2022DSR-10	There is an operational requirement which requires the TSF perimeter berm to be breached under TSF high water level conditions, causing loss of storage capacity that was specifically reserved for an extreme event.	The legacy requirement to breach the TSF perimeter berm under high water level conditions should be re-evaluated during the next EPRP and OMS manual Revisions.	3	March 2024	The requirements to construct an emergency spillway was introduced as part of the restart of operations in 2016 to mitigate potential insufficient storage capacity due to delays in construction. After the initial raise of the Perimeter Embankment at Corner 1 and start of tailings deposition, the pond was moved to a central location between Corner 4 and Corner 5.	MPMC and EoR to confirm consistency in QPOs, EPRP, and OMS manual and remove legacy requirement to build an emergency spillway.

Table 3: 2022 Dam Safety Review Recommendations (Tetra Tech 2023) and WSP Recommended Actions

DSR ID	DSR Description of Actionable Item, Deficiency, or Non-Conformance	DSR Recommended Action	DSR Priority	DSR Recommended Deadline	WSP EoR Comment	Status or EoR Recommended Action
2022DSR-11	It is unclear if the TSF Clean Water Diversion Ditch could withstand the design freshet and summer PMP events.	An assessment is required to determine if the TSF Clean Water Diversion Ditch can withstand design freshet and summer PMP events. If the ditch is vulnerable to blockages or breaches, TSF inflows for IDF events should include runoff from the diverted basin.	2	December 2023	The TSF inflows for IDF events assume that the TSF Clean Water Diversion Ditch is non-operational and runoff from the diverted basin reports to the TSF (Golder 2017c).	No new action required.
2022DSR-12	The site-wide water balance modelling that identified 200-year freshet inflows may have also identified TSF 200-year water levels with insufficient freeboard to satisfy dam safety requirements.	A conflict between the TSF freeboard QPOs and EPRP emergency levels to trigger implementation of imminent failure response measures should be reviewed and resolved to be consistent with dam safety requirements.	3	March 2024	The TSF freeboard QPO is consistent with dam safety requirements.	MPMC and EoR to review EPRP emergency levels to confirm that it is not in conflict with the TSF freeboard QPO.
2022DSR-13	There are multiple inconsistencies and/or deficiencies noted in the OMS manual, as detailed in Section 9.1.5 and Section 9.2.3.	Correct the various inconsistencies and/or deficiencies noted in the OMS manual, as detailed in Section 9.1.5 and Section 9.2.3, and summarized below. ▪ Update OMS manual headers/footers throughout the entire document, including appendices, with applicable Document ID and Revision date. ▪ The OMS manual appendix fly sheets discrepancies (e.g., referencing incorrect OMS manual revision, incorrect sequence) should be corrected. ▪ It is recommended all appendix fly sheets identify the title and date of the report being appended. ▪ The OMS manual table of contents should be updated to correctly show all appendices and their respective sub-headings. ▪ It is recommended that the update date be included page footers in subsequent versions. These discrepancies and/or omissions should be corrected in subsequent updates. ▪ The undated organization chart and table of key contacts in Appendix C of the EPRP (OMS manual Appendix E) can be removed since it is redundant to information provided in the EPRP and OMS manual. If it is kept in, it should be maintained with up-to-date information and revision date. ▪ The EPRP table of contents should be updated to present a list of figures and tables within the EPRP.	3	March 2024	-	MPMC to address inconsistencies in OMS manual.

Table 3: 2022 Dam Safety Review Recommendations (Tetra Tech 2023) and WSP Recommended Actions

DSR ID	DSR Description of Actionable Item, Deficiency, or Non-Conformance	DSR Recommended Action	DSR Priority	DSR Recommended Deadline	WSP EoR Comment	Status or EoR Recommended Action
		▪ Key DBI maps should be included in the EPRP and provided to downstream stakeholders.				
2022DSR-14	It is unclear what locations and volumes of material sources are available for TSF repairs.	Identify locations and volumes of material sources that may be required for repair of TSF, including person(s) responsible for authorizing and directing their use.	3	March 2024	Location and quantities of construction materials are identified in the QPOs (WSP 2023b).	MPMC to include in OMS manual person(s) responsible for authorizing and directing production and use of construction materials.
2022DSR-15	It is unclear what procedures and personnel are responsible for completing incident investigation, and for the communication and implementation of any required changes.	Identify procedures and personnel responsible for completing incident investigation, and for communicating and implementing any required changes.	3	March 2024	The EPRP and OMS manual should include this information.	MPMC to confirm that reference to procedures and personnel responsible for completing incident investigation is included in the EPRP and OMS manual.
2022DSR-16	EPRP document clerical error review.	Review the EPRP for clerical errors to ensure consistency with OMS manual.	4	March 2024	-	MPMC to address clerical errors in EPRP.
2022DSR-17	A test of the EPRP is required with all applicable personnel.	Complete a test of EPRP by the end of 2023, which includes mine management and operation staff, and downstream emergency response and management personnel. Complete periodic EPRP tests thereafter.	3	March 2024	-	EPRP test completed on November 30, 2023.
2022DSR-18	There might be opportunities for improvement in scheduling construction activities.	Seasonal construction planning and coordination could be improved to avoid late season work on the clay core and upstream materials.	3	March 2024	MPMC to plan and coordinate construction yearly.	MPMC to plan and coordinate construction yearly.
2022DSR-19	At present, for each embankment raise the power building and pump system infrastructure needs to be moved.	Consider improvements to avoid this requirement.	3	March 2024	The current location of the reclaim system is incompatible with required beach width upstream of the Perimeter Embankment near Corner 5. Reclaim system is to be relocated to a central location between Corner 4 and Corner 5.	MPMC to consider recommendation when relocating the reclaim system.

DSR = dam safety review; WSP = WSP Canada Inc.; EoR = Engineer of Record; DSI = dam safety inspection; MPMC = Mount Polley Mining Corporation; QPO = quantitative performance objective; VWP = vibrating wire piezometer; SAA = shape acceleration array; OMS = operation, maintenance, and surveillance; TSF = tailings storage facility; SWMP = Site Water Management Plan ; EPRP = emergency preparedness and response plan; PMP = probable maximum precipitation; IDF = inflow design flood.

8.0 FINDINGS AND RECOMMENDED ACTIONS

The Perimeter, Main, and South embankments were observed to be in generally good condition at the time of the 2023 site inspection. No significant changes in condition were noted based on the review of instrumentation, visual monitoring records, and dam stability. Table 4 summarizes the DSI key issues, recommended actions, and timing for completion or status. Each recommendation has been given a priority level from 1 to 4 as described in Table 5. None of the key issues identified represent a dam safety concern at this time.

Table 4: Summary of Key Issues and Recommended Actions

ID	Identified Issue	Potential Dam Safety Impact or Risk	Recommended Action	Priority	Recommended Timing for Completion or Status
2023DSI-01	The tailings pipeline is installed on a 2 to 3 m high berm immediately upstream of the upstream fill which is at a higher elevation than the TSF embankment at Corner 5.	Risk of discharging tailings upstream of the berm to a higher elevation than the embankment (i.e., >970 m). The berm is not engineered to retain tailings. Increased risk of potential pipeline leaks flowing over and eroding the embankment.	Relocate the tailings slurry pipeline onto a berm along the upstream slope of the upstream fill or onto the crest of the upstream fill, locally raised with blocking or similar.	2	Complete.
			Excavate the existing pipeline berm upstream of the embankment.		Spring 2024.
2023DSI-02	Beach slopes upstream of the embankment are flatter than prior to resuming operations in 2022. In 2023, the beach slopes were surveyed to be in the order of 0.5%.	Increased difficulty to maintain the minimum beach width quantitative performance objective of 100 m upstream of the embankment. Increased hydraulic head against the embankment.	Breach or remove tailings berms used to channel the tailings slurry along the tailings beach upstream of the embankment. Continue to perform periodic topographic and bathymetric surveys to monitor the beach slopes. Implement changes to the tailings deposition method to increase the beach slopes (e.g., spigots) if surveys do not show steeper beach slopes in 2024.	3	Winter/Spring 2024.
2023DSI-03	The TSF pond volume is being estimated throughout the year based on topographic and bathymetric surveys completed between spring and autumn. Pond estimate becomes less accurate with time (e.g., winter).	Increased risk of over or underestimating the TSF pond volume and potential accumulation of excess water in the TSF prior to freshet.	Implement and maintain a TSF water balance to estimate the pond volume. Check and refine the TSF water balance assumptions using periodic surveys of the tailings surface.	3	Spring/Summer 2024.
2023DSI-04	Shallow ravelling observed of the downstream slope of the Main Embankment near Corner 3 (Photograph 22).	If left unattended, minor erosion and gullies could form on the downstream slope.	Continue monitoring and cover with coarse rockfill or re-slope.	4	During construction to re-slope the embankment to 2H:1V.
2023DSI-05	Erosion gullies along the upstream fill due to snowmelt ponding on the crest of the upstream fill between the till core and the tailings slurry pipeline.	Progressive erosion of the upstream fill. If left unattended, more erosion could occur and displace the tailings slurry pipeline or reach the till core.	Continue monitoring and re-grade the upstream fill surface if excessive erosion occurs prior to embankment construction in 2024.	3	Winter/Spring 2024.
			Relocate the tailings slurry pipeline onto a berm on the upstream slope of the upstream fill. Alternatively, locally raise the tailings slurry pipeline from the crest of the upstream fill (with blocking or similar) to limit water ponding between the till core and the tailings slurry pipeline.		Autumn/Winter 2024.
2023DSI-06	Tailings were observed at the west bank of the PETBP where the ditch from the CCS connects to the PETBP. No signs of tailings were observed along other sections of the ditch between the CCS and the PETBP. The tailings are interpreted to have deposited during the TSF repairs in 2014/2015.	Potential migration of tailings from other sources and deposition in the PETBP may not be identified in a timely manner.	Excavate the tailings and continue to monitor the ditch between the CCS and the PETBP, and the drains at Corner 1.	3	Spring 2024.
2023DSI-07	Recommendation 2017DSR-09 has been addressed for the MESCP and PETBP (Golder 2018b). Documentation of peak flow, inflow volumes, and pumping requirements pending for the SESCP.	Potential insufficient storage or pumping capacity resulting on overtopping of the SESCP.	Determine and document the peak flow, inflow volumes, and pumping requirements for the SESCP.	2	Spring 2024.

Table 4: Summary of Key Issues and Recommended Actions

ID	Identified Issue	Potential Dam Safety Impact or Risk	Recommended Action	Priority	Recommended Timing for Completion or Status
2023DSI-08	Stress-deformation analyses (Zabolotnii et al. 2022) indicate that slope inclinometers could provide indication of movement in advance of a potential foundation failure through a layer of GLU in the foundation if the slope inclinometers are located where plastic strains would first occur. Slope inclinometers are installed downstream of the embankment along the South Embankment. Two slope inclinometers are installed near the toe of the starter dam at the Main Embankment.	Potential stability issues may not be identified in a timely manner.	Install and monitor slope inclinometers near the toe of the starter dam near Sta. 0+700 and 1+100 at the South Embankment and near the toe of the starter dam near Sta. 1+900, 2+300, and 2+600 at the Main Embankment.	2	During construction to re-slope the embankment to 2H:1V in 2024.
2023DSI-09	The groundwater quality trends for monitoring wells located around the TSF show that sulfate concentrations in the shallow groundwater downgradient of the TSF approached or reached levels observed in the TSF pond water next to the Perimeter Embankment at GW16-2B and GW96-2B and next to the South Embankment at GW96-4B. However, it does not exceed the BC ENV (1997) Contaminated Sites Regulation water quality standards for protection of freshwater aquatic life (WSP 2023e).	Potential to affect water quality at surface water receptors downgradient of the TSF.	Additional groundwater monitoring downgradient of the TSF between monitoring wells showing elevated sulfate concentrations and surface water receptors should be planned.	3	2024
2022DSI-01	Inclinometer readings show systematic reading errors greater than the capability of the instrument.	Potential issues may not be identified in a timely manner. Misinterpretation or overestimation/underestimation of movement of the embankment.	Periodic review of data collection technique by experienced operator followed by retraining as required. Periodic recalibration of the inclinometer probe by manufacturer on an as required basis.	2	Ongoing. MPMC repaired and purchased new inclinometer probes in 2023; however, malfunctions persisted. MPMC purchased inclinometer probes supplied by another manufacturer and is in the process of re-establishing baselines for each inclinometer.
2022DSI-02	The OMS manual and EPRP were last updated in 2021 before tailings deposition into the TSF resumed. Changes made to slurry deposition in 2022 need to be included in the OMS manual.	Increased risk due to potential miscommunication or misunderstanding of TSF operation, maintenance, surveillance, and emergency response.	Complete updates of the OMS manual and EPRP as required (minimum once per year) and train personnel as required.	2	Completed August 2023. Updates to the OMS manual and EPRP were in progress at the end of 2023.
2022DSI-03	By the end of 2022, the minimum elevation of the till core was about 968.2 m near Corner 3 while the filter and transition zones remained lower at an elevation ranging from 965 to 968 m. The till core connection at the North Abutment remained at an estimated elevation of 966.2 m.	Potential insufficient storage capacity to store target tailings production in 2023.	Complete construction of the filter and transition zones to match the minimum elevation of the till core and abutments. Review tailings production forecast and storage capacity and plan construction as required.	2	Complete.
			Complete construction to raise the embankment to elevation 970 m. Review tailings production forecast and storage capacity and plan construction as required.		Complete.

Table 4: Summary of Key Issues and Recommended Actions

ID	Identified Issue	Potential Dam Safety Impact or Risk	Recommended Action	Priority	Recommended Timing for Completion or Status
2022DSI-04	Tailings slurry has not been deposited from the Main Embankment since the restart of operations in 2016. Deposition of tailings from the Main Embankment is required to build beaches and maintain the pond away from the embankment.	Inability to maintain the minimum beach width quantitative performance objective of 100 m upstream of the embankment. Increased hydraulic head against the embankment. Increased risk due to having ponded water against the embankment.	Complete field trial to confirm that deposition of tailings slurry from the Main Embankment is feasible and implement changes if required. Deposit tailings slurry from the Main Embankment to build up the tailings beach.	3	No progress in 2023. In 2023, the tailings slurry pipeline was extended along the South Embankment and down a berm on the beach towards the central portion of the Main Embankment.
2022DSI-05	Monitoring well GW22-01 at the Perimeter Embankment has not been developed and could be providing misleading readings.	Misinterpretation of phreatic conditions at the west side of the Perimeter Embankment at Corner 1.	Develop the monitoring well.	3	No progress in 2023.
2022DSI-06	Sinkholes developed on the upstream crest of the Main Embankment near Sta. 2+100 due to water (i.e., TSF pond) transporting fine material from the tailings sand layers of the upstream fill into voids of the rockfill layers of the upstream fill or upstream to the tailings beach. Sinkholes developed in the same area in 2020 when the pond was against the embankment.	If left unattended, sinkholes could redevelop and potentially reach the till core.	Deposit tailings slurry from the Main Embankment to build the tailings beach. Maintain the TSF pond size within the specified operating volume range. Confirm that water from the MESCP discharge line does not flow towards the upstream fill. Confirm that ponding does not occur on the crest of the upstream fill.	3	Complete.
2022DSI-07	Sinkholes developed on the upstream fill of the Perimeter Embankment near Sta. 4+450 due to water (i.e., TSF pond and tailings slurry) transporting fine material from the upstream fill sand into voids of the underlying rockfill (i.e., remaining temporary upstream rockfill berm).	If left unattended, sinkholes could redevelop.	Maintain the TSF pond size within the specified operating volume range. Confirm that ponding does not occur on the crest of the upstream fill. Confirm that tailings slurry does not pond against the upstream fill during deposition.	3	Complete.
2022DSI-08	A topographic and bathymetric survey of the TSF was completed in October 2022; however, survey errors were identified and the TSF storage curve could not be updated. The estimated TSF pond volume is increasingly inaccurate.	Inaccurate estimation of the pond volume could result in accumulating excess water in the TSF.	Perform topographic and bathymetric surveys of the TSF twice per year. Develop and maintain a solids and water volume tracking sheet to estimate the TSF pond volume.	3	Complete for 2023. Continue surveying the TSF in the spring and autumn each year.
2021DSI-01	By the end of 2021, an approximate total of about 7.0 Mm^3 of water remained on site at the Springer Pit, Cariboo Pit, and TSF. The restart of mining operations requires dewatering the Springer Pit and Cariboo Pit and reduces the ability to use these pits to store the current excess water on site. The TSF cannot be used to store excess site water.	Increased risk due to the accumulation of a larger volume of water on site that reduces the capacity to manage runoff from freshet and extreme events.	Implement actions to increase the site water discharge rate so the current excess water on site is eliminated, the TSF pond size is maintained within the specified operating volume range, and accumulation of water does not occur within the TSF. Actions could involve: ▪ obtaining approval to discharge untreated water that meets the requirements of the permit ▪ developing a flowchart and triggers to help determine the magnitude of precipitation events in a timely manner	2	Ongoing since 2020. In 2023, the TSF pond had an estimated net water reduction of about 0.9 Mm^3 and has remained within or below the normal operating pond volume range since about June 2023. MPMC reported a year-over-year site-wide water reduction of about 2.7 Mm^3 in 2023; however, approximately 3.2 Mm^3 remained on site by end of 2023.

Table 4: Summary of Key Issues and Recommended Actions

ID	Identified Issue	Potential Dam Safety Impact or Risk	Recommended Action	Priority	Recommended Timing for Completion or Status
2021DSI-02	The tip used to connect the GPS unit to survey monument SM18-01 was observed to be loose.	Misinterpretation or overestimation/underestimation of movement of the Perimeter Embankment at Corner 1.	Secure the tip to the top of the settlement monument.	3	Complete. Survey monument SM18-01 was decommissioned during construction of the embankment in 2023. The tip at survey monument SM17-02 was secured at the time of the inspection.
2021DSI-03	Longitudinal cracks were observed along the crest of the sidewall of the clean water ditch near Corner 4.	Runoff exiting the ditch during freshet or large storm events and reporting to the TSF. Washout of the access road along the west side of the facility.	Excavate and reconstruct the damaged section of the sidewall with suitable till material. Place and compact the till in lifts.	3	No progress in 2023.
2021DSI-05	Vegetation growing along the downstream toe of the South Embankment.	Increased risk due to difficulty of inspecting the embankment regularly. Potential issues may not be identified in a timely manner.	Remove vegetation as part of routine maintenance of the facility.	3	No progress in 2023.
2020DSI-04	Erosion of the upstream fill around the sprinklers and water discharge from the PETBP.	Progressive erosion of the upstream fill. If left unattended, more erosion could occur and reach the till core.	Extend the PETBP discharge line farther into the facility and relocate sprinklers farther upstream. Re-slope the upstream fill to prevent increased erosion and place rockfill at the location of water discharge from the PETBP.	3	Complete. Sprinklers are not used.
2020DSI-06	Flow rate measurements of the Freshet Embankment seepage collection pipe have not been taken regularly since 2018 as the pipe outlet has been submerged.	Increased risk as seepage rate through the Perimeter Embankment at Corner 1 cannot be monitored regularly. Potential changes to the seepage conditions may not be identified in a timely manner.	Raise or trim back the pipe outlet so the seepage flow rate can be monitored.	3	No progress in 2023.
2020DSI-07	The diversion ditch along the north and west sides of the Perimeter Embankment buttress extension at Corner 1 does not flow to the breach pond or the PETBP.	If left unattended, water flowing through the Perimeter Embankment buttress extension that reports to the ditch may be released to the downstream environment.	Install a sump to direct the water to the PETBP. Regrade the ditch or berm so water flows to the PETBP.	3	No progress in 2023.
2019DSI-01	The downstream slope of the Perimeter Embankment at Corner 1 is locally overbuilt and steeper than designed from about Sta. 4+200 to 4+450.	This is a deviation from the design; however, the slope stability factor of safety meets the design criteria. The steeper slope does not impact dam safety.	Re-slope the overbuilt section of the downstream slope to the design slope of 2H:1V.	3	Ongoing. A portion of the overbuilt section was re-sloped during 2023.The remaining overbuilt portion should be re-sloped in spring 2024.
2018DSI-02	Clean water diversion ditch along the west side of the TSF is partially blocked by fallen trees and woody vegetation.	Overtopping of the ditch during large storm events, with washout of access road along the west side of the TSF.	Remove obstructions (i.e., fallen trees, woody vegetation, and branches) and re-establish the diversion ditch along the perimeter of the TSF.	2	Ongoing. No progress in 2023.
2018DSI-06	Localized erosion of sandy tailings along the downstream slope of the Perimeter Embankment buttress at Corner 1.	Progressive erosion of sandy tailings from the downstream slope of the Perimeter Embankment buttress at Corner 1. If left unattended, more erosion and the formation of gullies could occur.	Monitor, cover exposed sandy tailings slopes, and install filter material if necessary.	3	Ongoing, no significant changes noted during 2023 inspection.

DSI = dam safety inspection; TSF = tailings storage facility; PETBP = Perimeter Embankment Till Borrow Pond; CCS = Central Collection Sump; DSR = dam safety review; MESCP = Main Embankment Seepage Collection Pond; SESCP = South Embankment Seepage Collection Pond; GLU = glaciolacustrine unit; OMS = operation, maintenance, and surveillance; EPRP = Emergency Preparedness and Response Plan.

Table 5: Description of Priority Levels

Priority Level	Description
1	A high probability or actual dam safety issues considered immediately dangerous to life, health or the environment, or a significant risk of regulatory enforcement.
2	If not corrected, could likely result in dam safety issues leading to injury, environmental impact or significant regulatory enforcement; or, a repetitive deficiency that demonstrates a systematic breakdown of procedures.
3	Single occurrences of deficiencies or non-conformances that alone would not be expected to result in dam safety issues.
4	Best Management Practice – Further improvements are necessary to meet industry best practices or reduce potential risks.

