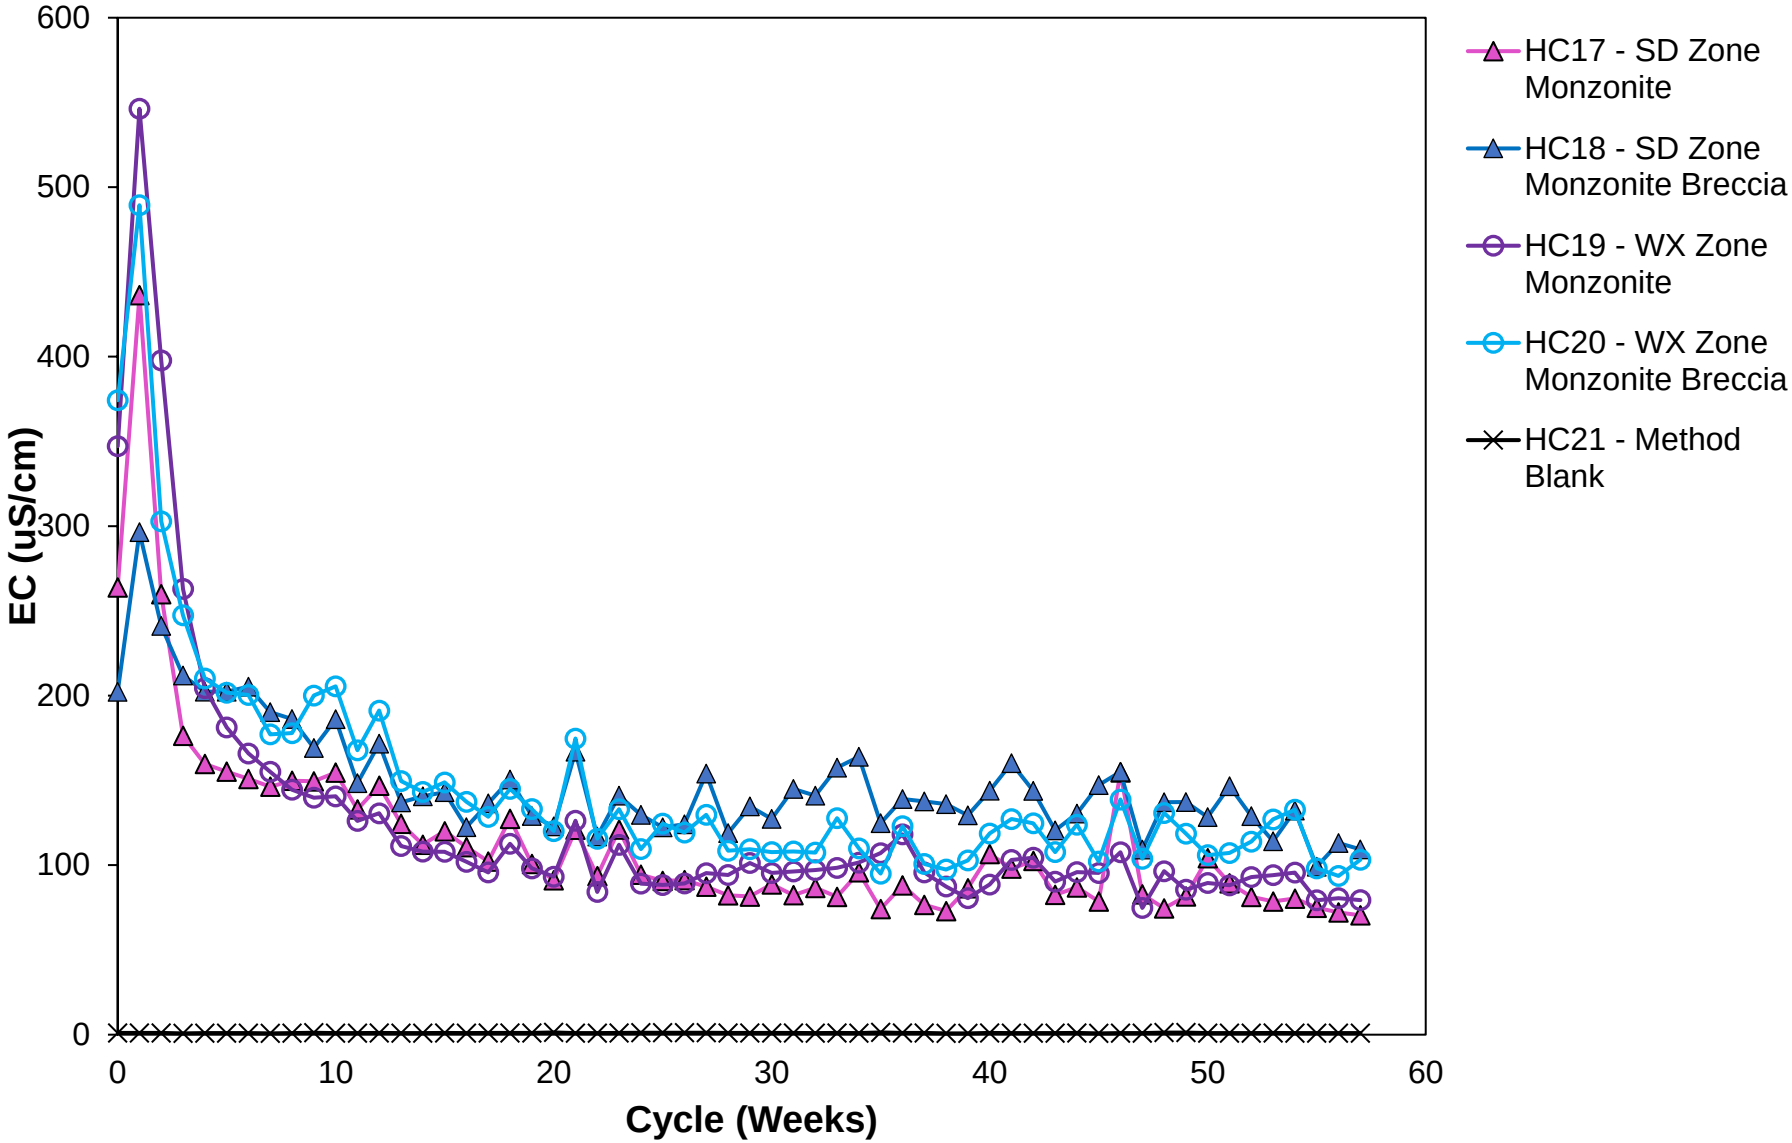
NOTES:
Acceptance criteria at Global ARD Testing for all CRMs is ±10 % of certified value.
Job No: YVR2210450

Date of Analysis (24 h): May 3-5, 2022
pH of DI water (pH Units): 5.69
EC of DI water (µS/cm): 1.21



METHODS:
Total sulphur by Leco.
Total Inorganic Carbon (TIC): HCl leach, evolved CO_2 analysed by CO_2 Coulometer.

ABBREVIATIONS:
R = Rep = Replicate (is a sub-sample scooped from a single pulp sample bag produced per client sample)
D = Dup = Duplicate (is 2nd sub-pulp sample bag produced by processing a 2nd split of the head sample received. A duplicate pulp sample is prepared only at client request)
EC = Electric Conductivity
ORP = Oxidation Reduction Potential
NP = Neutralization Potential
Calc. = Calculation
IND = Indeterminate
NR = Not Requested



CALCULATIONS:
- *1 CaCO3 Equivalents: based on TIC
- *2 Sulphide-Sulphur: Total-sulphur - sulphate-sulphur
- *3 AP (Acid Potential): Sulphide-Sulphur x 31.25
- *4 NNP (Net Neutralization Potential): NP - AP
- *5 NPR (Neutralization Potential Ratio): NP/AP

REFERENCES:
Sample Preparation: ASTM E877-08; MEND Report 1.20.1, Version 0 (2009)
ABA: Dried below 40°C (as requested by client), jaw-crushed if necessary, split by riffling and pulverized to 85% passing 200 mesh (75 µm).
Modified ABA (Sobek) NP: MEND Acid Rock Drainage Prediction Manual, MEND Project 1.16.1b (pages 6.2-11 to 17), March 1991.
Paste pH / Fizz Rating: Sobek, A.A., Schuller, W.A., Freeman, J.R. and Smith, R.M.; US EPA-600/2-78-054 (1978).
Sulphate Sulphur: Based on MEND method. The S extracted is determined by analysing the extract for SO4 using UV-Vis Spectrophotometer (STD Method 4500-SO42- E).

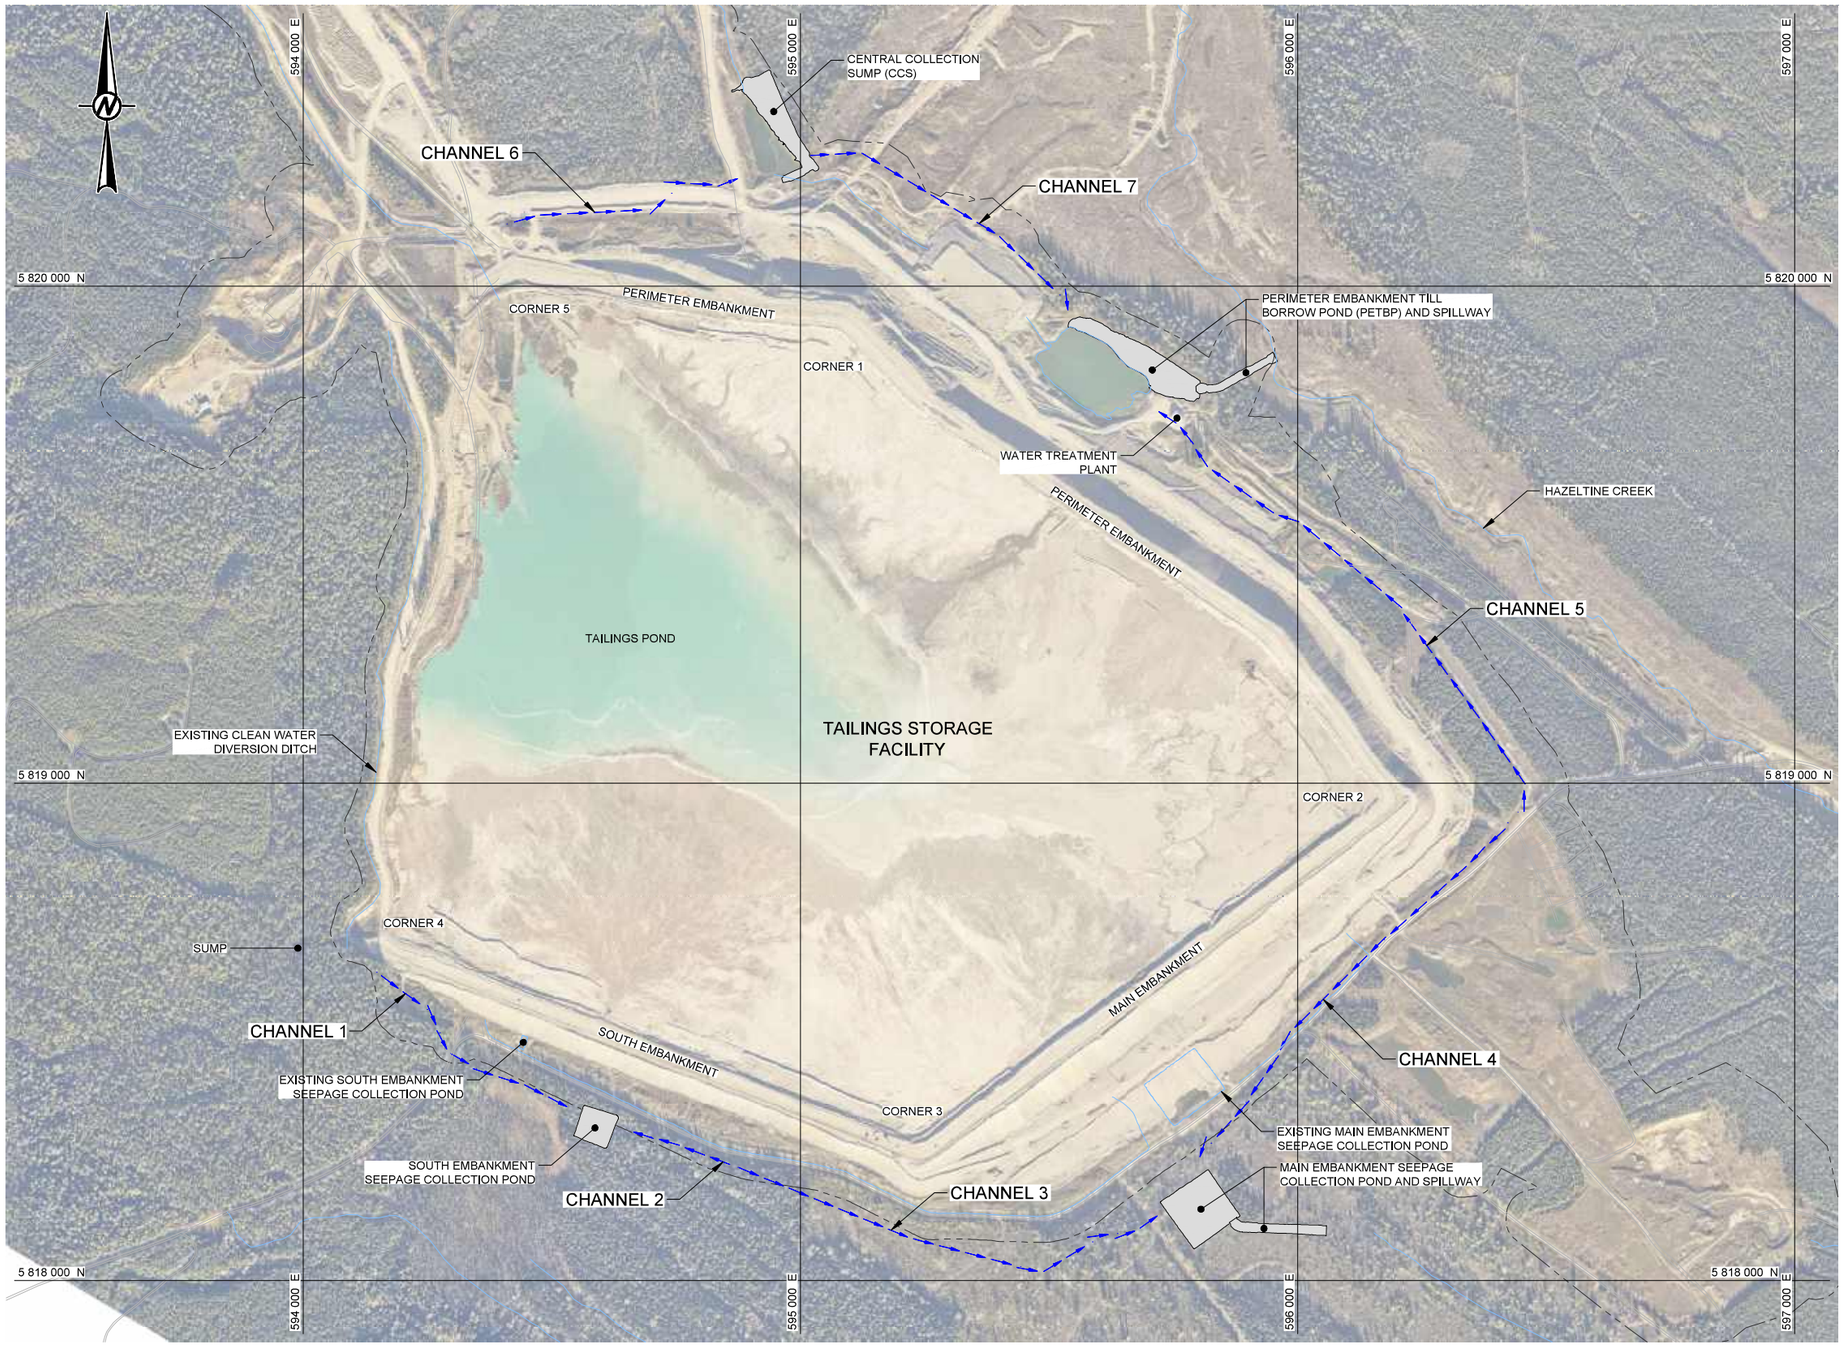
TAILINGS STORAGE FACILITY SURFACE WATER MANAGEMENT INFRASTRUCTURE PERMITTING DESIGN MEMORANDUM (974 M RAISE)– MOUNT POLLEY MINE

1.0 INTRODUCTION

The Mount Polley Mine (the Mine) is a copper and gold mine operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. MPMC has retained WSP Canada Inc. (WSP) to complete the permit level design for the surface water management infrastructure of the tailings storage facility (TSF) to support raising the TSF to a crest elevation of 974 m at the Mount Polley Mine.

The Mine is located approximately 56 km northeast of Williams Lake, British Columbia, between Polley Lake and Bootjack Lake. The Mount Polley Mine began production in 1997. The TSF is located about 3 km southeast of the mill and includes one embankment that is approximately 4.8 km in length. The embankment is subdivided into three sections: the Main Embankment, Perimeter Embankment, and South Embankment. The TSF embankment for the Mount Polley Mine is planned to be raised for future operations from its currently permitted elevation of 970 m to 974 m (WSP 2024b).



This technical memorandum and attached design drawing package (Attachment 1) present the permit level design of the TSF surface water management infrastructure to support raising the TSF to a crest elevation of 974 m.

2.0 BACKGROUND

Diversion and collection channels are currently in place at the project site around the TSF (Attachment 1, Drawing 03). The TSF 974 m raise design will partially or fully cover some of the existing surface collection and diversion structures around the TSF by the embankment raise to the 974 m elevation. Therefore, water management infrastructure designs (Figure 1) are required to support the TSF embankment raise design and permit amendment.

Permit level design includes the following water management infrastructure:

- Design of TSF seepage management infrastructure, including seepage and surface runoff collection channels listed in Table 1.
- Relocation of the South Embankment Seepage Collection Pond (SESCP) (Attachment 1, Drawing 09) and the Main Embankment Seepage Collection Pond (MESCP) (Attachment 1, Drawing 14).
- Channel 7 is the connection channel between the Central Collection Sump (CCS) and Perimeter Embankment Till Borrow Pond (PETBP) (Attachment 1 – Drawing 21).
- Extension of the PETBP (Attachment 1, Drawing 23).
- Extension of the CCS (Attachment 1, Drawing 26).

2.1 Design Inputs

According to *Environmental Management Act* Permit 11678 (EMA 2022), surface water structures "must be designed to convey all flows up to 1:10-year 24-hour storm event and must be designed to withstand all flows up to the 1:200-year 24-hour storm event, without significant damage". The collection ponds will be designed to store the inflow volume reporting to the ponds during a 1:10-year 24-hour storm event with a spillway designed to convey the 1:200-year 24-hour storm event. The water management system will be designed to convey peak flow rates during events up to and including the 1:200-year 24-hour storm event.

The design basis for the TSF water management system is included in Attachment 2.

2.2 Climate

This section summarizes the climate characteristics (precipitation, air temperature, and humidity) in the area of the Mine; further details can be found in the climate baseline update report (WSP 2022).

Local climate characterization for the site was completed using climatic data recorded at the Mine and nearby Environment and Climate Change Canada (ECCC) climate stations. The local climate stations included Mill Site Weather Station, Weather Station #1 (near mill), and Weather Station #2 (TSF). The ECCC climate stations included Likely, Spokin Lake, Williams Lake, Barkerville, and Quesnel, and were selected due to their proximity to the Site, length of record, elevation range, and concurrent time-period with local site records.

A long-term precipitation time series representative of the climate conditions at the Mine was derived using the long-term data from the ECCC Likely station (1974 to 1993) and data from the three on-site climate stations with data recorded from 1995 to 2021 (WSP 2022). The data set was infilled using historical data from additional regional climate stations and adjusted for orographic effect. The Mine experiences high summer precipitation due to summer storms, with the lowest monthly precipitation occurring in February. Precipitation typically occurs as snowfall starting in November and accumulates until March. Average annual precipitation at the site is estimated to be 612 mm with a standard deviation of 118 mm.

The estimated mean annual air temperature at the site varies between 1.7°C to 6.3°C, with a long-term mean of 3.9°C. The mean monthly temperature ranges from -6.7°C in January to 15.1°C in July. The historical daily maximum and minimum air temperatures were recorded at 38.1°C in June 2021 and -39.8°C in December 1996, respectively. The mean monthly air temperature usually becomes positive in April and negative in November. The mean annual relative humidity is 68.1%, and the monthly mean relative humidity values range from 57.7% in April to 82.2% in December. The 25th and 75th percentiles for monthly relative humidity indicate little variation from the median, which suggests that the site experiences relatively consistent relative humidity on a monthly basis from year to year.

2.3 Design Storm Depths

A frequency analysis was completed on annual maximum 24-hour rainfall depths from the long-term derived precipitation record (WSP 2022) to estimate design storm rainfall depths. 24-hour rainfall depths for select return periods are presented in Table 2.

Table 2: 24-hour Precipitation Depths for the Mount Polley Mine (1974 to 2021)

Return Period (yr)	24-hour Rainfall Depth (mm)[(a)]
2	33
10	47
25	54
100	64
200	69
1000	80

Source: WSP 2022.

(a) Log Pearson III distribution.

The largest runoff volumes are anticipated to be associated with extreme rainfall events occurring during freshet. The snowmelt is expected to occur between March and May with a relatively greater portion melting in April. Snowmelt estimates induced by a corresponding rainfall event (rain plus snowmelt event) were calculated for spring conditions (April) using the equation below (Dunne and Leopold 1978).

$$M_R = 1.42T_a + 2.5 + \frac{RT_aC_W}{L} + 0.0059T_au_2 \quad \text{(Equation 1)}$$

Where:

M_R = snowmelt in mm/d snow water equivalent

R = rainfall depth in mm for return period event duration t, averaged over the duration of the storm

T_a = average air temperature over the duration in °C

C_W = specific heat of water (equal to 1 calorie per gram Celsius [cal/g°C])

L = latent heat of fusion of ice equal to 80 calorie per gram (cal/g)

u_2 = wind speed in km/d

The input parameter values for Equation 1 are summarized in Table 3. The estimated spring maximum 24-hour snowmelt rates are presented in Table 4.

Table 3: Snowmelt Parameter Values

Parameter	Value	Rationale
R_t	See Table 2	snowmelt generated by rainfall events
T_a	3.7°C	average April air temperature (assumed snowmelt period)[(a)]
u_2	225 km/d (2.6 m/s)	average April wind speed[(b)]
C_W	1 cal/g/°C	assumed
L	80 cal/g	assumed

Notes: cal/g°C = calorie per gram Celsius; cal/g = calorie per gram.
(a) WSP 2022.
(b) Golder 2017.

Table 4: 24-Hour Rainfall, Snowmelt, and Rain Plus Snowmelt Depths

Return Period (Years)	Mean Daily Temperature in April (°C)	24-Hour Rainfall (mm)	24-Hour Snowmelt (mm)	24-Hour Rain Plus Snowmelt (mm)
10	3.7	47	14.8	61.8
200	3.7	69	15.9	84.9

2.4 Catchment Characteristics

The catchment delineation was adopted from the previous water management plan study (refer to Golder 2020). The catchment areas were further refined using LiDAR provided by MPMC (Fullerton 2024), TSF embankment and buttress design contours for the 974 and 987[1] m raises, and the alignment of the new water management infrastructure.

The catchment areas for the overall the Mount Polley Mine site are shown in Figure 2. The relevant catchment areas around the TSF embankment raise to 974 m that were refined and used to model runoff for the collection channels are shown in Figure 3 and provided in Table 5. Note that for the design of the ponds, only sloping catchments that generated gravity flow were considered.

[1] The TSF embankment and buttress design for the 987 m raise is currently in progress as of the preparation of this document.

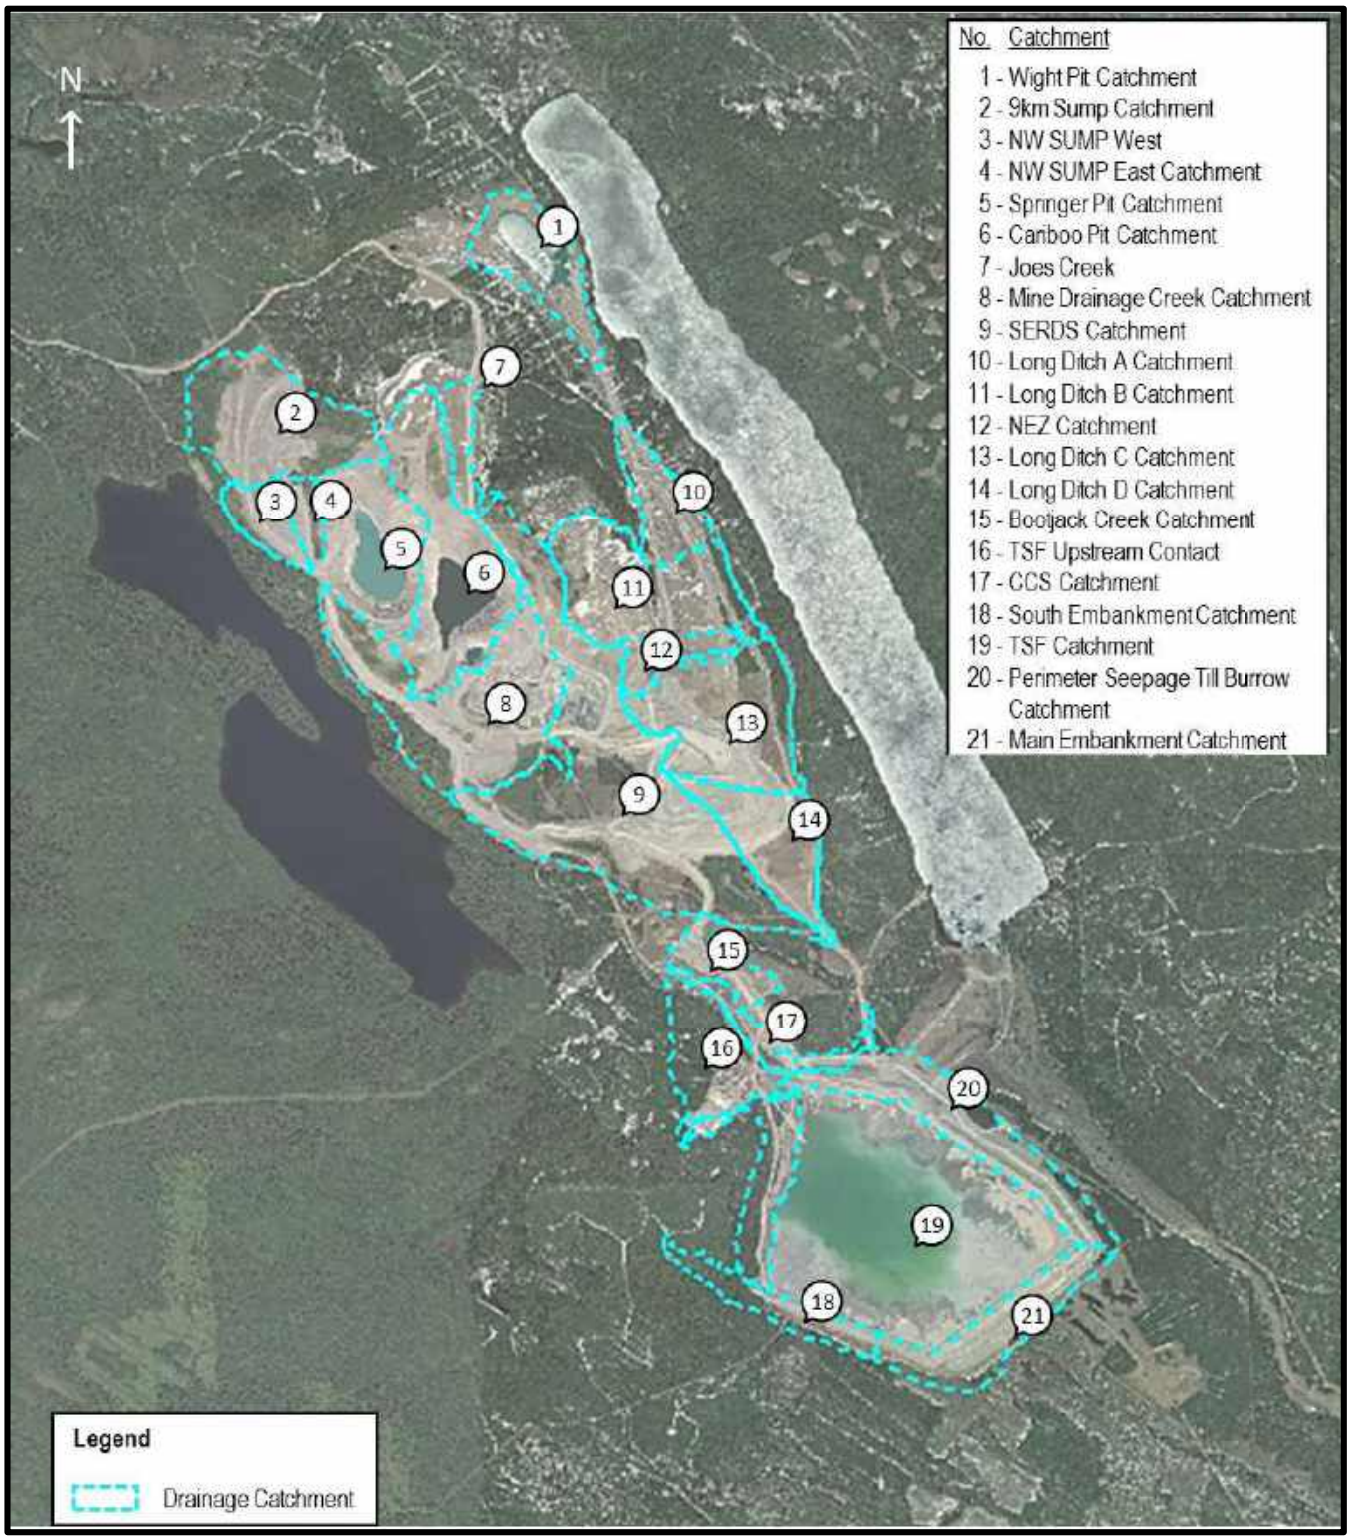

Figure 2: Catchment Areas

Figure 3: Catchment Areas Around the Tailings Storage Facility

Table 5: Catchment Areas

Collection Sump/Pond	Contributing Catchment[(a)]	Receiving Channel	Watershed Area (km^2)
SESCP	1, 2	Channels 1, 2	0.225
MESCP	3, 4, 5, 6, 7	Channels 3a, 3b, 4a, 4b	0.44
CCS	11, direct catchment area plus 2.4 km^2 from Long Ditch, 1.87 km^2 from SERDS ditch, and TSF upstream contact catchment	Channel 6	4.37
PETBP	8, 9, 10, direct catchment area plus catchment reporting to CCS	Channels 5, 6, 7	4.87

Notes: km^2 = square kilometres; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; CCS = Central Collection Sump; PETBP = Perimeter Embankment Till Borrow Pond.

(a) As shown on Figure 3.

2.5 Seepage and Drain Flow Rate to Collection Channels

Seepage analyses were undertaken to estimate flows through the upstream drain and seepage rates through the embankment and foundation at elevation 974 m to inform the design of the downstream water management infrastructure. Potential groundwater inflow rates to seepage collection ponds, seepage flow through the upstream drain, and seepage through the embankment and foundation are summarized in Table 6 (WSP 2024b). The seepage and drain inflows were considered in the design of the collection channels in Section 4.1.

Table 6: Estimated Seepage Inflow to Collection Ponds

Embankment	Flow through the Embankment and Foundation (m^3/s)[(a)]	Flow Through Upstream Drains at TSF Elevation 974m (m^3/s)[(a)]
South Embankment	4.3×10^{-3}	3.7×10^{-2}
Main Embankment	8.1×10^{-3}	3.8×10^{-2}
Perimeter Embankment	1.5×10^{-2}	5.1×10^{-2}
Perimeter Embankment at Corner 1	9.1×10^{-3}	2.3×10^{-2}

Notes: m^3/s = cubic metres per second; TSF = tailings storage facility.

Source: WSP 2024b.

(a) Seepage rate listed assumes the TSF pond against the embankment.

3.0 HYDROLOGIC ANALYSIS

A rainfall runoff model was implemented using the Hydrologic Engineering Center Hydrologic Modeling System (HEC-HMS) software, developed by the US Army Corps of Engineers (USACE 2022). This model was used to estimate the peak runoff flows from the catchments reporting to the surface water management infrastructure.

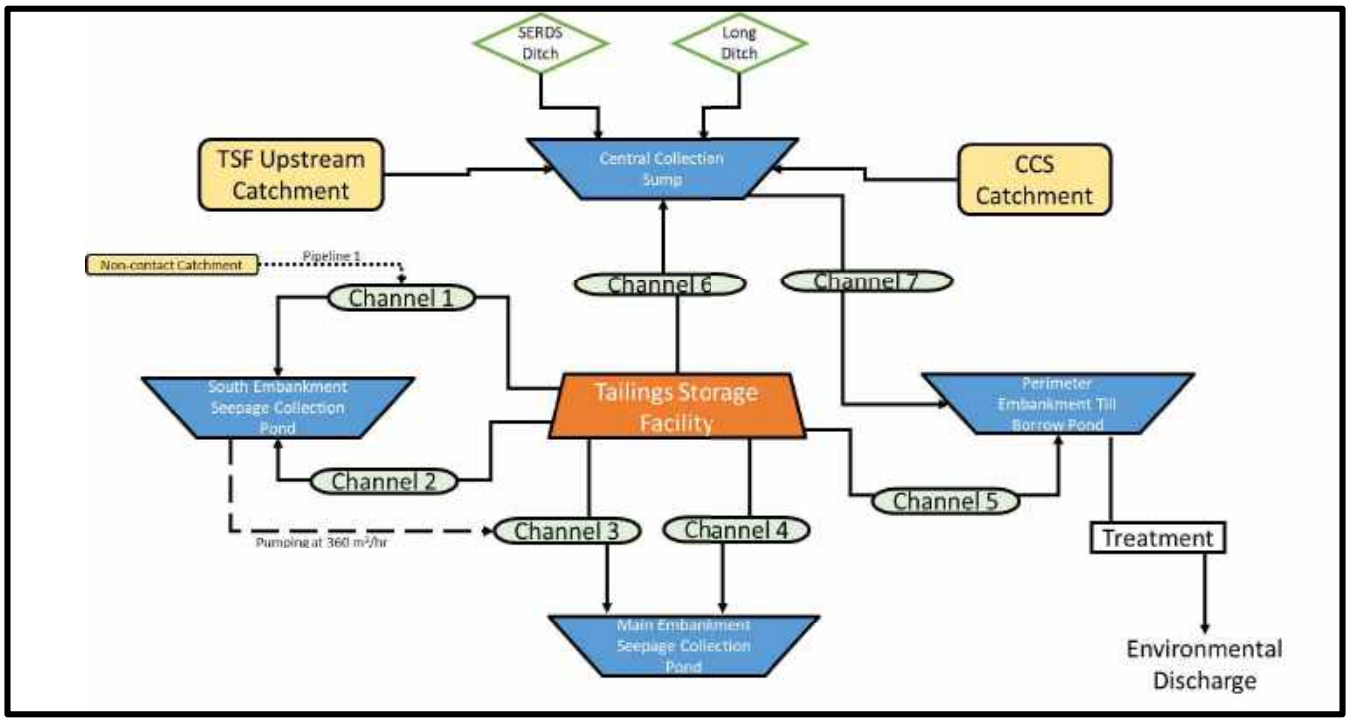
The rainfall component of the design event was distributed using the US Soil Conservation Service (SCS) Type II rainfall distribution (USDA 2009) (Attachment 2, Section 2.3). The time of concentration was estimated using the SCS TR-55 method (USDA 2009), which divides the longest flow path into sheet flow, shallow concentrated flow, natural channel flow, and constructed channel flow and considers a minimum time of concentration of 3.6 minutes. The lag time was estimated as 60% of the time of concentration. Catchment areas and corresponding time of concentration values are provided in Table 7.

The snowmelt depth was distributed evenly over a 12-hour period each day centred on the peak rainfall intensity of the events.

Catchment curve number (CN) values for different land types were provided in the design basis memorandum (Attachment 2). The weighted CN values to predict direct runoff are provided in Table 7. The wet antecedent moisture condition (AMC III) was considered in the modelling. A schematic flow diagram used for the design of the TSF collection channels and ponds is presented in Figure 4.

Table 7: Catchment Parameters

Catchment	Lag Time (min.)	Catchment Area Type	Weighted CN Value (AMC III)
Channel 1	8.7	TSF embankment and buttress	84
Channel 2	9.5	TSF embankment and buttress	84
Channel 3a[(a)]	8.9	TSF embankment and buttress	84
Channel 3b[(a)]	8.3	TSF embankment and buttress	84
Channel 4a[(b)]	8.6	TSF embankment and buttress	84
Channel 4b[(b)]	10.2	TSF embankment and buttress	84
Channel 5	15.2	TSF embankment and buttress	84
Channel 6	7.6	TSF embankment and buttress	84
Channel 7	3.6–5.6	TSF embankment and buttress	84
Long Ditch[(c)]	17.4–45.8	waste rock, disturbed, haul road, and undisturbed[(d)]	84
SERDS ditch[(c)]	35.3	waste rock, disturbed areas, haul road, mill site, and undisturbed areas[(d)]	84
TSF upstream contact[(c)]	11.4	undisturbed and disturbed areas	78
CCS direct catchment	9.7	disturbed areas, haul road, and undisturbed areas[(d)]	81
Perimeter Embankment	14.5	waste rock, disturbed areas, haul road, and undisturbed areas[(d)]	86
TSF upstream non-contact	15.2	undisturbed and disturbed areas	74



Notes: CN = curve number; AMC III = antecedent moisture condition III; TSF = Tailings Storage Facility; SERDS = Southeast Rock Disposal Site; CCS = Central Collection Sump.

(a) Channel 3 includes channels 3a and 3b for design discharge analysis purposes.

(b) Channel 4 includes channels 4a and 4b for design discharge analysis purposes.

(c) These catchments report to CCS.

(d) Source: Golder 2016a.

Notes: TSF = tailings storage facility; SERDS = Southeast Rock Disposal Site; CCS = Central Collection Sump.

Figure 4: Flow Diagram – Tailings Storage Facility Collection Channels

The estimated peak flows for the channels resulting from the 24-hour 1:200-year rain plus snowmelt event that includes seepage flow from the TSF and pumped flow from other ponds are provided in Table 8. The estimated peak runoff inflows and volumes, from the 24-hour 1:10-year and 1:200-year rain plus snowmelt events to the SESCP, MESCP, CCS, and PETBP are provided in Table 9. Discharge from the Long Ditch and the SERDS Ditch to the CCS is limited by their conveyance capacity (3.5 cubic metres per second [m^3/s] and 2.9 m^3/s, respectively [Golder 2016b and 2016c]). These peak flows were used in the design as peak discharges to the CCS during a 1:200-year event.

Table 8: Estimated Peak Flow in Channels

Channel	Peak Flow[a] (m^3/s) (1:200-year 24-hr rain plus snowmelt)
Channel 1	1.8
Channel 2	0.7
Channel 3a[b]	0.9
Channel 3b[b]	2.7
Channel 4a[c]	1.5
Channel 4b[c]	3.1
Channel 5	2.7
Channel 6	1.3
Channel 7	10.1

(a) Peak flows include runoff, seepage flow from the TSF and pumped flow from other ponds.
(b) Channel 3 includes channels 3a and 3b for design discharge analysis purposes.
(c) Channel 4 includes channels 4a and 4b for design discharge analysis purposes.

Table 9: Estimated Runoff Inflow Rate and Volume to South and Main Embankment Seepage Collection Ponds, Central Collection Sump, and Perimeter Embankment Till Borrow Pond

Pond/Sump	Runoff Inflow Volume (1000 m^3)		Peak Runoff Inflow Rate (m^3/s)[a]	
	1:10-year	1:200-year	1:10-year	1:200-year
SESCP	4.30	7.32	0.34	0.58
MESCP[b]	15.78	26.71	1.25	2.13
CCS	115.5	168.5	10.0	13.8
PETBP	128.3	188.8	8.4	12.6

Notes: m^3/s = cubic metres per second; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; CCS = Central Collection Sump; PETBP = Perimeter Embankment Till Borrow Pond.

(a)Peak flows include direct precipitation to ponds.

(b) Estimated runoff and volume include contingency for extension of catchment reporting to Channel 4 as per potential elevation 987 m tailing storage facility embankment raise.

4.0 HYDRAULIC AND CIVIL DESIGN

This section describes the TSF surface water management infrastructure design. The estimated peak design flows used in the design are described in Section 3.0.

4.1 Channels

The collection channels were sized to convey the peak flow generated from the 1:200-year 24-hour storm event, as well as any seepage/drain flow plus any pumped flow from other ponds if applicable. The seepage flow rates are presented in Section 2.5. The channels were designed to include a minimum 0.3 metre freeboard.

The channels were sized assuming uniform flow conditions using the Manning's equation and accounting for superelevation in the curves. The Manning's coefficient values used for the channels are presented in Table 10. Manning's values for capacity were used in Manning's equation to size the channel for conveyance capacity. Manning's values for stability were used to verify the stability of the channel lining during design flow conditions; the maximum channel longitudinal slope was used for stability verification. Superelevation for each curve along the channels was estimated using the US Army Corps of Engineers (USACE 1972) method and results from the Manning's equation. The estimated superelevation was minimal, eliminating the need for any local increase in channel depth. For erosion protection of the channels, the riprap class was selected considering the maximum permissible velocity of the riprap provided in Table 11.

Table 10: Manning's Values for Channel Materials

Material	D_{50}	Manning's Values for Capacity	Manning's Values for Stability
Plastic	-	0.012	0.010
Gravel, uniform section, clean[(a)]	-	0.030	0.022
Riprap class 10 kg	200	0.038	0.034
Riprap class 25 kg	270	0.039	0.035
Riprap class 50 kg	340	0.042	0.037
Riprap class 100 kg	425	0.044	0.039
Riprap class 280 kg	610	0.046	0.042
Riprap class 1 000 kg	915	0.049	0.044
Grouted riprap	380	0.040	0.028

Notes: - = not applicable; D_{50} = median particle size.
(a) Manning's n for channels (Chow 1959).

Table 11: Maximum Permissible Velocity for Riprap and Plastic

Riprap Class	Velocity (m/s)
Plastic	5.0
Gravel, uniform section, clean	1.0
10 kg	2.7
25 kg	3.1
50 kg	3.5
100 kg	3.9
280 kg	4.5
Riprap class 1 000 kg	5.0
Grouted riprap	refer to Figure 7

Notes: m/s = metres per second.
Source: BC MOTI (2020) – values rounded.

Each of the TSF surface water management infrastructure channels is described below. The channel dimensions, normal flow depth, and normal flow velocity for each channel are provided in Table 12.

Table 12: Collection Channels Design Summary

Channel (Approximate Station PVI [m])	Total Flow (m^3/s)[(b)]	Base Width (m)	Channel Depth) (m)	Side Slopes (xH:1V)	Channel Slope (%)	Flow Depth (m)	Flow Velocity (m/s)	Material
Channel 1 (0+080 to 0+370)	1.8	1.0	1.0	2.0	12.00	0.3	3.4	50 kg class riprap
Channel 1 (0+370 to 0+614)	1.8	3.0	0.8	2.0	0.40	0.5	1.0	10 kg class riprap
Channel 2 (0+000 to 0+190)	0.7	1.0	1.0	2.0	0.3	0.5	1.0	compacted earth
Channel 2 (0+190 to 0+263)	0.7	1.0	1.0	2.0	2.0	0.3	1.4	10 kg class riprap
Channel 3 (0+000 to 0+400)	0.9	1.0	1.0	2.0	0.5–2.3	0.5	1.6	10 kg class riprap
Channel 3 (0+400 to 0+860)	2.7	1.0	1.0	2.0	5.0	0.5	2.7	25 kg class riprap
Channel 3 (0+860 to 0+928)	2.7	1.0	1.2	2.0	0.5	0.9	1.2	10 kg class riprap
Channel 4 (0+000 to 0+510)	1.5	1.0	1.0	2.0	0.50–4.3	0.7	2.2	10 kg class riprap
Channel 4 (0+510 to 0+630)	3.1	1.0	1.0	2.0	7.40	0.5	3.3	50 kg class riprap
Channel 4 (0+670 to 0+957)	3.1	1.0	1.3	2.0	0.5–2.40	0.9	2.3	10 kg class riprap
Channel 5 (0+000 to 0+810 and 0+967 to 1+153)	2.7	1.0	1.2	2.0	0.5–2.0	0.9	2.1	10 kg class riprap
Channel 6 (0+000 to 0+230 and 0+375 to 0+458)	1.3	1.0	1.0	2.0	2.5-5.0%	0.4	2.4	10 kg Class Riprap
Channel 6 (0+230 to 0+310)	1.3	1.0	1.0	2.0	8.0%	0.3	2.8	25 kg Class Riprap
Channel 7 (0+018 to 0+060 and 0+190 to 0+230)	10.1	6.0	1.5	2.0	10.00	0.4	3.9	100 kg class riprap
Channel 7 (0+060 to 0+146 and 0+172 to 0+190)	10.1	6.0	1.9	2.0	0.50	0.9	1.6	10 kg class riprap
Channel 7 (0+230 to 0+689)	10.1	6.0	1.6	2.0	0.10	1.2	1.2[(c)]	compacted earth
Channel 7 (0+689 to 0+692)	10.1	10.0	0.6	2.0	17.00	0.3	4.0	100 kg class riprap

Notes: PVI = point of vertical intersection; m^3/s = cubic metres per second.

(a) Total flow is the peak flow from storm events (presented in Table 8) plus the seepage flows.

(b) This is a temporary channel and some extension of erosion will be acceptable.

Channel 1—Channel 1 collects runoff from the embankment and the natural catchment (catchment 1 in Figure 3) and drains to SESCP. A pipeline (pipeline 1) is required to convey flow from the depression area to Channel 1. Channel 1 has a base width that varies between 1.0 m to 3.0 m with 2H:1V side slopes and channel depth that varies between 0.8 to 1.0 m. The design for pipeline 1 is described in Section 4.2 and Table 15.

Channel 2—Channel 2 collects runoff from the embankment and drains to SESCP. Channel 2 has a base width of 1.0 m with 2H:1V side slopes and channel depth of 1.0 m.

Channel 3—Channel 3 collects runoff from the embankment and drains to MESCP. In addition, pumping from the SESCP at a rate of 360 m^3/hr is to be conveyed to the MESCP by Channel 3 (Attachment 2). Channel 3 has a base width of 1.0 m with 2H:1V side slopes and channel depth of 1.0 to 1.2 m.

Channel 4—Channel 4 collects runoff from the embankment and drains to MESCP. The existing Channel 4 is to be maintained until future phases of TMF development (or site development). Channel 4 has a base width of 1.0 m with 2H:1V side slopes and channel depth varies between 1.0 to 1.3 m.

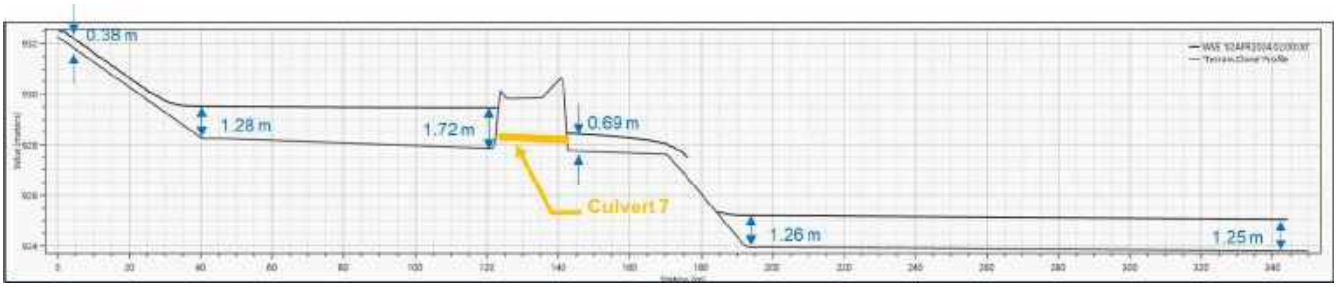
Channel 5—Channel 5 collects runoff from the embankment and drains to PETBP. Channel 5 has a base width of 1.0 m with 2H:1V side slopes and channel depth of 1.2 m.

Channel 6—Channel 6 collects runoff from the embankment and drains to CCS Pond. Channel 6 has a base width of 1.0 m with 2H:1V side slopes and channel depth of 1.0 m.

Channel 7—Channel 7 conveys discharge from the CCS to the PETBP and collects runoff from the perimeter embankment. Culvert 7 will be located approximately 130 m downstream from the CCS discharge point to convey discharge from the pond. The channel is designed to convey discharge from a 1:200-year 24-hour storm event to PETBP through culvert 7 plus runoff from catchment 10 (Figure 3) generated from a 1:200-year 24-hour storm event with a minimum of 0.3 m freeboard. Channel 7 has a base width of 6.0 m with 2H:1V side slopes and channel depth of 0.7 to 1.9 m.

A HEC-RAS 2D model was developed to simulate discharge of the design flow and flow depth from a 1:10-year 24-hour storm event and to confirm overtopping does not occur during the storm event. The HEC-RAS 2D model was developed using terrain generated by incorporating the proposed channel 7 design to LiDAR provided by MPMC (February 2024) and covers downstream of the CCS discharge point extending to approximately 200 m downstream of culvert 7. Culvert 7 is represented by a 2D connection structure as indicated in Figure 5; its characteristics are described in Table 15. The analysis indicates that discharge from a 1:200-year 24-hour storm event (9.58 m^3/s) is sufficiently conveyed without overtopping. The maximum flow depth within the model boundary was 1.7 m and occurs immediately upstream of culvert 7 (Figure 6).

Figure 5: Extent of Simulated 1:200 Year 24-Hour Storm Event for Channel 7



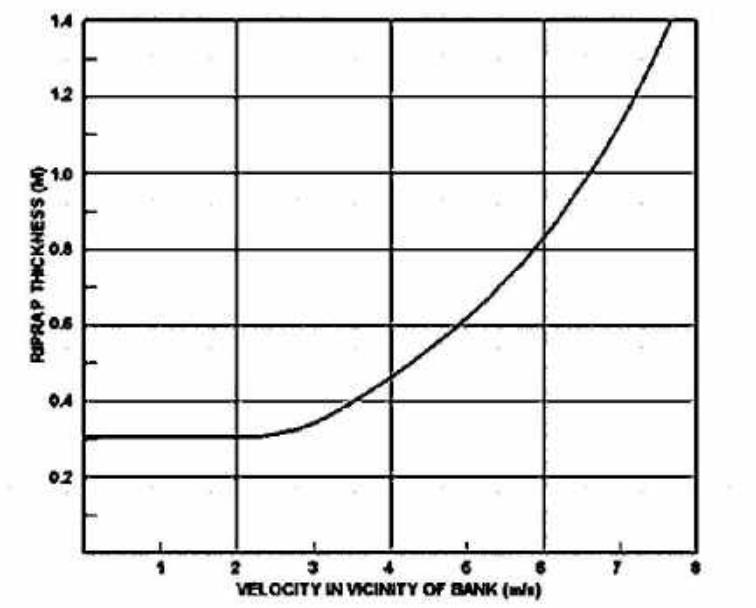


Figure 6: Channel 7 Simulated 1:200 Year 24-Hour Storm Event Water Surface Profile

4.1.1 Discharge Chute

Collection channels will require a steep (approximately 50% longitudinal slope) outfall structure for discharging to the collection ponds. Grouted riprap was selected for the lining material for erosion protection. The required riprap thicknesses were determined based on the peak flow velocity during a 1:200-year 24-hour storm event (Figure 7) and are summarized in Table 13.

Source: HEC 11 2024.

Figure 7: Required Blanket Thickness as a Function of Flow Velocity

Table 13: Discharge Chute Design Summary

Chute	Base Width (m)	Channel Depth (m)	Longitudinal Slope (%)	Flow Velocity (m/s)	Grouted Riprap Thickness (mm)	Grout Penetration Thickness (mm)
1	3.0	0.5	50	5.2	700	200
2	1.0	0.5	50	5.0	600	200
3	2.0	0.5	50	6.2	900	200
4	3.0	0.5	50	6.5	1000	200
5	2.5	0.5	50	6.5	1000	200
6	1.0	0.6	20	4.5	600	200
7	11.0	0.5	50	6.9	1,100	200

4.1.2 Energy Dissipation Structure

Energy dissipation structures (stilling basin) will be required for channels 6 and 7 at the hydraulic jump. A hydraulic jump forms during the conversion of kinetic energy to potential energy where the channel slope decreases significantly and leads to a sudden change in flow depth and velocity.

The stilling basins were sized using results from the Manning's equation and three hydraulic design methods from the Department of the Interior Bureau of Reclamation (USBR 1984; USACE 1977) and the Prairie Farm Rehabilitation Administration (PFRA 1979).

The stilling basins will be constructed with a longitudinal slope of 0%. Consistent with the channel design inputs (Attachment 2), 0.3 m of freeboard was accounted for in defining the required depth of the energy dissipation structures. The design dimensions of the stilling basins are provided in Table 14.

Table 14: Stilling Basin Dimensions

Channel	Upstream Slope%	Downstream Slope%	Flow Velocity V_1 (m/s)	Basin Depth (m)	Basin Length (m)
Channel 6	16.7%	1%	3.5	1.1	1.0
Channel 7	10.0%	0.1%	3.9	1.0	6.0

As a result, channel depth is increased to 1.4 m at station 2+507 of channel 7 for a distance of 5.9 m to maintain a minimum freeboard of 0.3 m. The freeboard requirement at station 2+209 of channel 7 is already satisfied by the 1.8 m deep channel; thus, no additional channel depth is required.

4.2 Culverts/Pipelines

Culverts will be placed along the channels at road crossings and a pipeline will be placed to convey runoff from the western portion of catchment 18 (Figure 2) that collects in a natural depression to channel 1. Culverts and pipelines were sized using the HY-8 design software (USDOT 2022), which is a 1D steady-state hydraulic modelling program developed by the U.S. Department of Transportation, Federal Highway Administration. Culverts and pipelines were sized to convey the 1:200-year 24-hour storm event from the reporting catchment. A summary of the culvert designs is provided in Table 15 and a summary of the pipeline design is provided in Table 16. A typical cross-section and plan view of the culverts and the pipeline are provided in Attachment 1, Drawings 06, 13, 20, and 22.

Table 15. Culvert Design Summary

Culvert	Diameter (mm)	No. of Barrels	Material	Design Slope (%)	Design Flow (m^3/s)	Inlet Flow Depth (m)	Outlet Flow Velocity (m/s)
Channel 1 culvert	1000	2	corrugated steel	12.5	1.8	0.8	4.5[(a)]
Channel 4 culvert	1000	2	corrugated steel	5.8	1.5	0.8	3.2
Channel 6 culvert A (station 0+310 to 0+375)	800	2	corrugated steel	2.5	1.3	0.7	2.1
Channel 6 culvert B (station 0+470 to 0+501)	900	2	corrugated steel	0.5–33	1.32	0.7	1.8
Channel 7 culvert	1400	3	corrugated steel	0.5	9.6	1.8	2.9

Notes: m^3/s = cubic metres per second.

(a) Additional erosion protection measures required at the outlet to protect bedding.

Table 16: Pipeline Design Summary

Pipeline	Diameter (mm)	No. of Barrels	Material	Design Slope (%)	Design Flow (m^3/s)	Inlet Flow Depth (m)	Outlet Flow Velocity (m/s)
Pipeline 1	800	1	HDPE	1.0	0.61	0.7	2.9

Notes: m^3/s = cubic metres per second; HDPE = high-density poly ethylene.

Construction equipment on the site includes 789 (317,515 kg) and 785 (225,826 kg) mine haul trucks. A 2.0 metre cover depth is adopted for the culverts where conditions allow, based on experience with other mine sites with similar truck loading conditions. The minimum cover requirements were calculated using the methodology in the Corrugated Steel Pipe Institute handbook (CSPI 2007) and are summarized in Table 17. Pipeline 1 has a minimum cover of 0.3 metres as it will not be subjected to traffic loading.

Table 17: Culvert Cover

Culvert	Min. Cover Calculated (m)	Adopted Cover (m)
Channel 1 Culvert	0.6	2.0
Channel 4 Culvert	0.6	2.0
Channel 6 Culvert A	0.6	2.0
Channel 6 Culvert B	0.6	2.0
Channel 7 Culvert	0.9	2.0

4.3 Ponds

The SESCP and MESCP are required to be relocated, and the PETBP extended, to accommodate the TSF embankment 974 m raise footprint. The new ponds were designed to store the inflow generated from the 1:10-year 24-hour rain plus snowmelt event while allowing 0.5 m at the bottom for sediment storage. In addition, the design included 0.3 m of freeboard for the design storm event. The SESCP and MESCP locations were proposed outside the TSF 987 m extents as per MPMC request. The design inputs for collection ponds are provided in Attachment 2.

The inflow to the ponds includes the seepage and runoff that will be collected through the collection channels and the direct precipitation to the ponds. The water transfers between the collection channels and ponds are summarized below and a schematic flow diagram is provided in Figure 4 in Section 3.0.

SESCP—Surface water and seepage from the South Embankment will be directed to the pond through channels 1 and 2 (Attachment 1, Drawings 05 to 09). Currently, water from the pond is pumped to the MESCP at the pump capacity of 360 cubic metres per hour (m^3/h) and is conveyed by channel 3 (Donoso 2023). Dimensions for the SESCP are provided in Table 18.

MESCP—Seepage and runoff from the Main Embankment will be directed to the pond through channels 3a, 3b, 4a, and 4b (see Attachment 1, Drawings 10 to 16). Currently, water from the pond is being pumped to the TSF at the pump capacity of 360 m^3/h. Dimensions for the MESCP are provided in Table 18.

CCS and PETBP—Runoff and seepage from the Perimeter Embankment will be collected through channels 5, 6, and 7 (see Attachment 1, Drawings 17 to 26) in the PETBP. CCS receives contact water runoff from its direct catchment plus runoff from SERDS Ditch, Long Ditch, and TSF upstream catchment area via CCS (Attachment 1, Drawing 26; (Golder 2020)). The pond bottom elevation used in this study was taken from a previous Golder design study for the PETBP Spillway (Golder 2021). Dimensions for the PETBP are provided in Table 18

The SESCP and MESCP will be excavated in natural ground to a depth of 3 metres. It is noted that the ponds will receive groundwater flow underneath the embankments according to the *Tailing Storage Facility Site Characterization Report* (WSP 2023). WSP also estimated the potential groundwater inflow rate or seepage rate to seepage collection ponds (WSP 2024c). The results showed that seepage rate is predicted to be lower than 0.9 L/s for MESCP and 1.3 L/s for SESCP. The assessment was based on the design depth of 3 metres and a deepened design allowing for more water storage capacity or optimizing top surface area.

Table 18: Ponds Design Summary

Dimensions	SESCP	MESCP	CCS Pond	PETBP
Total Depth (m)(3)	3	3	2.0	8 (2)
Side Slopes	2H:1V(4)	2H:1V(4)	2H:1V(1)	2H:1V(1)
Dead Volume (0.5 m depth at bottom of pond) (1000 m^3)	1.25	6.82	7.63	5.6 (2)
Live Storage Below Spillway Invert (1000 m^3)	5.37	17.31	7.63	133.9
Spillway Crest Elevation (m)	936.3	908.3	933.0(5)	923.9
Crest Elevation (m)	937	909	934.5	925

Notes: SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; CCS = Central Collection Sump; PETBP = Perimeter Embankment Till Borrow Pond.

(1) Refers to extension of the Pond.

(2) Assumed PETBP pond bottom elevation of 917 m (Golder 2021).

(3) Between Pond Bottom Elevation and Minimum Crest Elevation.

(4) The stability analysis (WSP 2024a) indicates that the proposed cut slopes at a ratio of 2H:1V meets the desired safety standards across all loading conditions.

(5) Invert elevation of channel 7.

4.4 Spillways

4.4.1 Spillway Inlet

The spillway inlets for the MESCP, CCS Pond and PETBP were modelled in the HEC-HMS model (Section 3.0). The invert elevations of the spillways were estimated iteratively using the HEC-HMS model to provide the required 0.5 metre freeboard between the maximum water level design flow during 24-hr 1:200-year rain plus snowmelt event and the crest of the pond.

The spillways will be trapezoidal with side slopes of 2H:1V. The rectangular and triangular broad-crested weir equations were used to define the capacity of the weir. Rectangular weir coefficients of 1.4-1.7 and triangular weir coefficients of 1.0 to 1.3 were adopted depending on the hydraulic configuration of the spillway channel and crest (Smith 1995). Table 19 provides a summary of the spillway invert arrangements and resulting water level and discharge.

Due to the challenging topography in the vicinity of SESCP, implementing a spillway as a channel was not the most practical solution. Instead, alternative methods employing pumps to regulate and maintain specific elevation levels within the pond, will be employed. The details will be provided at the next stage of design.

Table 19: Summary of the Spillway Arrangements

Spillway	Pond Crest Elevation (m)	Spillway Invert Elevation (m)	Initial Pond Elevation (m)	Weir Bottom Width (m)	Weir Side Slope	Peak Discharge (m^3/s)	Peak Water Elevation (m)	Freeboard (m)
MESCP Spillway	909	908.3	908.3[(a)]	10.0	2H:1V	4.6	908.7	0.3
CCS Pond	934.5	933.0	933.0[(a)]	10.0	2H:1V	10.9	934.0	0.5
PETBP Spillway	925.0	923.9	922.7[(b)]	10.0	2H:1V	7.2	924.5	0.5

Notes: m^3/s = cubic metres per second.

(a) Initial water levels were assumed to be at the spillway invert elevation.

(b) Initial water level to be maintained to optimize the spillway outlet channel.

4.4.2 Spillway Outlet Channel

The MESCPand PETBP spillways and channels will be excavated in natural ground and discharge to the environment. The spillway channels will be lined with riprap along the reaches with flow velocity greater than 1 m/s. The results of the hydraulic sizing of the spillway channels are summarized in Table 20.

Table 20: Hydraulic Sizing of Spillway Channel Outlets

Spillways	Slope (%)	Channel Depth (m)	Side Slopes	Base Width (m)	Lining	Flow Depth (m)	Max Flow Velocity (m/s)
MESCP spillway outlet channel (Station 0+007to0+060)	0.54	1.8	2H:1V	2.0	10 kg class riprap	0.9	1.3
MESCP spillway outlet channel (Station 0+060 to0+201)	0.10	1.8	2H:1V	2.0	compacted earth	1.2	0.9
PETBP spillway outlet channel (Station 0+010 to 0+164)	8.0	0.7	2H:1V	5.0	50 kg class riprap	0.4	3.5
PETBP spillway outlet channel (Station 0+164 to 0+180)	1.0	1.2	2H:1V	3.0	10 kg class riprap	0.8	2

Notes: SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond.

4.4.3 Spillway Discharge Structure

Discharge (dissipation) structures will be placed at the outlet of the spillway channels to dissipate energy, prevent erosion and to spread the discharge to the downstream environment. The width of the discharge structure is based on the top width of the respective spillway outlet channel and the length is based on the channel depth reduced to natural grade following a 2H:1V slope (Attachment 1). The dissipation structure of the PETBP spillway will be lined with 400 mm of 10 kg class riprap. Table 21 summarizes the discharge structures dimensions.

Table 21: Spillway Discharge Structure Dimensions

Spillway	Slope (%)	Width (m)	Length (m)
MESCP spillway discharge structure	0.1	2-20	20.0
PETBP spillway discharge structure	1.0	13-20	11.0

5.0 RECOMMENDATIONS FOR FUTURE STUDIES

The design of surface water management structures included in this document were based on information available at the time of design preparation. The following activities are recommended to refine or update the water management structure design presented in this document:

- Resolve the conflict between the existing roads and proposed channels alignment near Corner 3, Corner 2, and between these two corners.
- Confirmation of up-to-date as built information of all the existing mine infrastructure in proximity to the proposed water infrastructure alignments.
- Test pit investigation within the SESCP and MESCP footprints and along channels near high phreatic surface area as part of their geotechnical assessment. The estimated potential groundwater inflow rates should be reviewed after hydraulic testing of the subsurface soils and the lithologic information and observations from the test pit investigation are available.
- Assessment of rock riprap sources of supply, focusing on cost, quality of rock, and availability of the rock riprap.

6.0 CLOSURE

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

We trust that the information presented herein meets the current MPMC requirements. Please do not hesitate to contact the undersigned with any questions or concerns.

TSF Surface Water Management Infrastructure – Design Basis Memorandum

TECHNICAL MEMORANDUM

DATE May 16, 2024 **Reference No.** 23590671-059-TM-Rev1-31151

TO Matt O'Leary
Mount Polley Mining Corporation

CC Lee Nikl and Germán Pizarro

FROM Nasim Hossein and Don Kidd **EMAIL nasim.hosseini@wsp.com; don.kidd@wsp.com**

TSF SURFACE WATER MANAGEMENT INFRASTRUCTURE – DESIGN BASIS MEMORANDUM – MOUNT POLLEY MINE

1.0 INTRODUCTION

The Mount Polley Mine is a copper and gold mine operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. The site is located approximately 56 km northeast of Williams Lake, British Columbia, between Polley Lake and Bootjack Lake. The Mount Polley Mine began production in 1997.

The Tailings Storage Facility (TSF) for Mount Polly mine is being extended for future operations. The TSF is located about 3 km southeast of the mill and includes one embankment that is approximately 4.8 km in length. This design basis memorandum (DBM) has been prepared by WSP to guide the design of TSF surface water management infrastructure, and to document the parameters and criteria to be used to develop the design inputs.

This memorandum provides the design basis of the TSF surface water management infrastructure to support raising the existing TSF from its currently permitted elevation of 970 m to about 974 m. This document is the updated version of Rev0 issued on 25 December 2023.

2.0 DESIGN BASIS

The design basis and criteria include hydraulic and hydrologic design assumptions for TSF water management at the Mount Polley Mine. This document does not include the design basis and criteria for the TSF spillway. The design basis and criteria for the TSF spillway, including the design event, freeboard, and catchments are provided in the design criteria technical memorandum for tailings storage facility raise to elevation 974 m (WSP 2024).

2.1 Hydrologic and Hydraulic Design Basis

The following tables summarize the criteria for design of the TSF surface water management infrastructure.

Table 1: Design Criteria – Water Diversion and Collection Channels

Parameter	Criteria	Reference/Comment
Design Storm	1:200-year, 24-hour rain plus snowmelt.	HSRC Part 10 guidance (2016), section 3.5.2 Sediment Ponds and Diversion Structures; BC Ministry of Environment-Section 5; Permit M-200
Pumped Flow	A pump capacity of 360 m^3/hr from South Embankment Pond to the collection channel near corner 3 flowing towards Main Embankment Pond.	Informed by MPMC, May 2023
Seepage Rate to the Collection Channels	Seepage rates will be based on the maximum seepage rate that will be estimated as part of the TSF design scope of work.	WSP2024b
Drain Flow Rate to Collection Channels	Drain flow rates will be based on the maximum drain flow capacity that will be designed as part of the TSF design scope of work.	WSP2024b
24-hr 1:200-year rainfall	69 mm	WSP 2022
24-hr 1:200-year snowmelt depth	15.9 mm (See section 2.2)	Estimated using Dunne & Leopold (1978) method for a corresponding rainfall event calculated for spring conditions (April).
Catchment Area	Delineated based on topography using 2023 contours with 0.1m resolution, 2023 LiDAR topography survey provided by MPMC, and embankment and buttress contours as part of the TSF design scope of work.	Channels 1-3 reporting to the South and Main Embankment Seepage Ponds will be designed considering the ultimate TSF embankment raise (987 m crest) . [(a)] other channels will be designed considering interim TSF raise (974 m crest).
24-hour storm distribution	Soil Conservation Service Storm Type II	Section 2.3
Side slopes	2H:1V	Adopted
Longitudinal slope	Minimum 0.1% slope, to optimize excavation volume	Adopted
Freeboard	Minimum 0.3 m	Permit M-200
Minimum channel base width	1.0 m	Adopted
Minimum channel depth	0.5 m	Adopted
Erosion Protection requirements and Permissible Flow Velocity	Erosion protection materials will be selected based on estimated peak velocities along the channel alignment using the hydraulic calculations.	BC MOTI 2019 Flows estimated using HEC-HMS model. Velocities estimated using Manning's equation.
Road Crossing Culverts	1:200-year, 24-hour rain plus snowmelt.	Match design flow inputs of adjacent conveyance structure.
Road Crossing Ford (as an alternative for culverts, if needed)	5H:1V maximum crossing side slopes.	BC Ministry of Forest Lands and Natural Resource Operations (2012).

MPMC = Mount Polley Mining Corporation; TSF = Tailings Storage Facility; BC MOTI = British Columbia Ministry of Transportation and Infrastructure.

(a) Design is in progress.