LEGEND

- EXISTING VIBRATING WIRE PIEZOMETER
- OCTOBER 2023 SURVEY (SEE REFERENCE 1)
- 2016 FOUNDATION PREPARATION (SEE REFERENCE 2)
- 2013 AS-BUILT (SEE NOTE 3)
- PREVIOUSLY CONSTRUCTED MATERIAL BOUNDARY
- EL. 940.0 — PIEZOMETRIC HEAD IN FEBRUARY / JUNE / DECEMBER 2023 (SEE NOTE 8)
- EL. 940.0 — PIEZOMETRIC HEAD IN DECEMBER 2022

NOTES

1. ALL UNITS IN METRES UNLESS OTHERWISE NOTED.
2. ELEVATIONS ARE RELATIVE TO TAILINGS GRID DATUM.
3. SECTION INFORMATION WAS DIGITALIZED USING THE AMEC 2013 AS-BUILT AND ANNUAL REVIEW REPORT, FILE NAME: "2014 03 12 - 2013 AS-BUILT & ANNUAL REVIEW REPORT (AMEC).pdf", DATED: 12 MARCH 2014.
4. DIGITALIZED SECTION WAS UPDATED WITH THE 2014 AS-BUILT SURVEY PROVIDED BY MPMC ON 14 SEPTEMBER 2015 AND MAY 2015 SURVEY.
5. SECTION AND INSTRUMENTATION SHALL BE USED AS REFERENCE ONLY. INSTRUMENTATION, FOUNDATION, MATERIAL BOUNDARIES AND DIMENSIONS ARE APPROXIMATE.
6. PIEZOMETER B10 LOCATION WAS UPDATED USING THE AS-BUILT REPORT WHEN THE PIEZOMETER WAS FIRST INSTALLED.
7. VW16-21 OUT OF THE SCALE OF THIS FIGURE, DISTANCE FROM TSF EMBANKMENT CENTRELINE PROVIDED.
8. PIEZOMETRIC HEAD READINGS TAKEN IN FEBRUARY AND JUNE 2023 ARE DEFINED WITH AN ASTERISK.

REFERENCES

PROJECT
MOUNT POLLEY MINE TAILINGS STORAGE FACILITY
2023 DAM SAFETY INSPECTION REPORT

TITLE
VIBRATING WIRE PIEZOMETERS
CORNER 1 EMBANKMENT

PROJECT NO.	PHASE/TASK/DOC.	REV.	FIGURE
CA0020527.4505	52300/52391/009	0	A21

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM ANSI B
23 mm

Corner 1 Embankment
Upstream Drain and Seepage

* The method used to estimate Corner 1 Drain Flow was changed by MPMC in September 2019.

** Freshet Embankment seepage outlet has been submerged most of the time and the flow could not be measured in 2022 and 2023.

NOTES:

1. Manual rainfall readings are not taken daily at the Mill Weather Station and may represent accumulation of rainfall from multiple days.
2. TSF rainfall gauge removed from:
   - November 2016 to April 2017
   - November 2017 to April 2018
   - November 2018 to April 2019
   - August 2019 to April 2020
   - November 2020 to April 2021
   - November 2021 to May 2022
   - November 2022 to April 2023
4. TSF rainfall gauge broken from:
   - 3 May 2019 to 22 May 2019
   - 1 June 2019 to 25 June 2019
   - 10 June 2020 to 11 August 2020
   - 17 August 2020 to 27 September 2020
5. The Corner 1 upstream drain flow was visually estimated before June 2019. Subsequent drain flow estimates are based on water depth measured in the pipe.

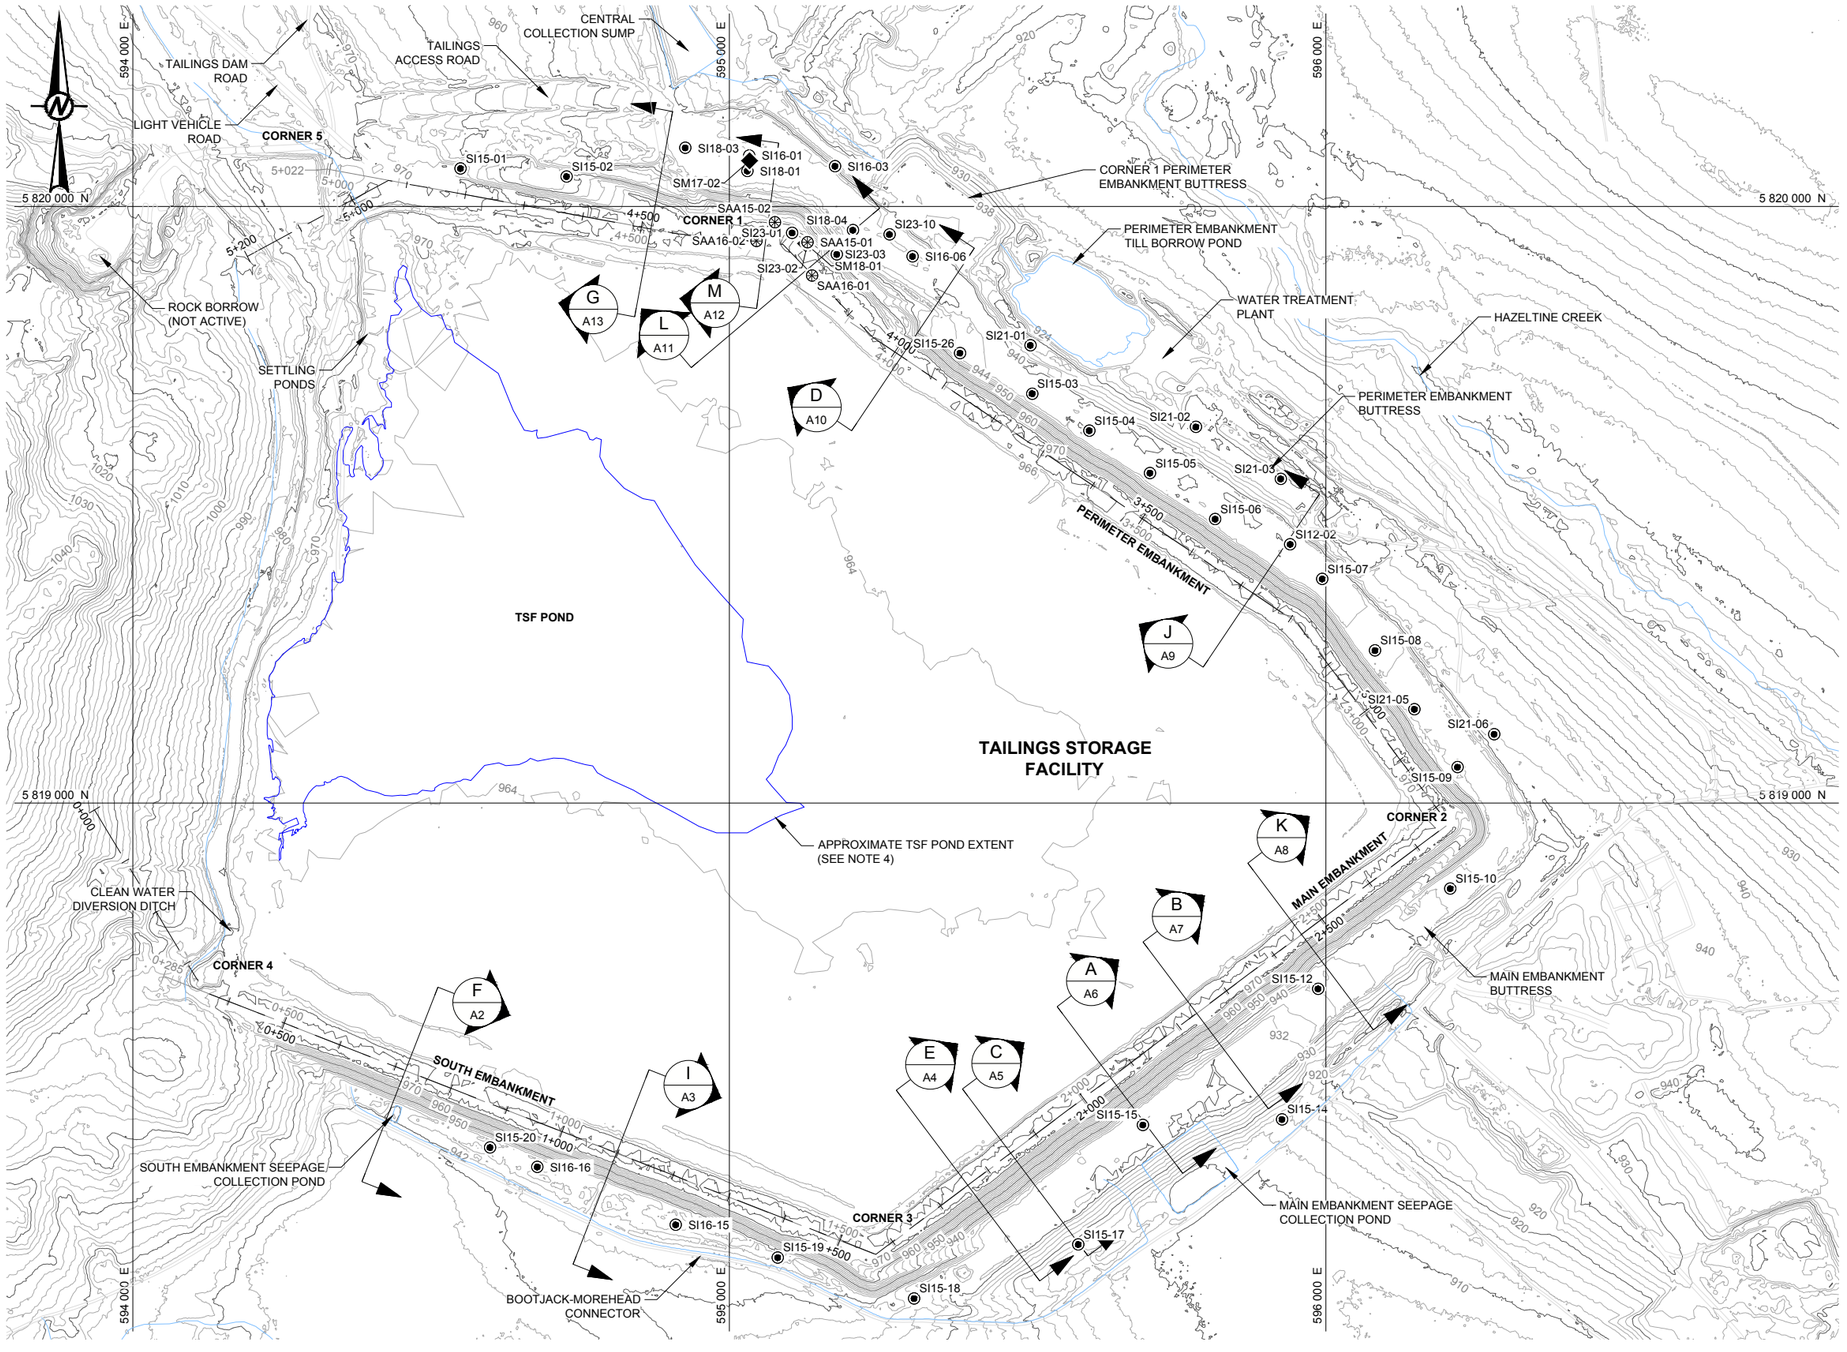
2023 DAM SAFETY INSPECTION REPORT



TITLE

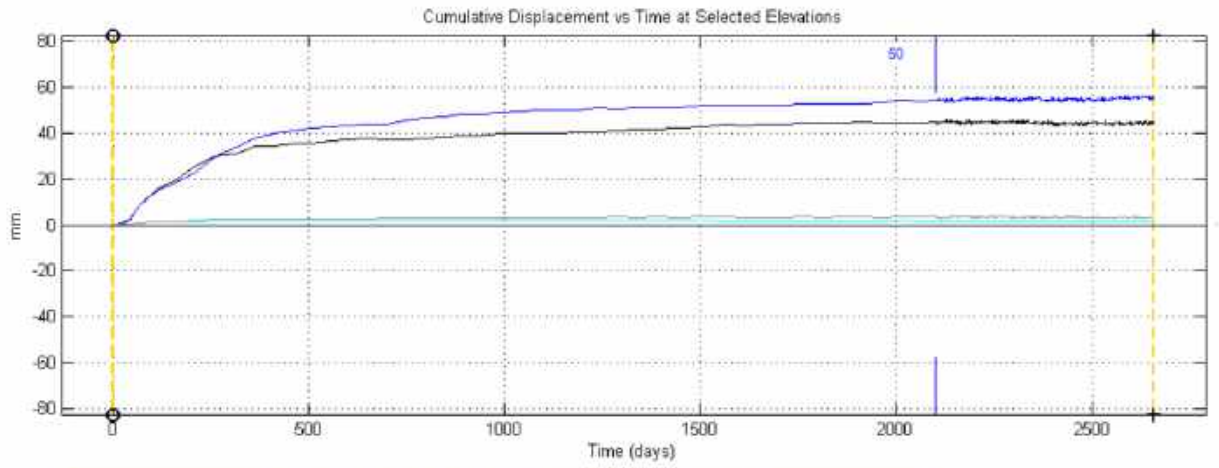
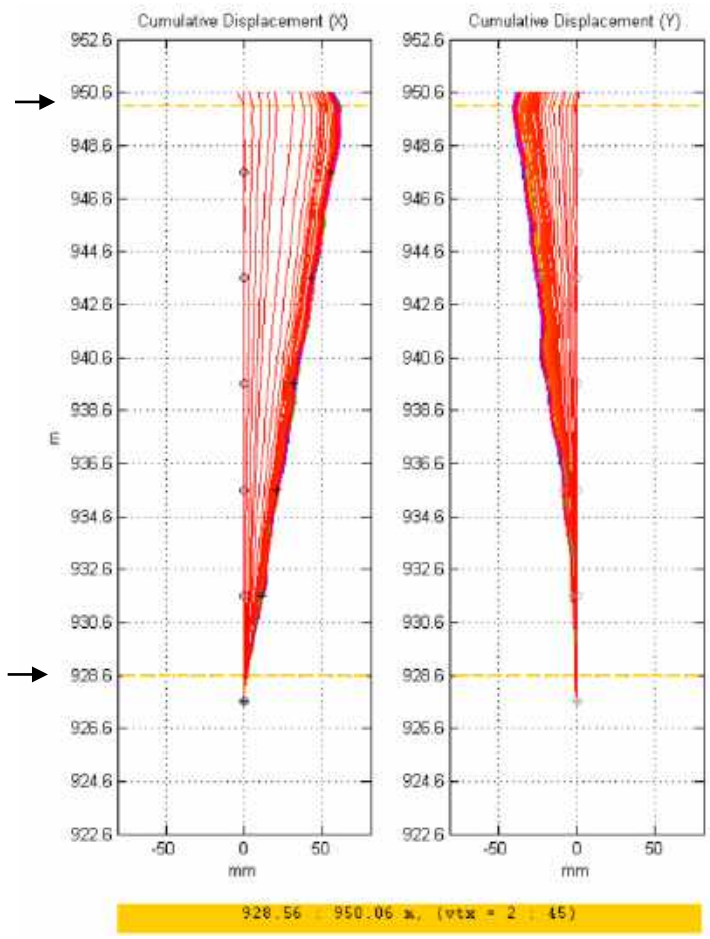
SHAPE ACCELERATION ARRAYS SAA15-01 AND SAA15-02 PERIMETER EMBANKMENT AT CORNER 1

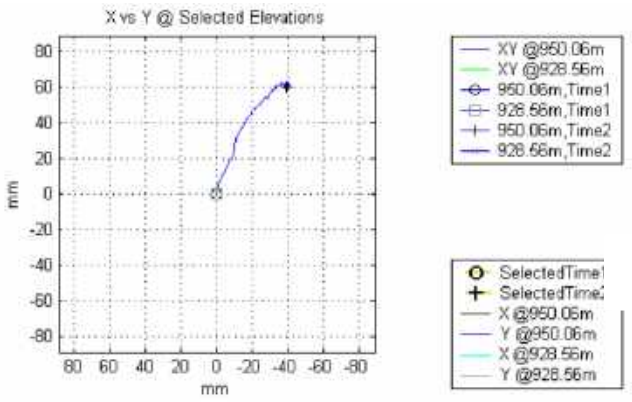


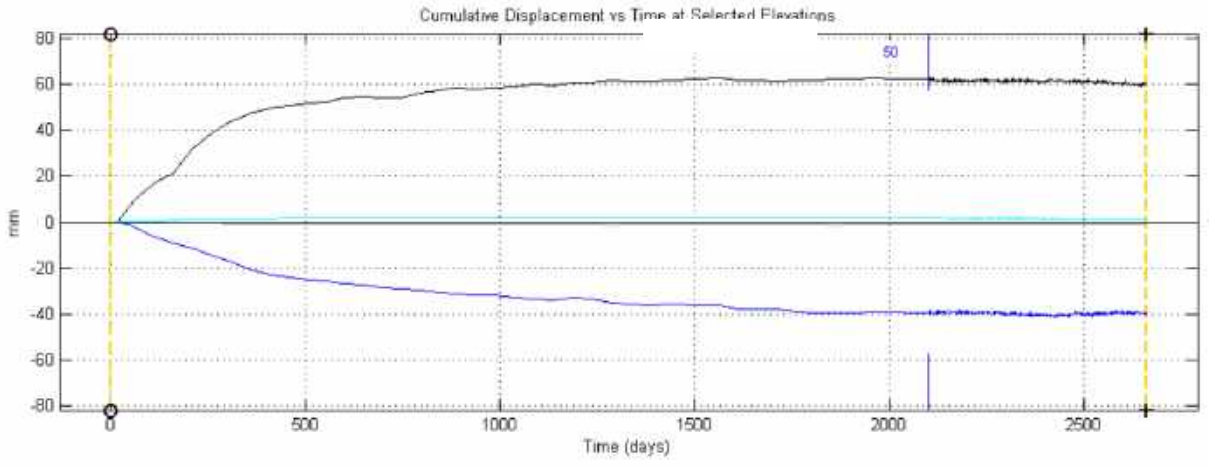
PROJECT NO.	PHASE/TASK/DOC.	REV.	FIGURE
CA0020527.4505	**52300/52391/009**	**0**	**B38**

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM ANSI B
20 mm



SAA16-01





SAA16-02

NOTES:

1. SAA16-01 and SAA16-02 grouted in place on 8 September 2016. First reading 15 September 2016.
2. SAA16-01 downstream direction perpendicular to dam crest has an azimuth of 47° East of North.
3. SAA16-02 downstream direction perpendicular to dam crest has an azimuth of 7° East of North.
4. Data is reduced; shows only every 50th frame of data for the first 80% of time, then shows all data.

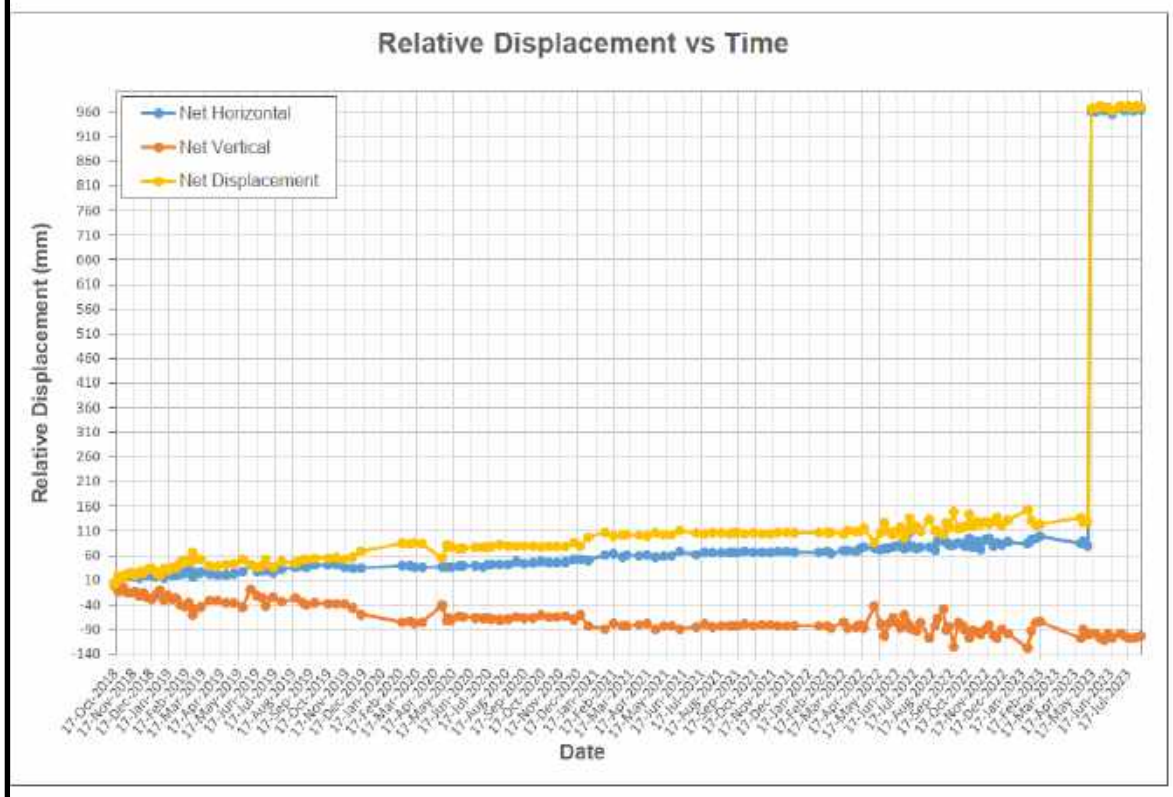
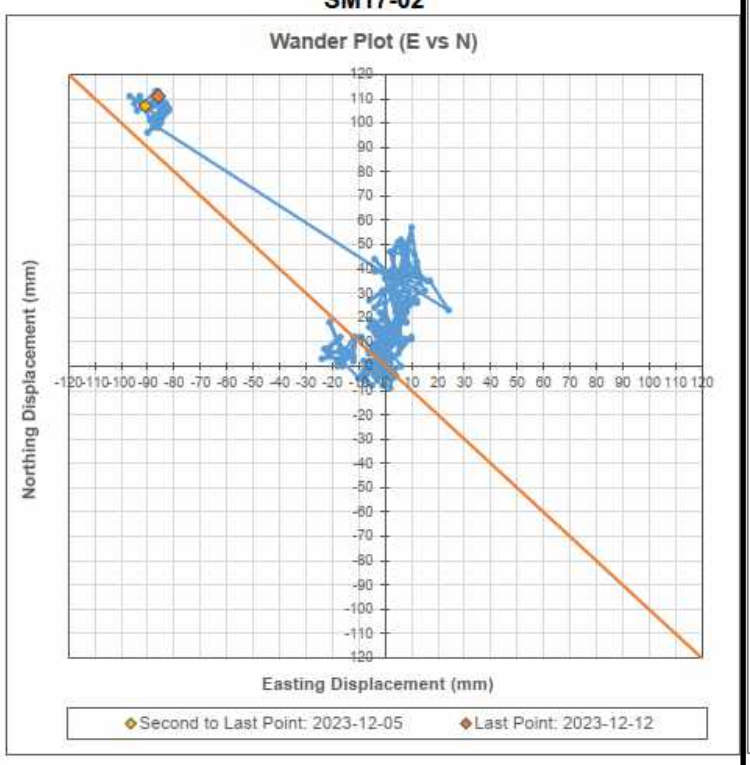
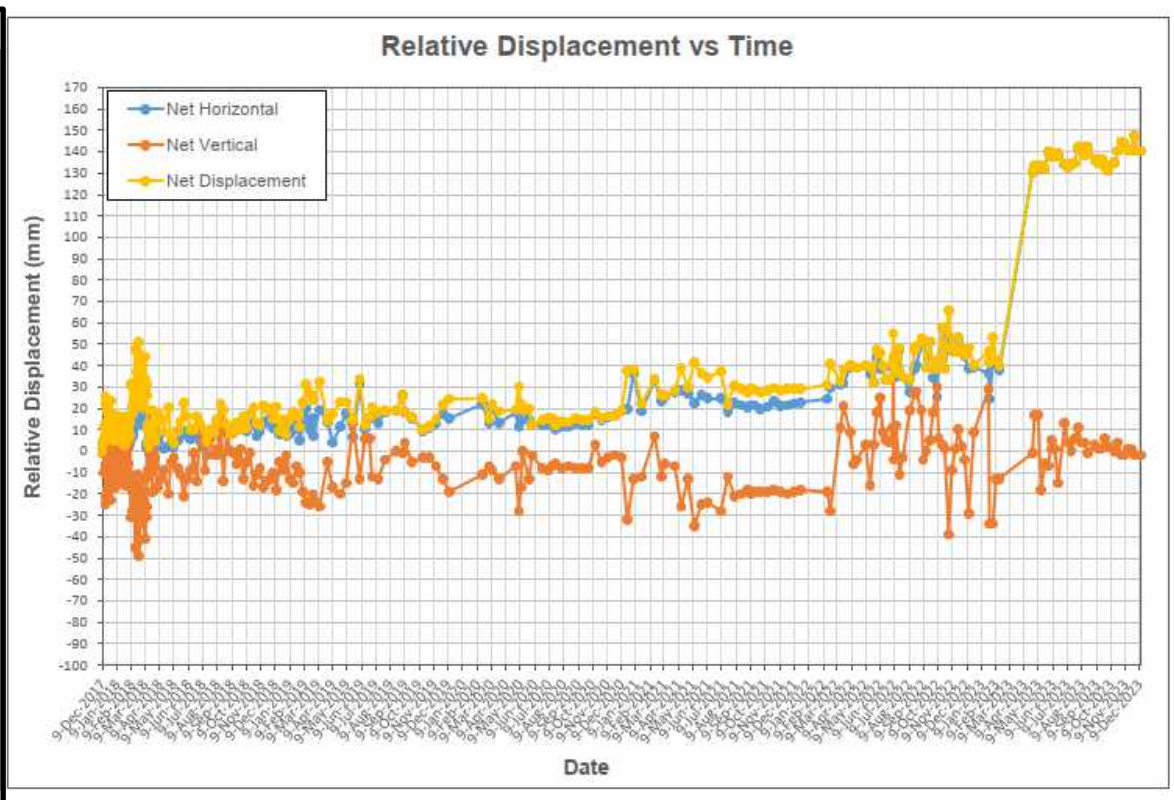
IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM ANSI B
25 mm