Table 2: Design Inputs– Collection Ponds

Parameter	Criteria	Comment/Reference
Storage Volume – Storm	Store 1:10-year, 24 hour rain plus snowmelt storm event	This design event is consistent with requirement in Environmental Management Act Permit 11678 (EMA 2022) Permit 11678 Paragraph 2.4.5, which states that "surface water control works must be designed to convey all flows up to a 1 in 10 year 24-hour storm event and must be designed to withstand all flows up to a 1 in 200 year 24-hour storm event, without significant damage".
Storage Volume – TSF Seepage	Excluded	Seepage inflow to the South and Main Embankment Ponds will be pumped out to the TSF or Perimeter Embankment Till Borrow Pit (PETBP). MPMC operates the ponds by a water level control and pumping system that ensures sufficient storage capacity is maintained in the pond for storm events. Seepage inflow to PETBP will be pumped out to the Treatment Plant or TSF. MPMC operates the pond by a water level control and pumping system that ensures sufficient storage capacity is maintained in the pond for storm events. Extra storage allowance may be an option to allow greater operational flexibility with pumping seepage flows. To be discussed and confirmed with MPMC.
Storage Volume – TSF Upstream drain flow	Excluded	Drain inflow to the South and Main Embankment Ponds will be pumped out to the TSF or PETBP. MPMC operates the ponds by a water level control and pumping system that ensures sufficient storage capacity is maintained in the pond for storm events. Drain inflow to PETBP will be pumped out to the Water Treatment Plant or TSF by the water level control system to leave enough storage capacity for storm events. Extra storage allowance may be an option to allow greater operational flexibility with pumping upstream drain flows.
24-hr 1:10-year rainfall	47 mm	WSP 2022
24-hr 1:10-year snowmelt depth	14.8 mm (See section 2.2)	Estimated using Dunne & Leopold (1978) method for a corresponding rainfall event calculated for spring conditions (April).
Dead Volume	0.5 m bottom of the pond	Adopted
Freeboard at Spillway Entrance	Minimum 0.3 m	Between the maximum water level design flow during 24-hr 1:200-year rain plus snowmelt event and the crest of the collection pond.
Pond geometry and side slope	Minimum 2H:1V	The stability analysis (WSP 2024a) indicates that the proposed cut slopes at a ratio of 2H:1V meets the desired safety standards across all loading conditions.
South and Main Embankment Ponds pumping capacity	The current pumping capacity is: South Embankment Pond to Main Embankment Pond = 360 m^3/hr. Main Embankment Pond to TSF = 360 m^3/hr.	Informed by MPMC, May 2023 The current pumping rates must be verified or updated according to the updates to the operational pumping rules and upstream drain and seepage flow rates. The opportunity of sending water from the South and Main Embankment Ponds to the PETBP to be evaluated.
Emergency Spillways	Convey the 1:200-year, 24-hour rain plus snowmelt storm event	EMA 2022 - Permit 11678

Table 2: Design Inputs– Collection Ponds

Parameter	Criteria	Comment/Reference
Freeboard at Spillway Outlet Channel	Minimum 0.3 m freeboard	Permit M-200
Pond Liners	Native material liner	Native material is anticipated to have sufficiently low permeability to act as pond lining.

2.2 Design Precipitation Depth

Extreme runoff volumes are anticipated to be associated with extreme rainfall events occurring during freshet. The snowmelt is expected to occur between March and May with a relatively greater portion melting in April. Snowmelt estimates induced by a corresponding rainfall event (rain plus snowmelt event) were calculated for spring conditions (April) using equation below (Dunne & Leopold, 1978).

$$M_R = 1.42T_a + 2.5 + \frac{RT_aC_W}{L} + 0.0059T_au_2$$

Where:

M_R = snowmelt in mm/day Snow Water Equivalent (SWE).
R = rainfall depth in mm/day averaged over the duration of the storm.
T_a = average air temperature over the duration in °C.
C_W = specific heat of water (equal to 1 cal/g/°C).
L = latent heat of fusion of ice equal to 80 cal/g.
u_2 = wind speed in km/day

The potential snowmelt during a rainfall event was estimated using the mean daily temperature in April of 3.7°C (WSP 2022). The spring average wind speed of 2.6 m/s (Golder 2017) was used for this equation. The estimated spring maximum 24-hour snowmelt rates are presented in Table 3.

Table 3: 24-Hour Rainfall, Snowmelt, and Rain Plus Snowmelt (mm)

Return Period (Years)	Mean Daily Temperature in April (°C)	24-Hour Rainfall (mm)	24-Hour Snowmelt (mm)	24-Hour Rain Plus Snowmelt (mm)
10	3.7	47	14.8	61.8
200	3.7	69	15.9	84.9

2.3 Design Storm Event Rainfall Distribution

Natural Resources Conservation Service (NRCS) (formerly known as Soil Conservation Service (SCS)) defines three storm distributions: Types I, Type IA, and Type II. The SCS storm type distribution over 24 hours at the Site was estimated based on the 1:100-year depth-duration-frequency (DDF) values at the Williams Lake (Station ID 1098940) and Quesnel (Station ID 1096631) climate stations operated by ECCC. The rainfall distribution at the Williams Lake and Quesnel climate stations for 5-minute to 12-hour durations were estimated as a percentage of the 24-hour rainfall and the results were compared to the representative percentages of each of the SCS curves. The DDF values were plotted and compared to the representative percentages of each of the SCS curves (Table 4 and Figure 1).

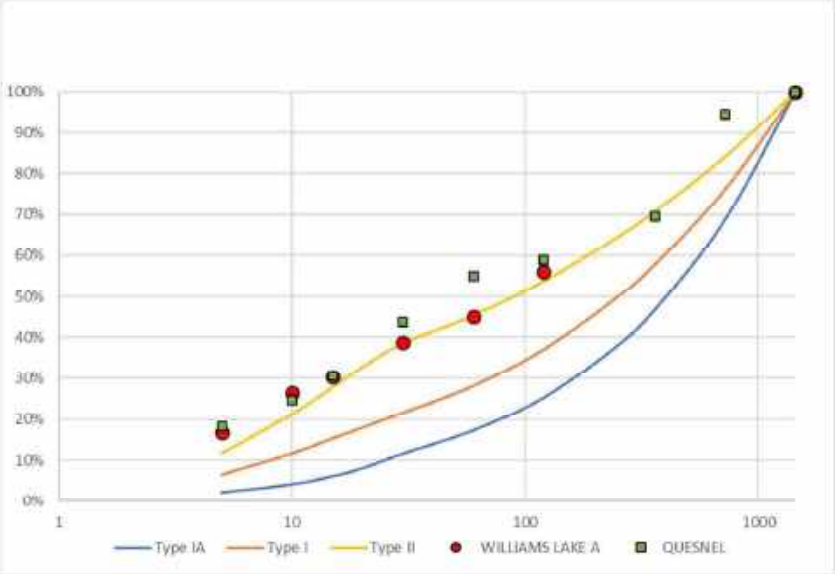

Figure 1: 1:100-year depth-duration values at the Williams Lake and Quesnel

Table 4: 1:100-year Depth-Duration-Frequency Values in mm for the Williams Lake and Quesnel Climate Stations

Duration	Williams Lake	Quesnel
5 min	7.8	8.8
10 min	12.4	11.9
15 min	14.2	14.7
30 min	18.2	21.1
1 hr	21.1	26.5
2 hr	26.3	28.4
6 hr	Not Available	33.5
12 hr	Not Available	45.6

Table 5: Comparison of DDF to NRCS Storm Distributions

Durations	DDF At Williams Lake	DDF At Quesnel	SCS Type IA	SCS Type I	SCS Type II
5 min	17%	18%	2%	6%	12%
10 min	26%	25%	4%	12%	21%
15 min	30%	30%	6%	15%	28%
30 min	39%	44%	12%	22%	39%
1 hr	45%	55%	17%	28%	45%
2 hr	56%	59%	25%	37%	54%
6 hr	Not Available	70%	47%	58%	71%
12 hr	Not Available	95%	69%	76%	84%

Table 5 indicates that the short-duration rainfall distribution at the Mt Polley mine site follows Type II distribution. Millar (2017) presented similar results and indicated that the SCS Type II distribution is considered representative of the 24-hour storm distribution for the Williams Lake climate station. For the design purpose, the SCS Type II storm was identified as the best representation of the typical rainstorm intensities at the site and was used to derive the design 24-hour rainfall distribution.

2.4 Hydrologic and Hydraulic Methods

The design of the TSF water management infrastructure will be based on design peak flows and volumes estimated using the Hydrologic Engineering Center hydrologic modelling system software (HEC-HMS) version 4.10 (USACE 2022). The US Department of Agriculture, Soil Conservation Service (SCS) Type IA rainfall distribution curve (USDA 1986) will be used to derive the design of storm hyetographs.

The SCS curve number (CN) method (USDA, 1986) will be used to estimate general catchment area losses. These losses are considered when determining the amount of rainfall during a storm that becomes direct runoff.

Time of concentration is estimated using SCS TR-55 method (USDA 2009), which divides the longest flow path into sheet flow, shallow concentrated flow, and open channel flow, and considers a minimum time of concentration of 6 minutes. The lag time was estimated as 60% of the time of concentration.

Catchment Curve Number (CN) values, to predict direct runoff, are provided in Table 4.

Table 6: Soil Conservation Services Curve Numbers Used for the Project

Land Type	CN (AMC II)	CN (AMC III)
Undisturbed catchment	55	73.8
TSF Embankment and Buttress	70	84.3
Disturbed catchment	79	89.6
Open Water	No loss	

CN = Curve number; AMC II = Average antecedent moisture conditions, AMC III = Wet antecedent moisture condition.

Channels will be sized for uniform flow conditions using Manning's equation for open channel flow. Manning's n values for different riprap sizes and plastic liner are shown in Table 5. For erosion protection of the channels, the riprap class was selected considering the maximum permissible velocity of the riprap provided in Table 8.

Table 7: Manning's n Values for Channels

Material Type	Manning's n for Capacity	Manning's n for Stability
Plastic	0.012	0.010
gravel, uniform section, clean(1)	0.03	0.022
Riprap class 10 KG	0.038	0.034
Riprap class 25 KG	0.039	0.035
Riprap class 50 KG	0.042	0.037
Riprap class 100 KG	0.044	0.039
Riprap class 250 KG	0.046	0.042

(1) Manning's n for Channels (Chow, 1959).

Table 8: Maximum Permissible Velocity for Riprap and Plastic (MOTI 2019)

Riprap Class	Velocity (m/s)
Plastic	5.0
Gravel, uniform section, clean	1.0
10 kg	2.7
25 kg	3.1
50 kg	3.5
100 kg	3.9
280 kg	4.5
Riprap class 1 000 KG	5.0
Grouted riprap	Refer to Figure 2

APPENDIX A
Springer Expansion LOM SWWBM Inputs

APPENDIX B
Flow Diagrams and 2022 Water Management Infrastructure

APPENDIX C
SWWBM Results

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) is currently submitting a permit application for the new Springer Expansion phase, extending assumed operations until March 31, 2031. The Site Wide Water Balance Model (SWWBM) presented in this report is a critical component, essential to support the Water Management Plan required for the Springer Expansion permit application. It should be noted that the specific operation, closure, and post-closure dates in this report have been assumed for the purpose of modelling. There are many factors that exist that can alter these dates, such as delays on the mine production as a result of metal prices, new exploration, care and maintenance periods, revisions to the mine plan. Thus, these time frames should not be considered static.

The SWWBM was originally developed for the Technical Assessment Report (TAR) to support the effects predictions in the Mount Polley Mine Long Term Water Management Plan (Golder 2016a) for the Mount Polley Mine (the Mine) and has since been calibrated on an annual basis (refer to WSP 2023a for the latest 2022 annual calibration). This report presents the SWWBM based on the Springer Expansion Life-of-Mine (LOM) Plan informed by MPMC (MPMC 2022), to a crest elevation of 987 m of the TSF.

The work presented in this report is as follows:

- A summary of the physical setting at the Site (Section 2.0)
- An overview of the climate and hydrology at the Site (Section 3.0)
- A description of the SWWBM, including inputs and assumptions (Section 4.0)
- A presentation of SWWBM results, including operational, closure, post-closure phases (Section 5.0)
- Tabular inputs of the SWWBM (APPENDIX A)
- Flow Diagrams and 2022 Water Management Infrastructure Drawing (APPENDIX B)

This report has been prepared in accordance with the “Study Limitations,” which are presented at the beginning of the report. The reader’s attention is specifically drawn to this information for reference during use of this report.

2.0 BACKGROUND

2.1 General Information

Mount Polley Mine is a copper and gold mine operated by MPMC, a subsidiary of Imperial Metals Corporation. The Mine is located approximately 56 km northeast of Williams Lake, British Columbia (BC), and is located between Polley Lake and Bootjack Lake. Within the area of the Mine, the plateau has somewhat higher relief, with the Mine rising approximately 300 metres (m) above the surrounding terrain. Topographically, the Site area consists of north–south trending ridges of moderate elevation and relief. Local elevations range from 922 metres above sea level (masl) at Polley Lake to 1,266 masl at the top of Polley Mountain with an average elevation of 1,038 masl. The total surface area of the Site is 17.8 square kilometers (km^2).

MPMC is applying for a permit for the new Springer Expansion phase, which extends operations until 2031. Updating the SWWBM to reflect the Springer Expansion LOM plan is required to support the Water Management Plan for this permit application. The updated SWWBM will generate results throughout the operational phase to a crest level of 987 m of the TSF (to be completed before the end of operations), extending into the closure and post-closure phases.

3.0 CLIMATE AND HYDROLOGY

3.1 Climate

In 2022, WSP Canada Inc. (WSP) updated the climate baseline data for the Mine. The climate of the Mine was characterized in the Baseline Climate Update Report (Golder 2022b) using historical measurements from local climate stations, supported by data obtained from five nearby regional Environment and Climate Change Canada (ECCC) climate stations. During the winter, snowpack is measured at four snow course sites at a minimum frequency of once per month, with more frequent measurements typically being taken during the melt phase. Detailed climate information can be viewed in Golder 2022b. The climate inputs for the SWWBM are presented in Section 4.5.1.

3.2 Site Drainage and Surface Hydrology

A network of ditches, sumps, and pumping systems are operated by MPMC to manage surface water at the Mine. The current water management infrastructure of Mount Polley is presented in the MPMC 2022 Water Management Infrastructure Drawing provided in APPENDIX B. Surface water is separated between contact (mine affected) and non-contact (non mine affected) sources of runoff. The two water sources can be characterized as follows:

- Contact water: water that may have come into direct contact with mining and milling activities. This water generally requires treatment before release to the environment.
- Non-contact water: runoff originating from areas unaltered by mining activity that does not contact mining areas. It is typically diverted to the maximum extent practicable and allowed to discharge directly to the receiving environment.

The objective of current water management practices is to minimize the mingling of contact and non-contact surface water sources whenever possible. These flows originate from direct precipitation, runoff, and snowmelt from catchments. Contact water is mainly collected along two ditches running north to south along the Site: West Ditch and Long Ditch. A block flow diagram provides a conceptual overview of the sumps and their respective connections across the Mine area presented in Figure 1.

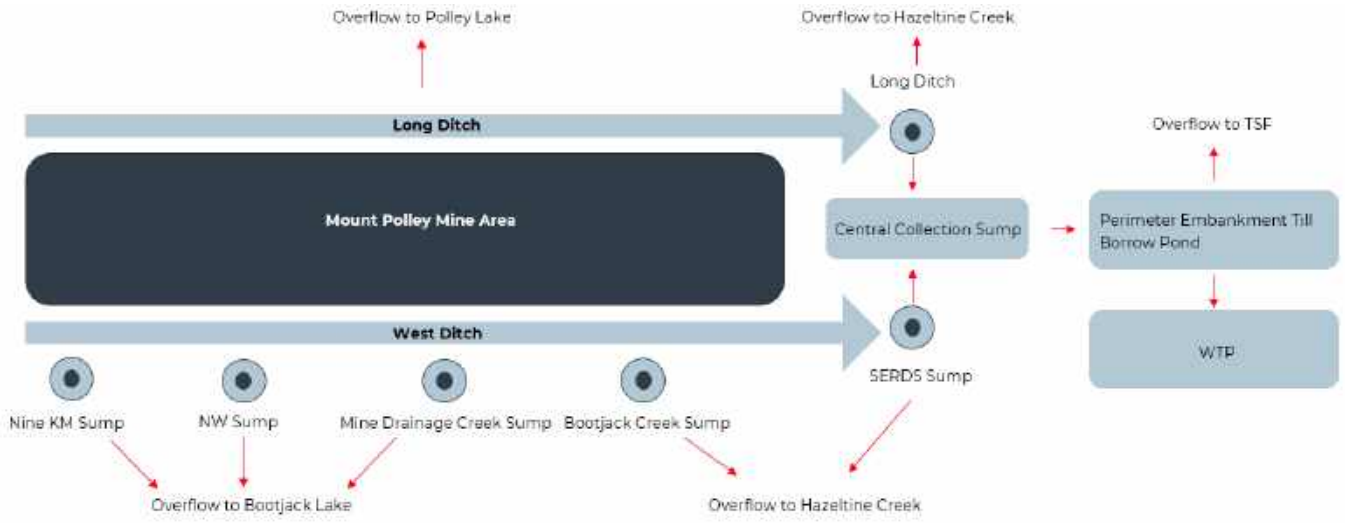

Figure 1: Conceptual Block Flow Diagram of Mount Polley Mine Contact Water Management Infrastructure

The West Ditch system collects contact water starting from the west side of the Site, progressing from the Nine KM Sump to the SERDS Sump. Components of the West Ditch system include various sumps, ditches, and pumping systems.

Similarly, the Long Ditch system manages contact water from the east side of the Site, extending from below the site access road to the Central Collection Sump. This system also comprises various sumps, ditches, and pumping systems.

3.3 Pit Groundwater Hydrogeology

Groundwater flow has been assessed for the following open pits at the mine: Springer Pit, Cariboo Pit, Wight Pit, and Boundary Pit. The analysis for each pit is described in a series of technical memoranda in Appendix B of the TAR (Attachments C, D, E, and F; Golder 2016a).

Hydrogeological assessments for the pits were conducted as part of the TAR to estimate groundwater seepage into and out of the pits. Seepage estimates have not been updated for the WBM results presented in this document, which relies on the estimates completed in the 2016 TAR. WSP is currently updating these seepage estimates for the Mine pits, the seepage estimates will be updated in the SWWBM when available. Results will be assessed to identify any notable changes to the seepage estimate. Updated seepage parameters are not expected to alter the water balance results for the site or alter the water treatment quantity design basis; however, this will be confirmed once updated parameters are available. Groundwater inputs for the SWWBM are presented in Section 4.5.3.

3.4 Tailings Storage Facility

Flows from the TSF have been discussed in the TAR (Golder 2016a). WSP is currently designing a new upstream drainage system within the TSF to accommodate the increase in the TSF pond elevation (WSP 2023e). Updated estimations of seepage flow rates have been developed for each embankment as part of the TSF embankment crest at elevation 987 m design and are provided in Section 4.5.7.5.

4.0 SITE WIDE WATER BALANCE MODEL

An update to the existing SWWBM was carried out using GoldSim™ (Version 14.0). This section presents SWWBM software, model objectives, general assumptions, processes, and inputs.

4.1 Model Software

GoldSim allows dynamic and complex water quantity interactions to be represented through a visual and highly modular framework. All input parameters and functions are defined by the user and are built as individual objects or elements linked together by mathematical expressions. GoldSim is widely used for mine water quantity studies and provides the following capabilities:

- Deterministic and probabilistic simulations can be run within the model, which allows statistics and probabilities to be assigned to the model outputs.
- Simulation periods can be varied within the same model.
- The model framework can be easily adjusted to account for evolving conditions on a mine site, which allows the model to be used as an operational planning tool.
- Water quantity and water quality modules can be directly linked within the model, which allows both modules to be updated simultaneously; this is particularly useful when evaluating a range of scenarios (e.g., alternative water management strategies).

4.2 Model Objectives

This SWWBM was updated to include the future operational phase, in line with the assumed Springer Expansion LOM plan. Additionally, it has been updated to reflect changes in the closure and post-closure phases since the Reclamation and Closure Model update completed in 2022 (Golder 2022a).

This SWWBM has the following objectives:

- Include a future operational phase that will extend from May 2, 2023, to March 31, 2031.
- Include a closure phase extending from April 1, 2031, to March 31, 2041.
- Include a post-closure phase commencing on April 1, 2041, and extending to March 31, 2131 (100 years including closure).
- Estimate the quantity of contact water collected on-site per the climate conditions.
- Estimate water retention requirements in major storage locations at site such as the TSF and pits.
- Estimate the quantity of contact water requiring treatment.
- Enable assessment of future operations water quality and associated water treatment and/or discharge options.
- Provide a model that can be linked to a water quality module that assesses site water quality during forecasted future operations.

4.3 Assumptions and Key Input Parameter Values

General assumptions applied to this model are as follows:

- Continuation of mining of the Springer Pit and Cariboo Pit will not significantly increase the footprint of the pits.
- There is no seepage from the ponds or sumps other than the TSF (i.e., all ponds and sumps are assumed to be lined, or seepage is assumed to be negligible).
- Direct precipitation, evaporation, and seepage loss from ditches are assumed to be negligible.
- Precipitation occurs as snow from December to February and as rain or a mixture of rain and snow in all other months.
- Snowpack is represented by the cumulative precipitation depths over the months of December, January, and February, spanning a period of three months.
- Snowmelt occurs in the months of March, April, and May as a percentage of the maximum snowpack at the end of February (5% in March, 90% in April, and 5% in May).
- The closure and post-closure phases are included in the SWWBM, and the flow logic and model wiring for these phases are based on the 2022 Reclamation and Closure Plan (RCP) (Golder 2022a). Flow diagrams for closure and post-closure phases are also presented in Appendix B.

Key input parameter values and assumptions for the operational phase simulations are presented in Table 1.

Table 1: Key Input Parameter Values and Assumptions

Parameter	Value	Reference
TSF emergency spillway invert elevation at 987 m dam crest elevation during operations	985.8 m	WSP 2023c
Initial TSF water volume	2.84 M-m^3	TSF Weekly Report (MPMC 2023a)
Initial Springer Pit water level	970.66 m	TSF Weekly Report (MPMC 2023a)
Initial Cariboo Pit water level	954.72 m	TSF Weekly Report (MPMC 2023a)
Initial Wight Pit water level	912.87 m	TSF Weekly Report (MPMC 2023a)
Tailings stored in Springer Pit	2.00 M-m^3	TSF Weekly Report (MPMC 2023a)
Water Treatment Plant (WTP) treatment capacity	25,000 m^3/d	Provided by MPMC (MPMC 2023b)

4.4 Model Domain

A description of the model flows is provided in APPENDIX A. The domain and structure of the SWWBM is outlined in the conceptual flow diagrams for the forecasted operational, closure and post-closure phases in Appendix B. The flow diagrams illustrate the assumed water circuit system at the Site during operations, closure, and post-closure, including the storage and conveyance of water. The water management infrastructure within the SWWBM for the operational phase is summarized in Table 2 and flow types are outlined in Table 3.

From closure and progressively to post-closure, certain Site areas will be reclaimed, and run-off will become non-contact water and the volume of annual contact water will reduce. Pumping rates for the Site will be reduced at the end of the closure period, as certain areas are assumed reclaimed. The progression of flow routes and discharges to the environment are shown on the flow diagrams presented in Appendix B.

Table 2: Water Management Infrastructure during Operations

Major Ditches	Sumps and Minor Ponds	Major Ponds and Storage Facilities
▪ Long Ditch ▪ SERDS Ditch (lower portion of West Ditch)	▪ South Seepage Pond ▪ Main Embankment Seepage Pond ▪ Central Collection Pond ▪ Bootjack Creek Sump ▪ Mill Site Sump ▪ Mine Drainage Creek Sump ▪ NW Sump ▪ 9K Sump ▪ Boundary Pit	▪ TSF ▪ Cariboo Pit ▪ Springer Pit ▪ Wight Pit ▪ Perimeter Embankment Till Borrow Pond

SERDS=Southeast Rock Disposal Site; TSF = Tailings Storage Facility

Table 3: Types of Flows Represented in the SWWBM

Site Inflows	Site Outflows or Transfers
▪ Direct precipitation ▪ Runoff ▪ Seepage (includes baseflows)	▪ Water consumption flows (turbo-misters, and water trucks) ▪ Water treatment discharge ▪ permanent, unrecoverable storage in tailings (interstitial water) ▪ Open water evaporation ▪ Pumped flows between facilities ▪ Transfer flows (gravity flows between facilities) ▪ Groundwater flows

4.5 Model Inputs

4.5.1 Climate Inputs

The following sections describe the climate inputs used in the SWWBM.

4.5.1.1 Precipitation

The SWWBM was run with probabilistic monthly climate inputs for this assessment. To develop probabilistic inputs, monthly precipitation data in the Mount Polley Mine Climate Baseline Update (Golder 2022b) were fitted to a log-normal probability distribution. The mean and standard deviation for the monthly precipitation values are shown in Table 4.The model is run using a daily time step, which represents better variation between months such as the water volume in the TSF or the pits.

The derived monthly means and standard deviations of the precipitation values, defined in the model as stochastic elements, were used to generate random values based on the distribution of the dataset. The stochastic generator was set to perform 2000 realizations to create a sample size that was sufficiently large to account for a range of conceivable monthly climatic precipitation scenarios for the study period. The results of these 2000 realizations were compiled to generate probability distributions that yield percentile values. To represent average and extreme climate scenarios, results for the 50th, 90th and 99.5th percentiles are presented in Section 5.0.

Table 4: Stochastic Climate Generator Log-Normal Distribution Input Arguments

Month	Mean of the Monthly Precipitation Depths (mm)	Standard Deviation of the Monthly Precipitation Depths (mm)
January	49.4	30.9
February	35.8	24.2
March	29.7	13.9
April	44.7	43.6
May	49.9	20.2
June	70.8	32.9
July	63.6	55.1
August	50.6	31.2
September	52.3	30.1
October	58.1	27.9
November	49.8	28.9
December	57.6	32.7

4.5.1.2 Evaporation

The median annual shallow lake evaporation rate is estimated to be 670 mm. Monthly evaporation rates vary between 0 mm in December to 136 mm in July. Estimated median monthly and annual shallow lake evaporation from 1974 to 2001 are presented in Table 5.

Table 5: Median Monthly and Annual Shallow Lake Evaporation Statistics for the Site (1974-2001)

Month	Median Shallow Lake Evaporation (mm)
January	0
February	7
March	32
April	67
May	102
June	121
July	136
August	113
September	60
October	21
November	4
December	0
Annual	**663**

4.5.1.3 Climate Change

An ensemble of monthly temperature and precipitation projections were obtained from ClimateBC consisting of 8 Global Climate Models (UBC 2022) and two emissions scenarios (SSP2-4.5 and SSP5-8.5) covering mid to high emissions from the Sixth Intergovernmental Panel on Climate Change Assessment Report (IPCC 2021). A stochastic approach (outside the GoldSim model) was used to extend these projections from year 2100 to 2200 by resampling monthly data from 2071-2100 and relating projected changes in temperature and precipitation climate variables to a set of extended greenhouse gas concentration pathways beyond year 2100 (van Vuuren et al. 2011). The range of projected temperature and precipitation values for each month was summarized across the ensemble of climate models and emissions scenarios using a range of values. The mean, and the upper bound, have been included in the SWWBM to analyze the effects of climate change. Lake evaporation, snow accumulation and snowmelt were calculated in the same way as for the average scenario.

4.5.2 Hydrology Inputs

The following sections describe the hydrologic processes and inputs used in the SWWBM.

4.5.2.1 Runoff Parameters

Runoff in the SWWBM is estimated using seasonal runoff coefficients. Runoff coefficients represent the proportion of rainfall that reports as runoff or seepage, accounting for losses due to evaporation, storage, and infiltration. Adjustment during the calibration process resulted in a 30% increase of the general runoff coefficients in cases where the monthly precipitation exceeds 50 mm. The runoff coefficients account for the following two seasonal climate periods:

- **General (July to February)** – mid-range coefficients to reflect soil moisture contents for intermittent runoff events.
- **Freshet (March to June)** – highest runoff coefficients to represent expected higher soil moisture content, and therefore greater runoff.

The seasonal runoff coefficients defined for the catchment types considered in the SWWBM are presented in Table 6.Runoff coefficients are adjusted during the annual SWWBM calibration to align estimated runoff volumes with Site monitoring data.

Table 6: Seasonal Runoff Coefficients

Catchment Type	General	Freshet
Exposed tailings	0.6	0.9
Disturbed areas	0.3	0.9
Rock disposal site areas	0.1	0.6
Open pits	0.75	0.9
Undisturbed catchments	0.4	0.42
Haul roads and access roads	0.15	0.9
Mill site area	0.1	0.1

Source: Golder 2020

4.5.2.2 Catchment Areas

To model runoff, direct precipitation, and evaporation, the catchment areas for each storage element were defined in the model. The catchment/reporting area for each storage element remains consistent with the TAR (Golder 2016a). However, there's one exception: the TSF impoundment catchment at the projected 987 m crest. Any alterations would mainly affect the infrastructure downstream of the TSF, but these changes are expected to have minimal impact on the model results. The catchments are shown in Table 7. Subdivision of catchments areas by land type are presented in Table A-1 in APPENDIX A.

Table 7: Current Catchment Areas for SWWBM Storage/Conveyance Elements

Storage or Conveyance Element	Total Reporting Area (m^2)
South Seepage Pond	385
Main Embankment Seepage Pond	376,900
TSF Upstream Catchment (External)	622,800
TSF Impoundment Catchment (Internal – current)	2,269,700
TSF Impoundment Catchment (Internal – projected at 987m raise) [(a)]	2,860,000
Perimeter Embankment Till Borrow Pond (PETBP)	524,300
Central Collection Sump (CCS)	438,600
Bootjack Creek Sump	175,200
SERDS Ditch[(b)]	1,537,600
Mill Site Sump	1,630
Mine Drainage Creek Sump	1,115,900
Long Ditch	2,494,000
Cariboo Pit	1,320,400
Springer Pit	651,900
NW Sump	330,200
9K Sump	698,700
Wight Pit	413,900
Boundary Pit	23,400
Total Reporting Area	**12,997,315**

Source: Golder 2016a. Update on TSF impoundment based on TSF projections.

(a) The raise of the TSF will affect the catchments producing runoff into the TSF pond. To consider the increase of the TSF impoundment catchment, the model interpolates the TSF impoundment catchments between the current state and the TSF raise to 987m. Changes in other catchments are minor.

(b) The current SERDS Tailings Co-Disposal project does not affect the delineation of the catchment.

After finishing operations, some mining features become remediated during closure and become non-contact water during post-closure. This is modelled by changing the land types, from disturbed to not disturbed areas. The land types define the runoff coefficients (Table 6) and the water quality, which is analyzed in the Water Quality Report (WSP 2023d). The model logic to convert the land types it is as follows (all timeframes are from start of closure on April 1, 2031 – assumed for the purpose of modelling):

- Roads:
  - 14% of total road area switch to disturbed at year 3.
  - 21% of total road area (additional 7%) switch to disturbed at year 4.
  - Negligible amount of road surface is fully reclaimed (no undisturbed road area ever).
- Dump areas transition to disturbed at the following rate:
  - Closure + year 1 = 22%.
  - Closure + year 2 = 37%.
  - Closure + year 3 = 61%.
  - Closure + year 4 = 100%.
- Mill site
  - Areas switch to disturbed at year 2.
- All Disturbed areas, not including unreclaimed roads, will transition to undisturbed at the following schedule:
  - year 5 = 25%.
  - year 10 = 50%.
  - year 15 = 75%.
  - year 20 = 100%.

After this time all areas will be undisturbed except Pit areas and unreclaimed roads.

4.5.3 Groundwater Inputs

Groundwater flow has been assessed for the following open pits at the mine: Springer Pit, Cariboo Pit, Wight Pit, and Boundary Pit. Groundwater flows with dependency on the water level of the pits are presented in Appendix B of the TAR (Attachments C, D, E, and F; Golder 2016a) and repeated in Appendix A of this report.

4.5.4 Storage Capacities

Free water volumes in storage ponds, sumps, and the TSF depend on a balance between their inflows and outflows. The stage (elevation) can be directly correlated to a specific storage volume using bathymetric and topographic data. These relationships are referred to as stage-storage curves.

Dynamic storage facilities such as the TSF, where tailings deposition changes the available storage, require regular survey updates to confirm whether existing stage storage curves are appropriate for projecting free water volumes. Stage-storage curves for the TSF up to a crest elevation of 987 m were developed from the 2020 TSF survey. These curves were obtained from preliminary tailings deposition modelling carried out in support of the design of the 987 m TSF.

The stage-storage curves projected up to a crest elevation of 987 m constitute a 2-D element that considers the tailings tonnage. These curves will interpolate according to the dry tailings volume across the Springer Expansion LOM schedule. Additionally, these curves are limited by the spillway invert stated in Table 1, serving as the upper boundary for the maximum TSF elevation. The stage-storage curves up to a crest elevation of 987 m crest in this report are provided in APPENDIX A.

Stage-storage curves were available for the following major storage elements and are provided in APPENDIX A:

- Springer Pit (November 7, 2019, bathymetry survey)
- Cariboo Pit (June 3, 2022, topographic survey)
- TSF (June 17, 2020, bathymetric survey tied-in with October 22, 2019, topographic survey)
- Wight Pit (January 13, 2022, bathymetric survey)

The estimated volume capacities for the facilities listed above and other storage locations are presented in Table 8.

Table 8: Maximum Capacities for Major Storage Facilities

Major Storage Facility	Estimated Capacity (M-m^3)
Springer Pit[(a)]	14.8
Cariboo Pit[(a)]	5.1
Combined Springer-Cariboo Pit final mine-out	30.3
TSF – 987 m crest elevation design	5.7[(b)]
Wight Pit	3.8
PETBP	0.17

(a) Represents current individual pit volumes (i.e., before pits are combined or further mined.)

(b) Capacity at the final stage of the TSF, when tailings deposition ends.

When the embankment reaches an elevation of 987 m, the TSF pond will be pushed towards the north abutment. The TSF will be available to store freshet water until four months after the start of the closure phase (July 31, 2031) in order to capture the last freshet period during the operations phase. Commencing August 1, 2031, TSF volume will be progressively reduced to 0.25 M-m^3 over the course of two months due to construction of the closure spillway.

4.5.5 Mine Plan

The mine plan for the Springer Expansion was updated in the SWWBM and assumed a milling operational end date of March 2031. Tonnage/volume of dry tailings during the project is provided in Table 9 (MPMC 2022). It is assumed that 6.55 M-tons of dry tailings have been placed in the TSF between the mine plan start date of July 1, 2022, and the assumed SWWBM operations start date of May 2, 2023.

Table 9: Mine Plan (Annual Totals)

Year	Dry Tailings (tons)
2022[(a)]	3,530,469
2023	7,300,000
2024	7,300,000
2025	7,300,000
2026	7,300,000
2027	7,300,000
2028	7,300,000
2029	7,300,000
2030	7,300,000
2031[(b)]	860,381

(a) Mine plan starts on July 1, 2022.

(b) Mine plan ends on March 31, 2031.

4.5.6 TSF Pond Volumes

Temporary detention of water in the TSF is necessary to manage large site runoff volumes that can be generated during freshet; however, a fundamental basis of the water management plan is to not accumulate water on-site year over year (including within the TSF) by treating and discharging water.

The minimum and maximum operational water volumes in the TSF under normal conditions are 1.5 M-m^3 and 1.7 M-m^3, respectively.

The water balance model activates and deactivates pumping flows. As a result, the TSF pond volume is set at 1.5 M-m^3 prior to freshet and it returns to the specified normal operating range after freshet. TSF volume conditions are presented in Table 10.

Table 10: TSF Pond Volume Values

Condition	TSF Pond Volume (M-m^3)
Minimum under normal conditions	1.5
Maximum prior to freshet (February-April)	1.5
Maximum after freshet and until freeze-up	1.7

Note: M-m^3 = 1 × 10^6 m^3

4.5.7 Flow Derivation and Logic

This section describes the model logic for pumped flows, seepage (from the TSF), groundwater inflows and outflows, consumption, and transfer flows.

In general, the model localizes the outflows of the TSF and pits and ponds; based on demand priorities using modeling elements known as "allocators." When water is present in storage, the allocator calculates evaporation as the first priority, followed by all pumping flows depending on the configured priorities. The maximum pumping capacity is utilized when water is available. If the total outflow is restricted, a lower or zero pumping rate is applied.

4.5.7.1 Pumped Flows

The most relevant transfer rates, including rates between TSF, Pits and PETBP; have been informed by MPMC (MPMC 2023b), while the remaining rates remain consistent with the TAR model and were based on engineering judgement (Golder 2016a). Maximum pumping rates for the operational, closure, and post-closure phases (2023 to 2131) are shown in APPENDIX A.

It should be noted that the capacity set for transfer from TSF to Wight Pit (P30) was assumed at a capacity to avoid PETBP overflow during operations. Capacity set for transfer from CCS to Wight Pit (P35) during closure is a WSP assumption to allow suitable water transfer capacity between CCS and Wight Pit during the closure phase, and this future conveyance system will require design confirmation as the Site approaches closure.

4.5.7.2 PETBP Pumping Logic

PETBP will begin pumping water to the TSF when the water elevation at the PETBP surpasses 923.25 m or when the TSF water volume drops below the minimum threshold by 50,000 m^3 or more.

4.5.7.3 Mill Process Flows

The mill process water requirements are based on 2.0 m^3/t of tailings. Interstitial water sequestered in the deposited tailings is based on 0.347 m^3/t of tailings deposited.

4.5.7.4 Consumption Flows

Consumption flows are system losses attributed to the operation of dust suppression equipment. Consumption flows were estimated by MPMC staff for operations (MPMC 2023b) and are modelled according to the following logic:

- Turbo-misters operate from May to September.
- Water trucks withdraw water at variable rates from May to September.

Consumption flow rates are presented in APPENDIX A.

4.5.7.5 Tailings Storage Facility Flows

WSP is currently designing a new upstream drain system to accommodate the increase in the TSF pond elevation (WSP 2023e). The new upstream drain system will capture water within the tailings above 970 m and convey it to the seepage collection system, downstream of the TSF embankment. WSP has estimated the water flows through the upstream drains based on the distance between the pond and the embankment (beach width).

Estimation of flows have been made for each embankment:

- S1: South Embankment
- S2: Main Embankment
- S4: Corner 1 Embankment
- S5: Perimeter Embankment

Seepage flows from the TSF (S1 to S5) during operations were estimated using a two-dimensional numerical groundwater flow model to quantify anticipate seepage rates through the embankment and foundation. Seepage analyses for typical sections of the elevation of 987 m configuration of the South Embankment, Main Embankment, Perimeter Embankment, and Corner 1 Embankment under steady-state conditions. The analyses were conducted using GeoStudio 2021, developed by GEOSLOPE International Ltd. Seepage from the TSF has been defined to occur continuously without interruption in the SWWBM. Table 11 presents the estimated seepage flow rates through each embankment with dependency on the beach width.

Table 11: Seepage Flow Rates

Beach (m)	Flow Rate (L/s)			
	S1	S2	S4	S5
0	79	96	81	89
50	39	50	53	46
100	25	32	38	31
200	14	18	23	18
300	9	12	15	13

Note: includes flows through upstream drains and embankment. All flows estimated for the 987 m raise.

The progressive location of the TSF pond will depend on operational decisions during the deposition of tailings; thus, the change in beach widths have been assumed consistent for each embankment. Based on estimates of the TSF pond volume and satellite imagery of the pond location since restart of operation in 2016, an estimation of embankment beach width has been made for different pond sizes. The estimates are provided in Table 12, which outline a conservative scenario, in terms of seepage flow quantities.

Table 12: Tailings Beach Width

TSF Pond Volume (m^3)	Beach Width (m)			
	S1	S2	S4	S5
0	300	300	300	300
1,500,000	300	300	300	300
2,500,000	200	200	200	200
3,000,000	100	100	100	100
5,500,000	0	0	0	0

The model uses both Table 11 and Table 12 presented above to calculate the beach width and consequently the seepage flow rates through the embankments during operations. For every time step the model calculates the TSF volume and consequently the beach width, and finally the seepage flow rate.

Starting from four months into closure (August 1, 2031), the TSF pond reduces its volume to 0.25 M-m^3 within two months due to the construction of the closure TSF spillway. This is estimated to increase in the seepage flow rate on the perimeter embankment close to corner 1, as the TSF pond will be pushed to that corner. For modelling purposes, it is considered that the seepage flow rate in Table 13 will be in effect 6 months after the end of the operation phase and throughout the post-closure phase.

Table 13: Tailings Beach Width at Last Year of Operation and Closure

Flow Rate (L/s)			
S1	**S2**	**S4**	**S5**
70	0	0	0

Note: Values start 6 months after end of operation. Maximum capacity of TSF pond is limited to 250,000 m³.

5.0 WATER BALANCE RESULTS

The following sections present major model results for the operational and closure phases, and partial results for post-closure phase. Full extension of post-closure results are presented in Appendix C.

5.1 WTP Treatment Capacity

Throughout the entire planned future operations and closure periods to March 31, 2041, the maximum treatment capacity of the WTP in the model is assumed to be 25,000 m^3/day (0.29 m^3/s, 9.15 M-m^3/year). Excess water beyond this discharge rate is temporarily stored within the TSF until it can be treated and discharged. Centralized collection and treatment of contact water is assumed during operations, closure, and post-closure. The Mine's current discharge permit authorizes an annual discharge volume of 10.59 M-m^3.

In year 2041, the assumed treatment capacity of the WTP in the model remains at 25,000 m^3/day (0.29 m^3/s). However, annual contact water requiring treatment is reduced over the post-closure phase as site areas are remediated and some runoff is considered non-contact water, as shown in the flow diagram Figure B-3 provided in Appendix B. The annual contact water treated discharge volume declines further in year 2051 when the South Seepage Pond and Main Embankment Seepage Pond catchments are considered remediated, commencing 10 years after the post-closure phase. At the end of the operations phase, contact water requiring treatment notably increases in 2031, as milling is assumed to terminate in 2031 and the demand for milling process water also terminates.

Estimated annual contact water volumes requiring treatment from operations to post-closure are presented in Table 14, and Figure 2 illustrates daily WTP discharge rates from operations to 10 years after post-closure.

Table 14: WTP Annual Volume Requiring Treatment (M-m^3)

Year	Annual Volume Requiring Treatment at WTP (M-m^3)		
	50th Percentile	90th percentile	99.5th percentile
2023[a]	3.90	4.57	5.72
2024	5.00	5.94	7.24
2025	3.50	4.97	6.79
2026	3.37	4.72	6.53
2027	3.35	4.79	6.60
2028	3.36	4.80	6.70
2029	3.39	4.78	6.46
2030	3.31	4.75	6.56
2031[b]	3.93	4.39	5.04
2032	5.56	6.68	7.82
2033	5.54	6.57	7.57
2034	5.50	6.54	7.49
2035	5.42	6.42	7.44
2036	5.43	6.44	7.36

Table 14: WTP Annual Volume Requiring Treatment (M-m^3)

Year	Annual Volume Requiring Treatment at WTP (M-m^3)		
	50th Percentile	90th percentile	99.5th percentile
2041[(c)]	2.36	2.88	4.04
2046	1.80	2.27	3.31
2051	0.46	0.83	1.39
2071	0.33	0.71	1.48
2091	0.32	0.69	1.60
2111	0.32	0.71	1.44
2131	0.02	0.03	0.05

(a) Model simulation start date: May 2, 2023.
(b) Closure starts on April 1, 2031.
(c) Post-closure starts on April 1, 2041.

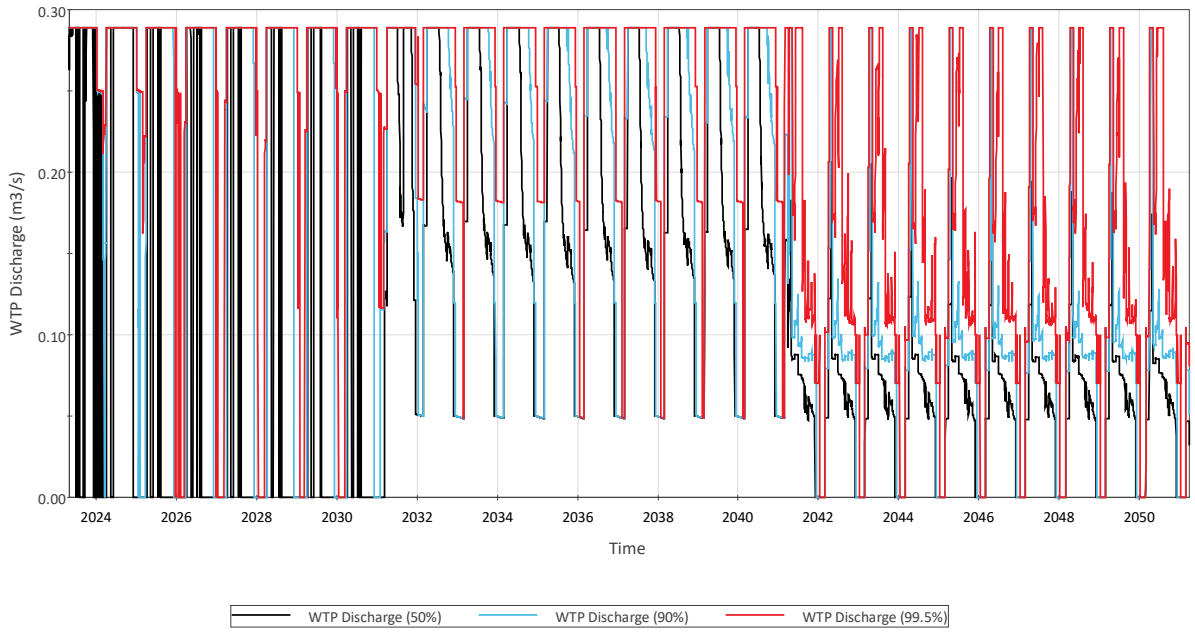

Figure 2: WTP Discharge Rate from Operations to 10 years after Post-Closure

5.2 Tailings Storage Facility

Temporary detention of water will be necessary to manage the large runoff volumes generated during freshet (typically April to June). The inflows during freshet will exceed treatment capacity, and detention volume is required to prevent uncontrolled release from the PETBP and to equalize the flow for treatment. The TSF is available to store excess freshet water until four months after the start of closure. At that time, the TSF pond will decrease its volume to 0.25 M-m³, the maximum allowable volume at closure.

To create the reduced TSF pond, a closure spillway will be constructed at the north abutment (Corner 5) of the TSF. Water will discharge from the TSF to the CCS, and then flow to the PETBP for treatment prior to discharge.

During closure and post-closure, the TSF pond is modelled to discharge annually via the spillway, and the TSF pond volume will vary seasonally, limited by the spillway invert, to a maximum of approximately 0.25 M-m^3. As from Figure 3, the volume fluctuation follows a consistent pattern during both closure and post-closure periods, with minimum values occurring in winter and reaching maximum capacity during freshet (0.25 M-m^3).

Figure 3 shows the water volume in the TSF throughout future operations and into closure until 10 years after post-closure. The TSF volume pattern shown for the 2041-2051 post-closure period is continued for the remaining 80 years of post-closure (until 2131). Table 15 shows tabulated minimum, average, and maximum bounds for the three percentile trends shown in Figure 3.

Table 15: TSF Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	1,330,244	1,390,394	1,429,751
	Average	1,493,500	1,576,822	1,809,717
	Maximum	2,840,000	2,840,000	3,493,139

	Maximum	252,571	252,571	252,571

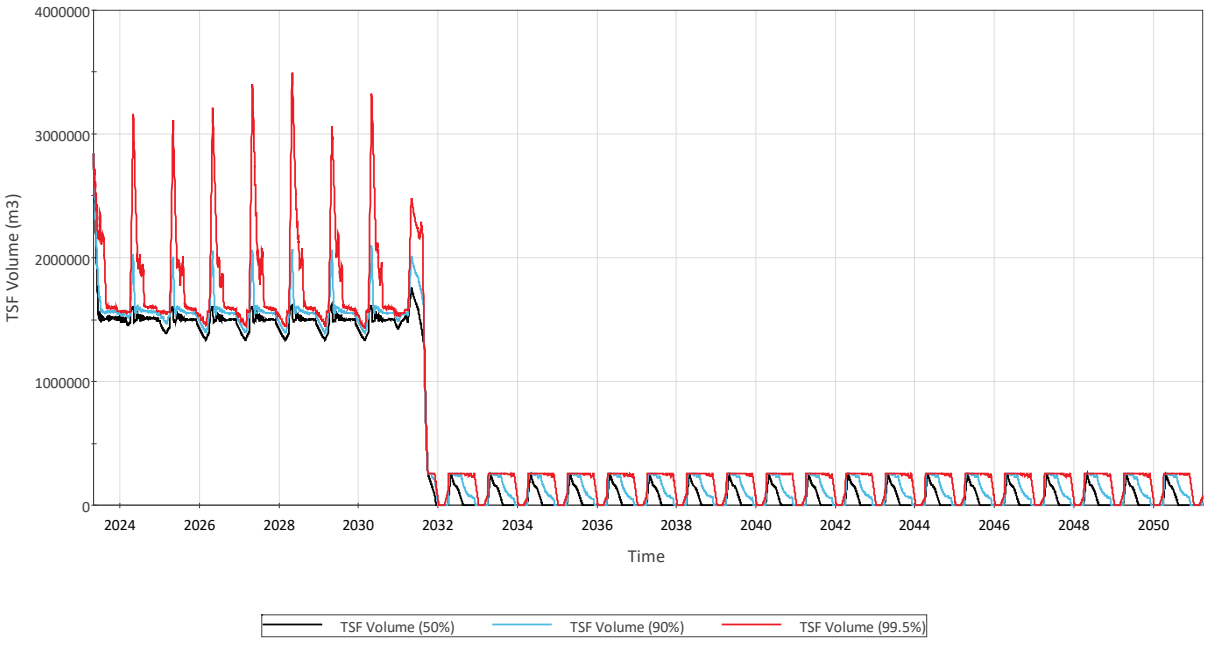

Figure 3: TSF Water Volume from Operations to 10 Years after Post-Closure

5.3 Springer Pit

The simulated Springer Pit water volume during the operational phase is shown in Figure 4 for the 50th, the 90th, and the 99.5th percentiles. The simulations were run from an initial Springer Pit storage volume of 0 m^3 on May 2, 2023. During the operational phase, the volume in Springer Pit is reduced to the minimum volume before each freshet, and temporary storage will occur during the freshet, as freshet inflow exceeds pit dewatering pumping capacity.

Springer Pit and Cariboo Pit are modelled as a single pit in the closure phase, using the stage-storage curve based on the ultimate projected topography, as detailed in Section 5.5.

Table 16: Springer Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0
	Average	8,620	35,720	117,745
	Maximum	74,124	169,623	361,074

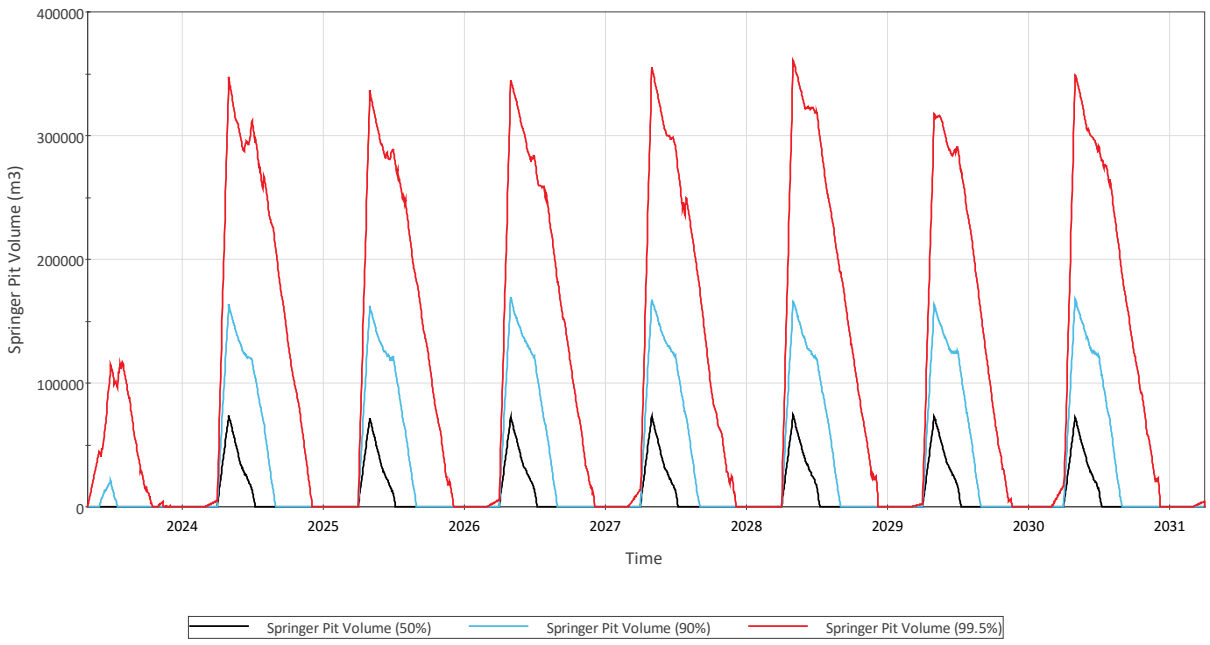

Figure 4: Springer Pit Water Volume during Operations

5.4 Cariboo Pit

Simulated Cariboo Pit water volumes during the operational phase are shown in Figure 5 for the 50th, the 90th, and the 99.5th percentiles. The simulations were run from an initial Cariboo Pit storage volume of 0.24 M-m^3 on May 2, 2023. During the operational phase, the volume in Cariboo Pit is reduced to the minimum volume before each freshet, and temporary storage will increase to its maximum volume of 0.26 M-m^3 during the freshet. Springer Pit and Cariboo Pit have been modelled as one combined pit in the closure phase as explained in Section 5.3.

Table 17: Cariboo Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0
	Average	81,256	112,813	169,463
	Maximum	259,249	259,249	259,249

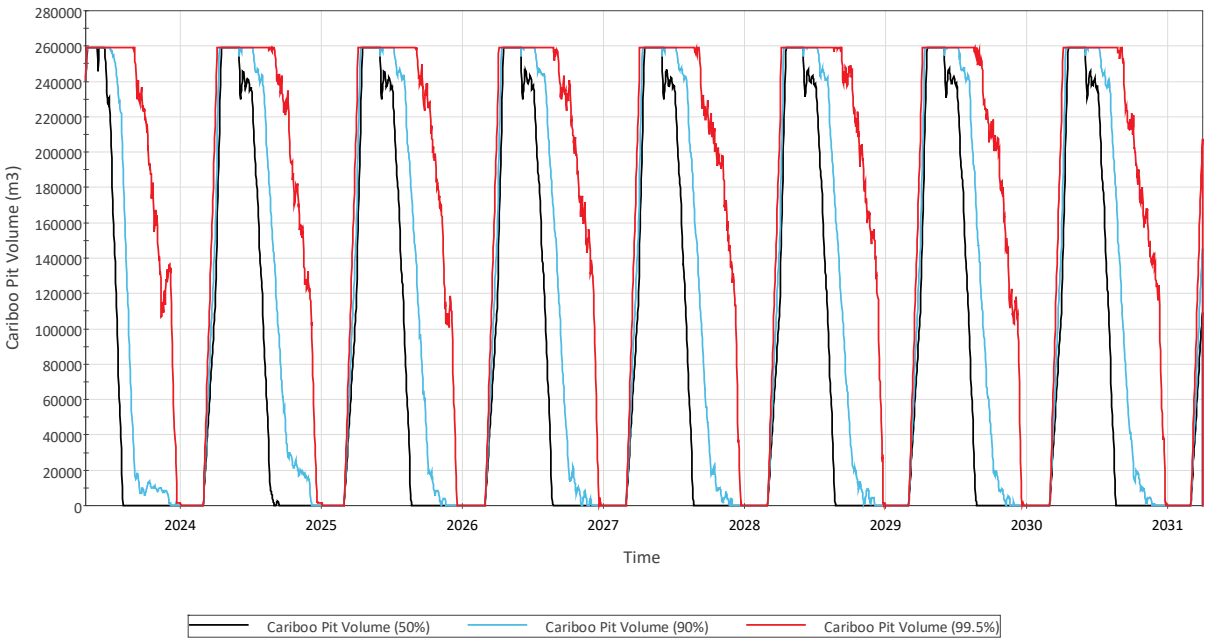

Figure 5: Cariboo Pit Water Volume during Operations

Table 18 shows the modelled average annual overflow volume from the Cariboo Pit during operations, and these overflow volumes are included in the total annual volumes required for treatment shown in Table 14.

Table 18: Cariboo Pit Annual Overflow (m^3)

Phase	Cariboo Pit Annual Average Overflow (m^3)		
	50th Percentile	90th percentile	99.5th percentile
Operations	283,897	574,260	1,221,920

5.5 Combined Springer-Cariboo Pit

Springer Pit and Cariboo Pit were modelled as a single pit for the closure phase (starting April 1, 2031). A result comparison between different percentiles for Combined Springer-Cariboo Pit volume during closure and post-closure is provided in Figure 6 . Potentially Acid Generating (PAG) waste rock will be stacked uniformly to an elevation of 1,004 m in the base of the Combined Springer-Cariboo Pit at the end of the operations phase. Results of the simulations indicate that water levels within the pit will cover the PAG material placed in pit by approximately 2033 under the 99.5th percentile condition, while under the rest of the climate conditions it is estimated to cover the PAG material placed in pit by 2034. Under the 50th percentile results, the combined Springer-Cariboo Pit lake is estimated to start overflowing in 2058, while under the 90th percentile it is estimated to start overflowing in 2056, and in 2055 under the 99.5th percentile. The Water Quality Report (WSP 2023d) discusses modelled water quality of the Springer-Cariboo pit lake at the estimated time of overflow.

Table 19: Combined Springer-Cariboo Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Closure	Minimum	109,345	145,263	211,031
	Average	4,827,785	5,199,295	5,652,177
	Maximum	9,030,590	9,598,661	10,300,000
Post-Closure	Minimum	9,032,744	9,600,627	10,300,000
	Average	20,033,811	20,167,573	20,287,305
	Maximum	21,100,000	21,100,000	21,100,000

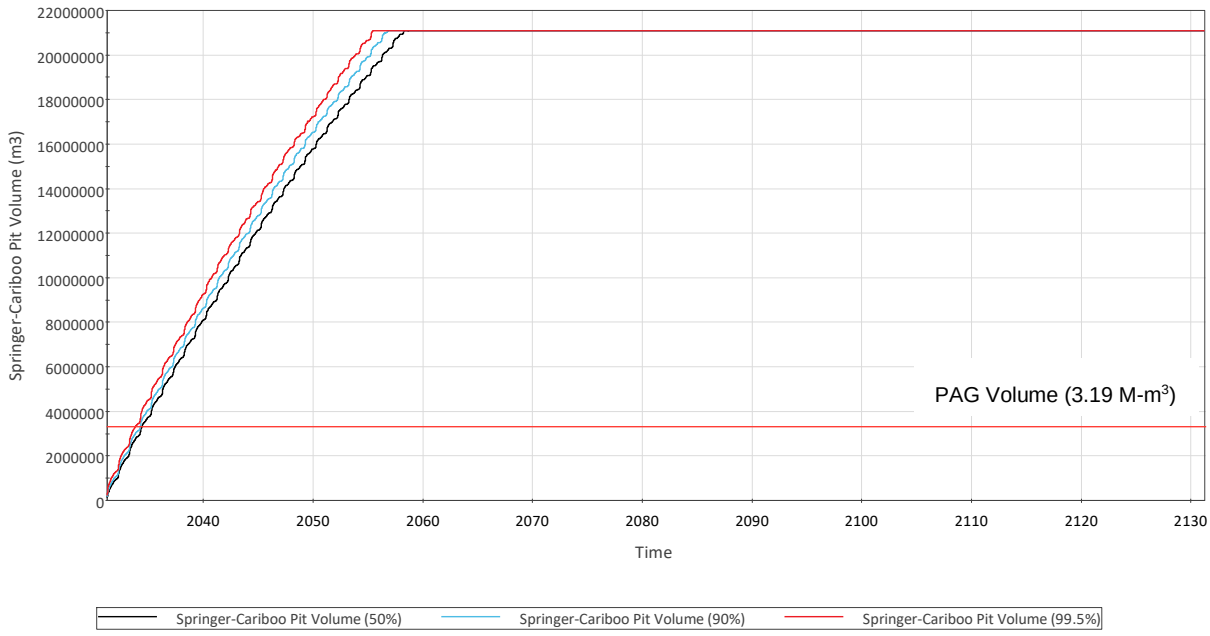

Figure 6: Combined Springer-Cariboo Pit Water Volume from Closure

The combined Springer-Cariboo Pit is modelled to fill to its maximum volume during post-closure. Following that time, additional volume collected in the combined pit will overflow from the pit's spillway and is assumed to direct discharge to the receiving environment in the SWWBM. Water quality and water treatment discussion is included under separate cover regarding this assumption of direct environmental discharge of pit lake overflow during post-closure.

Table 20 shows the modelled average annual overflow volume from the combined Springer-Cariboo Pit.

Table 20: Combined Springer-Cariboo Pit Annual Overflow (m^3)

Phase	Combined Springer-Cariboo Pit Annual Average Overflow (m^3)		
	50th Percentile	90th percentile	99.5th percentile
Post-Closure	469,711	1,051,048	2,249,910

5.6 Perimeter Embankment Till Borrow Pond (PETBP)

The PETBP serves as the final component of the centralized water management infrastructure, collecting water from the entire site. From this point, the water is pumped back to the mine for reuse, storage, or treated and discharged through the adjacent WTP. The current maximum capacity of the PETBP is 170,000 m^3. When the water volume in the PETBP exceeds 121,700 m^3 during the operations phase, modelled pumps to the TSF are activated to prevent overflow.

The 50th percentile results show that the maximum volume in the pond approaches 125,000 m^3 during the freshet. There are no occurrences of overflow from the PETBP under the simulated conditions during the future operational phase. During closure and post-closure, less storage is available in the overall water management system, and the PETBP reaches higher maximum volumes during freshet periods and does not have the capacity to prevent overflow for the 99.5th percentile results (as shown in PETBP overflow volumes listed in Table 22). The SWWBM predicts that the PETBP will have sufficient capacity to prevent overflow for the 50th and 90th percentile climate conditions. It is assumed that sufficient storage will be implemented during closure to prevent any unwanted overflow of contact water requiring treatment during the closure phase. The volumes listed in Table 22 are included in the total annual volumes required for treatment shown in Table 14.

Estimated storage volumes in the Perimeter Embankment Till Borrow Pond (PETBP) from operations to 10 years after post-closure are presented in Figure 7, with minimum, average, and maximum bounds of those trends shown in Table 21.

Table 21: PETBP Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	57,800	57,800	57,800

(a) Model simulation start date: May 2, 2023.
(b) Closure starts on April 1, 2031.
(c) Post-closure starts on April 1, 2041.

5.7 Wight Pit

The water volume in Wight Pit is expected to increase during every freshet season. Four months into the closure phase, the TSF pond will be reduced to 0.25 M-m^3 within two months. Once the TSF can no longer provide freshet storage, Wight Pit will be used to store excess water. During post-closure, Wight Pit will no longer be used for freshet storage and will be allowed to fill. Wight Pit is projected to start overflowing in 2049 under the 50th percentile results, and in 2047 under the 90th and 99.5th percentile results. Overflow from Wight Pit during post-closure is assumed as direct environmental discharge to Polley Lake and the water quality implications of this assumption are discussed under separate cover. Estimated volumes stored in Wight Pit from operations to 10 years after post-closure are presented in Figure 8 and the average annual post-closure overflow volumes are shown in Table 24.

Table 23: Wight Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0

6.0 SUMMARY

The SWWBM was updated to reflect the Springer Expansion LOM plan during the operational phase and incorporates closure and post-closure phases for the Mount Polley Mine. The SWWBM supports water management planning and the assessment of water quality and associated water treatment and discharge options.

The model was run from May 2, 2023, to March 31, 2131, and included the following LOM phases:

- operational phase extending from May 2, 2023, to March 31, 2031.
- closure phase extending from April 1, 2031, to March 31, 2041.
- post-closure phase commencing on April 1, 2041, and extending, for the purposes of this analysis, to 2131.

The model was run stochastically for 2000 realizations to present 50th, 90th, and 99.5th percentile model results. The results for the modelling during the operational phase are presented as follows:

- The average annual treated discharge for the 50th percentile is approximately 3.65 M-m^3 between 2023 and 2031, while the milling process water demand exists.
- The maximum annual treated discharge for the 99.5th percentile 7.21 M-m^3 in 2031.
- The maximum TSF pond volume during the operational phase is approximately 3.49 M-m^3 for 99.5th percentile, and 1.62 M-m^3 for the 50th percentile results (excluding 2023 when the TSF is initially set to 2.84 M-m^3 in the model).
- During the operational phase, the volume in Springer Pit and Cariboo Pit are both decreased to empty before each freshet, and temporary storage will occur during the freshet.
- There are no overflows from the PETBP under the simulated conditions during the operational phase.

The conclusions for the modelling during closure and post-closure phases are as follows:

- The average annual treated discharge for the 50th percentile result is approximately 0.95 M-m^3.
- The TSF pond volume will vary seasonally, limited by the spillway invert, to a maximum of approximately 0.25 M-m^3.
- The combined Springer-Cariboo Pit Lake is estimated to start overflowing between 2055 and 2058, with an average annual 50th percentile overflow volume of approximately 0.47 M-m^3.
- PAG material placed in the combined Springer-Cariboo Pit is estimated to be inundated and covered by the pit lake between 2033 and 2034.
- During closure, the volumes in PETBP are reduced to the minimum volume before each freshet, and temporary storage will occur during the freshet under each of the climate conditions simulated. During closure and post-closure phases, the PETBP does not have sufficient storage capacity to prevent overflow during freshet for the 99.5th percentile condition; however, these overflow volumes are included with the annual treatment requirement volumes.
- The Wight Pit is expected to initiate spilling between 2047 and 2049, with an average annual 50th percentile overflow volume of approximately 0.47 M-m^3.

7.0 CLOSING

This report summarizes the SWWBM to support the water management information requirements for the Springer Expansion LOM plan.

We trust that this report satisfies your current requirements. Please contact the undersigned should you have any questions.

A3.0 FLOW RATES

A3.1 Pumped Flows

Except for P13 and P15, which were measured at 545 m^3/d and 2.5 m^3/d, respectively (Golder 2016a), all maximum pumping rates have been assumed. Among these rates, P4b, P5, T6, P9b, P17b, P21, P30, and P32 were provided by MPMC (MPMC 2023b), while the remaining rates remain consistent with the TAR model and were based on Golder's engineering judgement (Golder 2016a).

Maximum pumping rates for operational flows are shown in Table A-3, and maximum pumping rates for closure flows are shown in Table A-4. It should be noted that any pumped flows shown in Table A-3, but not shown in Table A-4, are assumed to be decommissioned with zero transfer capacity.

Table A-3: Maximum Pumping Rates for Operational Flows

Flow ID	From	To	Flow Rate (m^3/day)	Reference
P4b	Cariboo Pit	PETBP	13,000	MPMC 2023b
P5	PETBP	TSF	100,000	Golder 2016a

(a) No maximum pumping rate applied. This pumping demand is dynamic and depend on the required pumping rate to dewater the Mine Drainage Creek Sump.

(b) Based on measured flow rates (Golder 2016a).

(c) 14,088 m3/day effective starting September 2023.

(d) Capacity assumed to avoid PETBP overflow during operation. See Section 4.5.7.1 in the main report.

(e) No maximum pumping rate applied. These are defined based on the process flow requirements from the Mill, where P27 is defined as process water (including interstitial water) in addition to tailings solids, and P28 is defined as process water demand.

Table A-4: Maximum Pumping Rates for Closure Flows

(a) Active to use Wight Pit to store water when TSF is not available for storage during closure. See Section 4.5.7.1 in the main report.

A3.2 Consumption Flows

The flow parameters for the turbomisters are shown in Table A-5 and Table A-6.

Table A-5: Operational Hours per Day for Turbomisters

Flow ID	From	Hours per Day				
		May	June	July	August	September
C1	Main Embankment Seepage Collection Pond	10	10	10	10	10
C10	Wight Pit	10	10	10	10	10

Table A-6: Operational Flow Rates for Turbomisters

Flow ID	From	Evaporation Rates (m^3/hr)	
		May and June	July to September
C1	Main Embankment Seepage Collection Pond	5.5	12.7
C10	Wight Pit	5.5	12.7

The flow parameters for water trucks are shown in Table A-7 and Table A-8 below.

Table A-7: Operational Days per Month for Water Trucks

Flow ID	From	Days per Month				
		May	June	July	August	September
C4	Wight Pit	0	0	20	20	15
C8	CCS	4.5	19	12.6	21.5	10.6

Table A-8: Operational Flow Rates for Water Trucks

Flow ID	From	Flow Rates (m^3/day)
C4	Wight Pit	818
C8	CCS	818

A3.3 Transfer Flows

The flow rates for the transfer flows were defined in the model as described in Table A-9.