SM18-01 (October 17, 2018, to May 9, 2023)[5]



SM18-01 (May 15, 2023, to August 8, 2023)[5]



First Reading: 17 October 2018
Last Reading: 08 August 2023

SM17-02

First Reading: 10 December 2017
Last Reading: 12 December 2023

NOTES:

1. Monument SM17-01 was decommissioned on October 14, 2018, prior to placement of rockfill to raise the Corner 1 Embankment crest.
2. Monument SM18-01 was installed during placement of rockfill to raise the embankment to about El. 968 m. October 2018 initial reading was selected based on interpreted movement attributed to construction.
3. Monument SM18-01 was decommissioned in September 2023 prior to placement of rockfill to raise the Corner 1 Embankment crest to El. 970 m.
4. Monument SM17-02 was struck by an equipment between the readings of February 16, 2023, and April 27, 2023.
5. Monument SM18-01 was struck by an equipment between the readings of May 9, 2023, and May 15, 2023.
    1. Northing Displacement (Cumulative): 10 mm
    2. Easting Displacement (Cumulative): 983 mm
    3. Established a new baseline reading from May 15, 2023, for all the data onwards until decommissioning in September 2023.

RECALIBRATION OF THE GROUNDWATER FLOW MODEL FOR THE SPRINGER/CARIBOO OPEN PIT AND PREDICTIONS OF HYDROGEOLOGICAL CONDITIONS NEAR THE PITS AT CLOSURE – MOUNT POLLEY MINE, BC

1.0 INTRODUCTION

This technical memorandum presents the results of the groundwater model recalibration for the Springer/Cariboo Pit Lake at the Mount Polley Mine that is operated by the Mount Polley Mining Corporation (MPMC). This review was made in support of the Springer Expansion Permit Amendment Application that is currently being prepared for the site. The objective of the assessment is to update the model calibration (i.e., recalibration). The recalibration will improve model predicted groundwater conditions in the vicinity of the pit crest and south of the Spinger Pit in response to pit dewatering and seasonal changes in recharge after 2016, the last time the model was calibrated. Following model recalibration, the model was then used to predict groundwater conditions near the pits during closure.

The analysis presented in this memorandum builds on that which was completed by Golder Associates Ltd. (Golder; now WSP Canada Inc. [WSP]) in 2010 for the ultimate configuration of the Springer Pit that assumed no tailings/waste rock deposition in the pit (Golder 2010). It also builds on the analysis completed between 2014 and 2016 as part of mine water management that assumed the presence of tailings/waste rock in the pit (Golder 2014, 2015a, 2016) and on the model calibration check that was conducted in 2023 (WSP, 2024a). These analyses used a numerical groundwater model that considered hydrogeological data available at the time, and in particular the hydrogeological investigations that were conducted along the southwest wall of the Springer Pit in the spring of 2015 (Golder 2015b). The updated analysis presented in this memorandum considers hydrogeological and hydrologic data collected at the site, specifically groundwater elevations through 2023 (WSP, 2023, 2024b) and mine as-builts information from 2016 to 2023 provided by MPMC.

2.0 REVIEW OF MPMC HYDROGEOLOGICAL AND MINE DATA SINCE 2016

2.1 Water Levels

Water level monitoring data for the period 2016 to 2023 were collected as part of the groundwater monitoring program for the Mount Polley mine and were compiled and summarized in the annual monitoring reports by WSP (WSP 2023, 2024b). Groundwater monitoring has been ongoing at the mine site since 1995 with the objective of monitoring the direction, quantity, and quality of groundwater seepage near mine facilities (MPMC, 2019).

Groundwater levels were measured, at a minimum, semi-annually on approximately the same day of the year, and sometimes more frequently, in monitoring wells to detect changes in groundwater flow directions. Pressure transducers were also installed at GW12-2a and GW12-2b to record changes in pressures every hour. A barologger installed at GW12-2a records barometric pressure at the same frequency, allowing for correction of pressure transducer data for barometric changes. Water levels in Springer and Cariboo Pits were also reported usually once a month from 2016 to 2022, with a few short periods of increased frequency of measurements for the Springer Pit Lake. Figure 1 shows the location of the monitoring wells considered in this assessment. Figure 2 presents the water level data collected from 2015 to 2023 in monitoring wells located in the vicinity of the Springer Pit Lake and water level in the Springer Pit Lake and Cariboo Pit Lake. Key observations for select locations are summarized below.

Wells GW15-1a/b and GW15-2a/b

The available data indicate that hydraulic heads in wells GW15-1a/b and GW15-2a/b, immediately southwest of the Springer Pit crest, have been rising in response to the increases in the pit lake level between December 2015 and June 2016. The Springer pit lake reached an elevation of approximately 1037 metres above seal level (masl) in June 2016. Between January and June 2016, the water level elevation in the Springer Pit Lake was above the hydraulic heads in these four wells. These hydraulic head measurements indicate that, during this period, exfiltration of Springer Pit Lake water had likely occurred while the pit lake elevation was above 1025 masl. Following the aggressive drawdown of the Springer Pit Lake starting in June 2016, hydraulic heads in these four monitoring wells also declined, limiting the time period when the exfiltration of the pit lake occurred. As the Springer pit lake level progressively declined starting in 2017, water levels in these four wells remained above the elevation of the Springer Pit Lake. However, nested wells GW15-1a/b, the closest to the pit crest, appear to have a strong connection with the pit lake as the water level in both wells mimics the elevation of the pit lake until it drops below 1005 masl in February 2018. As the pit lake level continues to decline, the shallow well GW15-1b becomes dry (bottom of the well screen is at 1002 masl) and the water level in the deep well GW15-1a continues to drop and remains approximately 5 m above the pit lake level. Water level in wells GW15-2a/b remained at approximately 1020 masl, and they did not appear to be influenced by changes in the Springer Pit Lake water level after it dropped below 1010 masl.

Wells GW12-2a/b and GW16-6a/b

The hydraulic head measured in monitoring wells GW12-2a/b located approximately half-way between the crest of the Springer Pit and Bootjack Lake to the west was observed to gradually rise between December 2015 and June 2016 as the water level in the pit lake rose; in June 2016, when the pit lake reached its maximum elevation of 1037 masl, the hydraulic head in the shallow well GW12-2b was approximately 19 m below the elevation of the pit lake. Water levels in these two wells remained relatively constant and above the Springer Pit Lake elevation, when it dropped below 1010 masl in January 2017. Water levels in these two wells also remained above the water level elevation of the Bootjack Lake (987 masl) indicating that a groundwater divide between the Springer Pit and Bootjack Lake remains in the area of GW12-2(a,b) and GW15-2(a,b). This groundwater divide results in groundwater flow both towards the east and west from the groundwater divide. This is also confirmed by available monitoring data from wells GW16-6a/b, located south of the Springer Pit crest and approximately 120 m from Bootjack Lake that showed that water levels in these two wells remained constant and above the water levels in the Springer Pit and Bootjack Lake for the monitoring period (2017-2023).

Overall, the available data indicate that exfiltration from the Springer Pit might have occurred for a short period between January and June 2016, when the Springer Pit Lake elevation was above 1025 masl. From June 2016 to December 2023, following drawdown of the pit lake, the hydraulic heads in wells close to the Springer Pit crest have remained above the pit lake level, indicating that no exfiltration has likely occurred after this period.
The hydraulic head at wells GW12-2a/b has remained below the pit lake level until January 2017, when the lake level dropped below 1010 masl, indicating the presence of a groundwater divide between the Springer Pit and Bootjack Lake.

2.2 Climate and Recharge to Groundwater

Climate information for the mine site was obtained from the Climate Baseline Update Report (WSP, 2022). MPMC has operated climate stations on site since 1995, although the station data records are not continuous. From 1995 through 2012, MPMC maintained one climate station at the Mill Site that measured and recorded rainfall (1997 to 2012), temperature (1995 to 2012) and wind velocity and directions (1997 to 2003). In 2012, this station was replaced with two stations: one near the Mill site (WS1) and one adjacent to the TSF (WS2). These new stations measure and record wind speed, relative humidity, solar radiation, temperature, and rainfall. Details of these stations are provided in Table 1.

Table 1: Local Climate Stations for the Mount Polley Mine

Station Name	Northing (m N)[1]	Easting (m E)[1]	Elevation (masl)[2]	Data Type	Period of Record
Mill Site Weather Station	5822420	592495	1,118	R, T, WS, WD	1995-2012
Weather Station #1 (WS1) [near mill]	5822420	592792	1,171	R, T, RH, SR, E, WS	2012-2021[3]
Weather Station #2 (WS2) [TSF]	5819955	594059	964	R, T, RH, SR, E, WS	2012-2021[3]

1) UTM Coordinate system – Zone 10U.

2) Elevation for on-site climate stations measured with handheld GPS device.

3) Station still in operation.

TSF = tailings storage facility; masl = metres above sea level.

R = Rainfall; S = Snowfall; T = Temperature; RH = Relative Humidity; SR = Solar Radiation; E = Evaporation; WS = Wind Speed; WD = Wind Direction.

During the winter, snowpack is measured at four snow course sites at a minimum frequency of once per month, with more frequent measurements typically taken during the melt phase. The details of these snow course stations are provided in Table 2.

Table 2: Local Snow Course Sites at the Mount Polley Mine

Station Name	ID	Northing (m N)[1]	Easting (m E)[1]	Approximate Elevation (masl)[2]	Period of Record
Snow Course # 1 (near mill)	N/A	5823182	592792	1,171	1997–2010, 2015–current
Snow Course # 2 (near TSF)	N/A	5819976	594092	964	1997–current
Snow Course # 3	N/A	5823895	593632	976	2012–current
Snow Course # 4	N/A	5823537	590835	1,112	2015–current

1) UTM Coordinate system - Zone 10U.

Elevation for on-site climate stations measured with handheld GPS device.

masl = metres above sea level; N/A = not applicable; TSF = Tailings Storage Facility.

The site experiences high summer precipitation due to storms, with the lowest monthly precipitation occurring in February. Precipitation typically occurs as snowfall starting in November and achieves its maximum in March, reducing to 0 mm in April. Average annual precipitation at the site is estimated to be 612 mm.

Groundwater recharge due to the infiltration of precipitation at ground surface was estimated as a percentage of total precipitation recorded at the MPMC climate stations. In 2018, researchers from the University of Victoria and Simon Fraser University modeled recharge over British Columbia using both the HELP (Hydrologic Evaluation of Landfill Performance) and a global hydrologic model (PCR-GLOBWB). These studies projected that, for current climate conditions over much of British Columbia, recharge is about 30% of precipitation under natural watershed conditions (Forstner et al. 2018). Based on the type of land cover and recharge estimates included in a previous assessment (Golder, 2016), groundwater recharge was estimated to be approximately 30% of total precipitation, or 183 mm/y, in the site area. An increase in recharge to groundwater is anticipated to occur during the freshet period (April-June) following melting of the snowpack accumulated during the winter months. Water levels in the monitoring wells show an increase of up to 2–3 m starting in April.

2.3 Springer and Cariboo Pit Mine Progression 2016-2023

On September 20, 2023, MPMC provided the mine as-builts for the Springer Pit and Cariboo Pit for the following stages:

- January 2016 (file "*1601-Contour.dxf*"): at this stage the bottom of the Springer Pit is at 935 masl and the bottom of the Cariboo Pit is at 1050 masl.
- January 2017 (file "*1701-Contour.dxf*"): at this stage the bottom of the Springer Pit is at 935 masl and the bottom of the Cariboo Pit deepens at 1023 masl, expanding toward north and west.
- January 2018 (file "*1801-Contour.dxf*"): at this stage the bottom of the Springer Pit is still at 935 masl and the bottom of the Cariboo Pit is at 979 masl.
- January 2019 (file "*1901-Contour.dxf*"): at this stage the bottom of the Springer Pit is still at 935 masl and the bottom of the Cariboo Pit is at 979 masl.
- December 2021 (file "*2112-Contour.dxf*"): at this stage the bottom of the Springer Pit is still at 935 masl and the bottom of the Cariboo Pit is at 979 masl. No changes from previous stage.
- January 2023 (file "*2301-Contour.dxf*"): at this stage the separation between the two pits is a small ridge between the two pits at 1003 masl and the pit bottom 923 masl in the area of the Cariboo Pit.
- September 2023 (file "*230920-Pit.dxf*"): at this stage the separation between the two pits is a small ridge between the two pits at 965 masl and the pit bottom 923 masl in the area of the Cariboo Pit.

The as-built information outlined above was used to update the existing groundwater model to represent groundwater conditions between 2016 and 2023. In addition to the information above, MPMC provided the mine development plan from 2023 to 2031 to the end of mine life. The final configuration of the Springer and Cariboo pit (file "*Sp-6 v4 topomerge.dxf*") was also reviewed as part of this assessment to ensure that the current extent of the groundwater model was still adequate to simulate groundwater conditions to the end of mine life for model predictions during operations and closure.

3.0 GROUNDWATER MODEL RE-CALIBRATION

The details of the numerical hydrogeological model that was developed for the area adjacent to the Springer Pit have been documented in Golder Associates Ltd. (2010, 2014, 2015abc, 2016 and 2024a). These details are not repeated in this memorandum, except for the description of additional model modifications that were implemented to include changes in mine settings since the end of 2022 (model calibration check, WSP, 2024a). The numerical hydrogeological model was re-calibrated to groundwater conditions that existed immediately prior to the formation of the Springer Pit Lake (2014) and during mining operations between 2015 and 2023, described in Section 2.3. The calibration process involved refining the numerical model parameters to achieve the desired degree of correspondence between the model simulation results and the observations of the groundwater flow system (BC ENV, 2012), while reasonably representing the conceptual understanding of groundwater conditions described in previous assessments. The following section presents the calibration approach and metrics, calibration targets, and results of calibration.

3.1 Groundwater Model Update

Based on the review of the information described in Sections 2.0 and 2.3, the existing groundwater model was modified as follows:

- The Springer and Cariboo pit mine progression was implemented in the updated model based on the pit as-builts provided by MPMC (see Section 2.3) to simulate effects on groundwater conditions up to September 2023.
- Water levels in the pit lakes were assigned to the model based on the available monitoring data up to September 2023, as presented in Figure 2.

The remaining model settings and hydrogeological parameters that resulted from previous model calibration in 2016 were not modified and were used as initial parameters for model recalibration, which is the purposes of the current assessment.

3.2 Approach and Calibration Targets

Previous model calibration considered calibration targets and hydrogeological data collected in the existing monitoring wells, as follows:

- **Dewatered Conditions:** steady state calibration to hydraulic heads measured in mid-2014 in the pre-2015 monitoring wells installed near the Springer Pit and corresponding estimates of groundwater inflow to this pit, prior to the formation of the pit lake.
- **July 2015 Pit Lake Conditions:** steady state calibration to hydraulic heads measured in July 2015 in the pre-2015 monitoring wells and new monitoring wells installed in 2015 (i.e., the conditions when the Springer Pit Lake level was approximately 1017.2 masl).
- **Transient Pit Lake Conditions:** the hydraulic head data collected following the installation of the 2015 series wells until late January 2016 was used to conduct additional model calibration that simulated transient groundwater conditions over that period.

Previous model calibration stages were re-evaluated for model re-calibration purposes. The transient pit lake simulations were extended to September 2023.

During calibration, the model was run repeatedly and the model input parameters (hydraulic conductivity, storage properties, recharge) were iteratively adjusted until there was reasonable agreement between predicted and observed hydraulic heads, groundwater flow directions and groundwater flow rates to the slope seepage collection system. Parameter adjustments considered the conceptual understanding of groundwater conditions and were limited to the range of measured data, or, where no site-specific data were available, were limited to the published range of values for similar lithologies.

Quantitative and qualitative evaluation of model predictions against measured observations was conducted during calibration. Qualitative metrics included an evaluation of the patterns of groundwater flow based on predicted hydraulic head contours. Quantitative metrics included comparisons of measured to predicted hydraulic heads (spatial distribution differences), seepage rates and the calculation of the following calibration statistics for hydraulic head:

- Root Mean Squared Error (RMSE) and normalized RMSE (nRMSE): RMSE is a statistical measure of the mean difference between the predicted and measured hydraulic head (h) (i.e., residual head). The nRMSE is the RMSE divided by the range of observed hydraulic head values and is commonly expressed as a percentage. Normalized errors are typically more appropriate to use in areas of high relief and gradients, to account for significant variation in hydraulic head elevations (BC ENV, 2012). Generally, nRMSE under 10% is considered acceptable for model calibration, and a value of less than 5% is considered very good (BC ENV, 2012).

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n} h_{predicted} - h_{measured}}$$

$$nRMSE = \frac{RMSE}{max\ h_{measured} - min\ h_{measured}}$$

- Calculation of the mean absolute error (MAE) and normalized mean absolute error (nMAE) to get an estimate of the average difference between measured and predicted hydraulic heads.

$$MAE = \frac{1}{n}\left|\sum_{i=1}^{n} h_{predicted} - h_{measured}\right|$$

$$nMAE = \frac{MAE}{max\ h_{measured} - min\ h_{measured}}$$

The following sets of information were used as calibration targets to assess the overall steady-state and transient model calibration, as follows:

- Hydraulic heads measured between 2014 and 2023 at 15 observation points located within the model domain. The locations of the monitoring wells and hydraulic head values are presented on Figure 1.
- Observed groundwater inflow into the Springer Pit in 2014, as described in previous assessment (Golder, 2016).

- Visual inspection of the predicted hydraulic head contours and groundwater flow patterns compared to observations and the conceptual understanding of the groundwater regime in the model domain.

The following time steps were selected for these simulations if predicted conditions still reasonably matched observed conditions, based on available water level data:

- **May 2014**: groundwater conditions observed in the pre-2015 monitoring wells installed near the Springer Pit and corresponding estimates of groundwater inflow to this pit, prior to the formation of the pit lake (dewatered conditions).
- **July 2015**: groundwater conditions observed in July 2015 in the pre-2015 monitoring wells and new monitoring wells installed in 2015, when the Springer Pit Lake level was approximately 1017.2 masl.
- **June 2016**: groundwater conditions when the Springer Pit Lake reaches its maximum elevation (1037.9 masl).
- **November 2018**: groundwater conditions when the Springer Pit Lake is dewatered to 986 masl.
- **November 2019**: groundwater conditions when the Springer Pit Lake reaches its lowest elevation (980 masl) and Cariboo Pit Lake is at 995 masl.
- **May 2021**: groundwater conditions when the Springer Pit Lake is at 999 masl and the Cariboo pit lake is at 1015.8 masl.
- **June 2022**: groundwater conditions when the Springer Pit Lake is at 982 masl and the Cariboo pit lake is at 1025.4 masl.
- **September 2023**: groundwater conditions when the Springer Pit Lake is at 952 masl and the Cariboo has been mined to 923 masl (no pit lake present).