Table A-9: Transfer Flows

Flow ID	From	To	Flow Definition/Rates
T1	Long Ditch	Central Collection Sump	Flow rates determined by runoff and baseflow from the Long Ditch catchment.
T2	SERDS Ditch	Central Collection Sump	Flow rates determined by runoff and baseflow from the SERDS ditch catchment.
T3	Central Collection Sump	PETBP	Modelled as the overflow rate from the CCS.
T6[(a)]	PETBP	Water Treatment Plant	Maximum capacity 25,000 m^3/day during operations until post-closure.

(a) Provided by Maximum pumping rates provided by MPMC (MPMC 2023b).

A3.4 Groundwater inputs

Springer Pit

A hydrogeological assessment was conducted to predict the quantity of long-term groundwater seepage from both the Springer and the Cariboo pits towards Bootjack Lake (Golder 2016b). The analysis considered placing waste rock in the ultimate pit prior to the pit lake formation. As the pit lake level increases between 1,020 masl and 1,030 masl, seepage in the range of 10 to 100 m^3/d from the Springer Pit Lake into the subsurface was predicted to occur (Table A-10). Seepage was found to gradually increase to approximately 400 m^3/d when the pit lake reaches the spillway at 1,050 masl.

Table A-10: Springer Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Flow (m^3/d)	
	Into the Pit	Out of the Pit
880	520	0
940	510	0
960	490	0
980	460	0
1000	420	0
1020	320	10
1030	300	100
1040	280	250
1050	270	400

Cariboo Pit

Predicted groundwater flows of Cariboo Pit remain consistent from Golder 2016b. In the Cariboo Pit, seepage towards the Bootjack Lake of approximately 20 m^3/d was predicted to occur only when the pit lake level approaches 1,050 masl.

Table A-11: Cariboo Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Flow (m^3/d)	
	Into the Pit	Out of the Pit
880	600	0
940	610	0
960	610	0
980	590	0
1000	540	0
1020	460	0
1030	420	0
1040	380	0
1050	320	20

Wight Pit

Groundwater inflow to the Wight Pit is projected to gradually decrease from 2,600 m^3/d at of 804 masl, to 600 m^3/d at 935 masl (Golder 2015). Table A-12 shows the predicted groundwater flows for Wight Pit.

Table A-12: Wight Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Flow (m^3/d)	
	Into the Pit	Out of the Pit
804	2600	0
880	2600	0
900	2500	0
910	2100	0
920	800	0
926	600	500
930	600	500
935	600	500

Boundary Pit

MPMC reported that seepage was not observed along the pit walls during mining. However, seepage out of the pit could still occur due to water entering via surface water runoff and direct precipitation. Potential seepage rates out of the pit were estimated to incorporate them into the pit water balance and to characterize a possible seepage pathway originating from this pit (Golder 2016c).

Seepage rates out of the Boundary Pit were estimated from a Darcy's Law calculation that considers changes in the dimensions of the seepage area as the pit is being flooded. The estimated seepage rate from the Boundary Pit when the pit lake surface level is 5m above its base (1,072 masl) is approximately 59 m^3/d, with a potential range between 35 m^3/d and 177 m^3/d due to uncertainty in bedrock permeability. Seepage outflow is estimated to decrease as the height of water column above the pit bottom decreases as shown in Table A-13.

Table A-13: Boundary Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Outflow (m^3/d)
1067	3
1068	10
1069	20
1070	26
1071	53
1072	59
1073	59

C3.0 TOTAL ANNUAL RUNOFF VOLUME FROM STOCKPILES/DUMPS

C3.1 Temp PAG Stockpile

The total annual runoff volume during operations for Temp PAG Stockpile is shown in Table C-5. The runoff was generated over the catchment area, which was broken down by different land types (i.e., waste rock, disturbed, undisturbed, and haul road). This catchment area breakdown was inserted as input into SWWBM. Table C-4 presents the distribution of these land types.

Table C-4: Temp PAG Stockpile Catchment Area Breakdown by Land Type

Land Type	Catchment Area (m^2)
Waste Rock Area	703,147
Disturbed Area	120,945
Undisturbed Area	140,272
Haul Road Area	63,800

Table C-5: Temp PAG Stockpile Annual Runoff Volume during Operations (m^3)

Year	50th Percentile	90th percentile	99.5th percentile
2023	122,711	226,570	445,588
2024	248,347	421,842	768,449
2025	247,456	422,850	766,070
2026	247,757	428,520	753,043
2027	247,936	425,785	793,090
2028	248,912	426,147	794,141
2029	249,343	422,660	755,345
2030	248,572	425,593	777,709
2031	26,050	41,089	68,748

C3.2 SERDS

The total annual runoff volume during operations for SERDS is shown in Table C-7. The runoff was generated over the catchment area, which was broken down by different land types (i.e., waste rock, disturbed, undisturbed, haul road, and mill site). This catchment area breakdown was inserted as input into SWWBM. Table C-6 presents the distribution of these land types.

Table C-6: SERDS Catchment Area Breakdown by Land Type

Land Type	Catchment Area (m^2)
Waste Rock Area	401,235
Disturbed Area	313,059
Undisturbed Area	383,918
Mill Site Area	273,919
Haul Road Area	165,456

Table C-7: SERDS Annual Runoff Volume during Operations (m^3)

Year	50th Percentile	90th percentile	99.5th percentile
2023	192,874	365,010	738,562
2024	360,384	625,704	1,163,887
2025	359,170	627,159	1,167,189
2026	359,541	635,520	1,138,079
2027	359,635	632,119	1,195,850
2028	360,975	631,021	1,198,955
2029	361,394	625,581	1,140,716
2030	360,604	629,622	1,172,763
2031	34,619	54,596	91,336

C3.3 NEZ Dump

The total annual runoff volume during operations for NEZ Dump is shown in Table C-9. The runoff was generated over the catchment area, which was broken down by different land types (i.e., waste rock, disturbed, undisturbed, and haul road). This catchment area breakdown was inserted as input into SWWBM. Table C-8 presents the distribution of these land types.

Table C-8: NEZ Dump Catchment Area Breakdown by Land Type

Land Type	Catchment Area (m^2)
Waste Rock Area	199,116
Disturbed Area	237,889
Undisturbed Area	202,646
Haul Road Area	261,421

Table C-9: NEZ Dump Annual Runoff Volume during Operations (m^3)

Year	50th Percentile	90th percentile	99.5th percentile
2023	134,053	250,501	499,643
2024	261,170	448,211	824,647

APPENDIX 5-4: Responses to Comments from the Ministry of Environment and Climate Change Strategy – Technical Assessment Report for the Quesnel Lake Interim Discharge Extension

TECHNICAL MEMORANDUM

DATE 25 July 2022 **Reference No.** 22514095-052-TM-Rev0-81100

TO Mathieu O'Leary
Mount Polley Mining Corporation

CC Don Parsons

FROM Jesse Maddaloni, Lee Nikl and Tom Rutkowski **EMAIL Jesse.Maddaloni@wsp.com; Lee.Nikl@wsp.com; Tom.Rutkowski@wsp.com**

RESPONSES TO COMMENTS FROM THE MINISTRY OF ENVIRONMENT AND CLIMATE CHANGE STRATEGY – TECHNICAL ASSESSMENT REPORT FOR THE QUESNEL LAKE INTERIM DISCHARGE EXTENSION

1.0 INTRODUCTION

This technical memorandum (memo) supports assumptions made in Golder Associate Ltd. (Golder)'s memo 22514095-051-TM-Rev0-81112 (Golder 2022a) which addressed water quality information requests received 21 June 2022 from the British Columbia Ministry and Environment and Climate Change Strategy (BC ENV) resulting from the Screening Phase review of the Technical Assessment Report for the Quesnel Lake Interim Discharge Extension. This memo specifically discusses the performance and operation of the Water Treatment Plant (WTP) upstream of the Quesnel Lake discharge.

The water quality memo (Golder 2022a) provided concentrations of parameters at the edge of the initial dilution zone in Quesnel Lake assuming that Environmental Management Act (EMA) Permit 11678 limits for parameters are met at the WTP outlet. This memo describes the performance and operation of the WTP from 2016 through 2021 and provides justification that parameter permit limits are achieved at the WTP outlet. This memo only discusses parameters of interest (Total Suspended Solids, Copper, and Selenium); information regarding other permitted parameters can be found in Golder 2022a.

2.0 WATER TREATMENT PLANT PERFORMANCE

The WTP receives influent from the Perimeter Embankment Till Borrow Pond (PETBP) and discharges effluent to a pipeline directed to the Quesnel Lake diffuser. Water quality is measured upstream of the WTP at point E19 and measured downstream of the WTP at point HAD-3. Figures in this memo show and compare parameter data recorded between these two monitoring points.

The WTP itself is a patented high-rate ballasted coagulation and flocculation process under the tradename Actiflo supplied by Veolia. The WTP is primarily designed for removal of Total Suspended Solids (TSS), but also removes metals mainly through TSS reduction.

Golder and the G logo are trademarks of Golder Associates Corporation **golder.com**

2.1 Total Suspended Solids

WTP influent, effluent, and permit limit concentrations for TSS are shown in Figure 1 over a six-year period between 2016 and 2021. Influent TSS is mainly below the permit limit (excluding one single sample) and effluent TSS is consistently below permit limit.

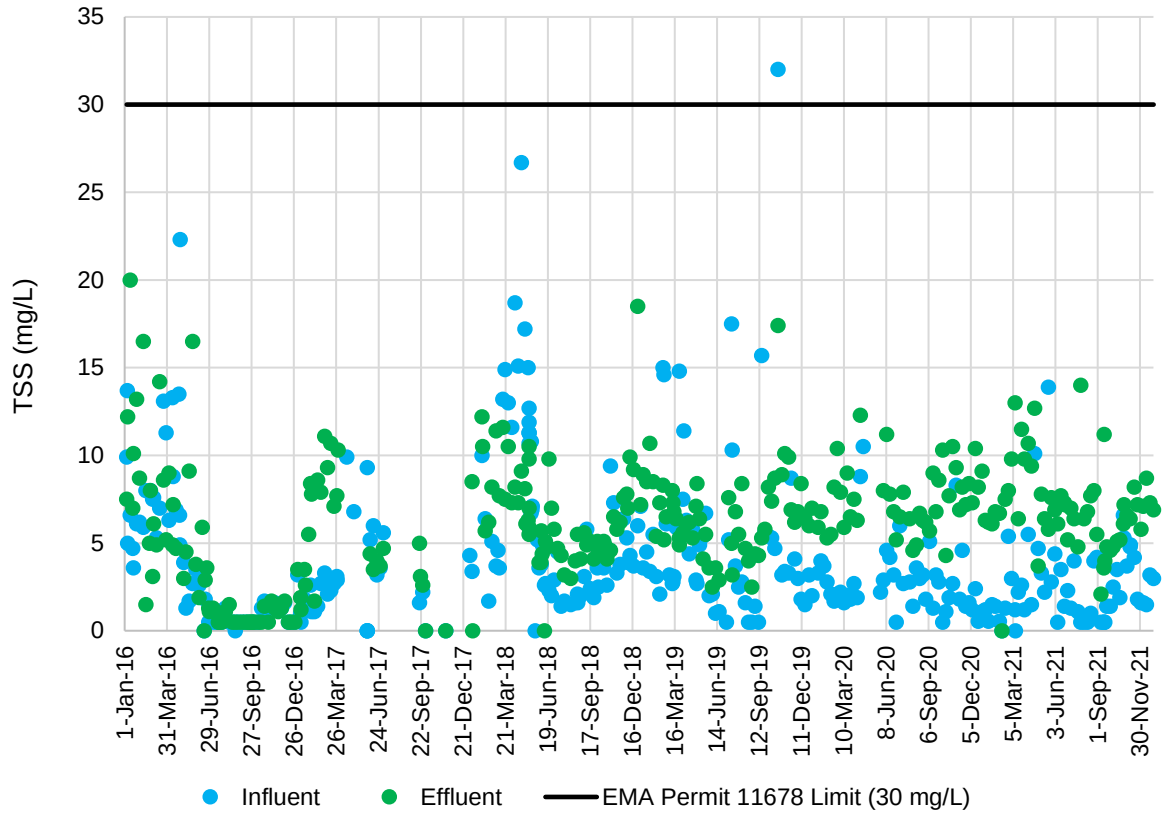

Figure 1: WTP Influent and Effluent TSS Measured at E19 and HAD-3 from 2016 to 2021

TSS treatment performance for the WTP is plotted in Figure 2, where influent TSS concentration is shown on the horizontal axis and TSS treatment efficiency (percent of influent TSS removed) is shown on the vertical axis. Figure 2 shows data points for samples collected over 2019 and 2021. It can be seen that TSS treatment performance ranges from approximately 0% to 70%, with the trend of growing treatment efficiency as influent TSS increases. At low influent TSS concentrations (approximately 5 mg/L and below), the WTP is not able to further reduce TSS and treatment efficiencies are low (and sometimes negative due to added TSS from treatment process). As influent TSS increases to the 10-20 mg/L range, the WTP is able to reduce effluent TSS and treatment efficiencies increase. Irrespective of the TSS treatment efficiency, Figure 1 shows that effluent TSS is consistently below the permit limit.

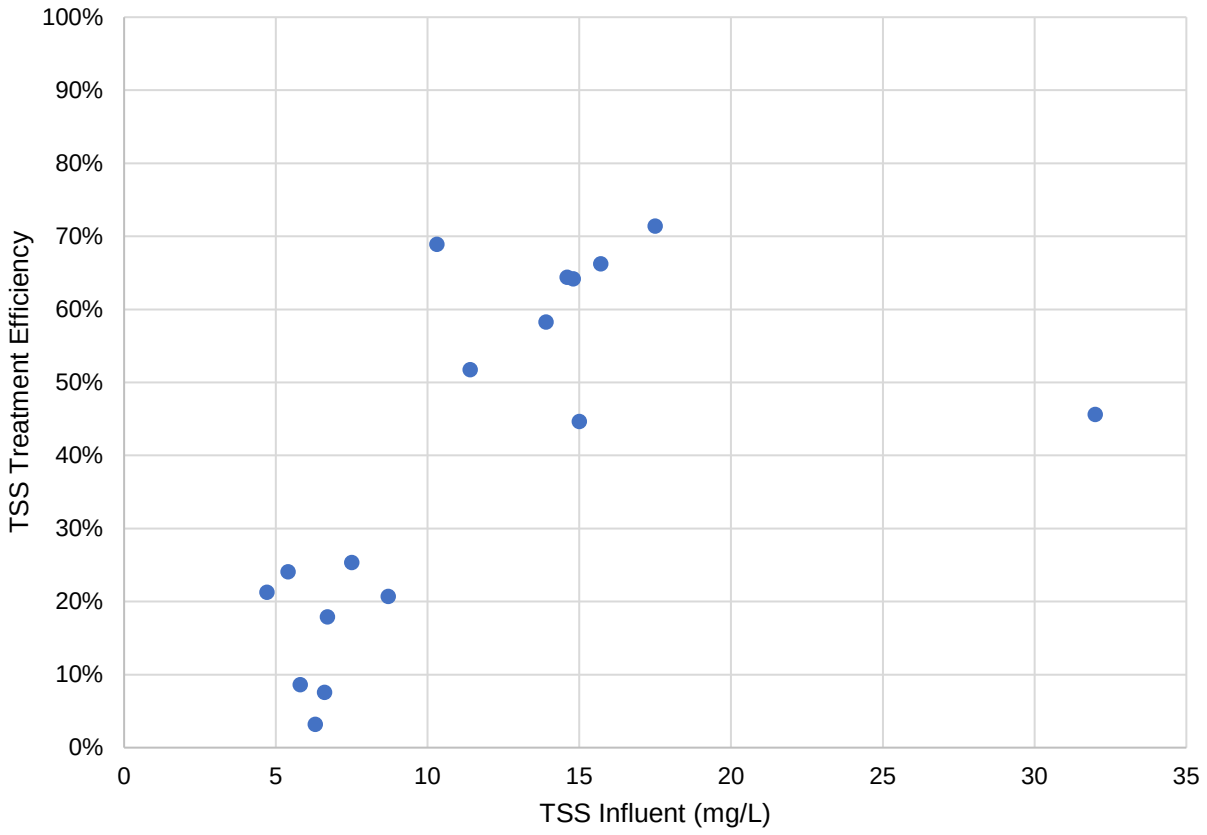

Figure 2: WTP TSS Treatment Efficiency vs. TSS Influent Concentration for Samples over 2019 and 2021

2.2 Copper

WTP influent, effluent, and permit limit concentrations for total copper are shown in Figure 3 over a six-year period between 2016 and 2021. Influent and effluent total copper concentrations are mainly below the permit limit, though there were some short infrequent periods where influent and effluent total copper levels were above the permit limit. Some data has been cropped from Figure 3 to allow a better zoomed view of data points near the permit limit. There is one copper occurrence that was cropped from the figure, occurring over 9 days in May 2018, where influent total copper had a maximum of 0.93 mg/L and effluent total copper had a maximum of 0.28 mg/L.

If total copper in the effluent exceeds the permit limit, the WTP is shut-down (or put into recirculation mode) and a Trigger Response Plan is activated, with WTP operation resumed once copper levels in the WTP effluent are confirmed below permit level. A summary of permit limit exceedances is provided in Table 7 of the Technical Assessment Report (Golder 2022b).

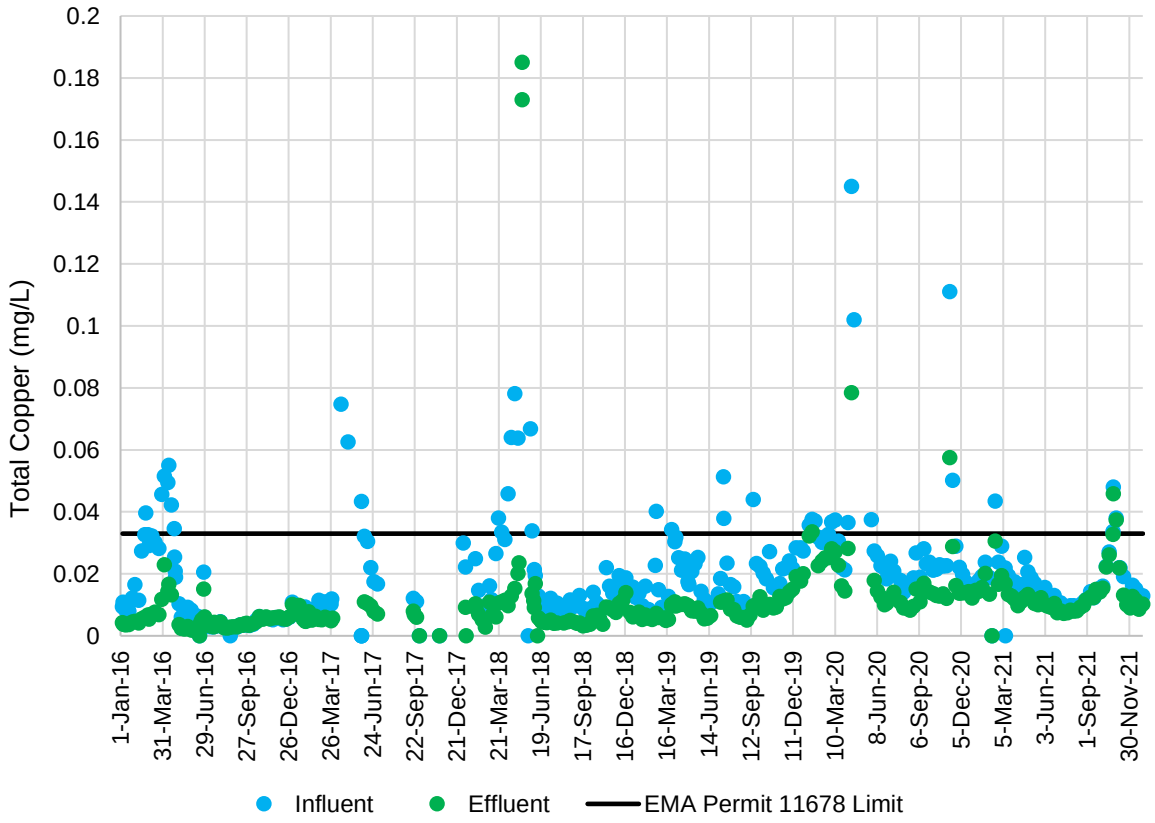

Figure 3: WTP Influent and Effluent Total Copper Measured at E19 and HAD-3 from 2016 to 2021

The water quality estimates provided in Golder 2022a show predicted WTP influent total copper concentrations from January 2023 through June 2025. The 95th percentile estimated concentration for total copper had a maximum of 0.061 mg/L. There are multiple instances in Figure 3 where influent total copper was near or above 0.061 mg/L and the WTP achieved an effluent total copper concentration below the permit limit, confirming that the WTP is able to treat that level of influent total copper. In the few instances where the WTP is not able to meet the permit limit for copper, the plant is shut-down or placed into re-circulation mode until the circumstances leading to that exceedance are remedied.

Total copper is the sum of dissolved copper and particulate copper. The WTP is primarily designed for TSS removal, and particulate copper is expected to be removed with TSS which is settled out during the treatment process. Dissolved copper also shows a reduction through the WTP, which may be attributable to co-precipitation with the Polyaluminum Chloride that is added at the start of the treatment process.

2.3 Selenium

WTP influent, effluent, and permit limit concentrations for total selenium are shown in Figure 4 over a six-year period between 2016 and 2021. Influent and effluent total selenium concentrations are consistently below the permit limit.

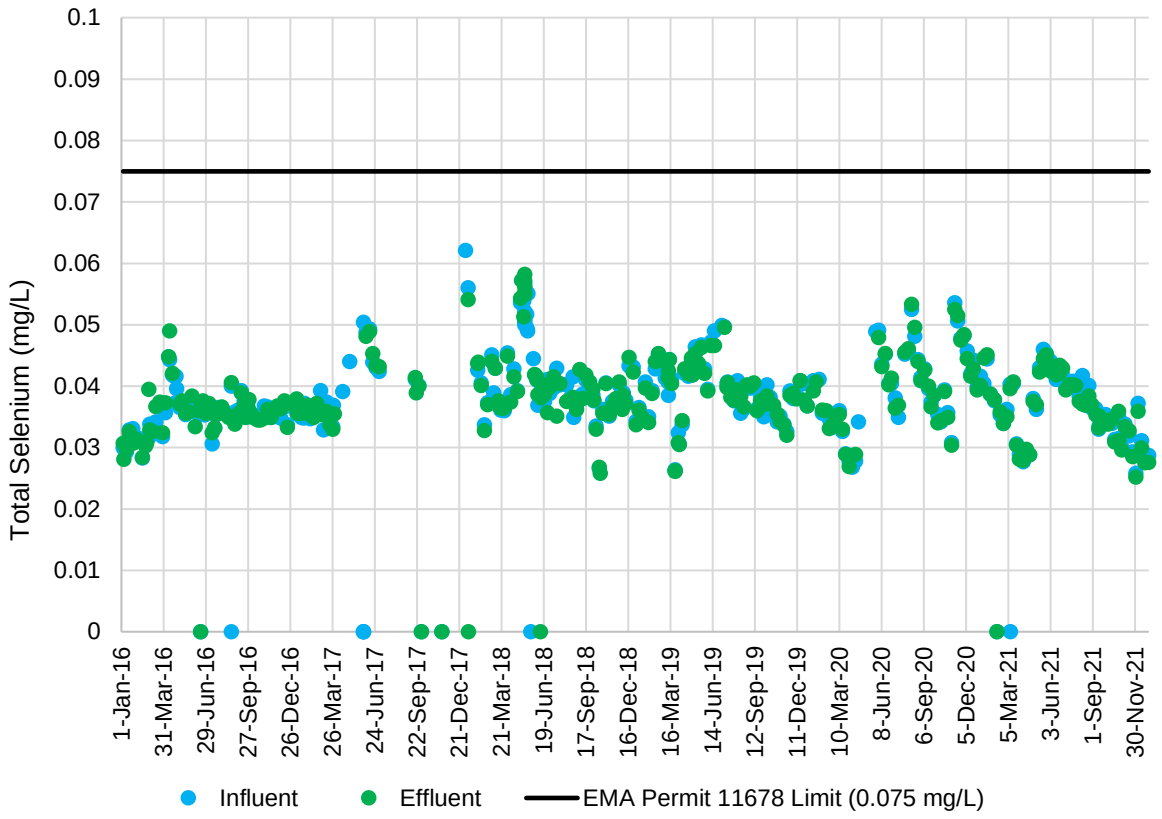

Figure 4: WTP Influent and Effluent Total Selenium Measured at E19 and HAD-3 from 2016 to 2021

The water quality estimates provided in Golder 2022a show predicted WTP influent total selenium concentrations from January 2023 through June 2025. The 95th percentile estimated concentration for total selenium had a maximum of 0.1 mg/L (with the maximum median value of 0.025 mg/L). The WTP is primarily designed for the removal of TSS and total selenium reduction through the plant is generally less than 10%. If WTP influent total selenium concentrations increase to 0.1 mg/L, then the WTP is not expected to meet the effluent permit limit; however, the historic data in Figure 4 demonstrates that influent selenium has not reached this level and that the maximum 95th percentile concentration of selenium is a conservatively high estimate. Current impacted water from mining activities at the site have not resulted in influent selenium concentrations beyond the permit limit.

Selenium concentrations may become an issue during mine post closure and development of passive treatment technologies targeting selenium reduction are currently being assessed and developed to address that possibility.

3.0 CLOSURE

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

We trust the above meets your present requirements. If you have any questions or require additional information, please contact the undersigned.

Site Runoff		To SERD Ditch	2,500		1,200

Comments

- The WTP is operating normally with average effluent at 1103m³/hour.
- All beach widths are in normal operating zones.
- Lake Excavating has started construction for the year and is currently working between corners 1 and 2.
- South embankment beach width is in concern zone.
- The sink hole was discovered on March 16th (Thursday) @ 4pm near corner 1 in the Zone U (upstream of the till core). The hole is ~2m deep.

- The team has been notified and area will be monitored.
- The sink hole was dug up and there was no continuity found into the underlaying rock fill. Area is still taped off due to open excavation still being present.

Executive Summary

This report presents the results of the 2023 annual dam safety inspection (DSI) for the tailings storage facility (TSF) at Mount Polley Mine, located near Likely, British Columbia. This report was prepared by WSP Canada Inc. (WSP) based on a site visit carried out on October 4 and 5, 2023, and a review of data provided by Mount Polley Mining Corporation (MPMC).

Facility Description

The TSF includes one embankment that is approximately 4.6 km long. The embankment is subdivided into three sections referred to as the Main Embankment, Perimeter Embankment, and South Embankment. The embankment is founded on glacially derived soils and was constructed in stages using centreline and modified centreline construction methods. Tailings generated at the mill have been deposited into the TSF as a low-density slurry.

The TSF Clean Water Ditch is located upstream of the facility between Corner 4 and Corner 5 and diverts runoff into a small wetland downstream of the South Embankment. The Main Embankment Seepage Collection Pond (MESCP), South Embankment Seepage Collection Pond (SESCP), and Perimeter Embankment Till Borrow Pond (PETBP) collect seepage and runoff from the embankments.

Operation and Construction History

Mount Polley Mine began production in 1997 and operated until October 2001 when operations were suspended for economic reasons. In March 2005, the mine restarted and was in operation up to the time of the TSF breach in August 2014. The embankment crest was near elevation 968 m relative to the Mount Polley Tailings Grid system at the time.

In 2015, the Freshet Embankment was constructed to elevation 950 m through the breach area to allow the capture and temporary storage of the 2015 and 2016 freshet flows. The Freshet Embankment design includes a low-permeability cut-off wall constructed using the cutter-soil mixing technique. The construction of buttresses along the Perimeter Embankment and Main Embankment was completed in October 2016 (Golder 2015a, 2017a).

The June 23, 2016, amendment of *Mines Act* Permit M-200 authorized the return to full operations at the mine, including construction and operation of the TSF to design elevation 970 m (Golder 2015b). Construction to raise the Freshet Embankment at Corner 1 to elevation 970 m started in June 2016. By September 2018, construction of the embankment at Corner 1 had been completed to elevation 968 m (Golder 2019a). The raise of the Freshet Embankment is referred to as the Perimeter Embankment at Corner 1.

Mining operations were halted in May 2019 for economic reasons. In June 2022, the mill restarted operations and tailings deposition into the TSF resumed. Construction to raise the embankments to elevation 970 m resumed in July 2022. By the end of 2022, the minimum elevation of the till core connection at the North Abutment remained at an estimated elevation of 966.2 m. Construction of the embankments and abutment connections was completed to about elevation 970 m between May and November 2023.

Summary of Key Hazards

The most relevant failure mode of the TSF is a failure through the foundation of the embankment. This failure mode has been the focus of geotechnical investigations, analyses, and design that have resulted in the construction of buttresses along the Main Embankment and Perimeter Embankment (including at Corner 1).

As the pond level rises due to deposition of tailings and the gradient across the till core increases, internal erosion of the embankment becomes a relevant failure mode. However, the highest TSF pond elevation since the restart of operation in 2016 has been 964.7 m, which is approximately 1.8 m lower than the maximum elevation prior to the breach. Wide tailings beaches, minimum 100 m, have generally been maintained between the embankment and the TSF pond, except from May to August 2020, May to November 2022, and May to June 2023. The current water level in the TSF imposes a hydraulic gradient across the till core that is less than the till core has previously resisted. No signs of turbid water or significant changes in flow rate have been observed at the seepage collection drains or ponds.

Overtopping of the embankment is an unlikely failure mode if the TSF is operated according to design. Most of the inflow to the TSF can be stopped by ceasing pumping water from the PETBP. The design freeboard criterion of 1.1 m was met throughout 2023. The freeboard remained above 2.3 m through 2023 and increased to more than 5.0 m after construction of the Corner 5 abutment in September/October 2023. The TSF pond level was about 964.7 m at the end of 2023, resulting in a freeboard of 5.3 m.

At the beginning of 2023, the TSF pond volume was estimated by MPMC to be in the order of 2.2 million m^3 (Mm^3) and exceeded the quantitative performance objectives (QPOs). The exceedance was due to MPMC allowing excess water to accumulate in the facility in 2021 and 2022. Prior to freshet, MPMC reduced the TSF pond volume to an estimated 1.5 Mm^3. The freshet flows increased the TSF pond volume to about 1.7 Mm^3 as estimated by MPMC. During the summer, MPMC continued reducing the pond volume, and by September 2023, it was estimated to be about 0.8 Mm^3. The TSF pond increased for the remainder of the year back towards the lower limit of the normal operating criteria. The TSF pond volume was estimated by MPMC to be about 1.4 Mm^3 as of December 2023.

It is important that MPMC continues to proactively manage site water, so the TSF pond size is maintained within the specified operating volume range and accumulation of water does not occur within the TSF.

Summary of Significant Changes

MPMC reported that approximately 5.9 million tonnes (Mt) of tailings were discharged into the TSF in 2023. A total of about 28.0 Mt of tailings have been deposited into the TSF since the restart of operations in June 2016.

Construction to raise the embankments from about elevation 968 to 970 m resumed in May 2023 and was completed by the end of October 2023.

Significant Changes in Instrumentation and/or Visual Monitoring Records

All inclinometers along the South Embankment, Main Embankment, and Perimeter Embankment show consistent conditions with measured movement within the accuracy of the instrumentation; however, weekly review of the inclinometer data during 2023 showed that at times the error was greater than what the system can achieve. Erratic readings started being recorded in deeper inclinometers along the Perimeter Embankment and Main Embankment in March 2022. Generally, the erratic readings included a combination of rotation from the base of the inclinometer and/or a sinusoidal shape from the base of the inclinometer. MPMC has sent its inclinometer probes for recalibration on multiple occasions; however, they have continued to malfunction periodically. The readings do not indicate downstream movement of the embankment, and the apparent movements are interpreted to be a systematic error. MPMC has purchased inclinometer probes supplied by another manufacturer and is in the process of re-establishing baselines for each inclinometer.

Survey monument SM18-01, installed at the downstream crest of the Perimeter Embankment at Corner 1, showed approximately 10 to 20 mm/year creep to the northeast since installation and until the monument was struck by equipment in May 2023. Settlement of the foundation and rockfill is expected. Survey monument SM18-01 was decommissioned in August 2023 while construction to raise the embankment to elevation 970 m was in progress.

On March 23, 2023, MPMC informed the Engineer of Record that the tailings slurry pipeline had leaked upgradient of the TSF and tailings had flowed along the toe of the Perimeter Embankment from Corner 5 to Corner 1 and deposited against the west side of the Perimeter Embankment buttress at Corner 1. High turbidity values were recorded at the Corner 1 north and south diversion ditches starting on March 23, 2023. The in situ turbidity test results remained elevated until May 2023 when conditions returned within the historical range. The high turbidity values are interpreted to be a result of the tailings slurry leak and freshet. Pore pressures at piezometers VW18-03A (till) and VW18-03B (till), located near the west side of the buttress at Corner 1, increased about 1.8 m to elevation 937.8 m (near original ground) in late March 2023 and have since stabilized at that level. The increase is interpreted to be a response to the tailings that deposited in the area on March 23, 2023. Piezometer VW18-03C, installed in the underlying bedrock, did not respond to these conditions and remained consistent for the year.

All other recorded seepage rates and turbidity values recorded in 2023 at all monitoring locations are within the historical range.

The groundwater quality trends for monitoring wells located around the TSF show that sulfate concentrations in the shallow groundwater downgradient of the TSF approached or reached levels observed in the TSF pond water next to the Perimeter Embankment at GW16-2B and GW96-2B and next to the South Embankment at GW96-4B. These wells are known or inferred to be completed in glaciofluvial units based on soil descriptions and the relatively high hydraulic conductivity results. The remaining wells indicated relatively stable or slightly decreasing sulfate concentration trends (WSP 2023e).

Erosion gullies have continued to form through the upstream fill due to snowmelt ponding on the crest of the embankment between the till core and tailings discharge pipeline. The tailings discharge pipeline should be relocated onto a bench along the upstream slope of the upstream fill. Alternatively, the tailings pipeline could be raised from the crest of the upstream fill to limit water ponding between the till core and the tailings slurry pipeline.

On March 16, 2023, MPMC reported that a sinkhole had developed on the upstream fill of the Perimeter Embankment near Sta. 4+465. The sinkhole is interpreted to have developed due to snowmelt ponding on the upstream fill at the crest of the embankment, infiltrating through the upstream fill and eroding the upstream fill tailings sands into the underlying rockfill (i.e., remaining temporary upstream rockfill berm). Details of the test pit investigation, review of construction record and instrumentation data, interpretation of the findings, and recommendations are presented in WSP (2023c). As indicated in the TSF sinkholes investigation and interpretation memorandums (Golder 2020c,d), sinkholes could redevelop if surface water conditions were allowed to repeat. The sinkhole that developed on the upstream fill of the Perimeter Embankment does not present a dam stability concern.

The tailings discharge pipeline was installed on a rockfill berm 2 to 3 m higher than the embankment crest immediately upstream of the embankment along Corner 5. The tailings pipeline has since been relocated onto the upstream crest of the embankment. However, the rockfill berm should be removed to allow tailings deposition to occur into this area of the TSF.

Significant Changes to Stability and/or Surface Water Control

The Perimeter Embankment, Main Embankment, and South Embankment were observed to be in generally good condition at the time of the site visit in 2023. No significant changes in stability were noted based on instrumentation and visual monitoring records.

The beach slopes upstream of the embankment were surveyed to be in the order of 0.5%, which is flatter than in previous years. The flatter beach slopes increase the difficulty to maintain the minimum beach width QPO of 100 m upstream of the embankment. Topographic and bathymetric surveys should continue to be performed periodically to monitor the beach slopes. The tailings deposition method should be assessed and modified to increase the beach slopes if surveys do not show improvements.

Dam Classification

The TSF embankment is classified as a significant consequence dam based on the guidelines presented by the Canadian Dam Association (CDA 2013, 2019).

Operation, Maintenance, and Surveillance Manual; Emergency Preparedness and Response Plan; and Dam Safety Review

The operation, maintenance, and surveillance (OMS) manual and the emergency preparedness and response plan (EPRP) for the TSF were updated in August 2023 to keep information up to date and to identify potential improvements. An additional update to the OMS manual and the EPRP was in progress at the end of 2023 to address comments made in the 2022 dam safety review (DSR) (Tetra Tech 2023).

A test of the EPRP was carried out on November 30, 2023, with Mine Rescue site personnel and the Technical Services Group simulating an exceedance of the TSF freeboard QPO (unsafe zone).

An audit level DSR was conducted by Tetra Tech Canada Inc. in 2022. The TSF embankment was considered reasonably safe with non-conformances (Tetra Tech 2023).

Recommendations

Table E-1 summarizes the status of priority level 1 and 2 outstanding recommended actions and the 2023 DSI recommended actions Each recommendation has been given a priority level from 1 to 4 as described in Table E-2. Priority level 3 and 4 recommended actions are presented in Table 4.

Table E-1: Summary of Priority Level 1 and 2 Key Issues and Recommended Actions

ID	Identified Issue	Potential Dam Safety Impact or Risk	Recommended Action	Priority	Recommended Timing for Completion or Status
2023DSI-01	The tailings pipeline is installed on a 2 to 3 m high berm immediately upstream of the upstream fill which is at a higher elevation than the TSF embankment at Corner 5.	Risk of discharging tailings upstream of the berm to a higher elevation than the embankment (i.e., >970 m). The berm is not engineered to retain tailings. Increased risk of potential pipeline leaks flowing over and eroding the embankment.	Relocate the tailings slurry pipeline onto a berm along the upstream slope of the upstream fill or onto the crest of the upstream fill, locally raised with blocking or similar. Excavate the existing pipeline berm upstream of the embankment.	2	Complete. Spring 2024.
2023DSI-07	Recommendation 2017DSR-09 has been addressed for the MESCP and PETBP (Golder 2018b). Documentation of peak flow, inflow volumes, and pumping requirements pending for the SESCP.	Potential insufficient storage or pumping capacity resulting on overtopping of the SESCP.	Determine and document the peak flow, inflow volumes, and pumping requirements for the SESCP.	2	Spring 2024.
2023DSI-08	Stress-deformation analyses (Zabolotnii et al. 2022) indicate that slope inclinometers could provide indication of movement in advance of a potential foundation failure through a layer of GLU in the foundation if the slope inclinometers are located where plastic strains would first occur. Slope inclinometers are installed downstream of the embankment along the South Embankment. Two slope inclinometers are installed near the toe of the starter dam at the Main Embankment.	Potential stability issues may not be identified in a timely manner.	Install and monitor slope inclinometers near the toe of the starter dam near Sta. 0+700 and 1+100 at the South Embankment and near the toe of the starter dam near Sta. 1+900, 2+300, and 2+600 at the Main Embankment.	2	During construction to re-slope the embankment to 2H:1V in 2024.
2022DSI-01	Inclinometer readings show systematic reading errors greater than the capability of the instrument.	Potential issues may not be identified in a timely manner. Misinterpretation or overestimation/underestimation of movement of the embankment.	Periodic review of data collection technique by experienced operator followed by retraining as required. Periodic recalibration of the inclinometer probe by manufacturer on an as required basis.	2	Ongoing. MPMC repaired and purchased new inclinometer probes in 2023; however, malfunctions persisted. MPMC purchased inclinometer probes supplied by another manufacturer and is in the process of re-establishing baselines for each inclinometer.
2022DSI-02	The OMS manual and EPRP were last updated in 2021 before tailings deposition into the TSF resumed. Changes made to slurry deposition in 2022 need to be included in the OMS manual.	Increased risk due to potential miscommunication or misunderstanding of TSF operation, maintenance, surveillance, and emergency response.	Complete updates of the OMS manual and EPRP as required (minimum once per year) and train personnel as required.	2	Completed August 2023. Updates to the OMS manual and EPRP were in progress at the end of 2023.

Table E-1: Summary of Priority Level 1 and 2 Key Issues and Recommended Actions

ID	Identified Issue	Potential Dam Safety Impact or Risk	Recommended Action	Priority	Recommended Timing for Completion or Status
2022DSI-03	By the end of 2022, the minimum elevation of the till core was about 968.2 m near Corner 3 while the filter and transition zones remained lower at an elevation ranging from 965 to 968 m. The till core connection at the North Abutment remained at an estimated elevation of 966.2 m.	Potential insufficient storage capacity to store target tailings production in 2023.	Complete construction of the filter and transition zones to match the minimum elevation of the till core and abutments. Review tailings production forecast and storage capacity and plan construction as required.	2	Complete.
			Complete construction to raise the embankment to elevation 970 m. Review tailings production forecast and storage capacity and plan construction as required.		Complete.
2021DSI-01	By the end of 2021, an approximate total of about 7.0 Mm^3 of water remained on site at the Springer Pit, Cariboo Pit, and TSF. The restart of mining operations requires dewatering the Springer Pit and Cariboo Pit and reduces the ability to use these pits to store the current excess water on site. The TSF cannot be used to store excess site water.	Increased risk due to the accumulation of a larger volume of water on site that reduces the capacity to manage runoff from freshet and extreme events.	Implement actions to increase the site water discharge rate so the current excess water on site is eliminated, the TSF pond size is maintained within the specified operating volume range, and accumulation of water does not occur within the TSF. Actions could involve: ▪ obtaining approval to discharge untreated water that meets the requirements of the permit ▪ developing a flowchart and triggers to help determine the magnitude of precipitation events in a timely manner	2	Ongoing since 2020. In 2023, the TSF pond had an estimated net water reduction of about 0.9 Mm^3 and has remained within or below the normal operating pond volume range since about June 2023. MPMC reported a year-over-year site-wide water reduction of about 2.7 Mm^3 in 2023; however, approximately 3.2 Mm^3 remained on site by end of 2023.
2018DSI-02	Clean water diversion ditch along the west side of the TSF is partially blocked by fallen trees and woody vegetation.	Overtopping of the ditch during large storm events, with washout of access road along the west side of the TSF.	Remove obstructions (i.e., fallen trees, woody vegetation, and branches) and re-establish the diversion ditch along the perimeter of the TSF.	2	Ongoing. No progress in 2023.

DSI = dam safety inspection; TSF = tailings storage facility; PETBP = Perimeter Embankment Till Borrow Pond; CCS = Central Collection Sump; DSR = dam safety review; MESCP = Main Embankment Seepage Collection Pond; SESCP = South Embankment Seepage Collection Pond; GLU = glaciolacustrine unit; OMS = operation, maintenance, and surveillance; EPRP = Emergency Preparedness and Response Plan.

Table E-2: Description of Priority Levels

Priority Level	Description
1	A high probability or actual dam safety issues considered immediately dangerous to life, health or the environment, or a significant risk of regulatory enforcement.
2	If not corrected, could likely result in dam safety issues leading to injury, environmental impact or significant regulatory enforcement; or a repetitive deficiency that demonstrates a systematic breakdown of procedures.
3	Single occurrences of deficiencies or non-conformances that alone would not be expected to result in dam safety issues.
4	Best Management Practice – Further improvements are necessary to meet industry best practices or reduce potential risks.

1.0 INTRODUCTION

WSP Canada Inc. (WSP) completed an annual dam safety inspection (DSI) of the tailings storage facility (TSF) at Mount Polley Mine, located near Likely, British Columbia. The mine is owned and operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. The following structures were inspected during the annual review:

- Perimeter Embankment and buttress
- Main Embankment and buttress
- Main Embankment Seepage Collection Pond (MESCP)
- South Embankment
- South Embankment Seepage Collection Pond (SESCP)
- TSF Clean Water Ditch

This DSI report has been prepared in accordance with Part 10 of the Health, Safety and Reclamation Code for Mines in British Columbia (EMLI 2022). It is understood that MPMC will submit this report to the British Columbia Ministry of Energy, Mines and Low Carbon Innovation Chief Inspector of Mines. The annual DSI report guidelines outlined by the British Columbia Ministry of Energy, Mines and Low Carbon Innovation (formerly British Columbia Ministry of Energy and Mines) were followed during the preparation of this report (BCMEM 2016).

This report is based on a review of annual data pertaining to the mine site and TSF, discussions with MPMC staff, and a site visit carried out on October 4 and 5, 2023. This report includes:

- site conditions and background information of the facility
- summary of the construction, operation, and maintenance activities in 2023
- review of climate data, water balance, TSF operation, failure modes, and instrumentation data
- review of dam classification and required operational documents
- recommendations for future operation, maintenance, and inspection activities
- site photographs and records of DSI
- figures with updated instrumentation in plan and cross-sections

A dam safety review (DSR) was conducted in 2022 (Tetra Tech 2023). The recommendations made in the DSR report and WSP's recommended actions to address the comments are included in Section 7.3.3 of this report.

All elevations and coordinates are presented relative to the Mount Polley Tailings Grid system unless otherwise noted. This report is to be read in conjunction with the Study Limitations provided at the beginning of the report.

2.0 METHOD

2.1 Site Inspection

A site inspection was carried out by Germán Pizarro, P.Eng., and Ryan Garritsen, P.Eng., on October 4 and 5, 2023. Germán Pizarro has been the Engineer of Record (EoR) for the Mount Polley Mine TSF since February 2019.

The weather during the site inspection was between about 4°C and 12°C, with cloudy to partly sunny conditions. The inspection involved observing and photographing the condition of the embankments and associated structures while walking the complete length of the following:

- crests of the Perimeter Embankment, Main Embankment, and South Embankment
- crests of the Perimeter Embankment buttress and Main Embankment buttress
- downstream toe of the South Embankment
  - Sections of the downstream toe were not accessible due to vegetation.
- downstream toe of the Perimeter Embankment buttress and Main Embankment buttress
- MESCP
- SESCP
- TSF Clean Water Ditch
  - Sections of the ditch were not accessible due to vegetation.

2.2 Review of Monitoring Information

The following monitoring records were reviewed as part of the annual DSI:

- weekly TSF inspection reports prepared by MPMC
- climate data including temperature, rainfall, and snowpack
- TSF pond elevation measurements and estimated TSF pond volume
- monthly tailings production rates
- weekly water treatment plant (WTP) operating rates
- geotechnical instrumentation installed within and downstream of the embankment including vibrating wire piezometers (VWPs); monitoring wells (i.e., standpipe piezometers); inclinometers (manual readings, in-place inclinometer probes, and shape acceleration arrays [SAAs]); and survey monuments
- turbidity and drain flow rates from the Freshet Embankment seepage collection ditch, north and south diversion ditches, Perimeter Embankment upstream drain at Corner 1, west and east Main Embankment toe drains, and South Embankment toe drain

3.0 FACILITY DESCRIPTION

3.1 General

Mount Polley Mine is a copper and gold mine operated by MPMC. The site is located 56 km northeast of Williams Lake, British Columbia, between Polley Lake and Bootjack Lake. The TSF is located about 3 km southeast of the mill.

The TSF includes one embankment that is approximately 4.6 km in length. The embankment is subdivided into three sections referred to as the South Embankment, Main Embankment, and Perimeter Embankment. The mine site layout with the TSF configuration is shown in Figure 1.

The embankment is founded on glacially derived soils. The embankment incorporates a staged expansion design using modified centreline and centreline construction methods. The general zoning of the embankment includes:

- upstream fill generally composed of tailings sand and rockfill
- low permeability till core
- filter zone
- transition zone
- rockfill forming the downstream zone of the embankment and the downstream buttress along the Perimeter Embankment and Main Embankment
    - Sandy tailings reclaimed from Hazeltine Creek were also used in the construction of the Perimeter Embankment buttress at Corner 1.

The TSF Clean Water Ditch is located to the west and upstream of the TSF between Corner 4 and Corner 5 and diverts runoff into a small wetland downstream of the South Embankment.

The MESCP and SESCP are located at the downstream toe of the Main Embankment buttress and South Embankment, respectively. The Perimeter Embankment Till Borrow Pond (PETBP) is located at the downstream toe of the Perimeter Embankment buttress. The ponds collect seepage and surface water runoff from the embankments. The PETBP also collects site contact water from the Central Collection Sump (CCS) and is the source of water for the WTP. The SESCP is pumped into a gravity-flow open ditch reporting to the MESCP. Water in the MESCP is pumped back into the TSF. Water in the PETBP is either pumped to the WTP or the TSF.

3.2 Recent Construction and Operation History

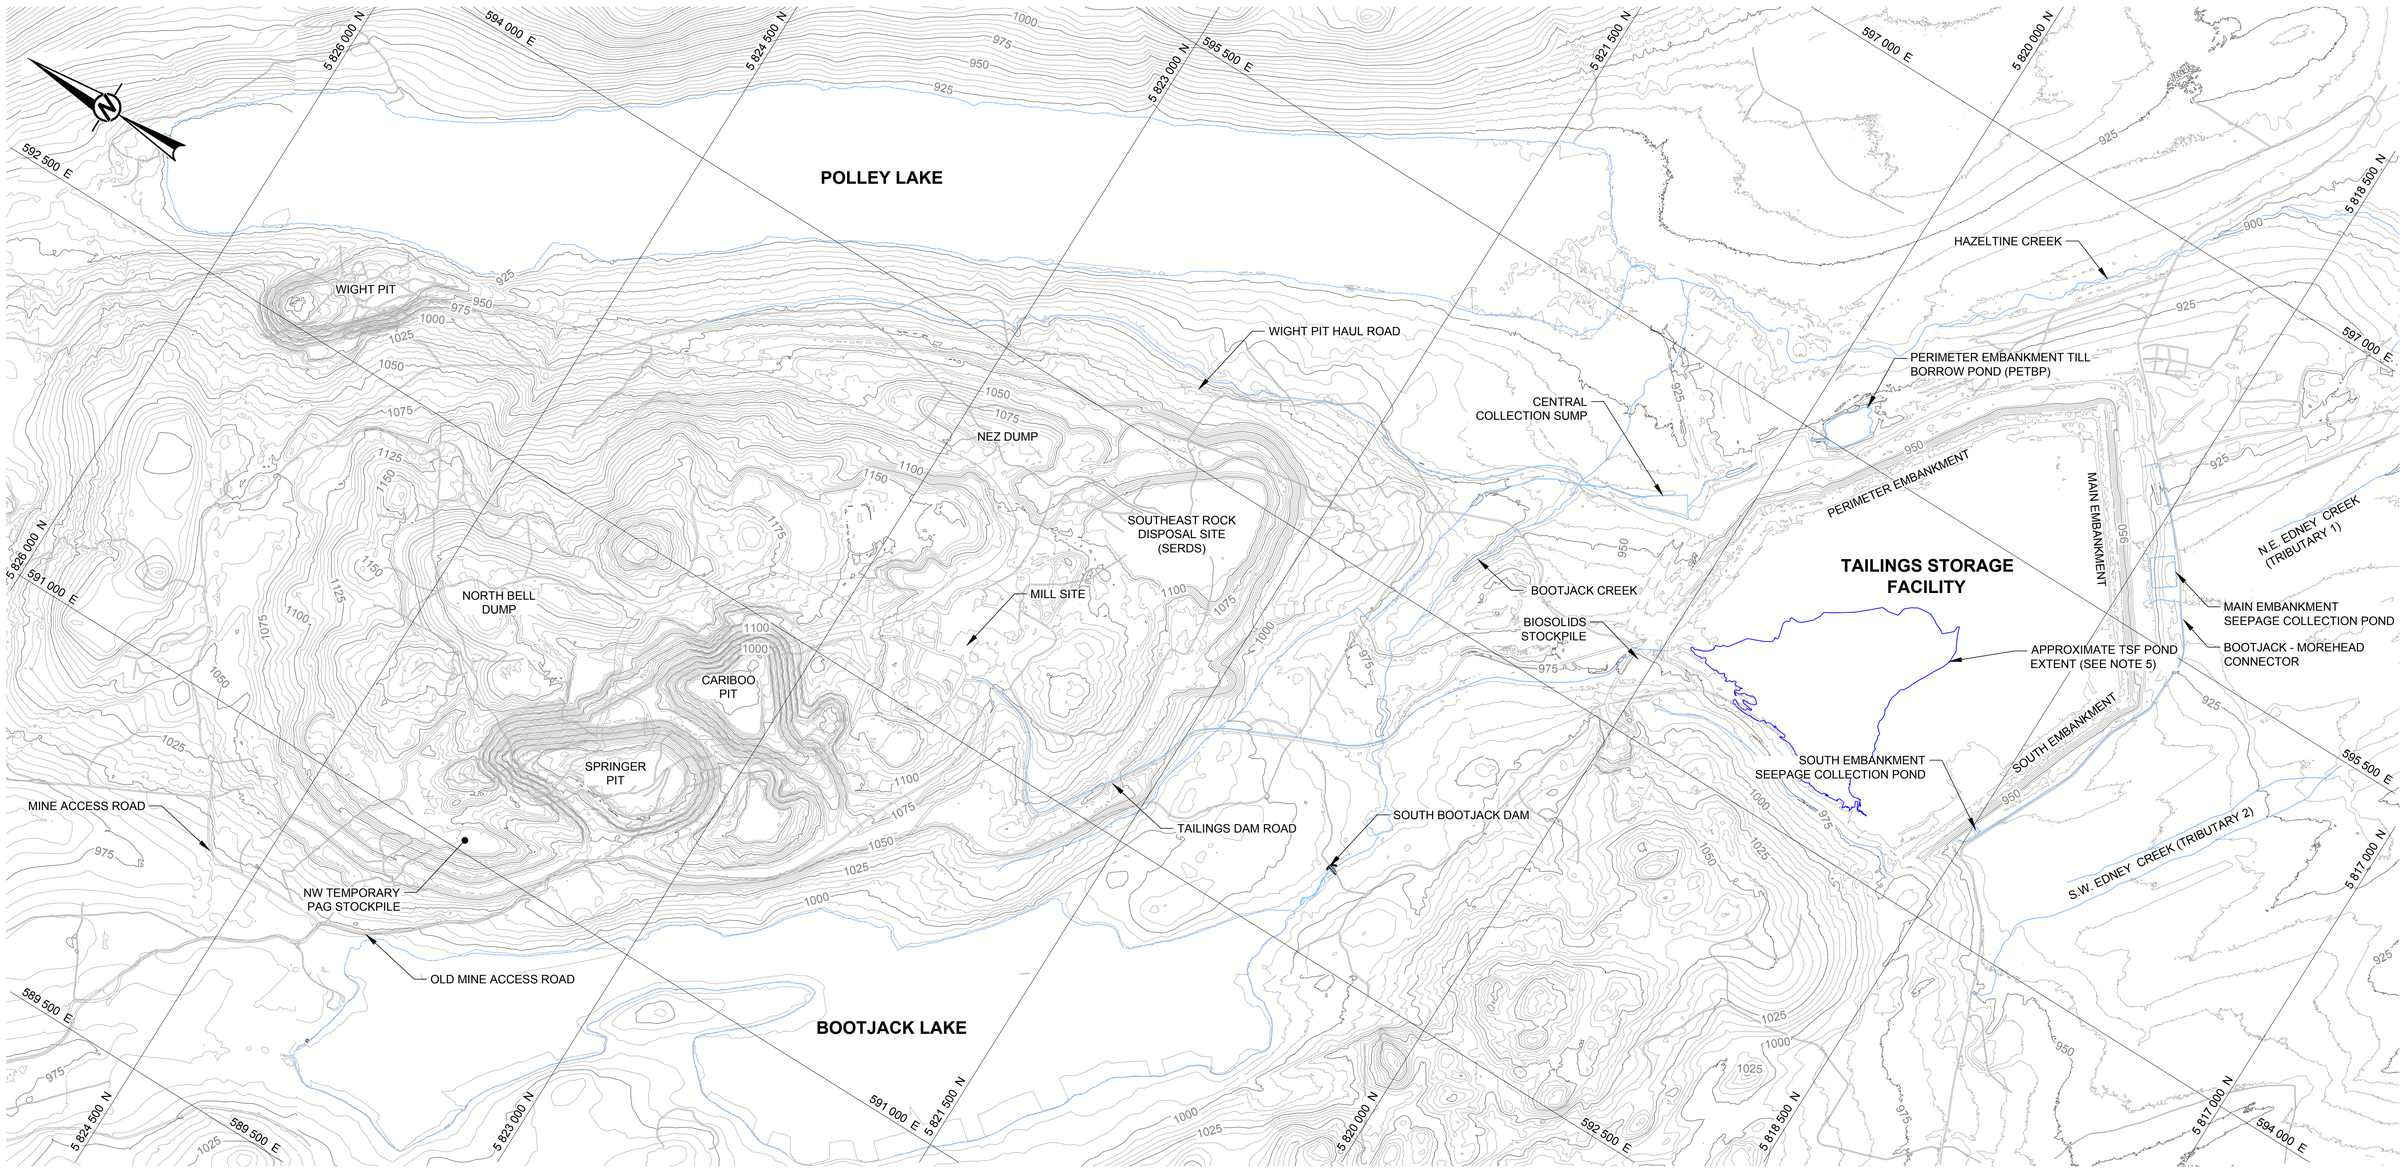
On August 4, 2014, a foundation failure at Corner 1 of the Perimeter Embankment near Sta. 4+300 resulted in a breach of the TSF. Placement of fill to raise the embankment crest to an elevation of 970 m was nearing completion at the time.

The Freshet Embankment was constructed to elevation 950 m through the breach area during the period from November 2014 to June 2015. The Freshet Embankment design includes a low permeability cut-off wall constructed using the cutter-soil mixing technique. The cut-off wall, cut-off wall aggregate, and transition materials are supported by tailings sand on the upstream side and rockfill on the downstream side. The construction of a buttress along the Perimeter Embankment was also completed as part of the 2015 Freshet Management Embankment (Golder 2015a).

Construction of a buttress extension along the Main Embankment and Perimeter Embankment commenced in December 2015. Construction of the buttress extensions was completed in October 2016 (Golder 2017a).

The June 23, 2016, amendment of *Mines Act* Permit M-200 authorized the return to full operations at the mine including construction and operation of the TSF to design elevation 970 m (Golder 2015b). Construction to raise the Freshet Embankment to elevation 970 m started in June 2016. The raise of the Freshet Embankment is referred to as the Perimeter Embankment at Corner 1. Construction of the Perimeter Embankment at Corner 1 was completed to elevation 958 m by the end of 2016 (Golder 2017b).

The Perimeter Embankment at Corner 1 was raised to about elevation 966 m in 2017. Construction of the buttress at Corner 1 (as per the elevation 970 m TSF design) was in progress in 2017 and was generally completed by April 2018 (Golder 2018a). The downstream slope of the buttress extension was re-sloped from October 2018 to January 2019. Construction to raise the Perimeter Embankment at Corner 1 resumed in July 2018 and was completed to elevation 968 m by September 2018 (Golder 2019a).



Mining operations were halted in May 2019 for economic reasons. The mine remained in care and maintenance until late 2021. No construction activities were carried out on the embankments during 2020 and 2021. The crest elevation remained at 968 m throughout this period.

Construction to raise the embankments to elevation 970 m resumed in July 2022. By the end of 2022, the minimum elevation of the till core was about 968.2 m near Corner 3, while the filter and transition zones remained lower at an elevation ranging from 965 to 968 m. Construction of the embankments and abutment connections was completed to about elevation 970 m between May and November 2023.

Tailings have been deposited as a low-density slurry since the restart of operations of the TSF in 2016. The tailings slurry has been conveyed from the mill to the TSF via gravity-driven tailings discharge pipelines. Tailings were not deposited in the TSF in 2020 and 2021 while the mine was in care and maintenance.

Since 2022, tailings slurry has been deposited in the TSF from multiple locations along the South Embankment and Perimeter Embankment to build tailings beaches upstream of the embankments and to maintain the pond in a centralized location within the TSF. Tailings deposition from the crest of the Main Embankment has not been attempted. However, the South Embankment tailings slurry pipeline was extended along a berm on the tailings beach upstream of the Main Embankment. The size of the TSF pond is managed by pumping supernatant water to the WTP for discharge from the mine site.

4.0 REVIEW OF CLIMATE DATA

Weather data is recorded at two weather stations on the mine site which are located near the mill and TSF. Climate data is recorded at both weather stations including daily temperature, relative humidity, wind speed, solar radiation, evaporation, and rainfall.

The daily temperatures recorded on site from January 2015 to December 2023 are shown in Figure 2 and Figure 3. Most of the temperature data were recorded at the TSF weather station except for years 2015, 2020, and 2023 where limited data were available. Temperature data were also not recorded at the TSF weather station in 2022 from about mid-January to mid-February and in December. In 2023, air temperatures on site were generally above average but still within the historical range throughout the year based on the climate baseline (WSP Golder 2022a).

The rainfall gauges are usually removed from the weather stations each year due to freezing conditions from about November to April. The rainfall data from 2015 to 2023 are shown in Figure 4. The precipitation data recorded for the mill site correspond to manual readings taken throughout the year. Manual readings are not collected daily and often represent multiple days of rainfall grouped together. The precipitation data recorded for the TSF correspond to automatic tipping gauge readings taken daily at the weather station. The recorded data generally show drier than average conditions in April, June, July, September, and October 2023. The combined precipitation from April to October was about 60% of the average amounts for those months based on the climate baseline (WSP Golder 2022a).

The measured snowpack of 263 mm in late February 2023 was slightly above average with an extended period of snowmelt from March to May 2023 as shown in Figure 5. The reported snowpack of 18 mm near year end is below average compared to the measurements taken since December 2014.