3.3 Results of Model Re-Calibration

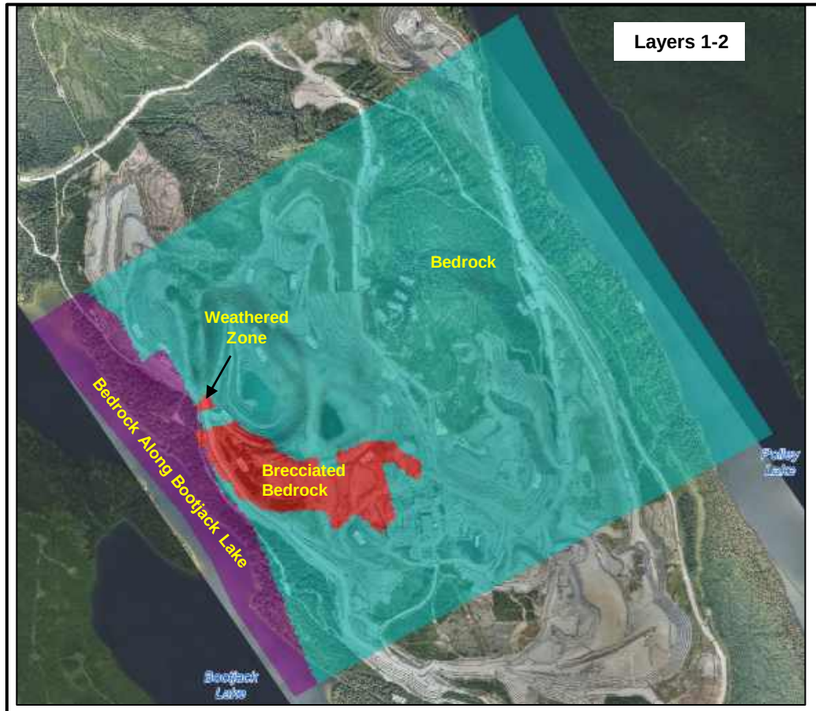
The following section presents the results of the hydrogeological model re-calibration, including a comparison of measured to predicted static hydraulic head, transient changes in groundwater levels and groundwater inflow to the Springer Pit. As described in this section, the model is reasonably well calibrated to groundwater conditions between 2014 and 2023 with a good reproduction of hydraulic heads and gradients across the model domain. Therefore, the calibrated model is considered suitable to support prediction of future conditions (groundwater inflow/seepage rates into and out of the ultimate pit lake at closure).

The applied hydraulic conductivity values and recharge rates outlined in the following section provided a reasonable approximation of the flow regime based on the available data for the model domain. Although additional localized adjustments in recharge and hydraulic properties could be made to improve the match between measured and predicted values used as calibration targets, such localized improvements are not considered warranted at the model scale needed to assess future groundwater conditions in the vicinity of the ultimate pit lake at closure.

3.3.1.1 Calibrated Hydraulic Parameters

The calibrated hydraulic conductivity (K) values for each of the hydro stratigraphic units and the calibrated recharge values from precipitation are presented in Table 3. The spatial distribution of hydraulic conductivity is shown in Figure 3.

Table 3: Calibrated Hydraulic Properties Assigned to the Hydrogeological Model



Hydro Stratigraphic Unit	Depth	Horizontal Hydraulic Conductivity (m/s)	Anisotropy Ratio* (-)	Specific Storage (1/m)	Specific Yield (-)
Bedrock	0-40 m (Layers 1-2)	1×10^{-6}	1	1×10^{-7}	0.001
	40-100 m (Layers 3–5)	$\underline{1 \times 10^{-7}}$	1	1×10^{-7}	0.0001

TITLE
CALIBRATED HYDRAULIC CONDUCTIVITY

PROJECT NO.		REV.	FIGURE
CA0020527.4505	31400	0	**3**

Modifications made to the hydrogeological model during the calibration process are presented in the bullets below and summarized in Table 4. Hydraulic parameter values were changed within the measured range in test data to improve the ability of the model to match measured hydraulic head and hydraulic gradients across the model domain; to match inflow observed in the dewatered Springer Pit; and to match the water level response to the dewatering and refilling of the Springer Pit Lake.

- Based on transient model simulations, the previous hydraulic conductivity distribution in the vicinity of the Springer Pit Lake did not correctly reproduce changes in hydraulic gradients to the refilling and dewatering of the Springer Pit Lake in near-pit wells. Therefore, the hydraulic conductivity of the bedrock unit was varied in the vicinity of the Springer and Cariboo pit in consideration of the observed groundwater levels and geology information as follows:
  - The shallow, more permeable bedrock between the pit crest and monitoring well GW15-01A/B that was considered more weathered was reduced in width and extended at depth up to Layer 4 (60 m depth) and its hydraulic conductivity was increased to 5×10^{-6} m/s, based on testing. This modification helped improve the match between observed and simulated response to the refilling and dewatering of the Springer Pit and the hydraulic gradient in this area.
  - The zone of the brecciated bedrock extending along the southwest portion of the Springer pit and south of the Cariboo Pit was modified based on geological mapping (Wafforn, 2013), to reduce the connection between the area of GW15-02 and the Cariboo Pit Lake. With the previous configuration, the dewatering of this lake and subsequent mining of the pit was influencing the water levels in this well too strongly. The hydraulic conductivity of this zone was increased to 5×10^{-6} m/s to improve the ability of the model to reproduce the response of water levels to refilling and dewatering of the Springer Pir Lake in GW15- 02A/B.
- The hydraulic conductivity of the bedrock at depth between 40 m and 100 m was decreased to 1×10^{-7} m/s. This change generally provided a better reproduction of hydraulic heads in deeper monitoring wells and the hydraulic gradients in the north and central portion of the model domain.
- The zone characterized with lower hydraulic conductivity around monitoring well GW12-2 was extended along the Bootjack Lake based on geological mapping (Wafforn, 2013) to improve the match between observed and simulated hydraulic heads in monitoring well GW16-6A/B and to better reproduce the hydraulic gradient and the groundwater divide observed between the Springer Pit and the Bootjack Lake. For the same purpose, an anisotropy of 5 (horizontal K 5 times greater than vertical K) was implemented in this zone.
- Recharge from precipitation was increased by approximately 20% from average value only for the period from April to June to better represent the increase in recharge following melting of the snowpack during the Freshet period. This change in recharge better represented the observed response of water levels in monitoring wells across the model domain during this period.

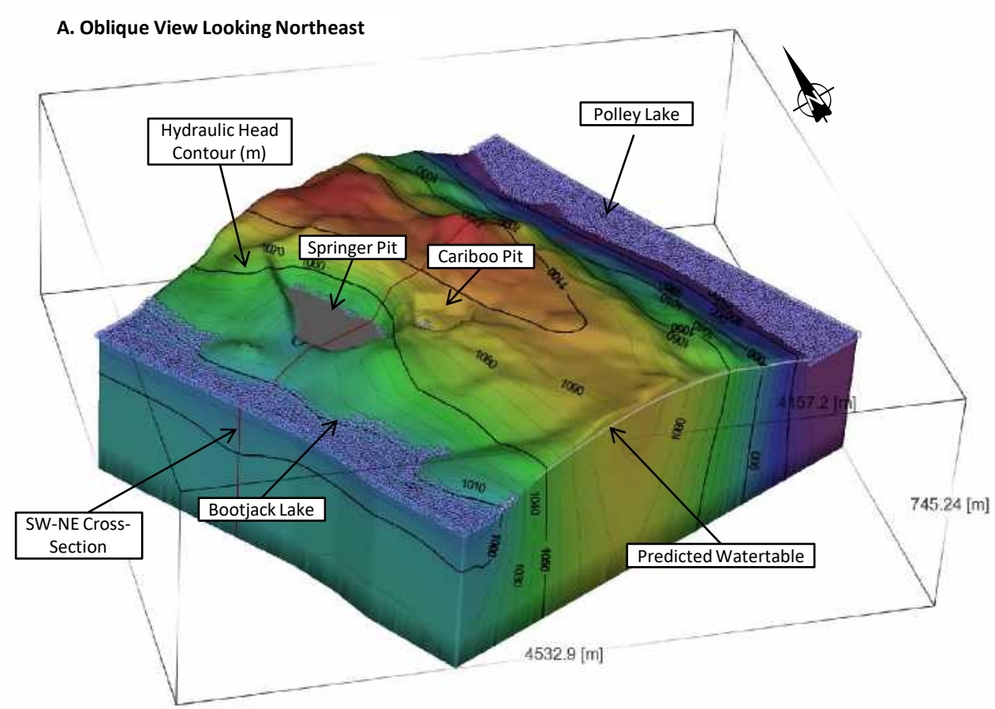
These model changes are summarized in the table below. All the other parameters were not modified from previous assessment.

Table 4: Hydrogeological Model Parameter Value Comparison and 2024 Modifications

Item	2016 Model Value	2024 Model Value
K value - Shallow bedrock between the pit crest and GW15-01A/B	3×10^{-6} m/s	5×10^{-6} m/s
K value - Zone of the brecciated bedrock extending along the southwest portion of the Springer pit and south of the Cariboo Pit	2×10^{-6} m/s	5×10^{-6} m/s
K value - Bedrock at depth between 40 m and 100 m	2×10^{-7} m/s	1×10^{-7} m/s
Anisotropy - Zone characterized with lower hydraulic conductivity around monitoring well GW12-2	Anisotropy – 1	Anisotropy – 5
Recharge from precipitation was increased by approximately 20% from average value based on climate data	October to April	April to June

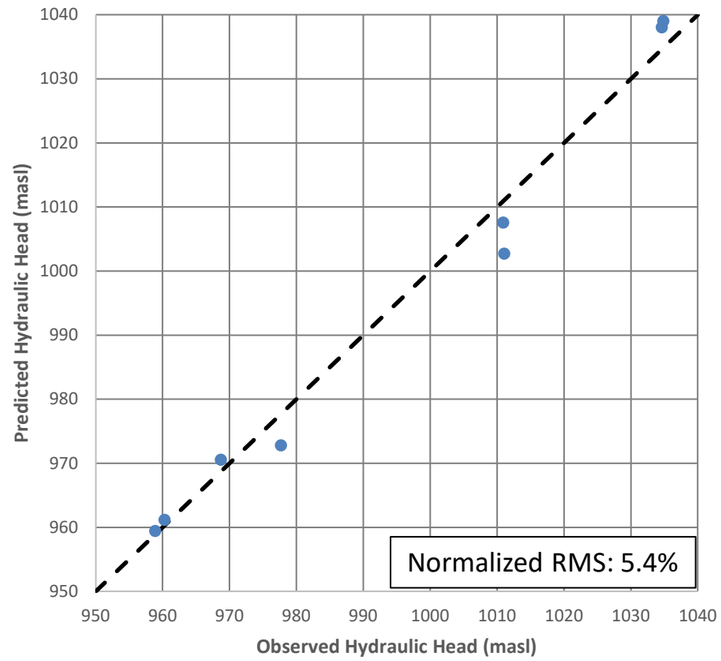
3.3.1.1 Measured Versus Predicted Hydraulic Head and Inflow

Figures 4, 5, 7, 8, 9 and 10 show a comparison of measured versus predicted hydraulic heads for the different stages considered for model calibration along with a 1:1 reference line for comparison (points which fall on this 1:1 line would indicate that the predicted hydraulic head exactly matches the measured hydraulic head). Figure 6 shows observed and predicted hydraulic heads in representative monitoring wells for transient pit lake conditions between 2015 and 2023.



Overall, a reasonable match between measured and predicted hydraulic heads was obtained for all the stages considered. For dewatered conditions (Figure 4) and Pit Lake conditions up to June 2016 (Figure 5), when the pit lake reaches its maximum elevation of 1037 masl, the model-predicted hydraulic heads matched the hydraulic heads measured in the monitoring wells reasonably well. The normalized root-mean-square (nRMSE) error, which considers the scale of head variation across the model domain, was less than 6% for the dewatered conditions and less than 5% and 8% for the Pit Lake conditions for July 2015 and June 2016, respectively. The model can reproduce the water level response to the refilling of the pit lake in the near-pit monitoring wells and in the ones locates between the Springer Pit and the Bootjack Lake, as shown in Figure 6. Following the dewatering of the Springer Pit Lake starting in June 2016, the model still reasonably reproduces the response to this change in the monitoring wells located immediately south near the pit crest, as shown in Figure 6. The model underestimates the drawdown in the vicinity of the pit crest, immediately west of the pit in the area of monitoring wells GW15- 01a/b, and slightly overestimates it farther south of the pit crest, in the area of wells GW15-2a/b. In the area between the Springer Pit and the Bootjack Lake the model is therefore conservative in that it predicts a higher seepage from the pit lake than observed under these conditions. Predicted hydraulic heads in monitoring wells GW16-6a/b located further south of the Springer Pit are accurately represented by the model. Therefore, calibration stages selected to verify model calibration following June 2016 showed that predicted hydraulic heads are in agreement with observed hydraulic heads, as shown in Figures 6 through 9. For snapshots in time between November 2018 and September 2023, the weighted RMS error is between 8% and 10%, which is below or equal to the 10% limit considered acceptable by the BC Guidelines for Groundwater Modelling (BC ENV, 2012).
The mean error ME and mean absolute error MAE between measured and predicted hydraulic heads were approximately 0.06 m and 4.6 m, respectively, over all the stages considered. This indicates that model-predicted hydraulic heads were on average slightly higher than measured data (by approximately 0.06 m), and overall, data was on average within 4.6 m of the measured values.

Groundwater conditions between the Springer Pit Lake and Bootjack Lake both when the pit lake level is high or very low are reasonably represented by the model in the area of monitoring wells GW12-2a/b and GW16-6a/b and the model is predicting the presence of the observed groundwater divide in this area. The model also predicts similar seasonal fluctuations in monitoring wells due to changes in recharge during the freshet period, due to snowmelt.



Maps showing the calibration residuals in hydraulic head (i.e., difference between the model calculated hydraulic head and observed hydraulic head for all well data used for model calibration) for each calibration stage are presented in Attachment 1. The largest residuals are mostly in nested wells GW15-01a/b and GW15-2a/b when the pit lake is dewatered or the water level is low, with predicted hydraulic heads mostly 5 m to 20 m lower than observed heads, depending on the calibration stage. These discrepancies could be related to localized variations in hydraulic properties of the bedrock close to the pit crest which could be highly weathered or anisotropic and these conditions are difficult to reproduce with the groundwater model. However, as discussed in this section, the model tends to overpredict the influence of the pit lake on groundwater levels southwest of the pit crest, providing conservative estimates of seepage from the pit lake for future conditions.

The model-predicted groundwater inflow to the Springer Pit in the Dewatered Conditions scenario (May 2014) was approximately 900 m^3/day (165 USgpm), which is within the range of inflows estimated for this pit by MPMC (600 to 1600 m^3/day, Golder, 2014 and 2016).

3.4 Limited Sensitivity Analysis

The calibrated model is considered to provide representative estimates of current groundwater conditions in the model domain, and these estimates are herein referred to as the Base Case scenario. However, as input parameters to the model are subject to some uncertainty, actual current groundwater conditions (groundwater levels and flow) might differ from what is computed by the model for the Base Case scenario. Following model calibration, the sensitivity of the predicted groundwater flow conditions to reasonable variations in model input parameters was assessed by conducting a limited sensitivity analysis, based on results of previous assessment (Golder, 2016). The results of this analysis provide the input parameter ranges that will reasonably bracket potential future effects on groundwater conditions within the model domain during closure.

The sensitivity analysis was conducted by means of additional steady-state and transient model simulations. In these simulations, selected model input parameters were varied over ranges that reflected their potential range of uncertainty, based on the previous assessment. The estimated hydraulic conductivity of the bedrock and recharge from precipitation were considered to have the highest degree of uncertainty, primarily because of the high variability that these parameters might have within the model domain and the expected high sensitivity of the model results on these parameters.

The model sensitivity simulations were run with the following changes to simulate two uncertainty scenarios:

- Upper Bound scenario: hydraulic conductivity of bedrock increased by a factor of 2 relative to Base Case values and recharge increased to 50% of total annual precipitation.
- Lower Bound scenario: hydraulic conductivity of bedrock decreased by a factor of 2 relative to Base Case values and recharge decreased to 20% of total annual precipitation.

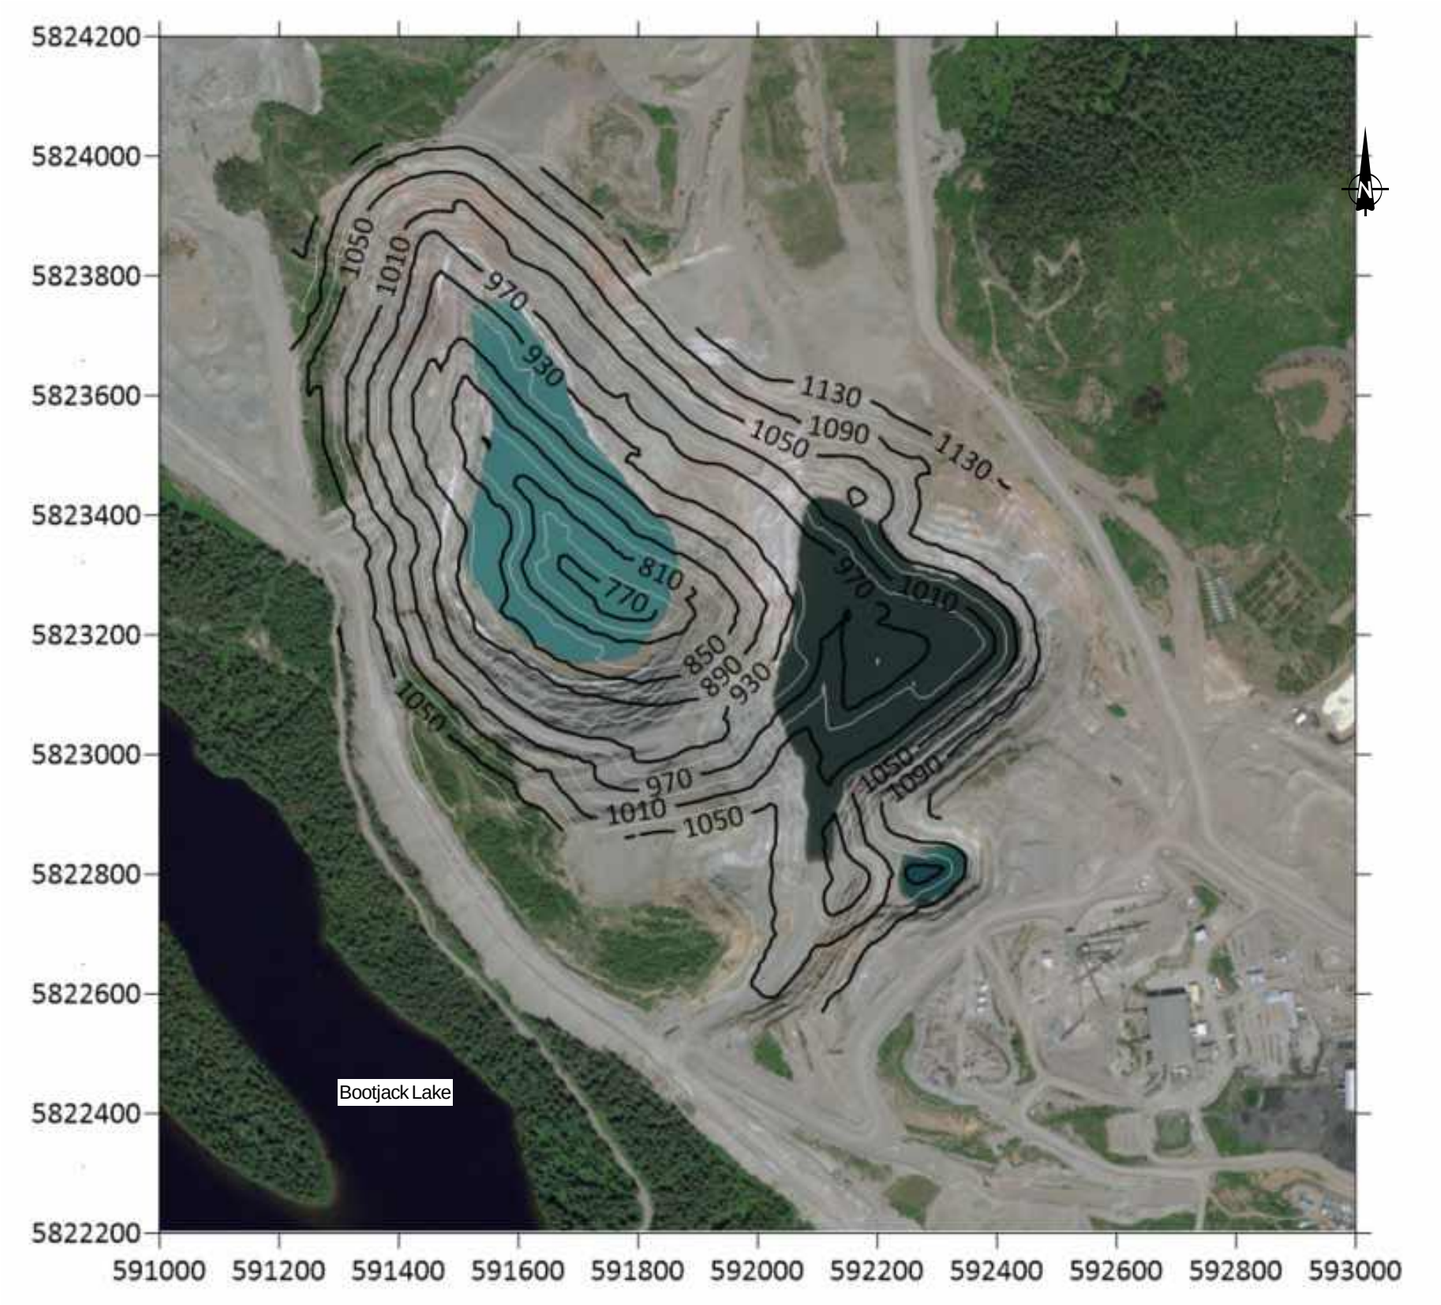
The upper and lower bound range for hydraulic conductivity of the bedrock and recharge were considered reasonable based on the available data.

Table 5 summarizes the results of the uncertainty scenarios, presenting the computed groundwater inflow to the Springer Pit when dewatered and the nRMS for hydraulic head through all the calibration stages relative to the Base Case scenario. Both Lower Bound and Upper Bound scenarios resulted in a poorer calibration in terms of hydraulic head. However, the computed groundwater inflow to the Springer Pit was at both extremes of the observed range, therefore still reasonable. Based on these results, the parameter ranges utilized in the two sensitivity scenarios are considered reasonable for bracketing the range in potential effects on groundwater conditions within the model domain during closure.

Table 5: Results of Sensitivity Analysis

Alternate Scenario	Parameter	Groundwater Inflow to Springer Pit (May 2014) (m^3/d)	nRMS (%)
Base Case	Calibrated Model	900	4.3 to 10
Upper Bound	K of bedrock x 2, recharge 50% of total annual precipitation	1,600	4.6 to 12.3
Lower Bound	K of Vashon Drift / 2, recharge decreased by 20%	550	10.8 to 16.8

4.0 SEEPAGE PREDICTIONS DURING CLOSURE



The calibrated hydrogeological model was used to simulate groundwater conditions near the Springer/Cariboo Pit during closure. These predictions are herein referred to as the Base Case predictions. The following sections describe the model modifications and assumptions used for model predictions. Uncertainty in the predicted groundwater inflows resulting from the uncertainty in model input parameters is based on the limited sensitivity analysis discussed in Section 3.4.