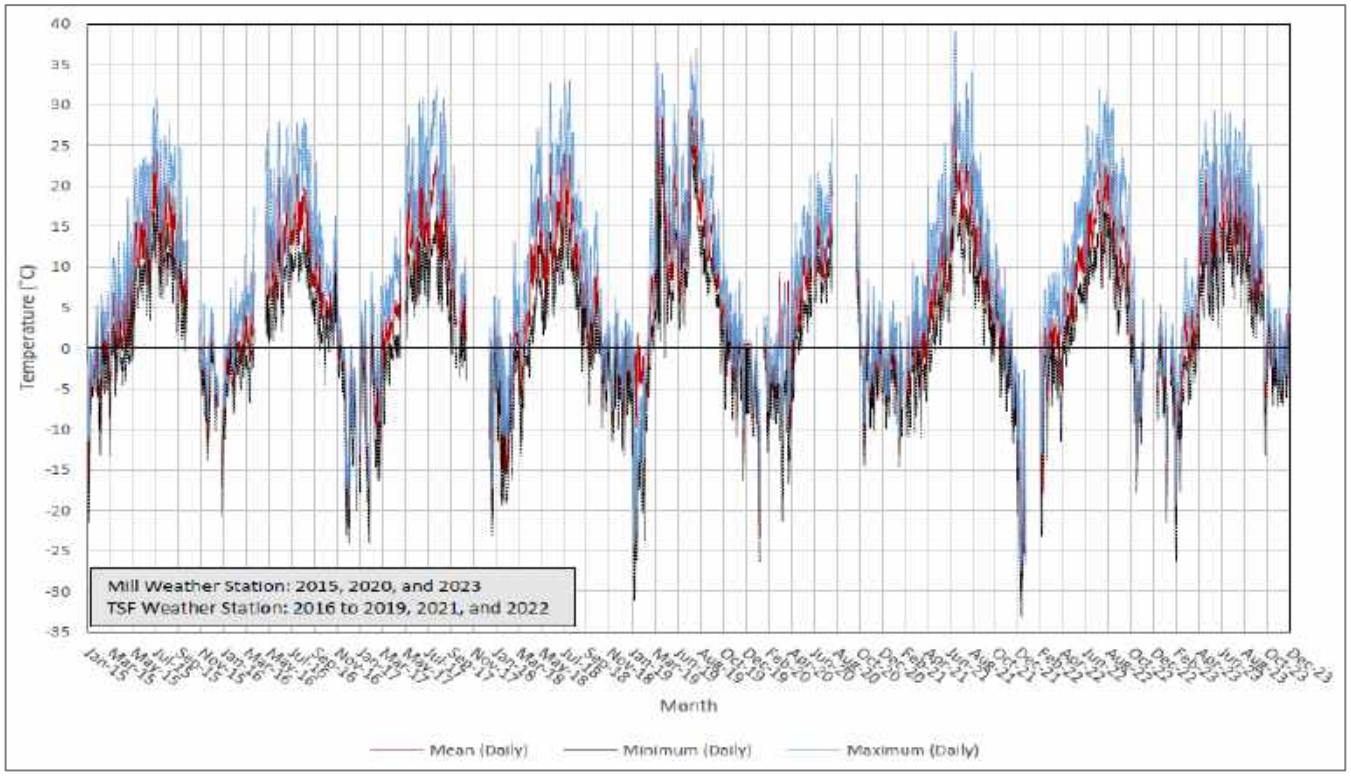

Figure 2: Daily Temperature Recorded at Mount Polley Mine

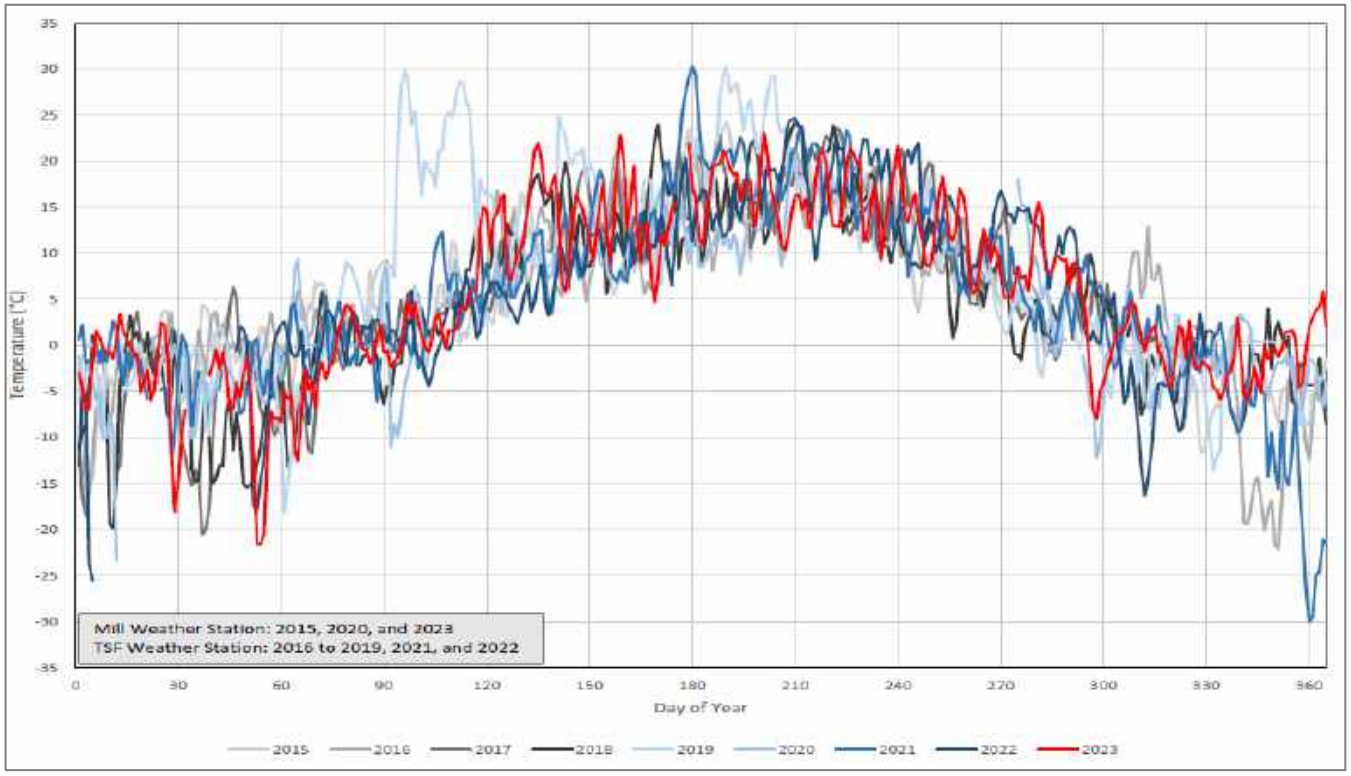

Figure 3: Mean Daily Temperature Recorded at Mount Polley Mine

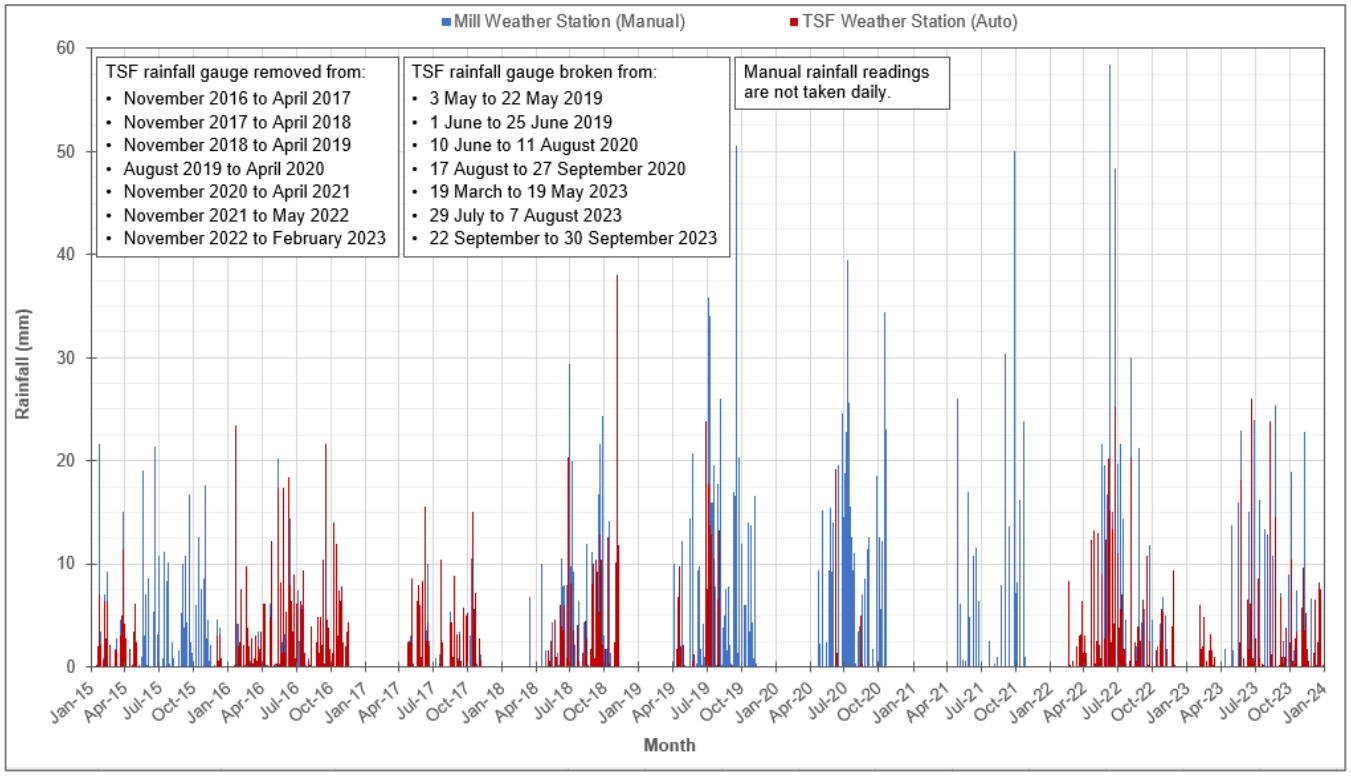

Figure 4: Measured Rainfall

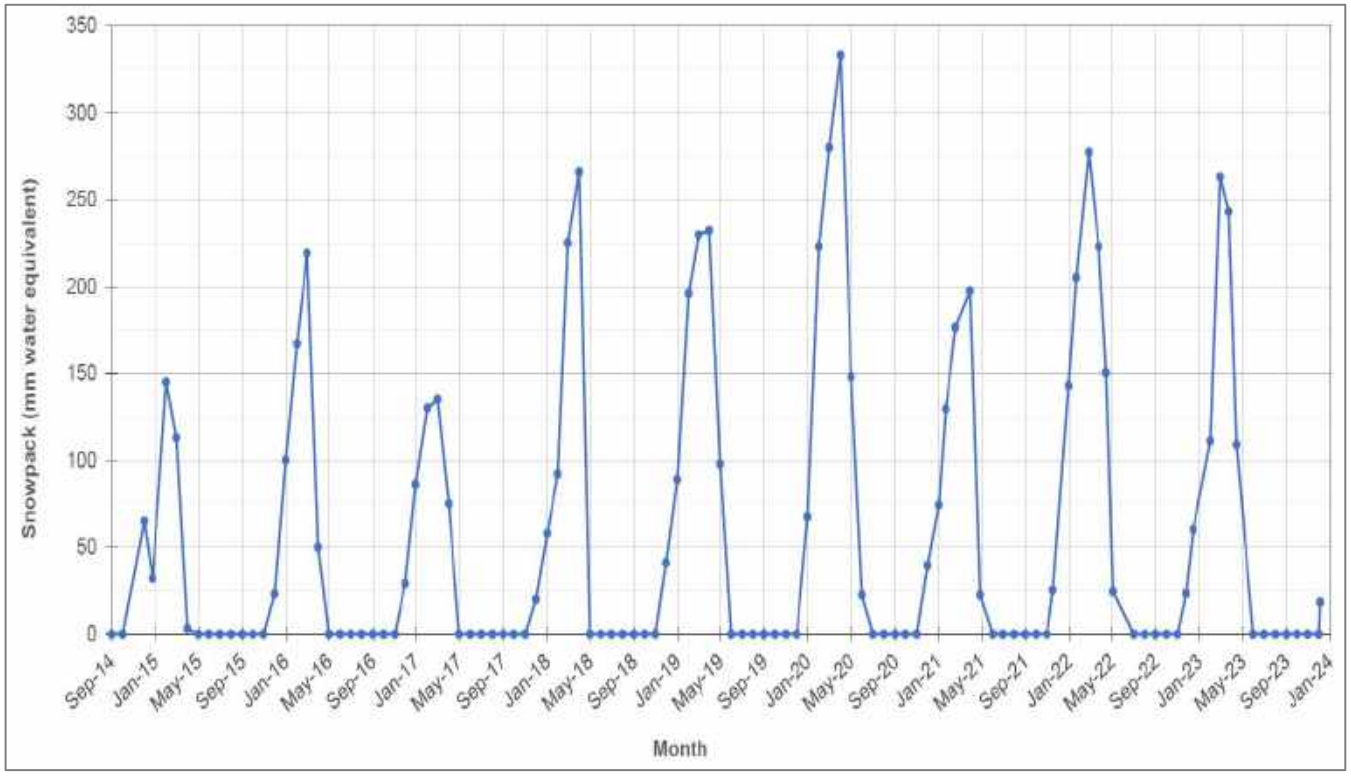

Figure 5: Snowpack Surveyed On Site

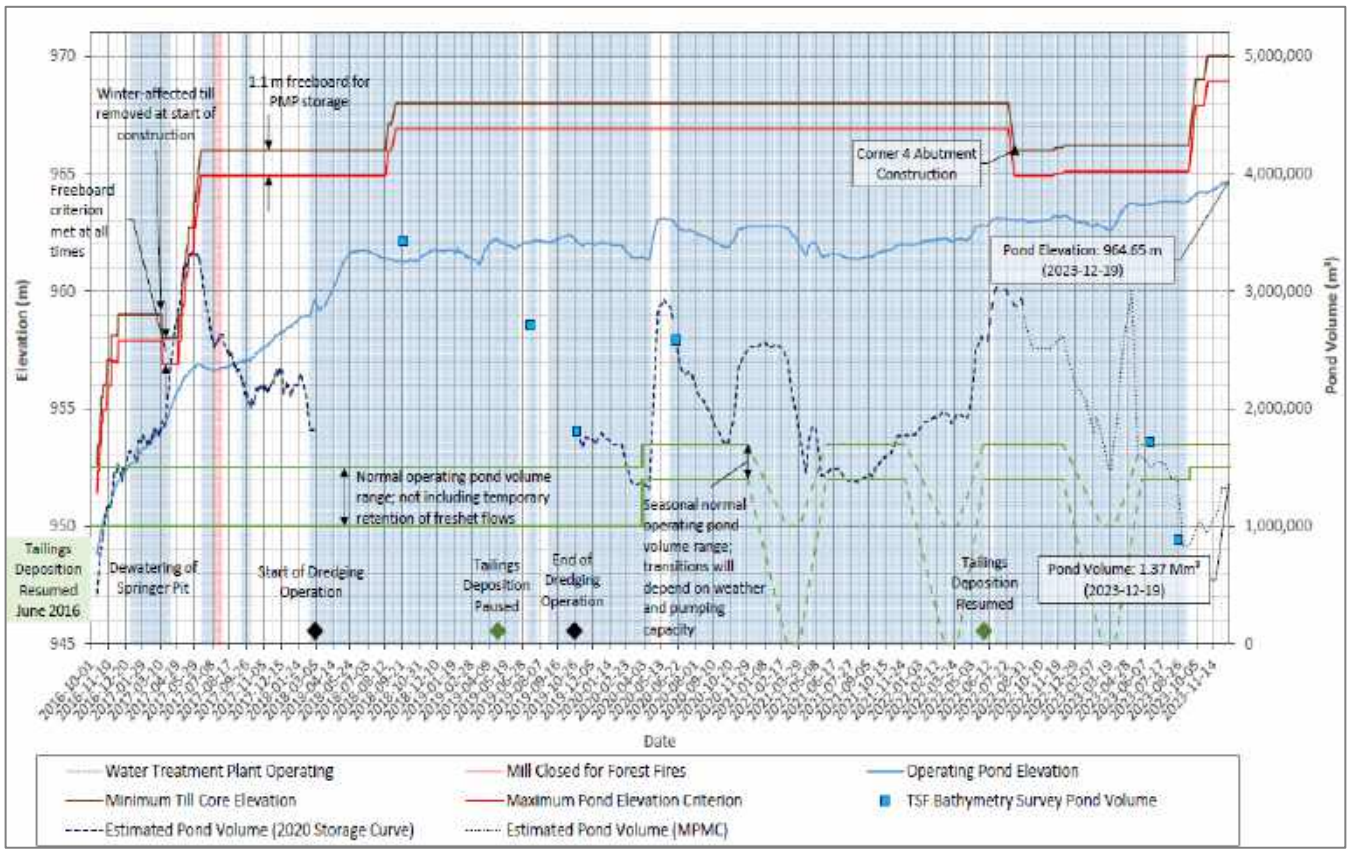
5.0 REVIEW OF TAILINGS STORAGE FACILITY OPERATION AND WATER BALANCE

Mining operations were halted in 2019, and the mine remained in care and maintenance until late 2021. The mill restarted operations and tailings deposition into the TSF resumed by the end of June 2022. MPMC reported that a total of 5.9 million tonnes (Mt) of tailings were discharged into the TSF in 2023. A total of about 28.0 Mt of tailings have been deposited into the TSF since the restart of operations in June 2016.

The TSF is required to have sufficient available storage capacity for containment of runoff from the contributing catchment area for the inflow design flood (IDF) event. The design spring and summer 72-hour IDF events are 1.16 Mm^3 and 0.67 Mm^3, respectively (Golder 2017c). The design freeboard criterion of 1.1 m provides storage capacity of approximately 1.9 Mm^3 for an embankment crest elevation of 968 m, which exceeds the requirement to store the 72-hour IDF.

Figure 6 shows the elevation and estimated volume of the TSF pond since the restart of operations in 2016. Since the restart of operations, the TSF pond elevation steadily increased to about 961.8 m by the end of June 2018 and then remained between elevation 961.1 and 963.2 m until the end of 2022. In 2023, the TSF pond elevation rose to 963.7 m during freshet and continued to increase gradually for the remainder of the year. The freeboard remained above 2.3 m and increased as construction to raise the embankment progressed in 2023. The TSF pond level was about 964.7 m by the end of 2023, resulting in a freeboard of 5.3 m. The beach width upstream of the embankments was generally greater than 100 m during the year. There were relatively short periods of time where the TSF pond encroached within these limits including:

- short sections, between deposition locations, along the Perimeter Embankment for a variable period after freshet from about Sta. 3+800 to 4+900
- a section along the Perimeter Embankment from about Sta. 3+050 to 3+600 where sand was borrowed from the beach for use as upstream fill during construction to raise the embankment; the beach widths were re-established to at least 100 m after about two-weeks



The TSF is designed to provide temporary retention of water to manage large runoff volumes generated during spring freshet or precipitation events (Golder 2015b). However, the pond volume is to be maintained within the normal operating pond volume criteria as outlined in the quantitative performance objectives (QPOs) (Golder 2020a; WSP 2023b). In September 2023, the normal operating pond volume range for the elevation 970 m embankment was revised to 1.5 Mm^3 to 1.7 Mm^3 year-round (as presented in Figure 6) based on input by MPMC that the required 1.0 Mm^3 prior to freshet resulted in inadequate water conditions for mill operation.

MPMC completed surveys of the tailings surface above and below the pond level after deposition of tailings was halted in 2019. However, surveys were not completed in 2022 after deposition of tailings resumed, and therefore the estimated pond volumes using the 2019 survey are progressively inaccurate after June 2022. In 2023, MPMC carried out surveys of the tailings surface in May, June, August, and October; however, inaccuracies were observed in the May survey, while the October survey did not include a bathymetry. MPMC revised the storage curves using the survey data to estimate the TSF pond volumes presented in Figure 6.

At the beginning of 2023, the TSF pond volume was estimated by MPMC to be in the order of 2.2 Mm^3 and exceeded the QPOs. The exceedance was due to MPMC allowing excess water to accumulate in the facility in 2021 and 2022. Prior to freshet, MPMC reduced the TSF pond volume to an estimated 1.5 Mm^3. The freshet flows increased the TSF pond volume to about 1.7 Mm^3 as estimated by MPMC. During the summer, MPMC continued reducing the pond volume and by September 2023, it was estimated to be about 0.8 Mm^3. The TSF pond increased for the remainder of the year back towards the lower limit of the normal operating criteria. The TSF pond volume was estimated by MPMC to be about 1.4 Mm^3 as of December 2023.

In 2023, a year-over-year site-wide water reduction of about 2.7 Mm^3 was achieved based on the water volumes inferred from measured water levels in the Springer Pit, Cariboo Pit, Wight Pit, and TSF.

It is important that MPMC continues to proactively manage site water, so the TSF pond size is maintained within the specified operating volume range and accumulation of water does not occur within the TSF.

PMP = probable maximum precipitation; Mm^3 = million cubic metres; MPMC = Mount Polley Mining Corporation; TSF = tailings storage facility.

Figure 6: Tailings Storage Facility Pond and Till Core Elevation

6.0 DAM CLASSIFICATION

Guidelines for the classification of dams are presented in the Canadian Dam Association (CDA) *Dam Safety Guidelines* (CDA 2013) and *Technical Bulletin: Application of Dam Safety Guidelines to Mining Dams* (CDA 2019). Tailings dams in British Columbia are regulated under the Health, Safety and Reclamation Code for Mines in British Columbia (BCMEM 2016; EMLI 2022), which references the CDA guidelines.

Consequence categories are based on the incremental losses that a failure of the dam might inflict on downstream or upstream areas, or at the dam location itself. Incremental losses are those over and above the losses which might have occurred in the same natural event or condition had the dam not failed. Infrastructure and economic consequences are based on third-party losses. The consequences of a dam failure are ranked as Low, Significant, High, Very High, or Extreme for each of the loss categories. The classification assigned to a dam is the highest rank determined among the loss categories. Table 1 presents the dam classification criteria outlined by the CDA (2013, 2019).

A dam break analysis and inundation study was carried out considering a hypothetical sunny day and flood-induced failure of the Main Embankment and South Embankment (Golder 2017d). A summary of the results is provided below.

- **Main Embankment**—The runoff would flow southeast along Hazeltine Creek and Edney Creek to Quesnel Lake.
- **South Embankment**—The runoff would flow south to Edney Lake and southeast along Hazeltine Creek and Edney Creek to Quesnel Lake.

There are no permanent structures in these areas.

The runoff from a breach of the Perimeter Embankment (as the breach at Corner 1) would flow southeast along Hazeltine Creek or Edney Creek to Quesnel Lake depending on the location of the breach. The WTP is the only permanent structure in this area.

The TSF was evaluated according to the dam classification and loss criteria summarized in Table 1. The TSF is ranked as a Significant consequence of failure based on the following assessment.

- The loss of life is considered unspecified based on the limited exposure time of the general population and mine staff.
  - The area at risk for the general population is limited to the section of Gavin Lake Road downstream of the TSF, bridge crossings on Edney Creek, and the area at the confluence of Hazeltine Creek and Edney Creek with Quesnel Lake. There is no permanent population in these areas.
  - The area at risk for mine staff is limited to the TSF (i.e., embankment crest and buttress) and the downstream water management infrastructure (i.e., WTP, SESCP, and MESCP). Mine staff conduct periodic inspections and maintenance activities at these locations but are not permanently in the area.
- Restoration of fish habitat is possible as demonstrated by the rehabilitation works completed in the Hazeltine Creek channel.
- Third-party economic losses would be low (e.g., Gavin Lake Road and Edney Creek bridge crossing).

Table 1: Dam Classification in Terms of Consequence of Failure (Source: Table 3-1 of CDA 2019)

Dam Class	Population at Risk[a]	Incremental Losses		
		Loss of Life[b]	Environmental and Cultural Values	Infrastructure and Economics
Low	None	0	▪ Minimal short-term loss. ▪ No long-term loss.	▪ Low economic losses: area contains limited infrastructure or services.
Significant	Temporary Only	Unspecified	▪ No significant loss or deterioration of fish or wildlife habitat. ▪ Loss of marginal habitat only. ▪ Restoration or compensation in kind highly possible.	▪ Losses to recreational facilities, seasonal workplaces, and infrequently used transportation routes.
High	Permanent	10 or fewer	▪ Significant loss or deterioration of important fish or wildlife habitat. ▪ Restoration or compensation in kind highly possible.	▪ High economic losses affecting infrastructure, public transportation, and commercial facilities.
Very High	Permanent	100 or fewer	▪ Significant loss or deterioration of critical fish or wildlife habitat. ▪ Restoration or compensation in kind possible but impractical.	▪ Very high economic losses affecting important infrastructure or services (e.g., highway, industrial facility, storage facilities for dangerous substances).
Extreme	Permanent	More than 100	▪ Major loss of critical fish or wildlife habitat. ▪ Restoration or compensation in kind impossible.	▪ Extreme losses affecting critical infrastructure or services (e.g., hospital, major industrial complex, major storage facilities for dangerous substances).

a) Definitions for population at risk:

None – There is no identifiable population at risk, so there is no possibility of loss of life other than through unforeseeable misadventure.

Temporary – People are only temporarily in the dam-breach inundation zone (e.g., seasonal cottage use, passing through on transportation routes, participating in recreational activities).
Permanent – The population at risk is ordinarily located in the dam-breach inundation zone (e.g., as permanent residents); three consequence classes (high, very high, extreme) are proposed to allow for more detailed estimates of potential loss of life (to assist in decision-making if the appropriate analysis is carried out).

b) Implications for loss of life:

Unspecified – The appropriate level of safety required at a dam where people are temporarily at risk depends on the number of people, the exposure time, the nature of their activity, and other conditions. A higher class could be appropriate, depending on the requirements. However, the design flood requirement, for example, might not be higher if the temporary population is not likely to be present during the flood season.

7.0 TAILINGS STORAGE FACILITY SAFETY ANALYSIS

7.1 General

This section presents the dam safety analysis for the TSF based on the observations and data review for the failure modes relevant to the current conditions and configuration of the facility. The most relevant failure modes of the TSF are a failure through the foundation of the embankment and internal erosion of the embankment since the hydraulic gradient across the till core increases as the pond level rises. Overtopping of the embankment remains an unlikely failure mode if the TSF is operated according to the design criteria and QPOs since most of the inflow to the TSF can be stopped by ceasing pumping water from the PETBP to the TSF.

The performance of the TSF relative to stability and pond level management is presented in more detail in Sections 7.2.1 to 7.2.3.

7.2 Potential Failure Modes

7.2.1 Foundation Instability

The design of the elevation 970 m TSF embankment is based on achieving a factor of safety greater than 1.5 at the end of construction and in the long term. The upstream loading condition was tailings and water impounded to elevation 969 m (Golder 2015b, 2017e).

Construction of the Main Embankment buttress and Perimeter Embankment buttress extension was completed in October 2016. Construction of the buttress at Corner 1 per the elevation 970 m TSF design was completed in January 2019.

The results of the stability analyses carried out for the 2019 as constructed configuration of the Perimeter Embankment at Corner 1 meet the stability design criteria (Golder 2020b).

7.2.1.1 Instrumentation

The following instrumentation is used to monitor the performance of the TSF embankment:

- VWPs to measure porewater pressure within the embankment, foundation, and tailings upstream of the embankment
- slope inclinometers (manual probe inclinometers and in-place inclinometers) and SAAs to measure horizontal movements of the embankment and foundation
- survey monuments to monitor movement of the surface of the Perimeter Embankment at Corner 1

The instrumentation is read in the field by MPMC staff and provided to WSP for review and interpretation by the EoR team. The collected data are assessed to determine if the embankment is responding to changing conditions as expected. The instrumentation data including plan and section figures showing instrument locations are presented in Appendix A and Appendix B and summarized in the following subsections.

Instrumentation monitoring procedures and the potential for errors or inaccuracies are discussed below:

- VWP readings are either recorded automatically with data loggers or manually with a readout box. The VWP data loggers were installed during the summer in 2023. The data loggers are configured to collect readings once every 12 hours, which are wirelessly transmitted or downloaded directly into a calculation file weekly. Reading errors can be random or systematic, systematic errors typically being the larger component of the error which can be more easily identified. The readout box displays a frequency and temperature value representative of the conditions at the time of the reading. These values are stored in the readout box and then converted into pressure using an instrument-specific calibration. The sources of error in the measurement are typically random, being incorrect recording of the instrument identification number. Errors of this type can be difficult to detect, but do not repeat over time and do not affect the interpretation of embankment performance over time. Larger errors are detected when the readings are reviewed, and if an error is confirmed, the reading is retaken.
- The slope inclinometer system used by MPMC has an accuracy, defined by the supplier, of ±6 mm accumulated over 25 readings. Errors in a reading can be random or systematic; systematic errors typically being the larger component of the error. Systematic errors can be reduced by careful operator attention and periodic recalibration of the tools, such that the maximum accuracy for 50 readings is ±1.4 mm.
    - Weekly review of the inclinometer data during 2023 continued to show that at times the error was greater than the accuracy defined by the supplier. In 2018, MPMC purchased a digital slope inclinometer probe, cable, and readout unit to ease operation of the system and reduce reading errors. However, the system provided increasingly inaccurate data until it finally malfunctioned in January 2019. Since then, multiple inclinometer probes have been purchased and recalibrated by the original manufacturer, but readings continue to provide inaccurate and erratic results at some locations (predominately recorded in the deeper slope inclinometers). MPMC has recently purchased inclinometer probes supplied by another manufacturer and is in the process of re-establishing baselines to improve the reliability and accuracy of the inclinometer readings.
- In 2016, MPMC purchased an in-place inclinometer system consisting of five 2 m long segments. The in-place inclinometer system is connected to a data logger, and the readings are downloaded directly into a calculation file, thereby reducing the potential for operator error. The repeatability of the in-place inclinometer probes is defined by the supplier as being ±0.1 mm per metre.
    - The in-place inclinometer system malfunctioned in May 2023 and has not been available since then.
- SAA readings are recorded with a data logger, and the data are downloaded directly into a calculation file, thereby reducing the potential for operator error. The repeatability of the SAA system is ±1.5 mm for a 32 m installation, as defined by the supplier. Erroneous readings can result when the system is low on power, but these errors are generally large and easily identified. Small bias shifts (generally less than 2 mm) have been observed in the SAA readings. Identification is done by checking the raw data prior to any correction or rotation following the direction of the instrument. Bias shifts are filtered after confirmation.

The instrumentation has been installed and distributed along the TSF embankments. At the South Embankment, VWPs have been installed at the tallest section of the embankment (Section F at Sta. 0+720) and in the area where a layer of low plasticity silty clay was identified in the foundation (Section I at Sta. 1+100). VWPs monitor the porewater pressure within the till core and filter of the embankment and foundation at each location. The VWPs currently installed at the South Embankment provide sufficient coverage. Four slope inclinometers have been installed downstream of the embankment between approximately Sta. 0+900 and 1+400.

Based on stress-deformation analyses (Zabolotnii et al. 2022), it is recommended that slope inclinometers be installed near the toe of the starter dam at the tallest section of the embankment near Sta. 0+700 and in the area where a layer of low plasticity silty clay was identified in the foundation (near Sta. 1+100).

At the Main Embankment, VWPs have been installed primarily along five sections (Section E, C, A, B, and K) distributed along the length of the embankment. VWPs monitor the porewater pressure within the till core, filter, and drains of the embankment and foundation (i.e., till, glaciofluvial, and glaciolacustrine unit [GLU]) below and downstream of the embankment at each location. The VWPs currently installed at the Main Embankment provide sufficient coverage. Six slope inclinometers have been installed through the buttress and downstream of the buttress. Based on stress-deformation analyses (Zabolotnii et al. 2022), it is recommended to install slope inclinometers near the toe of the starter dam near Sta. 1+900, Sta. 2+300, and Sta. 2+600.

At the Perimeter Embankment from Corner 2 to Corner 1, VWPs have been installed primarily in the foundation under the buttress. The VWPs currently installed at the Perimeter Embankment provide sufficient coverage in the foundation. Fourteen slope inclinometers have been installed through the buttress and downstream of the buttress. The slope inclinometers currently installed at the Perimeter Embankment provide sufficient coverage to monitor the performance of the embankment.

At the Perimeter Embankment at Corner 1, VWPs have been installed within the upstream fill and filter of the embankment and foundation (i.e., till, glaciofluvial, and GLU) below and downstream of the embankment. The VWPs currently installed at Corner 1 provide sufficient coverage. Ten slope inclinometers and four SAAs have been installed in the foundation and cut-off wall of the embankment. The slope inclinometers currently installed at Corner 1 provide sufficient coverage to monitor the performance of the embankment.

At the Perimeter Embankment from Corner 1 to Corner 5, two VWPs have been installed in the foundation under the buttress. The VWPs currently installed at the Perimeter Embankment provide sufficient coverage in the foundation. Two slope inclinometers have been installed through the ramp downstream of the embankment. The slope inclinometers currently installed at the Perimeter Embankment provide sufficient coverage to monitor the performance of the embankment.

South Embankment – Station 0+720 – Section F

There are four active VWPs at Sta. 0+720 (F2, F3, F4, and F5). The piezometers continue to show the trends observed since the restart of operations in 2016. Pressures in the till core (F3) remain between about elevation 954 and 956 m and vary following the trend of the TSF pond level. Piezometer F4 installed in the filter downstream of the till core continued to show unsaturated conditions. Pressures near the downstream toe of the till core (F2) remained stable during 2023. Piezometer F5, located in the till downstream of the embankment toe, recorded a pressure decrease of approximately 0.4 m after freshet. The lower pressure is interpreted as seasonal variability as recorded in previous years.

South Embankment – Station 1+100 – Section I

There are seven active VWPs at or near this section (I2, I3, I5, I6, VW15-19, VW16-17, and VW16-22). The piezometers continue to show the trends observed since the restart of operations in 2016. Measured groundwater levels downstream of the South Embankment at piezometers I5 and I6 remain near the natural ground surface as in previous years. Both piezometers recorded pressure decreases of approximately 0.4 m after freshet. The lower pressure is interpreted as seasonal variability similar to records from previous years. Pressures of the embankment foundation (I2) remained stable throughout the year. Piezometer I3, installed in the filter downstream of the till core, continued to show unsaturated conditions. Readings at the upstream tailings piezometer VW16-22 showed a pore pressure increase of approximately 1.2 m during freshet which is consistent with the TSF pond volume increase seen during this period. The pore pressure decreased about 0.6 m and stabilized at this level by the end of the year.

The measured pore pressure in the till core (I1) remained consistent and continued to show no increase in response to the pond elevation for readings collected up to June 2023. Erroneous and unreliable readings were observed for the remainder of the year. Piezometer I1 should continue to be monitored to confirm that it is operational.

The four slope inclinometers near this section (SI15-19, SI15-20, SI16-15, and SI16-16) show measured movement within the accuracy of the instrumentation. A compression response was recorded in inclinometer SI16-15 after installation and until July 2018. The recorded compression response has since changed direction towards the downstream. The change in direction is interpreted as an operator error (i.e., modifying the assigned inclinometer A+ direction) and is not considered to reflect a change in conditions near the original ground surface. An approximate additional 2 to 3 mm compression was recorded in 2023. The borehole log of GA16-15 shows a 2.3 m thick layer of fill (rockfill) and topsoil between elevation 944.8 and 947.1 m. The initial compression of the casing was due to placement of the drill pad (rockfill) on top of the natural ground. Continued compression of the casing might be related to work carried out in the area to remove vegetation.

Main Embankment – Station 1+760 – Section E

There are seven active VWPs at this area (E1, E2, E3, E6, E7, VW15-18A, and VW15-18B). The piezometers installed in the embankment (E2 and E3) show consistent conditions since the restart of operation in 2016. The core drained to below the level of piezometer E2, and the filter remains drained below the level of piezometer E3.

Piezometer E6, installed in the foundation of the Main Embankment buttress in a GLU at elevation 911.8 m, showed a 0.7 m pressure raise in early February 2020. Piezometer E7, installed in the same borehole in glaciofluvial at elevation 908.1 m, showed a pressure decrease of about 0.3 m at that time. Readings have remained consistent since the pore pressure change in early February 2020. Piezometer E1, installed in the foundation of the embankment, has shown consistent conditions since 2016. The pore pressure change recorded at piezometers E6 and E7 is interpreted to be a result of a localized change in the hydraulic connectivity at the location of the piezometers or an operator error (i.e., crossing the wires).

Piezometers VW15-18A and VW15-18B, located at Sta. 1+580, remain stable and continue to show a downward gradient in the foundation near Corner 3.

Inclinometer SI15-18 shows measured movement within the accuracy of the instrumentation. Readings show an apparent downstream movement from the base that increases up the inclinometer (i.e., rotation from the base) to about 2 mm at elevation 933 m. The apparent downstream movement is interpreted to be a systematic error in the readings (i.e., increases up the hole).

Main Embankment – Station 1+850 – Section C

There are nine active VWPs at this section. Piezometer C2 (till core) began functioning again in late fall 2023. The pore pressures remained consistent with conditions seen in previous years. Currently, the remaining active piezometers at the Main Embankment provide sufficient coverage to monitor the performance of the embankment.

Piezometer C1, installed in the till core, showed steady readings during 2023 near elevation 938 m. The pore pressures in the till core at the location of piezometer C3 continue to show a slow but steady decrease since the TSF breach in 2014. Piezometer C3 should continue to be monitored as the TSF pond rises and the till core re-wets to confirm that it is operational.

Piezometer C7, installed in the drain downstream of the till core, continues to show the water level is below the level of the piezometer. Piezometer C8, installed in the embankment foundation, has shown consistent conditions since 2016. The piezometers installed in the foundation downstream of the embankment (C11, C12, VW15-17A, and VW15-17B) continue to show an upward gradient with the groundwater level near the original ground surface. This condition was used in the stability analyses carried out during the design of the Main Embankment buttress.

The water level measured in standpipe piezometer GW21-09, installed in the foundation below the buttress, is consistent with adjacent VWPs.

Inclinometer SI15-17 continues to show measured movement within the accuracy of the instrumentation.

Main Embankment – Station 2+060 – Section A

There are 16 active VWPs at this section. The piezometer data remain consistent with seasonal and pond elevation changes since 2016.

The pore pressures in the till core (piezometers A1, A3, A4, and A14) remained stable throughout the year. Piezometer A1 had previously shown a slow and steady decrease since the TSF breach in 2014 but has since stabilized slightly above the elevation of the piezometer. Piezometer A1 should continue to be monitored as the TSF pond rises and the till core re-wets to confirm that it is operational.

Piezometer A5, installed in the upstream fill (immediately upstream of the till core), showed similar conditions and remained consistent throughout the year. The piezometer installed in the filter downstream of the till core (A13) continued to show unsaturated conditions.

Piezometer A6 in the chimney drain continued to show that the water level is below the level of the piezometer. Piezometer A7 in the foundation drain shows an elevated pore pressure that is consistent with the values measured since the piezometer was installed in 1996.

The piezometers installed in the foundation downstream of the embankment continue to show an upward gradient with the groundwater level at or slightly above the original ground surface. The pore pressures shown in these piezometers (A8, A9, A19, A20, A21, VW15-15A, and VW15-15B) remained consistent with minor changes, up to about 0.4 m, throughout the year. The pressure variations are interpreted as seasonal variability similar to records from previous years. These pressures are consistent with the pressures measured when these piezometers were installed and have been accounted for in the stability analyses carried out during the design of the Main Embankment buttress extension.

Inclinometer SI15-15 continues to show erratic readings, but measured movement is within the accuracy of the instrumentation (based on the reading from December 14, 2023). Some readings taken in 2022 and 2023 appear to show an apparent downstream movement (Direction A) near the base of the inclinometer, which is approximately 30 m below original ground in bedrock. The apparent downstream movement is interpreted to be a systematic error in the readings.

Main Embankment – Station 2+240 – Section B

Piezometers VW16-21 (tailings) and B9 (till core) malfunctioned in February and August 2023, respectively. There remain 17 active VWPs at this section. Currently, the remaining active piezometers at the Main Embankment provide sufficient coverage to monitor the performance of the embankment. The piezometer data generally remain consistent with seasonal and pond elevation changes since 2016.

Before malfunctioning in February 2023, piezometer VW16-21, installed in tailings upstream of the embankment, showed a pore pressure decrease of about 0.4 m in response to the pond volume reduction. Piezometers B14 and B15, installed in the upstream fill, showed stable conditions in 2023.

The pore pressures in the till core remained generally consistent. Piezometer B2 continued to show a slow but steady decrease since the TSF breach in 2014. Piezometer B9 showed consistent pore pressures until it malfunctioned in August 2023. The piezometer installed in the filter (B10) downstream of the till core continued to show unsaturated conditions.

The piezometers installed in the chimney and foundation drain downstream of the till core continue to show that water levels are below the level of the drain. The pressures measured in the piezometers installed in the foundation beneath the embankment show a downward gradient with the water level about 2.0 m above the original ground surface. The piezometers installed in the foundation beneath the buttress (B6, B7, B11, and B12) continue to show near hydrostatic conditions with the water level at the original ground surface. A pore pressure decrease of about 0.5 m was observed in piezometers B11 and B12 from June to August 2023 but, they have since returned to previous levels. Piezometers VW21-08A and VW21-08B, installed beneath the downstream crest of the buttress, show an upward gradient with the water level near the original ground surface.

Piezometer VW15-14A, installed in a layer of GLU in the foundation downstream of the Main Embankment buttress, showed a pore pressure decrease of about 1.3 m (elevation 908.7 m) from December 2021 to March 2022 and has since remained near elevation 909 m. Piezometer VW15-14B has shown a slow and steady decrease of about 3.2 m since December 2021. Piezometers VW21-08A and VW21-08B were installed upstream of these piezometers in the same interpreted soils units (GLU and glaciofluvial). The pore pressures recorded at piezometers VW21-08A and VW21-08B remained consistent during 2022 and 2023 and did not follow the pressure decreases recorded at VW15-14A and VW15-14B. All other piezometers installed in the foundation at the Main Embankment recorded readings that continue to follow previous trends. The pore pressure decrease recorded at piezometers VW15-14A and VW15-14B is interpreted to be a result of a localized change in the hydraulic connectivity at the location of the piezometers (e.g., grout around inclinometer) or a piezometer malfunction.

The inclinometer installed near this section (SI15-14) shows measured movement within the accuracy of the instrumentation. The compression response seen in inclinometer SI15-14 remains unchanged since June 2020.

Main Embankment – Station 2+460 – Section K

There are six active VWPs installed in the foundation beneath the buttress at this section (K1, K2, VW15-12A, VW15-12B, VW21-07A, and VW21-07B). The piezometers continue to show the trends observed in previous years.