4.1 Method

For the closure predictions, the following assumptions were made, based on information currently available on the closure plan:

- The combined Springer/Cariboo Pit will be mined to the ultimate depth of approximately 763 masl, based on the ultimate pit shape provided by MPMC (file “Sp-6 v4 topomerge.dxf”). Topographic contours representing the ultimate configuration of the Springer/Cariboo Pit are shown in Figure 10.
- The Springer/Cariboo Pit will be allowed to flood. The spillway elevation for this pit lake is approximately 1050 masl (Figure 10).
- Potentially Acid Generating (PAG) materials will be placed in the Springer/Cariboo Pit up to an elevation of approximately 1028 m. Similarly to the previous assessment, in these model simulations, it was assumed that the PAG materials that will be placed in the Springer/Cariboo Pit will have a hydraulic conductivity significantly higher than the surrounding rock mass, and thus offer no resistance to seepage entering or exiting the pit lake.
- Tailings will not be deposited in the Springer Pit/Cariboo Pit.

The model mesh and boundary conditions were modified to incorporate the extent of the ultimate Springer/Cariboo Pit and a sequence of steady-state simulations was completed to predict groundwater inflow/outflow to the Springer/Cariboo Pit Lake for different stages of pit flooding during closure. The stages ranged from a fully dewatered pit to progressively higher lake levels at approximate 20 to 50 m intervals, up to the expected maximum lake (spillover point) elevation of 1050 masl. For each simulation, the specified head boundaries were modified in the hydrogeological model to reflect the specified stage of flooding. This involved removing the constraints restricting the inflow of water and applying a specified head equivalent to the pit lake level to the pit nodes only where they occur below the simulated lake level elevation. This allows water to both enter or exit the pit lake based on the predicted hydraulic heads surrounding the Springer/Cariboo Pit.

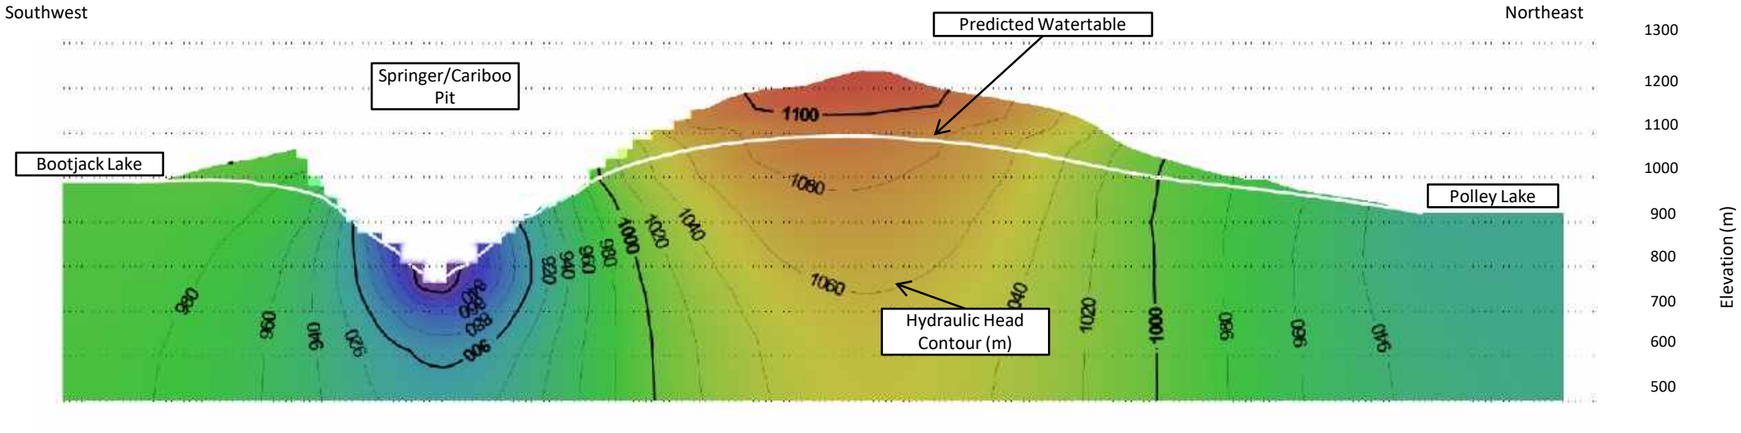
4.2 Results

Table 6 presents the predicted groundwater inflow and outflow rates during flooding of the Springer/Cariboo Pit for the Base Case predictions and for the two sensitivity scenarios. These predictions consider only groundwater flow to the open pit for the simulated pit lake elevation, and do not include potential inputs from direct precipitation within the footprint of the pit and/or surface water run-off (if not diverted) from the pit walls and from the surrounding areas. These surface water inputs are usually incorporated outside of the hydrogeological model in the Water Balance Model (WSP, 2023). Figure 11 and Figure 12 present hydrogeological conditions predicted by the calibrated model (Base Case) for the ultimate configuration of the Springer/Cariboo Pit when fully dewatered and at increased pit lake levels up to the spillway elevation of 1,050 m.

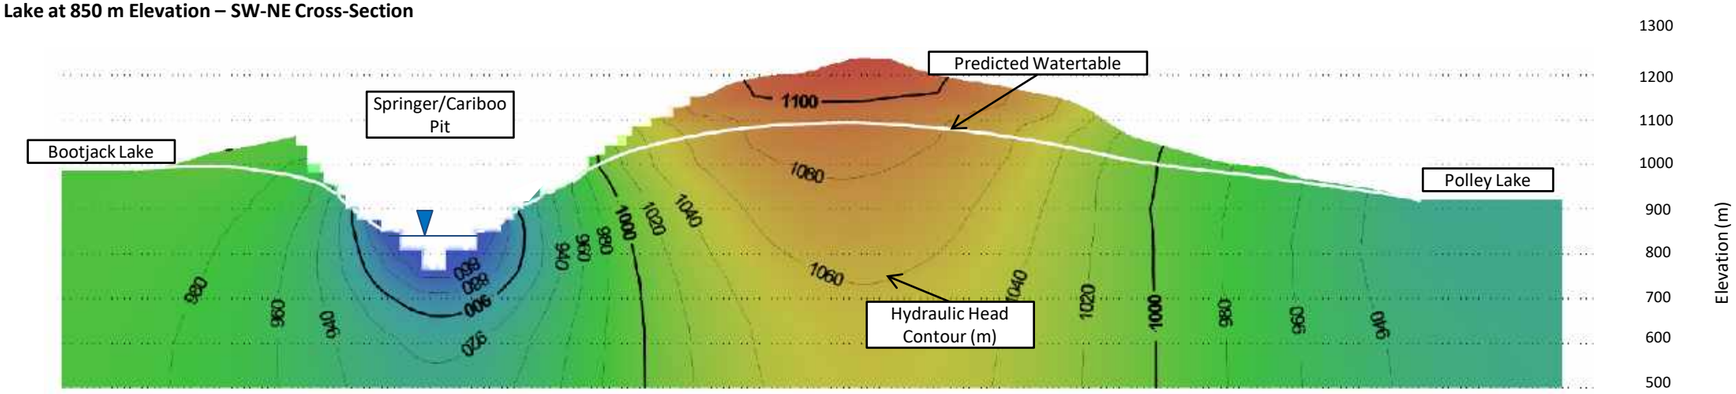
Table 6: Predicted Seepage Quantities for the Ultimate Configuration of the Springer/Cariboo Pit Lake

Springer-Cariboo Pit Lake Elevation (m)	Base Case		Upper Bound		Lower Bound	
	Groundwater Flow (m^3/day)		Groundwater Flow (m^3/day)		Groundwater Flow (m^3/day)	
	Into the Lake	Out of the Lake	Into the Lake	Out of the Lake	Into the Lake	Out of the Lake
760	640	-	1120	-	420	-
800	640	-	1120	-	420	-
850	640	-	1110	-	420	-
900	630	-	1090	-	410	-
940	620	-	1080	-	410	-
960	610	-	1040	-	400	-
980	580	-	980	-	390	-
1000	520	-	850	-	360	-
1020	430	20	690	60	320	<10
1030	390	90	620	200	300	30
1040	360	200	560	440	280	80
1050	330	360	510	780	270	150



Model results indicated that when the Springer/Cariboo Pit is at the ultimate configuration and is fully dewatered, the groundwater inflow to the pit is between approximately 420 m^3/day and 1,120 m^3/d. When fully dewatered, the combined pit would act as strong groundwater sink that would reverse groundwater flow between Bootjack Lake and the pit such that the seepage from Bootjack Lake to the underlying bedrock would occur. As the pit lake level is raised, the groundwater seepage into the pit lake was predicted to gradually decrease to between approximately 270 m^3/day to 510 m^3/d once the spillway elevation of 1,050 m is reached.

In addition, as the pit lake level increases between 1,020 m and 1,030 m elevation, seepage in the range of 20 m^3/d to 200 m^3/d from the Springer/Cariboo Pit Lake into the subsurface was predicted to occur. This seepage was found to gradually increase when the pit lake reaches the spillover elevation of 1,050 m (between 150 m^3/day and 780 m^3/d). At this elevation, the pit lake was predicted to act as a “flow-through” lake with groundwater recharge occurring from the uplands located northeast from the pit and recharge to groundwater occurring towards the southwest.



When compared to previous model predictions (Golder, 2016), updated average predicted inflow and outflow into and out of the pit lake are generally lower than previous estimates (between 10% and 45%), These differences are mainly due to the changes in hydraulic properties in the vicinity of the pit following model recalibration (i.e. reduction in hydraulic conductivity of the bedrock between 40 and 100 mbgs and changes to the brecciated bedrock) and to a lesser degree to the changes between the two simulated ultimate pits. While the updated ultimate pit is deeper and wider than the pit simulated in 2016, predicted flows are lower because of the reduced hydraulic conductivity of the units that are intersected by the ultimate pit.

The hydrogeological model was also used to estimate seepage pathways from the pit lake predicted for the conditions representing the pit lake at the spillway elevation (1050 masl) for the Base Case scenario, as presented in Figure 13. Particle tracking analyses indicate that seepage from the combined Springer/Cariboo Pit Lake when it reaches the spillover elevation is predicted to report to the northern portion of Bootjack Lake over an area of approximately 290 m by 1,200 m, approximately 1 km upstream of the outlet of Bootjack Lake. The advective travel times from the pit lake to the Bootjack Lake are estimated to be between approximately 3 months to less than one year, because of the relatively low transport porosity for bedrock (0.01 to 0.001 based on literature values presented in Guimera and Carrera, 2000), moderate permeability of shallow bedrock, and short travel distance (approximately 200 m from pit crest to Bootjack Lake). Updated seepage pathways when the pit lake reaches spillover elevation are very similar to previous estimates (Golder, 2016).

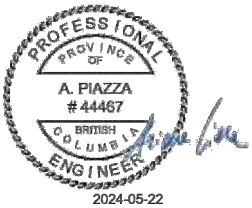
5.0 SUMMARY AND CONCLUSIONS



The existing groundwater model built for closure conditions at the Springer/Cariboo Pit Lake (Golder, 2016) was updated to reflect changes in mine settings since 2016 including the pit configuration and water levels in pit lakes up to 2023. Model calibration was refined based on hydrogeological data collected since 2016 in the mine monitoring wells within the groundwater model domain. Results of this assessment are presented as follows:

- Available water level data indicate that exfiltration from the Springer Pit may have occurred in the period between January and June 2016, when the Springer Pit Lake elevation was above 1025 masl. From June 2016 to December 2022, following drawdown of the pit lake, the hydraulic heads in wells close to the Springer Pit crest have remained above the pit lake level, indicating that exfiltration has not likely occurred after this period. The hydraulic head at wells GW12-2a/b and GW16-6a/b has remained below the pit lake level until January 2017, when the lake level dropped below 1010 masl, inferring the presence of a groundwater divide between the Springer Pit and Bootjack Lake.
- The model was successfully recalibrated for different stages in time between 2014 and 2023. The recalibrated model can adequately reproduce groundwater conditions for each of the stages considered and capture observed increases and decreases in the hydraulic heads in near-pit monitoring wells following refilling and dewatering of the Springer Pit Lake (Figures 4 to 9). Groundwater conditions between the Springer Pit Lake and Bootjack Lake both when the pit lake level is high or very low are reasonably represented by the model in the area of monitoring wells GW12-2a/b and GW16-6a/b and the model is predicting the presence of an observed groundwater divide in this area. The model also predicts similar seasonal fluctuations in monitoring wells due to changes in recharge during the freshet period, following snowmelt.
- The recalibrated model was used to simulate groundwater conditions near the Springer/Cariboo Pit during closure, based on the ultimate configuration of the combined Springer/Cariboo Pit. The model mesh and boundary conditions were modified to incorporate the extent of the ultimate Springer/Cariboo Pit and a sequence of steady-state simulations was completed to predict groundwater inflow/outflow to the Springer/Cariboo Pit Lake for different stages of pit flooding during closure (from dewatered pit to spillover elevation). When fully dewatered (Figure 11), the combined pit would act as strong groundwater sink that would reverse groundwater flow between Bootjack Lake and the pit such that the seepage from Bootjack Lake to the underlying bedrock would occur (groundwater inflow to the pit would between approximately 420 m^3/day and 1,120 m^3/d). As the pit lake level is raised (Figures 11 to 13), the groundwater seepage into the pit lake was predicted to gradually decrease to between approximately 270 m^3/day to 510 m^3/d once the spillway elevation of 1,050 m is reached. As the pit lake level increases between 1,020 m and 1,030 m elevation, seepage in the range of 20 m^3/d to 200 m^3/d from the Springer/Cariboo Pit Lake into the subsurface was predicted to occur, increasing between 150 m^3/day and 270 m^3/d when the pit lake reaches the spillover elevation of 1,050 m. At this elevation, the pit lake was predicted to act as a “flow-through” lake with groundwater recharge occurring from the uplands located northeast from the pit and recharge to groundwater occurring towards the southwest. When compared to previous model predictions (Golder, 2016), updated average predicted inflow and outflow into and out of the pit lake are generally lower than previous estimates (between 10% and 45%), These differences are mainly due to the changes in hydraulic properties in the vicinity of the pit following model recalibration.
- Particle tracking analyses (Figure 13) indicate that seepage from the combined Springer/Cariboo Pit Lake when it reaches the spillover elevation would report to the northern portion of Bootjack Lake over an area of approximately 290 m by 1,200 m, approximately 1 km upstream of the outlet of Bootjack Lake. The advective travel times from the pit lake to the Bootjack Lake are estimated to be between approximately 3 months to less than one year.

6.0 CLOSURE

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum. We trust that the above information is sufficient for your needs at this time. Should you have any questions or require clarification, please contact the undersigned at 604-296-4200.

STUDY LIMITATIONS

This technical memorandum was prepared for the exclusive use of Mount Polley Mining Corporation (MPMC). The assessment was performed according to current professional standards and practices in the groundwater field and has been made using historical and technical data obtained from the sources noted within this technical memorandum. Except where specifically stated to the contrary, the information contained in this memorandum (including reports, information and data) was provided to WSP by others and has not been independently verified or otherwise examined by WSP to determine its accuracy or completeness. WSP has relied in good faith on this information and does not accept responsibility for any deficiency, misstatements or inaccuracies contained in the report as a result of omissions, misinterpretation and/or fraudulent acts of the persons interviewed or contacted, or errors or omissions in the reviewed documentation.

The services performed as described in this technical memorandum were conducted in a manner consistent with the level of care and skill normally exercised by other members of the engineering and science professions currently practising under similar conditions, subject to the time limits and financial and physical constraints applicable to the services. Hydrogeological investigations and the development of conceptual and numerical site models are dynamic and inexact sciences. They are dynamic in the sense that the state of any hydrological system is changing with time, and in the sense that the science is continually developing new techniques to evaluate these systems. They are inexact in the sense that subsurface conditions are not known between the specific investigation locations, and there is invariably a lack of complete information both spatially and temporally about the geological and hydrogeological conditions. The validity and accuracy of the conceptual model depends on the amount of data available relative to the degree of complexity of the geologic formations, the site area hydrogeology, and on the quality and degree of accuracy of the data utilized it in its development. Therefore, every conceptual model is a simplification of reality and the model described in this technical memorandum is not an exception.

The content of this report is based on information collected during the study, our present understanding of the site area conditions, the assumptions stated in this report, and our professional judgement in light of such information at the time of this report. This technical memorandum provides a professional opinion and, therefore, no warranty is expressed, implied, or made as to the conclusions, advice and recommendations offered in this report. This technical memorandum does not provide a legal opinion regarding compliance with applicable laws. With respect to regulatory compliance issues, it should be noted that regulatory statutes and the interpretation of regulatory statutes are subject to change.

The findings and conclusions of this technical memorandum are valid only as of the date of the report. If new information is discovered in future work, or if the assumptions stated in this technical memorandum are not met, WSP should be requested to re-evaluate the conclusions of this technical memorandum, and to provide amendments as required.

The information, recommendations and opinions expressed in this technical memorandum are for the sole benefit of MPMC. No other party may use or rely on this technical memorandum or any portion thereof without WSP's express written consent. The technical memorandum, all plans, data, drawings and other documents as well as all electronic media prepared by WSP are considered its professional work product and shall remain the copyright property of WSP, who authorizes only MPMC to make copies of the report, and only in such quantities as are reasonably necessary for the use of the technical memorandum by those parties. MPMC may not give, lend, sell, or otherwise make available the technical memorandum or any portion thereof to any other party without the express written permission of WSP, except as required by law. MPMC acknowledges that electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore MPMC cannot rely upon the electronic media versions of WSP's technical memorandum or other work products.

APPENDIX 5-9: Near Field Dispersal Model Verification

TECHNICAL MEMORANDUM

DATE 27 March 2023 **Reference No.** 23590671-017-TM-Rev0-31242

TO Mathieu O'Leary
Mount Polley Mining Corporation

CC Don Parsons

FROM Steve Mitchell, Alison Snow and Lee Nikl **EMAIL** **Steve.Mitchell@wsp.com; Alison.Snow@wsp.com; Lee.Nikl@wsp.com**

2022 VERIFICATION OF NEAR-FIELD MODELLING IN QUESNEL LAKE FOR MOUNT POLLEY MINE

1.0 INTRODUCTION

This memorandum provides an update to the previous near-field model validation that was presented in the memorandum entitled "2021 Verification of Near-Field Modelling in Quesnel Lake – Mount Polley Mine" (WSP Golder 2022). For brevity, only the results of the updated model validation are presented, because the methods are the same as those described in the previous memoranda (Golder 2016, 2018, 2019, 2020, 2021, and WSP Golder 2022).

In brief, near-field dilution was calculated using measured water quality data at "end-of-pipe", in ambient Quesnel Lake water, and at the boundary of the initial dilution zone (IDZ) in Quesnel Lake. While this method can lead to large variations in calculated dilution factors on a parameter-by-parameter basis, it is the only validation method available that does not entail adding a tracer chemical to the effluent. Adding a tracer, especially one that might introduce colour to the lake, was not considered for this study because local stakeholders have expressed a strong desire to avoid adding chemicals to Quesnel Lake.

Dilution factors were calculated using Equation 1:

$$DF = \frac{[C_{eff}]-[C_{amb}]}{[C_{IDZ}]-[C_{amb}]} \quad \text{[Equation 1]}$$

where:

C_{eff} = concentration in the effluent from the water treatment discharge (HAD-3)

C_{amb} = concentration in ambient lake water (QUL-2a)

C_{IDZ} = concentration in lake water at the boundary of the IDZ (QUL-5)

2.0 DILUTION FACTORS AT THE INITIAL DILUTION ZONE OF QUESNEL LAKE

The updated model validation includes all applicable data collected in 2022. During this time, discharge was started and ceased on the dates listed in Table 2-1. All treated water during the period of discharge was directed from the water treatment plant (WTP) to Quesnel Lake directly through the pipeline and diffusers.

Table 2-1: Start and Cease Dates of Discharge from the Water Treatment Plant

Start Dates	Cease Dates
1 January	10 June
22 June	31 December

Water quality was measured at locations that enabled dilution factors to be calculated on 10 occasions during the present validation period (Figure 1 and Table 2-1). The calculated median dilution factors were at least 81 on days when discharge was active (Table 2-2). These values confirm the model prediction that the minimum dilution factor at the boundary of the IDZ would range from approximately 40 to well above 100. The calculated dilution factors based on the 2022 monitoring data (Table 2-3 to Table 2-8) are consistent with the model prediction and indicate that the model prediction was conservative (cautionary).

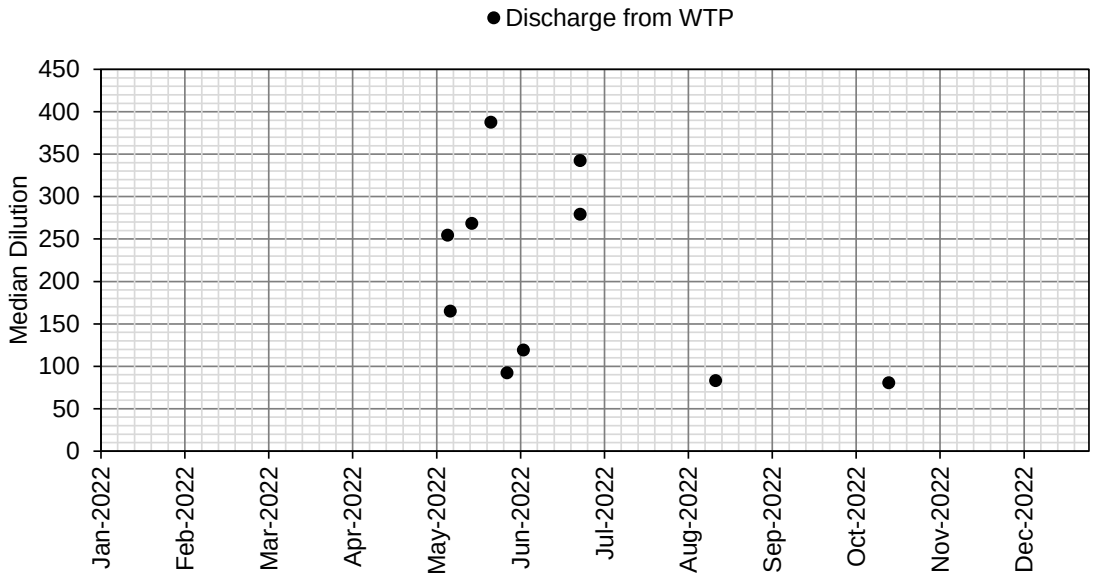

Figure 1: Calculated Dilution Factors at the Initial Dilution Zone Based on 2022 Monitoring Data

Table 2-2 : Calculated Dilution Factors at the Initial Dilution Zone

Discharge Condition	Sample Location at the Boundary of the Initial Dilution Zone	Date	Dilution Factor

APPENDIX 5-10: Long Term Far Field Diffuser Modelling

TETRA TECH EBA

TECHNICAL MEMO

ISSUED FOR USE

To:	Lyn Anglin, Imperial Metals Colleen Hughes, Mount Polley Mining Corporation	**Date:**	June 27, 2016
c:	Mike Herrell, Golder Associates	**Memo No.:**	001
From:	Daniel Potts, Tetra Tech EBA	**File:**	704-WTR.WTRM03015-01
Subject:	Mt. Polley Long Term Far Field Diffuser Modelling		

1.0 INTRODUCTION

Following the August 4, 2014 failure of its Tailings Storage Facility (TSF), Mount Polley Mine (the Mine) suspended operations. The failure of the TSF necessitated a new water management strategy, and in December 2015 the Mine was approved for short-term discharge of treated effluent into Quesnel Lake through two diffusers at a depth of approximately 50 m. For the present work, Tetra Tech EBA was retained to assess the potential long-term effects of continued discharge through these diffusers, currently installed.

1.1 Previous Related Work

Tetra Tech EBA previously completed several field and modelling studies related to water quality in Quesnel Lake.

- **Quesnel Lake Water Column Observations and Modelling** (Tetra Tech EBA, 2015a): Tetra Tech EBA was retained to perform both field measurements and numerical analyses to develop a predictive model that evaluated the fate of the suspended particulate material in Quesnel Lake and the turbidity resulting from that material.
- **Bathymetry Analysis and Volume Balance** (Tetra Tech EBA, 2015b): Tetra Tech EBA assessed the overall volume balance of the TSF failure event, giving consideration to all available sources of data, both on land and within Quesnel Lake.
- **Dilution Modelling at Potential Outfalls in Quesnel Lake** (Tetra Tech EBA, 2015c): Tetra Tech EBA was retained to assess the performance of proposed outfall designs in Quesnel Lake, particularly the long-term far field performance.

Golder Associates (Golder) conducted near-field modelling using CORMIX and conceptual outfall design (Golder, 2015a).

1.2 Objectives

The present work was undertaken in support of Mount Polley Mining Corporation (MPMC) in its application for a long-term permit for discharge into Quesnel Lake. This memorandum will be incorporated into a long-term Technical Assessment Report (TAR) as an appendix. The objectives of the present work were as follows:

- Assess the potential for dilution in Quesnel Lake under two preliminary “bookend” discharge scenarios, with consideration of long-term buildup over a decade.

Vancouver, BC V6C 1N5 CANADA
Tel 604.685.0275 Fax 604.684.6241

- Assess the potential for dilution in Quesnel Lake under three "detailed" discharge scenarios, with consideration of long-term buildup during the period of resumed mining operations.

1.3 Limnology Background Discussion

Quesnel Lake is a long, narrow fjord lake reaching from the Cariboo Mountains into the Interior Plateau of BC. Its average and maximum depths are 157 and 511 m, respectively, making it the deepest fjord-type lake in the world (Laval et al, 2008). It has a surface area of about 266 km^2 and a volume of 42 km^3. With a mean annual outflow of 128 m^3/s through the Quesnel River, the lake has an average hydraulic residence time of 10 years. At the west end of the lake, a contraction and sill at Cariboo Island partially separates the main body of the lake from the so-called "West Basin," which represents 8.6% and 2.3% of Quesnel Lake's surface area and volume, respectively. The West Basin's average and maximum depths are 43 and 107 m, respectively.

In temperate lakes, the temperature of the surface water passes through 4°C, the temperature of maximum density, twice annually in a well-understood cycle. Summer warming produces a layer of warm, buoyant water at the surface of a lake. The temperature difference, and thus density difference, between this layer and the cooler water beneath creates a resistance to mixing which stabilizes or stratifies the lake. In the fall, the surface layer cools, reducing the density difference between surface and deeper waters, until the stratification is overcome by wind-induced mixing. This mixing typically involves the entire water column and is commonly referred to as "fall overturn." Under winter conditions, cooling of the entire lake continues until the surface is less than 4°C, at which point a reverse winter stratification appears: a cold, buoyant surface layer overlies a warmer (closer to 4°C) deep layer. In the spring, warming of the surface layer leads up to "spring overturn" when, again, the stratification is overcome by wind-induced mixing. Continued warming of the surface layer re-forms the summer stratification and completes the annual cycle. These mixing episodes have previously been observed in Quesnel Lake in December and April. See, for example, thermistor data presented in Potts (2004) and in Laval et al (2012).

In temperate lakes deeper than about 100-200 m, the seasonal overturn cycle is complicated by high-pressure effects. The temperature of maximum density decreases with pressure, to approximately 3°C at a depth of 500 m. This means that seasonal overturn events can only involve the upper 100-200 m of the water column and deeper water is only renewed or displaced by subtle three-dimensional dynamics. For more discussion and numerous references, refer to Potts (2004) and Laval et al (2012). The main body of Quesnel Lake is subject to these effects. The West Basin of Quesnel Lake, however, with a maximum depth of just over 100 m, follows the normal seasonal overturn cycle for temperate lakes.

The three largest inflows to the lake are east of the sill, whereas Quesnel River flows out of the western tip of the West Basin, meaning that nearly all of the hydraulic throughput of the lake must pass through the West Basin. Based on an average annual outflow of 128 m^3/s, the West Basin's average residence time is about 90 days.

The sill separating the West Basin and the main body of the lake has a maximum depth of 35 m and forks around Cariboo Island. Wind setup and internal waves, or seiches, between the upper and lower layers in the water column cause two-layer exchange flow over the sill following strong wind events. Using temperature measurements, Potts (2004) estimated the rate of exchange flow to be on the order of 1500 m^3/s, which dwarfs the river outflow by an order of magnitude. This exchange is frequent enough and large enough to fully replace the water in the cool, deeper layer in 6-8 weeks (Laval et al, 2008), although the duration of individual exchange events is on the order of hours to a few days.

The key physical drivers of the lake are meteorological fluxes, wind, and rivers. Meteorological fluxes create the seasonal stratification and are dominated by shortwave and longwave radiation and evaporative heat transfer (Potts, 2004; Laval et al, 2012). Wind events are responsible for the seiche activity which can result in upwelling of cold water at the western tip of the lake and exchange flows across the sill (Laval et al, 2008) as well as episodic

deep water renewal (Laval et al, 2012). Rivers also influence circulation and deep water renewal, but to a lesser degree (Laval et al, 2012).

2.0 METHODS

2.1 Model Overview

Tetra Tech EBA used the EPA Visual Plumes UM3 model, embedded in the three-dimensional hydrodynamic model H3D, to evaluate the behaviour of an outfall plume in Quesnel Lake. UM3 is a numerical dilution model for outfall discharge into marine and freshwater environments, and is one of the models included in the Visual Plumes software. The model, developed and distributed by the US Environmental Protection Agency, is an accepted standard for determining environmental impacts from effluent discharge through an outfall. Tetra Tech EBA previously developed a three-dimensional hydrodynamic model of Quesnel Lake in order to describe the behaviour of the suspended material introduced to the lake after the August 4, 2014 TSF failure event. H3D is a three-dimensional hydrodynamic model that has been shown to accurately simulate the effects of tide, wind, river flow, density and time variability in receiving water bodies (Stronach et al., 1993). The Quesnel Lake implementation of the model was developed to simulate the temperature, turbidity, and total dissolved solids regime of the lake. The model is described in the report “Quesnel Lake Water Column Observations and Modelling” (Tetra Tech EBA, 2015a) including validation to historical data and simulation of the lake after the 2014 TSF failure event. The model grid for Quesnel Lake is shown in **Figure 2.1**, with diffuser locations and river inflow and outflow points labelled.

The existing hydrodynamic model of Quesnel Lake does not take into account pressure effects on water’s equation of state. Therefore, it does not reproduce the deep-water renewal processes of the main body of the lake. These processes are, however, inconsequential to the objectives of the present work focused in the West Basin, and generally only affect circulation in water bodies deeper than about 100-200 m.

For outfall assessments, the PLUMES UM3 code was integrated into H3D such that all of the simulated time-varying properties of velocity and density could have the appropriate influence on near-field plume behaviour, and the far-field behaviour could be simulated in a realistic manner. The UM3 model is valid in the near-field when boundary effects do not occur within the near-field, and when the plume dynamics do not cause significant recirculation in the receiving environment. The existing Quesnel Lake model resolution is relatively large (75 x 75 m at the diffuser location) in order to simulate the entire lake. As the point of interest for dilution modelling is 100 m from the outfall, the grid resolution is not suitable for near-field modelling. Near-field dilution is discussed in Golder (2015a) as well as Appendix H of the TAR; Golder used the CORMIX suite of near-field models to design and evaluate diffuser options. The salient difference between the long-term three dimensional approach (H3D-PLUMES) and the near-field approach (CORMIX) is the possibility of building up a background concentration of effluent in the three-dimensional model of the lake, reducing diffuser effectiveness regardless of near-field hydraulic performance.

Warm water is less dense than cool water, so a warm plume encountering the cool bottom waters of a lake is typically buoyant. On the other hand, given similar temperatures, a plume with higher suspended and dissolved solids than the receiving water will sink. The total dissolved solids (TDS) concentrations in the effluent (on the order of 1000 mg/L) are sufficient to overcome approximately 10°C worth of buoyancy. Therefore, the plume may tend either to sink or to rise, depending on its temperature and TDS concentration as well as those of the ambient water. The modelling method chosen is able to respond to these competing processes, including the background buildup of TDS and seasonal changes in effluent and lake temperature.

2.2 Representation of Effluent Characteristics

For modelling purposes, the diffuser effluent and receiving water were represented with the following properties: temperature, total suspended solids (TSS), TDS, and a dye tracer. Density was derived from temperature and TDS

by Chen and Millero's lake-specific equation of state (1986) at zero pressure, and modified for TSS using an assumed solids density of 2650 kg/m^3.

To enable a determination of the degree of effluent dilution achieved at a given point in the lake, the effluent was assigned a dye tracer concentration of 1.0, while the lake's other inflows were assigned a dye concentration of 0.0. The units of measurement for the dye can be interpreted as "m^3 of effluent per m^3 of sample." The dye was modelled as an inert, massless, soluble component. The dilution ratio can be calculated from the dye concentration at a given point; for example, a dye concentration of 0.01 represents 1 part effluent mixed with 99 parts ambient water – a dilution of 99:1.

In the "detailed" scenarios, selenium was added to the list of scalar constituents simulated.

2.3 Initial Conditions

The water temperature profile in the hydrodynamic model was initialized using the 26 November 2015 observation made by the Mine at QUL-66a (see **Figure 2.1**). This conductivity-temperature-depth (CTD) profile showed a nearly-homogeneous water column with temperature ranging from 5.7°C at the surface to 5.0°C at the maximum depth of the cast (90 m). Below 90 m, the initial temperature throughout the lake was assumed as 4.0°C.

For the "bookend" scenarios, the initial concentrations of TSS and TDS were taken as 1.5 and 78 mg/L, respectively, throughout the lake. These values were average measurements from sites near Hazeltine Creek mouth (Golder, 2015a). For the "detailed" scenarios, initial TSS was kept at 1.5 mg/L; however, initial TDS was adjusted to 69 mg/L and the initial selenium concentration was set to 0.00014 mg/L to match measurements east of Cariboo Island (values provided by Golder).

In all scenarios, the initial dye concentration was zero, to represent the absence of effluent.

2.4 Diffuser Discharge Hydrographs and Properties

The purpose of modelling the "bookend" scenarios was to provide preliminary estimates of dilution in Quesnel Lake before input data were available for a more detailed analysis. The defining characteristic of each of the two scenarios is the assumed hydrograph and properties of the discharge through the diffusers. The two "bookend" scenarios, Option 1 and Option 2, are described below.

The purpose of modelling the "detailed" scenarios was to provide best estimates of the resulting water quality in Quesnel Lake under a statistical range of predicted water quality in the discharge, from 5th to 95th percentile concentrations. The discharge characteristics for the "detailed" scenarios are described below.

2.4.1 Option 1 "Bookend" Discharge

Option 1 used a steady simulated flow rate of 0.33 m^3/s (10.4 Mm^3/yr). The steady flow represents discharge through a pipeline, bypassing the sedimentation ponds, and thus excluding any flow contribution from the lower reaches of Hazeltine Creek. Discharge was simulated beginning on 1 December 2005, to match the season that the Mine's discharge began under their short term discharge permit (1 December 2015). **Section 2.6.1** justifies the selection of 2005-2015 as the simulation period. The total simulated volume of effluent discharged from 1 December 2005 to 31 December 2015 was 105 Mm^3.

The temperature of the effluent was based on estimated monthly average temperatures at end of pipe, provided by Golder and consistent with the 2015 TAR (Golder, 2015a), and varied between 0.0 and 17.5°C. The TDS concentration in the effluent was assumed to be 1000 mg/L, based on the 75th percentile concentration in Springer Pit predicted by the Updated TAR Model (Golder, 2015b). Consistent with the Environmental Management Act

permit, the TSS concentration in the effluent was assumed to be 15 mg/L. As there was no mixing with Hazeltine Creek, the dye concentration was a constant 1.0. **Figure 2.2** illustrates the diffuser discharge hydrograph and properties for Options 1 and 2.

2.4.2 Option 2 "Bookend" Discharge

For the Option 2 scenario, the discharge is assumed to pass through the sedimentation ponds, thus mixing with water from Hazeltine Creek. Since the capacity of the diffuser system is 0.60 m^3/s, the treatment plant was assumed to shut down whenever the Hazeltine Creek flow exceeded 0.27 m^3/s. The discharge through the diffusers was therefore defined as indicated in **Table 2.1**, below. The total simulated volume of effluent discharged from 1 December 2005 to 31 December 2015 was 80 Mm^3, which is 76% of the total discharge in Option 1.

Table 2.1: Discharge Definition for Option 2

When Hazeltine Creek Base Flow Was	The Discharge Was
Less than 0.27 m^3/s,	Hazeltine Creek base flow plus 0.33 m^3/s of effluent.
Between 0.27 and 0.60 m^3/s,	Hazeltine Creek base flow only.
Greater than 0.60 m^3/s,	Exactly 0.60 m^3/s of Hazeltine Creek base flow.

The temperature and other properties of the effluent were assumed to be the same as in Option 1. Properties of the combined effluent and Hazeltine Creek discharge were calculated according to the proportion of flow from each source (**see Figure 2.2**). The properties of the Hazeltine Creek base flow are described in **Section 2.7**, below.

2.4.3 "Detailed" Scenario Discharges

The three "detailed" scenarios used discharge flow rates representing average-year hydrology at the mine site. The discharge was a mixture comprised of up to three streams at any given time, coming from the Perimeter Embankment Till Borrow Pond, Springer Pit, and Hazeltine Creek. The flow rates and concentrations of TDS and selenium for each of these streams were provided digitally to Tetra Tech EBA by Golder. Effluent flows are mingled with Hazeltine Creek flows from the simulation start until the end of November 2017, at which time a pipeline is assumed to be commissioned. A bypass conveying flows from Springer Pit is active from May 2016 to May 2017, inclusive, at which time the dewatering of Springer Pit is projected to be completed. For the concentrations of TDS and selenium, three time series were provided, corresponding to 5^{th}-percentile, median, and 95^{th}-percentile predictions of Golder's probabilistic water quality model (see Appendix D of the TAR). In this context, the 95^{th}-percentile water quality predictions are relatively high values which are exceeded in only 5% of the model cases.

The discharge temperatures were estimated from the monthly temperatures of Hazeltine Creek and the effluent, discussed above, and combined in proportion to the respective flow rates. The TSS concentrations in Hazeltine Creek and the effluent were both assumed to be a constant 5.0 mg/L, matching the average concentration observed in Hazeltine Creek (sample location HAC-12) after the water treatment plant became operational (data provided by MPMC). The simulated dye concentration was 1.0 in the effluent streams, and was diluted appropriately when the discharge included water from Hazeltine Creek.

Figure 2.3 shows the discharge characteristics for the 5^{th}-percentile, median, and 95^{th}-percentile water quality "detailed" scenarios. Flow rates are presented as a total for the two diffusers.

2.5 Diffuser Physical Characteristics

The physical characteristics of the diffusers were modelled based on the information shown in drawings 101 through 105 in "HDPE PIPELINE - TEMPORARY DISCHARGE TO QUESNEL LAKE," issued for record and sealed 13 November 2015. There are two diffusers, installed at depths of 45 and 50 m below the water surface. Each diffusers has two ports spaced 15 m apart, each 0.20 m (8 inches) in diameter, which angle up at 45° above the bed slope. The diffuser ports are approximately 1 m above the lake bed.

Although changes to the existing diffuser configuration may be considered for future operations, only the existing configuration was assessed by the modelling described in this memo.

2.6 Meteorological Inputs

One advantage of running a continuous simulation over a decade is the opportunity to see the effects of variable hydrologic and meteorological inputs year by year. Rather than constructing an artificial set of inputs by means of statistics, Tetra Tech EBA chose to use surrogate historical periods to represent the potential future conditions. This approach preserves the linkages between winds, temperatures, and precipitation that would be lost under a stochastic approach.

Meteorological inputs were chosen differently for the "bookend" scenarios than for the "detailed" scenario. The "bookend" runs aimed to make basic assumptions about effluent flow and assess long term buildup under a range of environmental conditions. By contrast, the "detailed" run aimed to make a best estimate of the discharge and assess long term buildup under unfavourable environmental conditions.

2.6.1 Inputs for "Bookend" Scenarios

For the "bookend" scenarios, a surrogate historical decade of hydrologic and meteorological inputs was used to simulate the natural range of environmental conditions, while the effluent flow was held constant. Selection of the most appropriate historical decade was based primarily on winds, which are the strongest driver of mixing in Quesnel Lake, and are therefore the dominant influence over long term buildup. Wind energy is most effective at mixing the lake during the spring and fall overturn processes, which typically happen during the April-May-June and October-November-December periods, respectively.

In keeping with the modelling completed for the short-term discharge permit, wind and other meteorological inputs to the model were derived from the Williams Lake Airport (YWL) records. The period of record at YWL runs from 1961 to present. This period was screened for wind mixing energy by evaluating the root-mean-square (RMS) wind speeds during the two sensitive periods for overturn: April-May-June and October-November-December. The decade with the greatest variation in wind mixing energy was 2006-2015. This decade was therefore selected for the "bookend" models.

Other meteorological parameters of interest are temperature and precipitation, which influence stratification and flow through the lake, respectively. Temperatures were characterized by calculating the average temperature during the expected summer stratification period – May through October. Precipitation was characterized using an annual total. Since river flows are significantly influenced by snow pack, the precipitation for a given year was totaled between September 1st of the preceding year and August 31st to account for winter accumulation.

Table 2.2 below summarizes the variability of wind mixing energy, summer temperatures, and annual precipitation in the decade chosen for the "bookend" simulations. Each parameter is described in terms of its variation from the mean over the period of record at YWL. For example, in 2013 the RMS wind speed in the sensitive periods was 13% lower than average, summer temperatures were 1.1°C warmer than average, and precipitation was 2% less than average.

Table 2.2: Variability in Meteorological Conditions during "Bookend" Decade

Yearly Variation In			
Year	**Windiness**	**Summer T (°C)**	**Precipitation**
2005	0%	-0.2	24%
2006	-1%	0.7	-16%
2007	-7%	-0.1	0%
2008	-6%	-0.1	15%
2009	-2%	0.7	-1%
2010	9%	0.2	-15%
2011	0%	-0.6	24%
2012	1%	0.2	-7%
2013	-13%	1.1	-2%
2014	4%	1.2	18%
2015	2%	1.3	-5%

2.6.2 Inputs for "Detailed" Scenarios

For the "detailed" scenarios, the buildup of effluent in the lake was assessed in relatively unfavourable environmental conditions. Maximum buildup of effluent in the lake would be expected when the least amount of wind energy is available for mixing. The year with the lowest wind energy was 2013, so this year was selected for the "detailed" scenarios. Since the simulations require multi-year duration, the hydrologic and meteorological inputs from 2013 were repeated, or looped, to extend the input period.

Results from the Option 1 "bookend" scenario confirmed that, as expected, the greatest increase in background effluent concentrations in the lake occurred in 2013 (see **Section 3.2**).

2.7 Hydrologic Inputs

The West Basin of Quesnel Lake, into which the diffusers discharge, is at the "downstream" end of the Lake, meaning that the hydraulic throughput of the Lake must all pass through the West Basin. Quesnel River, which flows out of the West Basin, has an annual average flow rate of 128 m^3/s. Based on this flow rate, the average hydraulic residence time of the West Basin is about 90 days.

The major rivers flowing into Quesnel Lake are Horsefly River, Mitchell River, and Niagara Creek. Numerous smaller streams enter the lake as well, including Hazeltine Creek. Inflows to the Quesnel Lake model were represented using the three major rivers, with flows from the lesser streams lumped together with the most appropriate major rivers, following the methods of Potts (2004). Potts's methods predict average monthly inflows to Quesnel Lake, based on historically gauged catchments within and surrounding the Quesnel Lake watershed. To account for yearly differences in precipitation, the average monthly inflows in each year were scaled up or down according to the year's variance in precipitation, as shown in **Table 2.2** above. For example, monthly inflows for 2006 were scaled down from the average by 16%.

For the major rivers, temperatures were taken as the average monthly temperatures measured by Potts (2004). TSS in the Horsefly and Mitchell Rivers was assumed to be 1.5 mg/L, matching the initial condition in the Lake, while TSS in Niagara Creek was taken as 81 mg/L, a value derived from the observations of James (2004). All three major rivers were assumed to have TDS and selenium concentrations matching the initial concentrations in the Lake for the respective runs.

Despite its very small annual average flow rate of approximately 0.24 m^3/s, Hazeltine Creek was included in the "bookend" scenarios as a distinct inflow since estimated flows were available. The flow rate for Hazeltine Creek was derived from synthetic data created by SNC-Lavalin, extrapolated from the gauge location to the creek mouth by a ratio of catchment areas. For simulation years in which the synthetic data had gaps, the gaps were filled by inserting data from other years with similar annual precipitation; for example, gaps in 2014 data were filled with values from the same dates in 1991 (precipitation year totals 516.8 and 518.1 mm, respectively, at YWL). For the "detailed" scenarios, Hazeltine Creek was not included as a distinct inflow to avoid conflict with the monthly flows provided by Golder.

Average monthly temperatures for Hazeltine Creek were taken from MPMC (2009). For the "bookend" scenarios, TSS and TDS were assumed to be 3.3 and 81 mg/L, respectively (Golder, 2015a). For the "detailed" scenarios, TSS was assumed to be 5.0 mg/L, matching the average concentration observed in Hazeltine Creek (sample location HAC-12) after the water treatment plant became operational (data provided by MPMC). TDS and selenium concentrations were assumed to be 247 and 0.001 mg/L, respectively, matching baseline water quality values provided by Golder.