Piezometers VW15-12A and VW15-12B continue to show an upward gradient with the water table located about 8 m below the original ground surface. Piezometers VW21-07A and VW21-07B, installed in the foundation below the downstream crest of the buttress, show a downward gradient with the water table located about 9 m below the original ground surface. Piezometers K1 and K2 continue to show an upward gradient with artesian conditions. The pressures measured in K1 and K2 are anomalous relative to the pressures measured in the other piezometers in the vicinity. The pore pressures measured in piezometers K1 and K2 have been essentially constant since the time of installation in 2011. The piezometers showed no significant response to the rising water level in the TSF prior to the breach nor during construction of the Main Embankment buttress in 2016.

Inclinometer SI15-12 continues to show erratic readings, but the measured movement is within the accuracy of the instrumentation (based on reading from December 18, 2023). The readings continued to show a sinusoidal type of deformation from the base of the inclinometer. This type of deformation could be associated with compression of the casing, but there has not been construction in this area of the buttress and the deformation starts from the base of the inclinometer, which is installed in bedrock (about 50 m below original ground). The apparent movement is interpreted to be a systematic error in the readings.

Main Embankment – Station 2+700

The two active VWPs at this section (VW15-10A and VW15-10B) are installed in the foundation beneath the buttress and have shown consistent readings since their installation in March 2015. Piezometer VW15-10A in glaciofluvial has remained unsaturated during this period.

Inclinometer SI15-10 showed measured movement within the accuracy of the instrumentation (based on reading from November 30, 2023). The multiple zones of casing compression observed in SI15-10 have remained consistent since 2018. Similar to previous years, readings taken in 2023 showed an apparent downstream movement (Direction A) near the base of the inclinometer approximately 70 m below original ground in bedrock. The apparent downstream movement is interpreted to be a systematic error in the readings.

Perimeter Embankment – Station 2+800 to Station 3+150

There are nine active VWPs in this region.

Piezometer VW15-08A, located in the foundation (silty sand) beneath the Perimeter Embankment buttress, showed a slow, approximately 1.5 m pressure increase during the spring of 2017, but the pressure slowly decreased by about 1.0 m from 2017 to 2021. The piezometer recorded a gradual rise of about 0.9 m from 2021 to 2022 and started to decrease by November 2022. Piezometer VW15-08A has since stabilized and showed consistent readings in 2023.

Piezometers VW15-08A and VW15-08B continue to show a strong downward gradient. Piezometers VW15-08B, VW15-09A, and VW15-09B, located beneath the Perimeter Embankment buttress, continue to show consistent readings since their installation in March 2015.

Piezometers VW21-05 (A, B, and C), installed in the foundation beneath the buttress, have showed consistent readings since their installation in October 2021. These three piezometers show a downward gradient, which aligns with the conditions seen at VW15-08. VW21-06 (A and B), installed in glaciofluvial layers near the toe of the buttress, continued to show unsaturated conditions in 2023.

The water level measured in standpipe piezometer GW21-06, installed in a till unit below the buttress, increased by about 1.0 m in February 2023. The water level reduced back to previous levels after about two weeks and has since remained unchanged. The adjacent VWPs did not show similar trends during this period.

Three of the inclinometers in this area (SI15-08, SI15-09, and SI21-06) showed measured movement within the accuracy of the instrumentation.

Inclinometer SI21-05 continued to show erratic readings in 2023 (mostly seen in Direction B). The readings do not show downstream movement; however, they show an upstream rotation from the base of the inclinometer. The apparent movement is interpreted to be a systematic error in the readings.

Perimeter Embankment – Station 3+150 to Station 3+500 – Section J

There are 10 active VWPs at this section.

Piezometers J1, VW15-06A, VW15-06B, VW15-07A, and VW15-07B, located beneath the Perimeter Embankment buttress, continue to show consistent readings to previous years.

Piezometers VW21-03 (A, B, and C) and VW21-11A, installed near till borrow excavations near the toe of the buttress, show pore pressure increases of up to about 1.5 m during and after freshet, similar to previous years. Piezometer VW21-11B continues to show unsaturated conditions.

Piezometers VW15-06, VW21-03, and VW21-11 show a downward gradient.

Inclinometers SI12-02, SI15-06, and SI15-07 continue to show erratic readings; however, the measured movement in the foundation is within the accuracy of the instrumentation.

The inclinometer installed in 2021 near the toe of the buttress (SI21-03) showed measured movement in the foundation within the accuracy of the instrumentation (based on reading from December 13, 2023). Some readings show an apparent upstream movement (Direction A) from the base that increases up the inclinometer (i.e., rotation from the base) to about 5 mm at the elevation of the original ground surface. The apparent upstream movement is interpreted to be a systematic error in the readings (increases up the hole).

Perimeter Embankment – Station 3+500 to Station 3+800

Piezometers VW21-01A and VW21-01B were damaged in August 2023. There remain 11 active VWPs in this area.

The piezometers located upstream of the PETBP and beneath the Perimeter Embankment buttress showed a response to freshet and water level changes in the PETBP similar to previous years. Piezometer VW15-03B (glaciofluvial) and VW15-05B (till) showed pore pressure increases of up to 1.1 m during and after freshet in 2023. Similar to previous years, the pressure increases occurred during freshet or when the PETBP water level rose. Piezometers VW21-01A (glaciofluvial), VW21-01B (glaciofluvial), VW21-01C (GLU), VW21-02A (glaciofluvial), VW21-02B (GLU), and VW21-02C (glaciofluvial) show pore pressure increases of up to 1.7 m during and after freshet in 2023.

Piezometers VW15-03, VW15-04, and VW15-05 continue to show a downward gradient.

Piezometer VW16-20, located in the tailings beach upstream of the Perimeter Embankment, showed readings consistent with TSF pond elevation changes in 2023.

The three inclinometers installed beneath the buttress in this section (SI15-03, SI15-04, and SI15-05) showed measured movement in the foundation within the accuracy of the instrumentation (based on readings from November and December 2023). However, some readings continued to show a sinusoidal type of deformation from the base of the inclinometer. This type of deformation could be associated with compression of the casing; however, there has been no construction on the buttress and the deformation is from the base of the inclinometers which are installed in bedrock (about 40 to 50 m below original ground). The apparent movement is interpreted to be a systematic error in the readings.

The two inclinometers installed in 2021 near the toe of the buttress (SI21-01 and SI21-02) showed measured movement in the foundation within the accuracy of the instrumentation. However, some readings showed a sinusoidal type of deformation of about 2 mm from the base of the inclinometer. The apparent movement is interpreted to be a systematic error in the readings.

Perimeter Embankment – Station 3+990 – Section D

There are nine active VWPs at this section. The piezometer data remain consistent with seasonal, TSF, and PETBP water levels during 2023. Piezometer D4, located in the till core, continues to show that the water level is below the elevation of the piezometer (elevation 948 m). Piezometer D2, installed in the foundation drain, also shows that the water level is below the elevation of the piezometer. Piezometer D3 installed in the filter downstream of the till core showed consistent conditions similar to previous years.

Piezometers SH14-21A, D6, and D7 installed in the foundation (glaciofluvial and GLU) showed pore pressure increases of up to 1.5 m during freshet in 2023. Similar to previous years, the pressure increases occurred during freshet or when the PETBP water level rose. The pore pressure measured at piezometers SH14-21A, D6, and D7 decreased by the fall. Piezometer SH14-21B, installed in the foundation till, showed a less pronounced response to freshet and water level changes in the PETBP. A pore pressure increase of 0.5 m was observed during freshet in 2023. Piezometers SH14-21C and D1, also installed in the foundation till, remained consistent throughout the year.

Piezometer VW16-06, installed in the foundation till below the buttress at Corner 1, continued to show consistent pore pressure readings during 2023. The piezometers in this area continue to show a downward gradient.

Inclinometer SI16-06 showed measured movement in the foundation within the accuracy of the instrumentation.

Inclinometer SI15-26 showed measured movement in the foundation within the accuracy of the instrumentation in 2023. However, readings showed a sinusoidal type of deformation from the base of the inclinometer. This type of deformation could be associated with compression of the casing; however, there has been no construction on the buttress, and the deformation is from the base of the inclinometer, which is installed in bedrock (about 30 m below original ground). The apparent movement is interpreted to be a systematic error in the readings.

Perimeter Embankment at Corner 1 – Station 4+000 to Station 4+450 – Section L and Section M

Fifteen VWPs were installed in the foundation underlying the Perimeter Embankment and buttress at Corner 1 during the investigation carried out from September to October 2023. There are now 31 active VWPs and one standpipe piezometer at Corner 1.

Piezometer VST14-03, installed in the upper GLU, showed pore pressure increases due to construction and raise of the embankment between 2015 and 2018. The excess pore pressures have dissipated since late October 2018 and have stabilized near elevation 930 m. In 2023, the pore pressure increased about 0.5 m during freshet but reduced back to previous levels by the end of the year. Piezometer VW16-04, installed in the upper GLU below the buttress, has remained constant and showed no response to construction in previous years. Piezometers VW18-04A and VW18-04B, installed in the upper GLU near the toe of the embankment under the buttress, have remained about constant since installation.

Piezometer VW18-01B, installed in foundation till under the buttress at approximate elevation 922.2 m, showed a pore pressure decrease of about 5 m in early December 2020 and has since steadily increased about 2.5 m during 2021 and 2022. Piezometer VW18-01A, installed at the same location at approximate elevation 925.0 m, showed a pore pressure increase of about 0.4 m in early December 2020 and has since increased about 3.5 m in steps during 2021 and 2022. Borehole GA22-01 was drilled within 5 m of GA18-01 to install a VWP (VW22-01) and standpipe piezometer (GW22-01) in the same units as VW18-01A and VW18-01B, respectively. Piezometer VW22-01, installed in till at approximate elevation 925.8 m, has shown a consistent pore pressure near the elevation of the original ground surface (about elevation 931 m), which correlates well with readings at VW18-01A prior to December 2020 (about elevation 929.5 m). Standpipe piezometer GW22-01, installed in till between approximate elevations 919.2 and 920.7 m, has shown a consistent pore pressure near elevation 932.5 m.

However, the monitoring well needs to be developed to confirm the readings. All other piezometers installed in the foundation at Corner 1 recorded readings that continue to follow previous trends.

Inclinometer SI18-01 has shown a compression response between approximate elevation 924 and 929 m since its installation. The compression response started to stabilize in 2019; however, an approximate 1 to 2 mm/yr creep has been recorded since 2020. A layer of high plasticity silty clay was identified at this elevation. Inclinometer SI16-01, installed immediately downstream of SI18-01, does not show movement or compression of the inclinometer. The pore pressure decrease recorded at piezometer VW18-01B and increase in piezometer VW18-01A is interpreted to be a result of a localized change in the hydraulic connectivity at the location of the piezometer (e.g., grout around inclinometer).

The piezometers installed in late 2023 have generally showed consistent readings since installation and should continue to be monitored to establish a trend in the following year.

The piezometers installed in glaciofluvial and till, SH14-07A and SH14-07B, beneath the upstream general fill at Corner 1 showed consistent readings near the elevation of the upstream drain. The response of the piezometers indicates that the Corner 1 upstream drain is performing as intended. Piezometer VW16-18, installed at elevation 954.5 m in the upstream fill, showed that the water level remains below the elevation of the piezometer.

Piezometer VW15-23, installed in the filter downstream of the cut-off wall, shows that the water level is below the level of the piezometer.

During construction of the Freshet Embankment in 2015, SAA15-01 and SAA15-02 were installed in inclinometer casings from the forensic investigation in 2014. The measured movement of about 1 to 3 mm in SAA15-01 within the upper and lower GLU in the direction perpendicular (Direction X) to the embankment axis remained consistent within the accuracy of the instrumentation in 2023. SAA15-02 shows a pattern of deformation consistent with settlement and compression of the cable due to settlement.

The readings of inclinometer SI16-03 show movement within the accuracy of the instrumentation within the foundation. The upper portion of SI16-03 is on the downstream slope of the buttress. At this location, the buttress was raised with sandy tailings and has not been re-sloped.

On July 15, 2021, inclinometer SI18-04 showed an apparent downstream movement (Direction A) from the base (approximately elevation 912 m) that increased up the inclinometer (i.e., rotation from the base) to about 2 mm at the elevation of the original ground (approximately elevation 928.7 m). The in-place inclinometer was installed between elevation 915 m (bedrock) and 923 m (above GLU) on September 23, 2021, and the readings have shown movement within the accuracy of the instrument. The in-place inclinometer sensors malfunctioned in May 2023 and were removed from the inclinometer casing in September 2023. Manual readings of inclinometer SI18-04 resumed while the in-place inclinometer was sent back to the manufacture for repairs. The measured movements of the foundation were consistent with the last manual inclinometer reading taken in July 2021. Piezometers VW18-04A and VW18-04B installed in GLU at elevation 922.1 and 921.5 m did not show pressure changes. Inclinometers SI16-01, SI18-01, SAA15-01, SAA15-02, SI16-03, and SI16-06 showed no discernable movement. The apparent downstream movement is interpreted to be a systematic error in the readings (increases up the hole).

Four additional inclinometers were installed within this area during the site investigation in late 2023 (SI23-01, SI23-02, SI23-03, and SI23-10). These inclinometers were installed at the crest, mid-slope, and buttress at Corner 1. The measured movements recorded to date are within the accuracy of the instrumentation.

Survey monument SM17-02, installed on the buttress was struck by equipment between February and April 2023. The readings show that movement has remained within the accuracy of the instrument since its installation in December 2017.

Survey monument SM18-01, installed at the downstream crest of the embankment, showed approximately 20 mm of movement to the northeast during the week after installation in October 2018 while rockfill placement at the crest of the embankment was in progress. Since then, the readings have shown approximately 10 to 20 mm/yr creep to the northeast until the monument was struck by equipment in May 2023. Settlement of the foundation and rockfill is expected. The survey monument was decommissioned in August 2023 while construction to raise the embankment to elevation 970 m was in progress.

Perimeter Embankment at Corner 1 – Cut-Off Wall

The SAA16-01 and SAA16-02 data show that the slight downstream rotation of the cut-off wall observed in the first few years after tailings deposition started upstream of the embankment (i.e., 2016 and 2017) has almost stopped. This is interpreted to be a result of the slower tailings beach raise rate in 2019 and stoppage in 2020 and 2021 and that there was no construction to raise the embankment until 2022. The maximum movement of the top of the cut-off wall has been measured at about 55 to 60 mm (including recorded data in SI15-28 and SI15-30 prior to installation of the SAAs), which is equivalent to a shear strain of about 0.2% over the height of the cut-off wall. The recorded movement of the cut-off wall is within the expected deformation due to tailings deposition in the TSF.

Perimeter Embankment – Station 4+480 – Section G

Piezometer SH14-20B (glaciofluvial) malfunctioned in 2023. There remain six active VWPs at this section.

Piezometer G5, installed in the foundation under the Perimeter Embankment, showed consistent pore pressures near the elevation of the original ground surface in 2023. As in previous years, the piezometers installed in the till, glaciofluvial, and bedrock (SH14-20A, SH14-20B, and SH14-20C) responded to TSF pond changes throughout 2023. Piezometer SH14-20A and SH14-20B showed a pore pressure increase of up to 1.2 m in May 2023, which followed the trend of the TSF pond at the time.

On March 23, 2023, MPMC informed the EoR that the tailings slurry pipeline had leaked upgradient of the TSF and tailings had flowed along the toe of the Perimeter Embankment from Corner 5 to Corner 1 and deposited against the west side of the Perimeter Embankment buttress at Corner 1. Pore pressures at VW18-03A (till) and VW18-03B (till) increased about 1.8 m to elevation 937.8 m (near original ground) around the same time in late March 2023 and have since stabilized at that level. The increase is interpreted to be a response to the tailings that deposited in the area. Piezometer VW18-03C, installed in the underlying bedrock, did not respond to these conditions and remained consistent for the year.

The inclinometer installed at this section (SI18-03) showed an apparent upstream movement (Direction A) from the base that increased up the inclinometer (i.e., rotation from the base) to about 3 to 5 mm at the elevation of the original ground. The apparent upstream movement is interpreted to be a systematic error in the readings (increases up the hole).

Perimeter Embankment – Station 4+600 to Station 4+800

The two VWPs at this section (VW15-01A and VW15-02A) are installed in the foundation till beneath the Perimeter Embankment buttress and show consistent readings since their installation in 2015. The piezometers recorded a slight increase in pore pressures as the TSF pond level increased during and after freshet.

The two inclinometers installed in this area (SI15-01 and SI15-02) showed measured movement in the foundation within the accuracy of the instrumentation.

7.2.1.2 Visual Inspection of Embankment Performance

In June and July 2020, MPMC reported sinkholes had developed on the upstream fill of the Perimeter Embankment near Sta. 4+490 and 4+560 and on the upstream fill of the Main Embankment between Sta. 2+100 and 2+170. Details of the investigations, review of construction record data, interpretation of the findings, and recommendations are presented in the TSF sinkholes investigation and interpretation memorandums (Golder 2020c,d). As indicated in those documents, sinkholes could redevelop if surface water conditions were allowed to repeat.

Sinkholes were reported to have redeveloped at about Sta. 2+100 at the Main Embankment in July 2022 and at about Sta. 4+450 at the Perimeter Embankment at Corner 1 in August 2022 (WSP Golder 2022b, 2022c).

In March 2023, a sinkhole was reported to have developed on the upstream fill of the Perimeter Embankment near Sta. 4+465. The sinkhole developed due to snowmelt ponding on the upstream fill at the crest of the embankment, infiltrating through the upstream fill and eroding the upstream fill tailings sands into the underlying rockfill (i.e., remaining temporary upstream rockfill berm). Details of the test pit investigation, review of construction record and instrumentation data, interpretation of the findings, and recommendations are presented in WSP (2023c). The sinkhole that developed on the upstream fill of the Perimeter Embankment does not present a dam stability concern.

The vegetation and trees along the South Embankment toe were in similar conditions compared to 2022. Vegetation should be removed as part of routine maintenance to allow suitable inspections of the facility.

Erosion of sandy tailings at the downstream slope of the Perimeter Embankment buttress at Corner 1 was observed to be in similar condition to that observed in previous years. The area should continue to be monitored.

Erosion gullies have continued to form through the upstream fill due to snowmelt ponding on the crest of the embankment between the till core and tailings discharge pipeline. The tailings discharge pipeline should be relocated onto a bench along the upstream slope of the upstream fill. Alternatively, the tailings pipeline could be raised from the crest of the upstream fill to limit water ponding between the till core and the tailings slurry pipeline.

The tailings discharge pipeline was installed on a rockfill berm 2 to 3 m higher than the embankment crest immediately upstream of the embankment along Corner 5. The tailings pipeline has since been relocated onto the upstream crest of the embankment. However, the rockfill berm should be removed to allow tailings deposition to occur into this area of the facility.

In 2023, the beach slopes upstream of the embankment were surveyed to be in the order of 0.5%, which is flatter than in previous years. The flatter beach slopes increase the difficulty to maintain the minimum beach width QPO of 100 m upstream of the embankment. Topographic and bathymetric surveys should continue to be performed periodically throughout the year to monitor the beach slopes. The tailings deposition method should be assessed and modified to increase the beach slopes if surveys do not show improvements.

Erosion and shallow ravelling were observed along the downstream slope of the Main Embankment near Corner 3. The area should continue to be monitored and covered with coarse rockfill or re-sloped to prevent further erosion.

Tailings were observed along the west bank of the PETBP where the ditch from the CCS connects to the PETBP. No signs of tailings were observed along other sections of the ditch between the CCS and the PETBP. Based on a review of historical data, the tailings are interpreted to have deposited during the TSF repairs in 2014/2015. The tailings should be removed, and the area should continue to be monitored.

Photographs taken during the site inspection on October 4 and 5, 2023 are provided in Appendix D.

7.2.2 Internal Erosion

A filter compatibility assessment of the embankment materials using the procedures described by the International Commission on Large Dams (ICOLD 2013) and Fell et al. (2015) was completed by Golder Associates Ltd. (amalgamated into WSP in 2023) (Golder 2016). Representative envelopes of grain size distribution curves for all stages of construction materials were used to evaluate the filter compatibility between the different zones of the existing embankment. The results of the assessment showed that most of the filter gradations reported meet modern filter criteria. However, a fraction of all the filter sample gradations did not satisfy the filter criteria. If the hydraulic gradients were to rise to a level sufficient to initiate backward erosion of the till core, some erosion of the till core could be expected before the filter seals it.

The TSF pond reached a maximum elevation of 966.45 m prior to the breach at Corner 1 of the Perimeter Embankment. The pond was in contact with the upstream fill and core in some areas, and no signs of erosion or sinkholes were reported. Since the restart of operations in 2016, the TSF pond elevation has steadily increased as tailings have been deposited. During 2023, the TSF pond elevation ranged between 962.6 m and 964.7 m. Wide tailings beaches, minimum 100 m, have generally been maintained between the embankment and the TSF pond, except from May to August 2020, May to November 2022, and short durations in 2023. Therefore, the current water level in the TSF imposes a hydraulic gradient across the till core that is less than the till core has previously resisted.

Turbidity and Flow Rate

Seepage from the Main Embankment is collected at the MESCP and pumped back into the TSF. Seepage from the South Embankment is collected at the SESCP and pumped into a ditch that flows to the MESCP. Seepage from the Perimeter Embankment flows by gravity ditches into the PETBP. No signs of turbid water were observed at the seepage collection drain at Corner 1 or in the seepage collection ponds at the South and Main embankments.

High turbidity values were recorded at the Corner 1 north and south diversion ditches on March 23, 2023. The in situ turbidity test results remained elevated until May 2023 when conditions returned to within the historical range. The high turbidity values were interpreted to be a result of a tailings slurry leak that deposited to the west of the buttress at Corner 1 during freshet.

Table 2 presents the range of seepage flows and turbidity recorded in 2023 at the east and west Main Embankment toe drains, South Embankment toe drain, Freshet Embankment seepage collection ditch (seepage through the foundation and cut-off wall, and direct infiltration into the rockfill), Corner 1 Embankment upstream drain flow, and Corner 1 Embankment north and south diversion ditches.

Table 2: 2023 Tailings Storage Facility Seepage Rates and Turbidity

Monitoring Location	Flow Rate (L/s)	Seepage Turbidity Range (NTU)	
		Field Tests	Laboratory Tests
Main Embankment West Toe Drain	0.5–1.3	0.10–1.58	0.12–0.28
Main Embankment East Toe Drain	1.8–3.3	0.04–1.07	0.14–0.23
South Embankment Toe Drain	7.2–12.8	0.06–1.03	1.01–1.33
Freshet Embankment Seepage Collection Ditch	Not measured	0.05–2.40	0.10
Corner 1 Embankment Upstream Drain	20 (visually estimated by MPMC)	0.02–1.97	0.11–0.30
Corner 1 North Diversion Ditch	Not measured	0.08–0.90[a]	Not tested
Corner 1 South Diversion Ditch	Not measured	0.10–0.71[a]	Not tested

a) Turbidity values recorded between March and May after tailings were deposited to the west of the buttress at Corner 1 were excluded from the range.

NTU = nephelometric turbidity unit; MPMC = Mount Polley Mining Corporation.

Appendix C presents historical seepage flows and turbidity data recorded at all the toe drains from 2010 to 2023. Turbidity was measured through laboratory testing of sampled water and in situ with a portable turbidity meter. The in situ turbidity tests are carried out with a YSI EXO sonde. The manufacturer reports a reading accuracy of ±2%. However, the results have been observed to be sensitive to entrapping bubbles in the sampling tube; therefore, additional laboratory tests were completed when the in situ turbidity testing results were higher than 1.0 nephelometric turbidity units (NTU). The in situ turbidity test result of 2.4 NTU recorded on the Freshet Embankment seepage collection ditch on March 29, 2023, is interpreted to be a sampling error based on subsequent test results and observations in the field.

The Freshet Embankment seepage collection ditch flow rate could not be directly measured since the seepage collection pipe outlet was submerged during 2023. In situ turbidity tests were completed when the pipe was not fully submerged. Instrument or modify the pipe outlet so the seepage flow rate can be monitored.

The recorded seepage rate and turbidity at all the monitoring locations is within the historical range. No significant changes in flow rate or turbidity were reported in 2023.

Groundwater Monitoring

Groundwater monitoring by MPMC has been ongoing at the mine site since 1995 with the objectives to monitor direction, quantity, and quality of groundwater flow near all mine facilities. The monitoring wells used to monitor groundwater levels around the perimeter of the TSF are also used to monitor groundwater quality. The monitoring well network is shown in Figure A1 in Appendix A.

Groundwater samples from the monitoring wells are collected quarterly or semi-annually, depending on location, and are analyzed for field parameters, anions, nutrients, and dissolved metals and are reported annually. The analyses are focused on nine parameters of interest which include hardness, sulfate, nitrate, and the following dissolved metals: aluminum, arsenic, cadmium, molybdenum, and selenium.

Over the last decade or so, although there were increasing parameter of interest concentration trends at some locations, significant changes to groundwater quality at the perimeter of the TSF had not been identified except with respect to sulfate. Sulfate concentrations in the shallow groundwater downgradient of the TSF approached or reached levels observed in the TSF pond water next to the Perimeter Embankment at GW16-2B and GW96-2B and next to the South Embankment at GW96-4B (WSP 2023e). The measured concentrations of sulfate do not exceed the BC ENV (1997) Contaminated Sites Regulation water quality standards for protection of freshwater aquatic life; however, they show that groundwater quality downstream of the TSF is being affected by seepage from the TSF. The remaining wells indicated relatively stable or slightly decreasing sulfate concentration trends.

7.2.3 Overtopping

Tailings Storage Facility Embankment

The TSF is required to have sufficient available storage capacity for containment of runoff from the contributing catchment area for the IDF event. The design freeboard criterion of 1.1 m provides storage capacity of approximately 1.9 Mm^3 for an embankment crest elevation of 968 m, which exceeds the requirement to store the 72-hour IDF. As shown in Figure 6, the TSF pond elevation steadily increased to about 961.8 m by the end of June 2018 and remained between about 961 and 963 m until the end of 2022. In 2023, the TSF pond elevation rose about 1.1 m during freshet to 963.7 m and continued to increase gradually for the remainder of the year. The freeboard remained above 2.3 m through 2023 and increased to more than 5.0 m after construction of the Corner 5 abutment in September/October 2023. The TSF pond level was at about elevation 964.7 m by the end of 2023, resulting in a freeboard of 5.3 m.

In 2023, the TSF pond had a net water decrease estimated to be about 0.9 Mm^3 and was returned to normal operating conditions as defined in the QPOs.

At the time of the inspection, obstructions along the clean water diversion ditch had not been removed and debris and branches were still observed. The diversion ditch needs to be re-established along the entire alignment and fallen trees, and woody vegetation should be removed as part of the routine maintenance.

The damaged section of the sidewall of the clean water diversion ditch near Corner 4 that eroded in 2020 was observed to be in similar conditions to 2021. The side wall repair should be excavated and rebuilt with adequate till material and placed in compacted layers.

Main Embankment Seepage Collection Pond

The MESCP has two corrugated steel pipe culverts that act as the emergency spillway. The culverts extend beneath Gavin Lake Road. The culverts were unobstructed during the inspection in October 2023.

7.3 Operational Documents and Dam Safety Review

7.3.1 Operation, Maintenance, and Surveillance Manual

The operation, maintenance, and surveillance (OMS) manual for the TSF was most recently updated as follows:

- in January 2021, as part of the annual update and to identify potential improvements
- in August 2021, as plans to restart mining operations were advancing
- in August 2023, as part of the annual update and to identify potential improvements

Another update to the OMS manual was in progress at the end of 2023.

7.3.2 Emergency Preparedness and Response Plan

The TSF emergency preparedness and response plan (EPRP) was most recently updated as follows:

- in April 2021, to keep information up to date and to identify potential improvements
- in August 2021, as plans to restart mining operations were advancing
- in August 2023, as part of the annual update and to identify potential improvements

Another update to the EPRP was in progress at the end of 2023.

A test of the EPRP was carried out on November 30, 2023, with Mine Rescue site personnel and the Technical Services Group simulating an exceedance of the TSF freeboard QPO (unsafe zone).

7.3.3 Dam Safety Review

An audit level DSR was conducted by Tetra Tech Canada Inc. (Tetra Tech) in 2022. The TSF embankment was considered reasonably safe with non-conformances (Tetra Tech 2023). Table 3 provides a summary of the recommendations presented in the DSR with corresponding actions to address each item.

Table 3: 2022 Dam Safety Review Recommendations (Tetra Tech 2023) and WSP Recommended Actions

DSR ID	DSR Description of Actionable Item, Deficiency, or Non-Conformance	DSR Recommended Action	DSR Priority	DSR Recommended Deadline	WSP EoR Comment	Status or EoR Recommended Action
2022DSR-01	Some recommendations from past DSIs and DSR have not yet been closed out.	Recommendations from previous DSIs and past DSR need to be addressed.	2	December 2023	The outstanding DSI recommendations are identified and tracked in the annual DSI reports (WSP 2023d). Recommendations included in the DSI reports need to be addressed following the priority and recommended timing for completion. DSR recommendations 2017DSR-08 and -09 have not been completed. DSR recommendation 2017DSR-08 is tracked as DSI recommendation 2020DSI-06. For tracking purposes, DSR recommendation 2017DSR-09 is included in this report as DSI recommendation 2023DSI-07. All other recommendations from the 2017 DSR are complete.	Actions to be implemented by MPMC following the priority and recommended timing for completion. Progress tracked by MPMC and in the annual DSI reports.
2022DSR-02	There are multiple instances where instruments have presented anomalous readings or where observed trends are interpreted as due to seasonal variation.	For all applicable embankments and instruments, ongoing assessment of new data should continue to: ▪ identify which instruments are providing anomalous readings ▪ confirm or further revise interpretations of seasonal variation vs. dam stability condition ▪ in both cases allowing MPMC to respond accordingly	2	December 2023	Instrumentation data are collected and reviewed by MPMC following the frequency specified in the QPOs. The data are provided to the EoR for review and interpretation weekly and a summary is provided to MPMC periodically (typically every 1 to 3 months). All available data are summarized and interpreted by the EoR as part of the DSI reports (WSP 2023a). DSR recommendation action is to continue assessing the data.	No new action required.
2022DSR-03	There are multiple instruments which have been destroyed, readings have ceased, or the readings have uncertain reliability.	For all applicable embankments, where instruments have been destroyed, readings have ceased or the readings have questionable reliability, a formal assessment of the spatial instrumentation coverage should be considered.	2	December 2023	The coverage of the instrumentation is reviewed periodically and documented in the annual DSI reports (WSP 2023d). Instrumentation was installed in 2015, 2016, 2018, 2021, 2022, and 2023 based on the findings of the instrumentation review.	No new action required.
2022DSR-04	Select instrumentation sections of the TSF have experienced/are experiencing gradual increases in pore pressure and/or movement.	For all applicable embankments, in areas where there are slow ongoing changes in the instrumentation data, a rolling comparison of these conditions against existing stability model inputs should be made to ensure the modelled dam safety conditions are representative.	2	December 2023	The VWP data remain consistent with seasonal and pond elevation changes since 2016. Seasonal changes are relatively small. Excess porewater pressure generated during construction and artesian pressures are monitored and have remained within expected values. The pond elevation is monitored, and the stability models were completed assuming 0 m beach for elev. 970 m embankment. Slope inclinometer data (including SAAs and in-place inclinometer) do not indicate downstream movement. Clarification was requested about which instruments were interpreted in the DSR to show gradual increases in movement or porewater pressure (email communication from Mathieu O'Leary to Bereket Fisseha dated March 25, 2023) but no specifics were provided.	No new action required.
2022DSR-05	There might be a situation where the stability model inputs and/or on-site conditions have changed (related to the previous recommendation – 2022DSR-04).	For all applicable embankments, if changes are made to governing stability models, updates should be made to all impacted dam safety documentation, such as the OMS manual.	3	March 2024	Refer to response to recommendation 2022DSR-04. Clarification was requested about which specific inputs or conditions were interpreted in the DSR to have changed (email communication from Mathieu O'Leary to Bereket Fisseha dated March 25, 2023) but no specifics were provided.	No new action required.

Table 3: 2022 Dam Safety Review Recommendations (Tetra Tech 2023) and WSP Recommended Actions

DSR ID	DSR Description of Actionable Item, Deficiency, or Non-Conformance	DSR Recommended Action	DSR Priority	DSR Recommended Deadline	WSP EoR Comment	Status or EoR Recommended Action
2022DSR-06	Following the previous development of erosion and sinkholes within the TSF, the EoR made recommendations to remediate and prevent from re-occurring.	For all applicable embankments, follow EoR recommendations for suitable beach lengths and discharge locations.	2	December 2023	EoR recommendations 2022DSI-06 and 2022DSI-07 (WSP 2023d).	Complete
2022DSR-07	It was found that understanding which design reports and stability models were valid versus superseded was challenging, given the complex structure history.	Tetra Tech suggests that MPMC consider a design summary report, or similar, to summarize the current design considerations and stability models of the structure in a single document. Note, this action would provide the most value if the information was presented in this recommended document, instead of only referencing a series of separate reports.	4	March 2024	There are two design reports that are applicable to the elev. 970 m TSF: ▪ *Tailings Storage Facility Detailed Design to Elevation 970 m* (Golder 2015b). ▪ *Tailings Storage Facility Detailed Design to Elevation 970 m Update* (Golder 2017e). The update to the detailed design report includes updates to the foundation characterization and updated seismic loading design criteria (BCMEM 2016). An additional section at the Corner 1 Embankment was analyzed following the 2018 instrumentation installation (Golder 2018c). Stability analyses of the as-constructed Main Embankment buttress and Corner 1 Embankment were completed in 2017 and 2020 (Golder 2017a, 2020b).	MPMC to include a table in the OMS manual listing the applicable design reports.
2022DSR-08	It was noted that the current SWMP, DSI, and DSRs did not include current TSF fill curves.	TSF stage-storage (or fill curve) relationships determined from regular bathymetric and drone surveys should be included in future SWMP, DSI, and DSR reports.	2	December 2023	Freeboard, pond volume, and available storage capacity are monitored by MPMC weekly and provided to the EoR. Stage-storage curves are updated with bathymetric and topographic survey twice per year by MPMC (2022DSI-08).	MPMC to include a note of current fill curve and a link to storage location in MPMC's server in weekly water management dashboard.
2022DSR-09	It was noted that the current Water Management Performance Objectives do not include Normal Operating Water Levels.	TSF Normal Operating Water Levels should be established and included in future updates to the Water Management Performance Objectives, either replacing or supplementing Normal Operating Pond Volumes.	3	December 2023	Pond water volumes have been used since the restart of operations in 2016. MPMC has a good understanding of assumptions and limitations of estimating the pond water volume. Normal operating pond volume QPOs are aligned with minimum beach width QPOs. Changing or adding pond water levels is not recommended at this point.	No new action required.