The outflow from the Quesnel Lake model was managed using a weir-type condition to represent Quesnel River's stage-discharge relationship.

Tetra Tech EBA validated the model's hydrology by comparing the simulated lake level against observed lake level at the Water Survey of Canada gauge near Likely from 2006 to 2014. The observed lake level varies 2.4 m in an average year, with a mean lake level of 0.8 m gauge; the simulated lake level varies 2.0 m in an average year with a mean level of 0.9 m gauge. This validation demonstrates that the weir-type outflow condition and the estimated inflows reasonably reproduce the natural rise and fall of the lake level. This degree of agreement is adequate for the present purpose, considering the scarcity of input data and the relatively small influence of hydrology on the model's predictions of long term effluent buildup.

2.8 Sources of Uncertainty

Table 2.3 lists sources of uncertainty in the predictions of water quality in Quesnel Lake stemming from the modelling approach and assumptions described above. Comments are provided describing how the uncertainty is addressed and what bias may be expected in the model's predictions.

Table 2.3: Uncertainty Analysis for Long Term Water Quality Predictions in Quesnel Lake

Source of Uncertainty	How Uncertainty is Addressed in Modelling	Expected Bias to Predicted Water Quality in Quesnel Lake
Future meteorological conditions.	Conditions from past years are used as surrogate data to represent future conditions.	No bias expected; however, random extremes or a changing climate could influence future outcomes.
Wind speed and direction over Quesnel Lake.	Wind speeds are assumed to match those measured at YWL; wind direction is rotated locally so that the dominant wind direction aligns with the lake's axis.	No bias expected; validations done in previous work support these assumptions as making the best use of the available data.
Hydrology in Quesnel Lake catchment area.	Average monthly inflows to the lake are modified by a factor for each year, based on precipitation at YWL.	No bias expected to long-term water quality; short-term variability (days to months) may be underestimated.
Coarseness of hydrodynamic model's horizontal resolution.	Complete mixing implicitly assumed in the model cell where EPA Plumes places the plume; results are reported only outside a 1-cell radius around the diffusers.	Dilution may be overestimated in the few cells closest to the diffusers; no bias expected in the far field.
Effluent flow rates in "bookend" scenarios.	High flow rates assumed, subject to simple rules.	Predictions biased toward worse water quality.
Effluent flow rates in "detailed" scenarios.	Monthly flow rates were provided by Golder as best estimates of average future conditions.	No bias expected to long-term water quality; short-term variability (days to months) may be underestimated.
Effluent temperatures and Hazeltine Creek temperatures, which strongly influence plume density.	Average monthly temperatures were applied in the model.	No bias expected to long-term water quality; short-term variability (days to months) may be underestimated.
Effluent quality in "bookend" scenarios.	Constant concentrations were assumed.	Variability due to effluent quality is not reflected.
Effluent quality in "detailed" scenarios.	Model included daily variation in concentrations, predicted at three probabilistic levels (5^{th}, 50^{th} and 95^{th} percentiles).	The 5^{th} and 95^{th} percentile predictions are expected to bias the predicted lake water quality downwards and upwards, respectively.

In general, the uncertainties described above were addressed in ways that resulted in the best estimate of long-term far field water quality. This was the primary objective of the modelling effort.

The corollary of this approach is that short-term variability and near-field dilution were lower priorities for modelling. For example, short-term variability due to effluent temperatures and flow rates is not reflected in the model due to the use of monthly averages for these parameters. Furthermore, near-field dilution (within a few cells of the diffuser) may be overestimated due to the coarseness of the model's horizontal resolution.

3.0 RESULTS

This section presents the results of the modelling introduced above. First, some example maps and sections are presented to orient the reader to the model's capabilities. Next, the results of the "bookend" scenarios are presented and discussed; and finally the results of the "detailed" scenarios are presented and discussed.

3.1 Example Model Outputs

Figures 3.1 and 3.2 show some examples of model output from the "bookend" scenarios. These examples facilitate discussion of some important model dynamics and set the background for further results presentation.

Figure 3.1 shows a snapshot of the West Basin condition on 12 August 2010 in the Option 1 scenario simulation. The main panel is a plan view or map showing most of the West Basin, with black line contours showing depth at 25-m intervals. The colour scheme represents dilution of the effluent as computed from the dye concentration in the model. The colour shown in each model cell represents the worst (lowest) dilution in the water column at that location and at the snapshot time.

For regulatory purposes, an initial dilution zone (IDZ) is commonly defined as a 100-m radius around the point of discharge. The horizontal resolution of the model is approximately 75 m at the diffuser location. To represent the IDZ, therefore, a 1-cell buffer has been applied around diffuser cells. The buffer was applied as a post-processing step and did not affect model dynamics. In the plan view, dilution within this IDZ has been blanked (light grey). In **Figure 3.1**, the worst dilution outside the IDZ is in the yellow cells southeast of the diffusers, in the range of 20:1 to 30:1.

The inset in **Figure 3.1** shows a cross-section of the West Basin at the diffuser location (see dashed red line on the map), viewed as if looking northwest. The diffusers are marked on the left slope of the lake bottom. The black line contours are temperature, at varying intervals chosen for visual effect. Colours represent dilution again, on the same colour scale as on the map. This section illustrates a strong temperature stratification in the West Basin, typical of summer conditions. The warm effluent discharging into the cool, deep ambient water is buoyant despite its TDS concentration, and the plume rises to approximately 20 m depth (yellow band above diffusers). The IDZ is not blanked on the inset.

Figure 3.2 shows a snapshot of the West Basin condition on 5 November 2014 in the Option 2 scenario simulation. The main panel is identical to **Figure 3.1** in its layout. The worst dilution outside the IDZ is in the yellow cells northeast of the diffusers, again in the range of 20:1 to 30:1.

The inset in **Figure 3.2** shows a longitudinal cross-section of the West Basin along its thalweg (path of greatest depth – see dashed red line on the map), viewed as if looking northeast. The diffusers are marked with dashed circles where the section passes them. At this point in the simulation, the summer temperature stratification has weakened significantly, and wind events can cause internal waves with vertical amplitudes in the tens of metres. These seiches draw the plume back and forth along the long axis of the basin, and can result in "re-dosing," where water carrying moderately-diluted effluent is drawn back past the diffusers to receive a second "dose" of effluent. The highest concentrations of effluent are off the section line and therefore do not appear in the inset.

3.2 Results from "Bookend" Scenarios

The objective of the "bookend" scenarios was to evaluate the capacity for dilution in Quesnel Lake, under a long-term discharge through a range of hydrologic and meteorological conditions. **Figure 3.3** provides time series of dilution for Option 1 (red; steady effluent flows) and Option 2 (black; effluent mixing with Hazeltine Creek). The vertical axis is dilution ratio on a log scale, with smaller numbers (worse water quality) towards the top. The dots

mark the lowest dilution in the model domain, outside the IDZ, from data archived at 24-hour intervals. The bold solid lines are 30-day moving averages of the worst dilution (dots). The fine dotted lines are 30-day moving averages of the worst dilution *at the water surface*. The 30-day moving averages were computed because some constituents, such as selenium, are subject to guidelines defined in those terms.

In Option 1, the worst predicted dilution was 23:1, occurring in summer while the plume was buoyant and subject to trapping under the thermocline. The example model output shown in **Figure 3.1** corresponds to this point in the Option 1 simulation: that is, the red dot at 12 August 2010 in **Figure 3.3** represents the 23:1 dilution in the worst yellow cell in **Figure 3.1**.

In Option 2, the worst predicted dilution was 27:1, occurring in fall with stratification weakening and significant seiche activity leading to local re-dosing. The example model output shown in **Figure 3.2** corresponds to this point in the Option 2 simulation: that is, the black dot at 5 November 2014 in **Figure 3.3** represents the 27:1 dilution in the worst yellow cell in **Figure 3.2**.

Simulated dilution in Option 2 is generally better than in Option 1 for two reasons. First, the Option 2 discharge was only 76% of the Option 1 volume, so there is less total buildup of effluent in the basin. Second, Option 2 involved mixing the effluent with Hazeltine Creek base flow, pre-diluting the effluent as well as affecting density.

To aid understanding of the circulation dynamics, Tetra Tech EBA computed a mass balance of the effluent in the West Basin for the Option 1 simulation. **Figure 3.4** presents a time series of the terms of the mass balance: cumulative effluent discharge, cumulative effluent exited via Quesnel River, cumulative effluent exited over the sill into the main body of the lake, and instantaneous effluent content of the West Basin. At any time, the cumulative effluent discharge must equal the sum of the other three terms. The Option 1 discharge was 0.33 m^3/s, or about 10.4 Mm^3/year. The buildup of effluent in the West Basin reached a quasi-steady state within 2 years. After this time, the West Basin generally contained about 3.5 to 6 Mm^3 of effluent (thick black line), or roughly half a year's worth of discharge. Of the remaining effluent, about 80% was transported out the Quesnel River, and 20% was exchanged over the sill into the main body of the lake. Exchange over the sill was episodic and occurred most often in late fall, whereas transport out Quesnel River was continuous and had its maximum rate during spring overturn (May and June). After steady state was reached, the only differences year-to-year were due to environmental conditions. The year with the greatest buildup of effluent was 2013, measured as the change in West Basin effluent content from 31 December to 31 December. Therefore, 2013 was deemed the worst year of the simulated decade in terms of effluent buildup.

3.3 Results from "Detailed" Scenarios

The objective of the "detailed" scenarios was to evaluate the capacity for dilution in Quesnel Lake, under a long-term discharge of varying properties estimated to represent discharge from the resumed operations of the Mine. **Figure 3.5** provides time series of dilution for discharges with 5th percentile (black), median (blue), and 95th percentile (red) estimated water quality. The layout of the figure is very similar to that of **Figure 3.3**, with dots representing instantaneous values at 24-hour intervals, and lines representing 30-day moving averages. The worst predicted dilutions occur in early summer, when the plume is buoyant, in the years 2018 through 2020. In these years the pipeline is in use, meaning that the effluent is not pre-diluted by Hazeltine Creek.

Examination of model outputs at hourly intervals (not shown) revealed that variations can occur at time scales as short as 3-6 hours. These variations could be due to changes in wind, solar heating, and internal waves in the lake. Instantaneous worst dilutions appearing in the simulations may not reflect daily averages, which are generally used for effects assessment. Therefore, data archived at hourly intervals were combined to produce daily-average worst dilutions during the critical periods of the "detailed" scenarios. **Table 3.1** lists the worst instantaneous dilutions found

at 24-hour intervals (midnights) beside the corresponding worst daily averages and worst 30-day averages, for the three water quality scenarios.

The "detailed" scenarios included selenium as a specific water quality parameter. **Figure 3.6** presents time series of the predicted selenium concentrations. The baseline Quesnel Lake concentration, 0.00014 mg/L, is indicated with a faint grid line, as is the British Columbia Ministry of Environment (MoE) 30-day average guideline of 0.002 mg/L (MoE, 2014). Similar to dilution, the worst selenium concentrations outside the IDZ were archived at 24-hour intervals. The thick lines plotted in **Figure 3.6** represent 30-day moving averages of these concentrations. The fine dotted lines represent 30-day moving averages of worst selenium concentrations *at the water surface*. **Table 3.1** also lists the worst 30-day average selenium concentrations for each scenario.

Table 3.1: Worst Conditions Predicted in "Detailed" Scenarios

Water Quality Scenario	Worst Instantaneous Dilution at Midnight	Worst Daily-Average Dilution	Worst 30-Day Average Dilution	Worst 30-Day Average Selenium Concentration (mg/L)
5th Percentile	24:1	23:1	38:1	0.0009
Median	26:1	28:1	39:1	0.0010
95th Percentile	27:1	28:1	40:1	0.0015

The worst predicted dilutions occur in the 5th-percentile water quality scenario. Worst dilutions generally occurred in summer when the plume was buoyant and was trapped below the thermocline. The 5th-percentile scenario had lesser TDS concentrations, and was therefore more buoyant in summer and more affected by the trapping dynamic, leading to worse predicted dilutions during the summer period. However, the worst predicted selenium concentrations occurred in the 95th-percentile scenario. The higher selenium concentrations in the effluent outweighed the slightly better dilutions generally achieved.

4.0 CONCLUSIONS

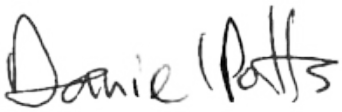
Tetra Tech EBA used a hydrodynamic model of Quesnel Lake in combination with the EPA Visual Plumes UM3 model to simulate water quality in Quesnel Lake with long-term discharge of mine water from the existing diffusers near the mouth of Hazeltine Creek.

Two "bookend" scenarios were simulated, with constant discharge characteristics and variable environmental conditions. Results from these scenarios indicated that:

- The worst water quality outside the IDZ typically occurs in summer when the effluent plume is buoyant and gets trapped below the thermocline;
- Buildup of background effluent concentration in the West Basin of Quesnel Lake reaches a quasi-steady state within 2 years, and this state represents approximately half a year's worth of discharge; and
- The strength of the wind during spring and fall overturn periods is the most significant environmental factor for long-term buildup.

Three "detailed" scenarios were simulated, with relatively unfavourable environmental conditions and varying discharge characteristics representative of resumed operations at the Mine. Results from these scenarios indicated that:

- The worst predicted daily-average dilution outside the IDZ would range from 23:1 to 28:1, depending on the concentration of TDS in the effluent;
- The worst predicted 30-day average dilution outside the IDZ would range from 38:1 to 40:1, depending on the concentration of TDS in the effluent;
- The worst predicted selenium concentration outside the IDZ would range from 0.0009 to 0.0015 mg/L, depending on the concentrations of selenium and TDS in the effluent; and
- Higher TDS and selenium concentrations in the effluent led to higher selenium concentrations outside the IDZ, despite an improvement in summer dilution due to reduced buoyancy of the effluent plume.



5.0 LIMITATIONS OF REPORT

This report and its contents are intended for the sole use of Mount Polley Mining Corporation and their agents. Tetra Tech EBA Inc. does not accept any responsibility for the accuracy of any of the data, the analysis, or the recommendations contained or referenced in the report when the report is used or relied upon by any Party other than Mount Polley Mining Corporation, or for any Project other than the proposed development at the subject site. Any such unauthorized use of this report is at the sole risk of the user. Use of this report is subject to the terms and conditions stated in Tetra Tech EBA's Services Agreement. Tetra Tech EBA's General Conditions are attached to this memo.

6.0 CLOSURE

We trust this technical memo meets your present requirements. If you have any questions or comments, please contact the undersigned.

Respectfully submitted,

APPENDIX A
TETRA TECH EBA'S GENERAL CONDITIONS

GENERAL CONDITIONS

HYDROTECHNICAL

This report incorporates and is subject to these "General Conditions".

1.0 USE OF REPORTS AND OWNERSHIP

This report pertains to a specific site, a specific development, and a specific scope of work. The report may include plans, drawings, profiles and other supporting documents that collectively constitute the report (the "Report").

The Report is intended for the sole use of Tetra Tech EBA's Client (the "Client") as specifically identified in the Tetra Tech EBA Services Agreement or other Contract entered into with the Client (either of which is termed the "Services Agreement" herein). Tetra Tech EBA does not accept any responsibility for the accuracy of any of the data, analyses, recommendations or other contents of the Report when it is used or relied upon by any party other than the Client, unless authorized in writing by Tetra Tech EBA.

Any unauthorized use of the Report is at the sole risk of the user. Tetra Tech EBA accepts no responsibility whatsoever for any loss or damage where such loss or damage is alleged to be or, is in fact, caused by the unauthorized use of the Report.

Where Tetra Tech EBA has expressly authorized the use of the Report by a third party (an "Authorized Party"), consideration for such authorization is the Authorized Party's acceptance of these General Conditions as well as any limitations on liability contained in the Services Agreement with the Client (all of which is collectively termed the "Limitations on Liability"). The Authorized Party should carefully review both these General Conditions and the Services Agreement prior to making any use of the Report. Any use made of the Report by an Authorized Party constitutes the Authorized Party's express acceptance of, and agreement to, the Limitations on Liability.

The Report and any other form or type of data or documents generated by Tetra Tech EBA during the performance of the work are Tetra Tech EBA's professional work product and shall remain the copyright property of Tetra Tech EBA.

The Report is subject to copyright and shall not be reproduced either wholly or in part without the prior, written permission of Tetra Tech EBA. Additional copies of the Report, if required, may be obtained upon request.

2.0 ALTERNATIVE REPORT FORMAT

Where Tetra Tech EBA submits both electronic file and hard copy versions of the Report or any drawings or other project-related documents and deliverables (collectively termed Tetra Tech EBA's "Instruments of Professional Service"), only the signed and/or sealed versions shall be considered final. The original signed and/or sealed version archived by Tetra Tech EBA shall be deemed to be the original. Tetra Tech EBA will archive the original signed and/or sealed version for a maximum period of 10 years.

Both electronic file and hard copy versions of Tetra Tech EBA's Instruments of Professional Service shall not, under any circumstances, be altered by any party except Tetra Tech EBA. Tetra Tech EBA's Instruments of Professional Service will be used only and exactly as submitted by Tetra Tech EBA.

Electronic files submitted by Tetra Tech EBA have been prepared and submitted using specific software and hardware systems. Tetra Tech EBA makes no representation about the compatibility of these files with the Client's current or future software and hardware systems.

3.0 STANDARD OF CARE

Services performed by Tetra Tech EBA for the Report have been conducted in accordance with the Services Agreement, in a manner consistent with the level of skill ordinarily exercised by members of the profession currently practicing under similar conditions in the jurisdiction in which the services are provided. Professional judgment has been applied in developing the conclusions and/or recommendations provided in this Report. No warranty or guarantee, express or implied, is made concerning the test results, comments, recommendations, or any other portion of the Report.

If any error or omission is detected by the Client or an Authorized Party, the error or omission must be immediately brought to the attention of Tetra Tech EBA.

4.0 ENVIRONMENTAL AND REGULATORY ISSUES

Unless expressly agreed to in the Services Agreement, Tetra Tech EBA was not retained to investigate, address or consider, and has not investigated, addressed or considered any environmental or regulatory issues associated with the project.

5.0 DISCLOSURE OF INFORMATION BY CLIENT

The Client acknowledges that it has fully cooperated with Tetra Tech EBA with respect to the provision of all available information on the past, present, and proposed conditions on the site, including historical information respecting the use of the site. The Client further acknowledges that in order for Tetra Tech EBA to properly provide the services contracted for in the Services Agreement, Tetra Tech EBA has relied upon the Client with respect to both the full disclosure and accuracy of any such information.

6.0 INFORMATION PROVIDED TO TETRA TECH EBA BY OTHERS

During the performance of the work and the preparation of this Report, Tetra Tech EBA may have relied on information provided by persons other than the Client.

While Tetra Tech EBA endeavours to verify the accuracy of such information, Tetra Tech EBA accepts no responsibility for the accuracy or the reliability of such information even where inaccurate or unreliable information impacts any recommendations, design or other deliverables and causes the Client or an Authorized Party loss or damage.

7.0 GENERAL LIMITATIONS OF REPORT

This Report is based solely on the conditions present and the data available to Tetra Tech EBA at the time the Report was prepared.

The Client, and any Authorized Party, acknowledges that the Report is based on limited data and that the conclusions, opinions, and recommendations contained in the Report are the result of the application of professional judgment to such limited data.

The Report is not applicable to any other sites, nor should it be relied upon for types of development other than those to which it refers. Any variation from the site conditions present at or the development proposed as of the date of the Report requires a supplementary investigation and assessment.

It is incumbent upon the Client and any Authorized Party, to be knowledgeable of the level of risk that has been incorporated into the project design, in consideration of the level of the hydrotechnical information that was reasonably acquired to facilitate completion of the design.

The Client acknowledges that Tetra Tech EBA is neither qualified to, nor is it making, any recommendations with respect to the purchase, sale, investment or development of the property, the decisions on which are the sole responsibility of the Client.

8.0 JOB SITE SAFETY

Tetra Tech EBA is only responsible for the activities of its employees on the job site and was not and will not be responsible for the supervision of any other persons whatsoever. The presence of Tetra Tech EBA personnel on site shall not be construed in any way to relieve the Client or any other persons on site from their responsibility for job site safety.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

Bolded values indicate concentration exceeds the permit limit.

- = no limit or no data; °C = degrees Celsius; µs/cm = microsiemens per centimetre; µg/L = micrograms per litre; $CaCO_3$ = calcium carbonate; mg/L = milligrams per litre; mV = millivolts; NTU = Nephelometric Turbidity Units.

APPENDIX 7-1: Comprehensive Environmental Monitoring Plan (CEMP)

Mount Polley Mining Corporation

an Imperial Metals company
Box 12 • Likely, BC V0L 1N0 • T 250.790.2215 • F 250.790.2613

Comprehensive Environmental Monitoring Plan 2019

Submitted to:

Ministry of Environment and Climate Change Strategy
Environmental Protection Division
South Interior Region – Cariboo

Prepared by:

Mount Polley Mining Corporation
Environmental Department

Box 12, Likely BC
V0L 1N0

1 INTRODUCTION

The Mount Polley Mine is located eight kilometres (km) southwest of Likely and 56 km (100 km by road) northeast of Williams Lake, British Columbia (BC; Figure 1.1). On November 29, 2015, Mount Polley Mining Corporation (MPMC), which operates the mine, received an amendment to Permit 11678 (herein referred to as the Permit) issued by the BC Ministry of Environment and Climate Change Strategy (ENV; previously known as the Ministry of Environment) pursuant to the *Environmental Management Act* (EMA; SBC 2003, Chapter 53) for a short-term water management strategy to discharge treated mine effluent into Quesnel Lake via Hazeltine Creek. The most recent amendment of the Permit was granted April 7, 2017 for a long-term water management strategy to discharge treated mine effluent directly to Quesnel Lake. Section 3.2 of the amended Permit requires MPMC to develop and implement a Comprehensive Environmental Monitoring Plan (CEMP) for the Mount Polley Mine site and surrounding receiving environment that combines pre-existing monitoring programs into an integrated plan as follows:

> *"The Permittee must continue to develop, submit, and implement an ongoing Comprehensive Environmental Monitoring Plan (CEMP) to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas.*
>
> *The CEMP will consolidate and integrate all of the pre-existing monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.*
>
> *The CEMP must at minimum address a three year time span, as well as at a minimum include all sampling sites, frequency of sampling, variables to be analysed, method detection limits, sampling methods, sample analysis methods, and data analysis methods."*

The June 23, 2016 version of the CEMP was approved in the April 7, 2017 Permit amendment. Subsequently, in 2017, MPMC submitted several versions of a CEMP to ENV for review, however, a plan for 2017 was not approved. This CEMP covers the 2018 to 2020 time period and was developed based on the approved updated Terms of Reference (TOR) included as Appendix A. Based on the requirements of the permit, the next CEMP will be submitted in March 2020.

This CEMP is a unique and integrated monitoring plan that has been developed to capture a number of independent and interdependent monitoring programs, including; site monitoring, water discharge, *Metal and Diamond Mining Effluent Regulations* (MDMER) requirements, and Tailings Storage Facility (TSF) embankment breach response and remediation. Monitoring programs are normally developed by requirements of sector-specific regulations (e.g., MDMER of the federal *Fisheries Act* [Government of

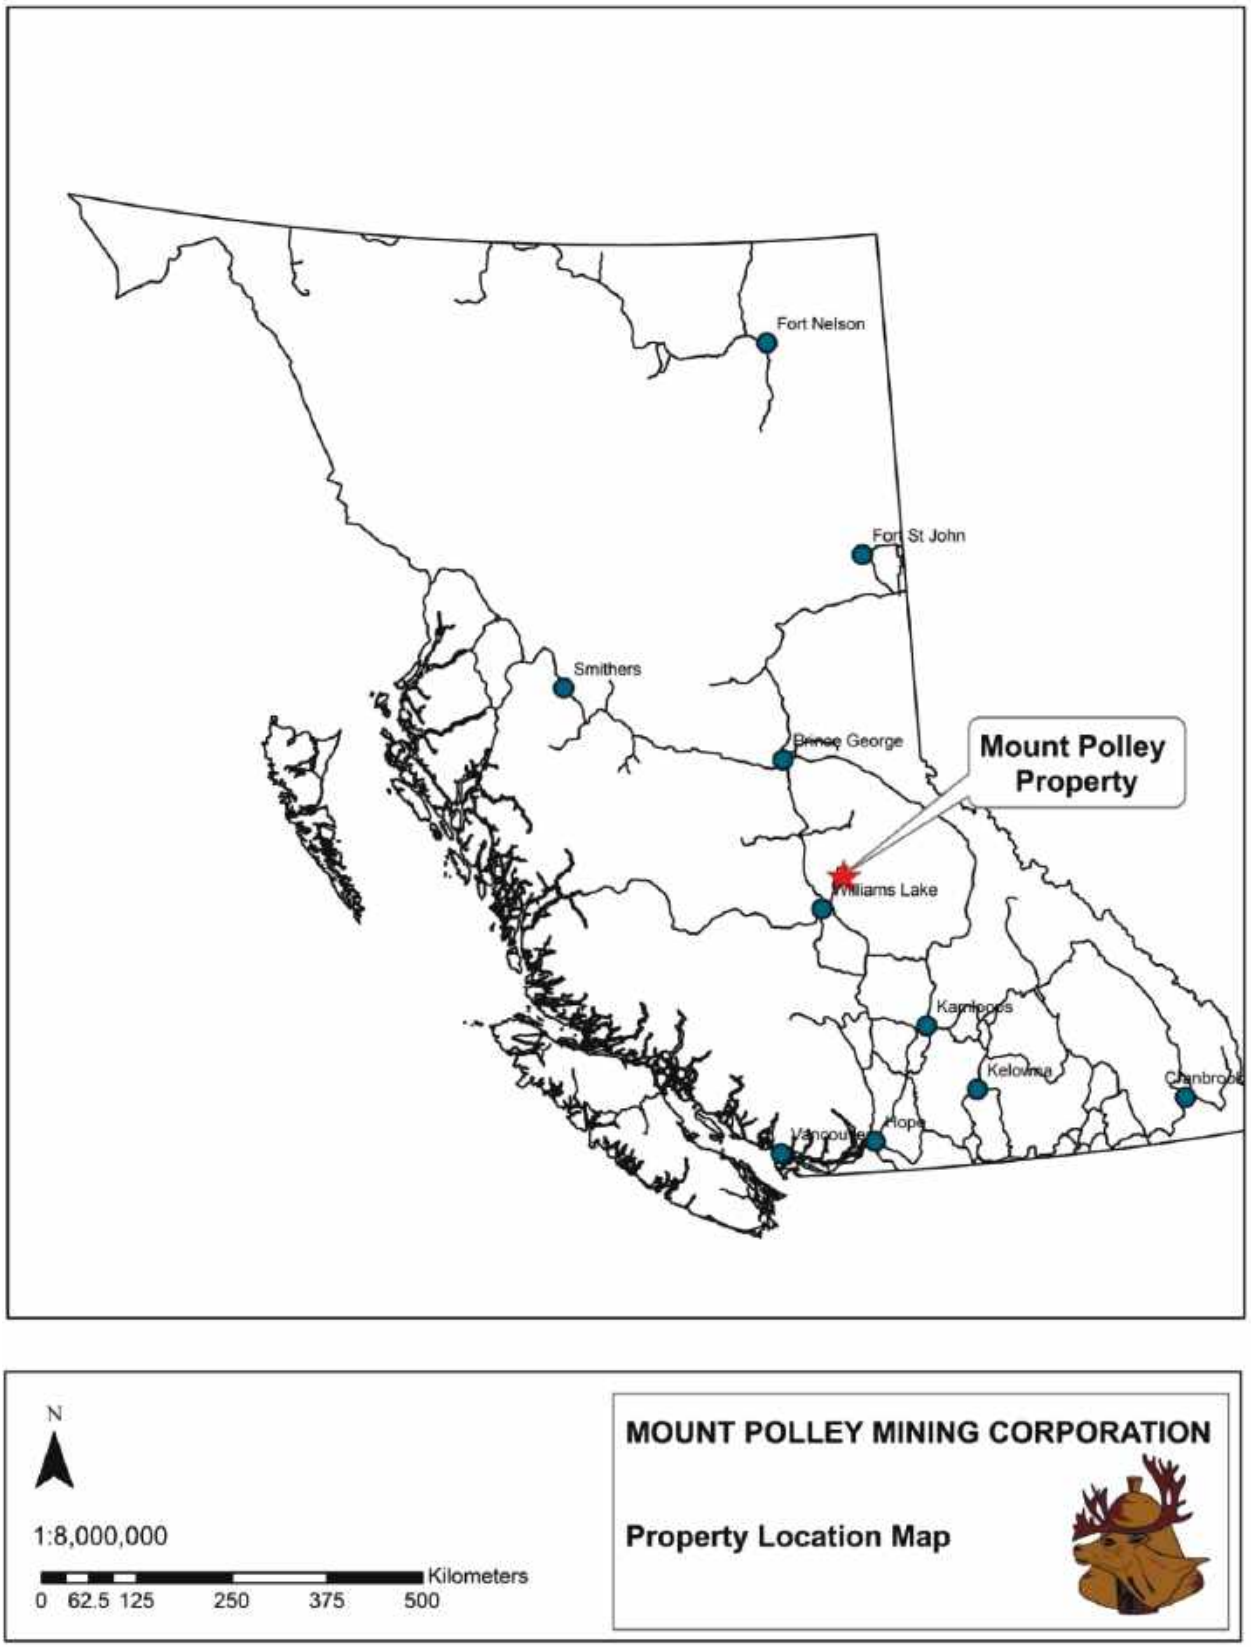

Figure 1.1 Mount Polley Mine property location

Canada 2018]) or by conditions in a permit with a specific monitoring plan that ties together permit-required and MDMER-required monitoring. As there is no ENV Technical Guidance document for this type of plan, this CEMP has been developed through an extensive consultative process that encompasses a number of permitting and other regulatory processes. Through these efforts, it has been suggested by various parties that all of the monitoring programs (e.g., water discharge monitoring, MDMER, TSF embankment breach response, etc.) be combined into one overarching program that takes advantage of the broader data set. This integrated monitoring plan offers the additional benefit of facilitating more efficient monitoring plan review by regulatory agencies, First Nations, and stakeholders. A constraint on this CEMP is where there are specific programs compelled by regulation such as the Environmental Effects Monitoring (EEM) Program that is required under the MDMER. In such instances, transparency of objectives and best efforts will be required to consolidate these different programs to the extent possible.

The CEMP is structured as follows:

- **Section 1:** Describes the CEMP objectives, a brief summary of the monitoring programs that have been integrated into the CEMP, and regulatory requirements.
- **Section 2:** Provides an overview of the integration of the various environmental monitoring programs being undertaken at the mine. Conceptual Site Models (CSMs) for the mine site and the TSF breach affected areas have also been provided, along with further details of the monitoring plans that have been integrated into the CEMP.
- **Section 3:** Provides an overview of First Nations and Stakeholders.
- **Section 4:** Provides a summary of the mine operations and the receiving environment.
- **Section 5:** Describes the environmental management practices in place, including water management.
- **Section 6:** Describes all monitoring components, including climate, surface water, hydrology, groundwater, contact water, seepage water, effluent, sediment quality, benthic invertebrate, plankton and chlorophyll *a*, periphyton, fish, wildlife, amphibian and reptile, soil, soil invertebrate, vegetation, and biosolids.
- **Section 7:** Describes the process for CEMP revisions and updates, along with a summary of changes made since the approved plan was submitted on June 23, 2016.
- **Section 8:** Summarizes relevant components of the post-TSF breach reclamation and remediation plans and interactions with CEMP components.
- **Section 9:** Provides an overview of the reporting of CEMP results.
- **Section 10:** Provides an overview of the future outlook.

The appendices attached to the CEMP are summarized below:

- **Appendix A:** Approved CEMP TOR (April 28, 2017).
- **Appendix B:** Contains the Detailed Study Designs for CEMP components, as referenced in document.
- **Appendix C:** Sample of Monthly Monitoring Schedule, which is a sample of the monthly environmental monitoring schedule provided to environmental department staff.

- **Appendix D:** Site Matrix, which describes all water sample locations in the CEMP, including site descriptions, site locations, access or safety concerns, and rationale for monitoring.
- **Appendix E** Declarations of Competency forms for Qualified Professionals contributing to the CEMP

1.1 OBJECTIVES

As specified in the Permit, the CEMP describes monitoring activities intended to support the evaluation of the potential for effects of mine-related activities on the physical, chemical, and biological characteristics of Bootjack Lake and Morehead Creek in the Springer Pit area, the Hazeltine and Edney Creek drainages, Polley Lake, Quesnel Lake, and Quesnel River, and associated riparian and upland areas. Specifically, the CEMP objectives are:

1. To evaluate if pollution[1] is occurring in the receiving environment as a result of the existing water discharge or mine-related activities;
2. To evaluate the environmental impacts of the August 2014 TSF embankment breach, to inform the rehabilitation plan, as well as to evaluate the effects of mitigation measures that are implemented as part of the rehabilitation strategy;
3. To integrate, to the extent feasible, the requirements of the MDMER; and
4. To inform reclamation and closure (*Mines Act* Permit M-200).

This CEMP includes monitoring of: effluent, surface water, groundwater, sediment, periphyton, plankton, benthic invertebrates, and fish in the aquatic environments; and soil, floodplain and upland vegetation, and wildlife in the terrestrial environments. Specific objectives for individual monitoring program components are stated in the subsequent sections. Supporting summary tables and maps are also provided.

Since the original integration of these plans and submission of the CEMP on March 31, 2016, many iterations of the CEMP have been reviewed, revised, and submitted in 2016 and 2017. Pre-existing monitoring plans that were integrated into the initial CEMP and have subsequently been revised within CEMP revisions (instead of individually) are:

- The *Monitoring Plan for Discharge of Treated Effluent to Quesnel Lake via Hazeltine Creek* (MPMC 2016a);
- The *Annual Monitoring Plan* for surface water and groundwater (MPMC 2015a);
- The *Biological Monitoring and Lake Sampling Plan* (MPMC 2015b); and
- The *Post-TSF Breach Monitoring Plan – 2015 Revision 1* (MPMC 2015c), which references the *Post Breach Fish Tissue Collection Plan – 2015* (MPMC 2015d) and the *Sampling and Analysis Plan: Detailed Site Investigation and Human Health and Ecological Risk Assessment* (Golder 2015a).

[1] Pollution as defined in the BC EMA (S.1(1)) means "*…the presence in the environment of substances or contaminants that substantially alter or impair the usefulness of the environment*".

Previous results were used to inform and structure this version of the CEMP and are summarized below in their respective sections or provided in Appendix B, as appropriate. A summary of results along with a discussion is provided in each relevant section. Throughout the CEMP, references are made to semi-x monitoring. This refers to monitoring that occurs twice per unit time, for example semi-annual monitoring indicates twice per year, and semi-monthly monitoring indicates twice per month.

It is expected that monitoring will be updated from time to time, consistent with an adaptive monitoring program (see Section 2.3). When changes are made to the monitoring, this amended plan (or relevant replacement pages) will be resubmitted to the Director and MPMC's Implementation Committee.

Work plans will be developed for all future monitoring programs and submitted to the ENV at least 30 days prior to commencing the program. These programs will be developed by a Qualified Professional (QP) and will consider linkages and dependencies with existing programs using previous data and review of the CSMs, which are presented in Section 2.2.

2 INTEGRATION OF MONITORING ACTIVITIES

The CEMP integrates environmental monitoring programs being carried out at the mine to meet multiple requirements which have different drivers and, therefore, objectives. Figure 2.1 shows the linkage between these drivers and associated monitoring objectives, as well as the resulting monitoring components that addresses those objectives. Further discussion is provided on these linkages in the sections following.

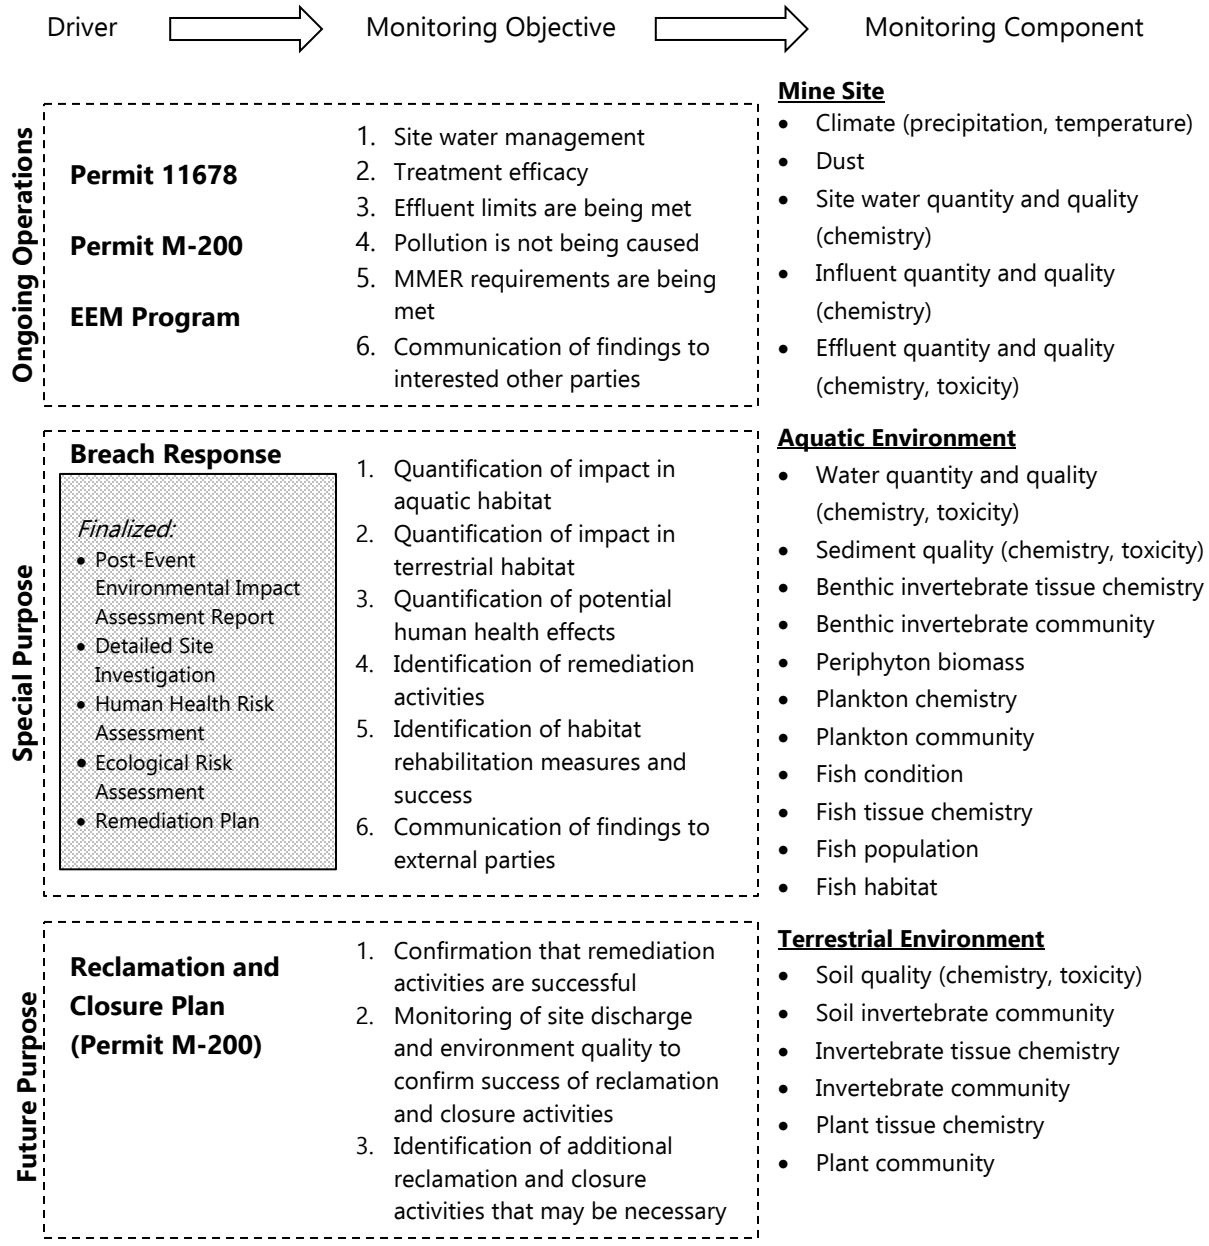

Figure 2.1 CEMP integration framework

2.1 MONITORING DRIVERS AND OBJECTIVES

There are three different drivers for current monitoring activities: ongoing operations, the TSF embankment breach response (special purpose program distinct from normal mine operations monitoring), and reclamation and closure planning (future purpose; note that some progressive reclamation has been done to date). These drivers and their associated monitoring objectives are described below. Previous monitoring results are continually reviewed to inform and structure the monitoring as well.

2.1.1 ONGOING OPERATIONS

Mount Polley Mine is an operational facility that is governed by provisions of the provincial EMA and *Mines Act* and the federal MDMER (a sector-specific regulation of the *Fisheries Act*). These permits and regulations contain specific requirements for on-going monitoring of site activities and downstream aquatic receiving environments. The objectives of ongoing operations monitoring are to:

1. Evaluate and plan for site water management.
2. Evaluate treatment efficacy to provide information for the ongoing management of the water treatment system installed at the time.
3. Verify that effluent limits are being met.
4. Verify that pollution is not being caused.
5. Verify that MDMER requirements are being met.
6. Communicate the findings to all interested parties.

Monitoring in accordance with conditions contained within BC *Mines Act* Permit M 200 is also summarized in the CEMP. This monitoring is only described in the CEMP for completeness purposes. Monitoring is summarized and future changes will be presented in CEMP revisions, but changes to this monitoring are subject to BC *Mines Act* Permit M-200 and not Section 7 in the CEMP or Section 5 in the CEMP TOR (Appendix A). This permit requires monitoring for metal leaching and acid rock drainage (ML/ARD) characteristics, water quality of on-site contact water (Section 6.11), and water quality of seeps from open pits and waste rock piles (Section 6.10). Permit M-200 also contains conditions related to reclamation and closure planning and monitoring. Results of monitoring conducted under the M-200 permit will continue to be reported annually, along with the monitoring results directed under the CEMP, in a combined AERR (Annual Environmental and Reclamation Report) that is submitted to ENV and the BC Energy, Mines, and Petroleum Resources (EMPR; formerly Ministry of Energy and Mines). Refer to Section 9 for information on reporting associated with the CEMP.

MPMC is also subject to the conditions of the BC *Water Sustainability Act* (which replaced the *Water Act* in 2016) that includes provisions related to sediment and erosion control and working around water. MPMC holds conditional water licences and is subject to Order 76930-40 following the TSF embankment breach, both of which were issued under the former *Water Act*.

2.1.2 SPECIAL PURPOSE

On August 4, 2014, a foundation failure of the Mount Polley TSF perimeter embankment occurred. ENV issued a Pollution Abatement Order (PAO) that specified the need for specific impact studies and monitoring to address impacts of the breach event, inform remedial measures, and evaluate changes over time. These studies are referred to as "special purpose" studies (now primarily monitoring) because they relate to a unique event with program objectives that differ considerably from an operating mine. The objectives of the special purpose monitoring are to:

1. Monitor and assess impact to aquatic habitat.
2. Monitor and assess impact to terrestrial habitat.
3. Monitor and assess potential human health risks.
4. Identify remediation activities needed to address identified impacts.
5. Identify habitat rehabilitation measures and related works as well as the success of those works.
6. Communicate findings of the impact assessment and ongoing monitoring to external parties.

2.1.3 FUTURE PURPOSE

As an operating mine, MPMC is required to plan for eventual closure. Reclamation and closure monitoring takes place after the closure plan is implemented. Although progressive reclamation and reclamation research have already been initiated at the site, the Reclamation and Closure Plan (RCP) continues to be refined during operations in preparation for closure and is not yet finalized. However, in the context of a CEMP, future monitoring needs are appropriate to start considering. Because this CEMP is intended to be an adaptive plan, these will be updated as reclamation and closure planning progresses and greater certainty of locations, measurement endpoints, etc. are available.

The objectives of the future monitoring program are to:

1. Confirm that mine site reclamation activities are successful in achieving their stated objectives.
2. Monitor site discharge quality and receiving environment quality as appropriate to confirm that reclamation and closure works have been successful in preventing pollution and that discharges are compliant with applicable requirements.
3. Identify additional reclamation and closure activities that may be necessary.

Additional and more specific objectives will be developed as the reclamation and closure planning process progresses.

2.2 MONITORING COMPONENTS AND CONCEPTUAL SITE MODEL

Figure 2.2 provides an overview of the Mount Polley Mine, in particular the CEMP study areas along with their respective monitoring components. Figure 2.3 and Figure 2.4 show greater detail of the TSF area and the mine site, respectively, of the sources of mine-contact water to the surrounding aquatic receiving environment and areas of ground disturbance. The measurement endpoints are detailed in the applicable sections later in this plan.

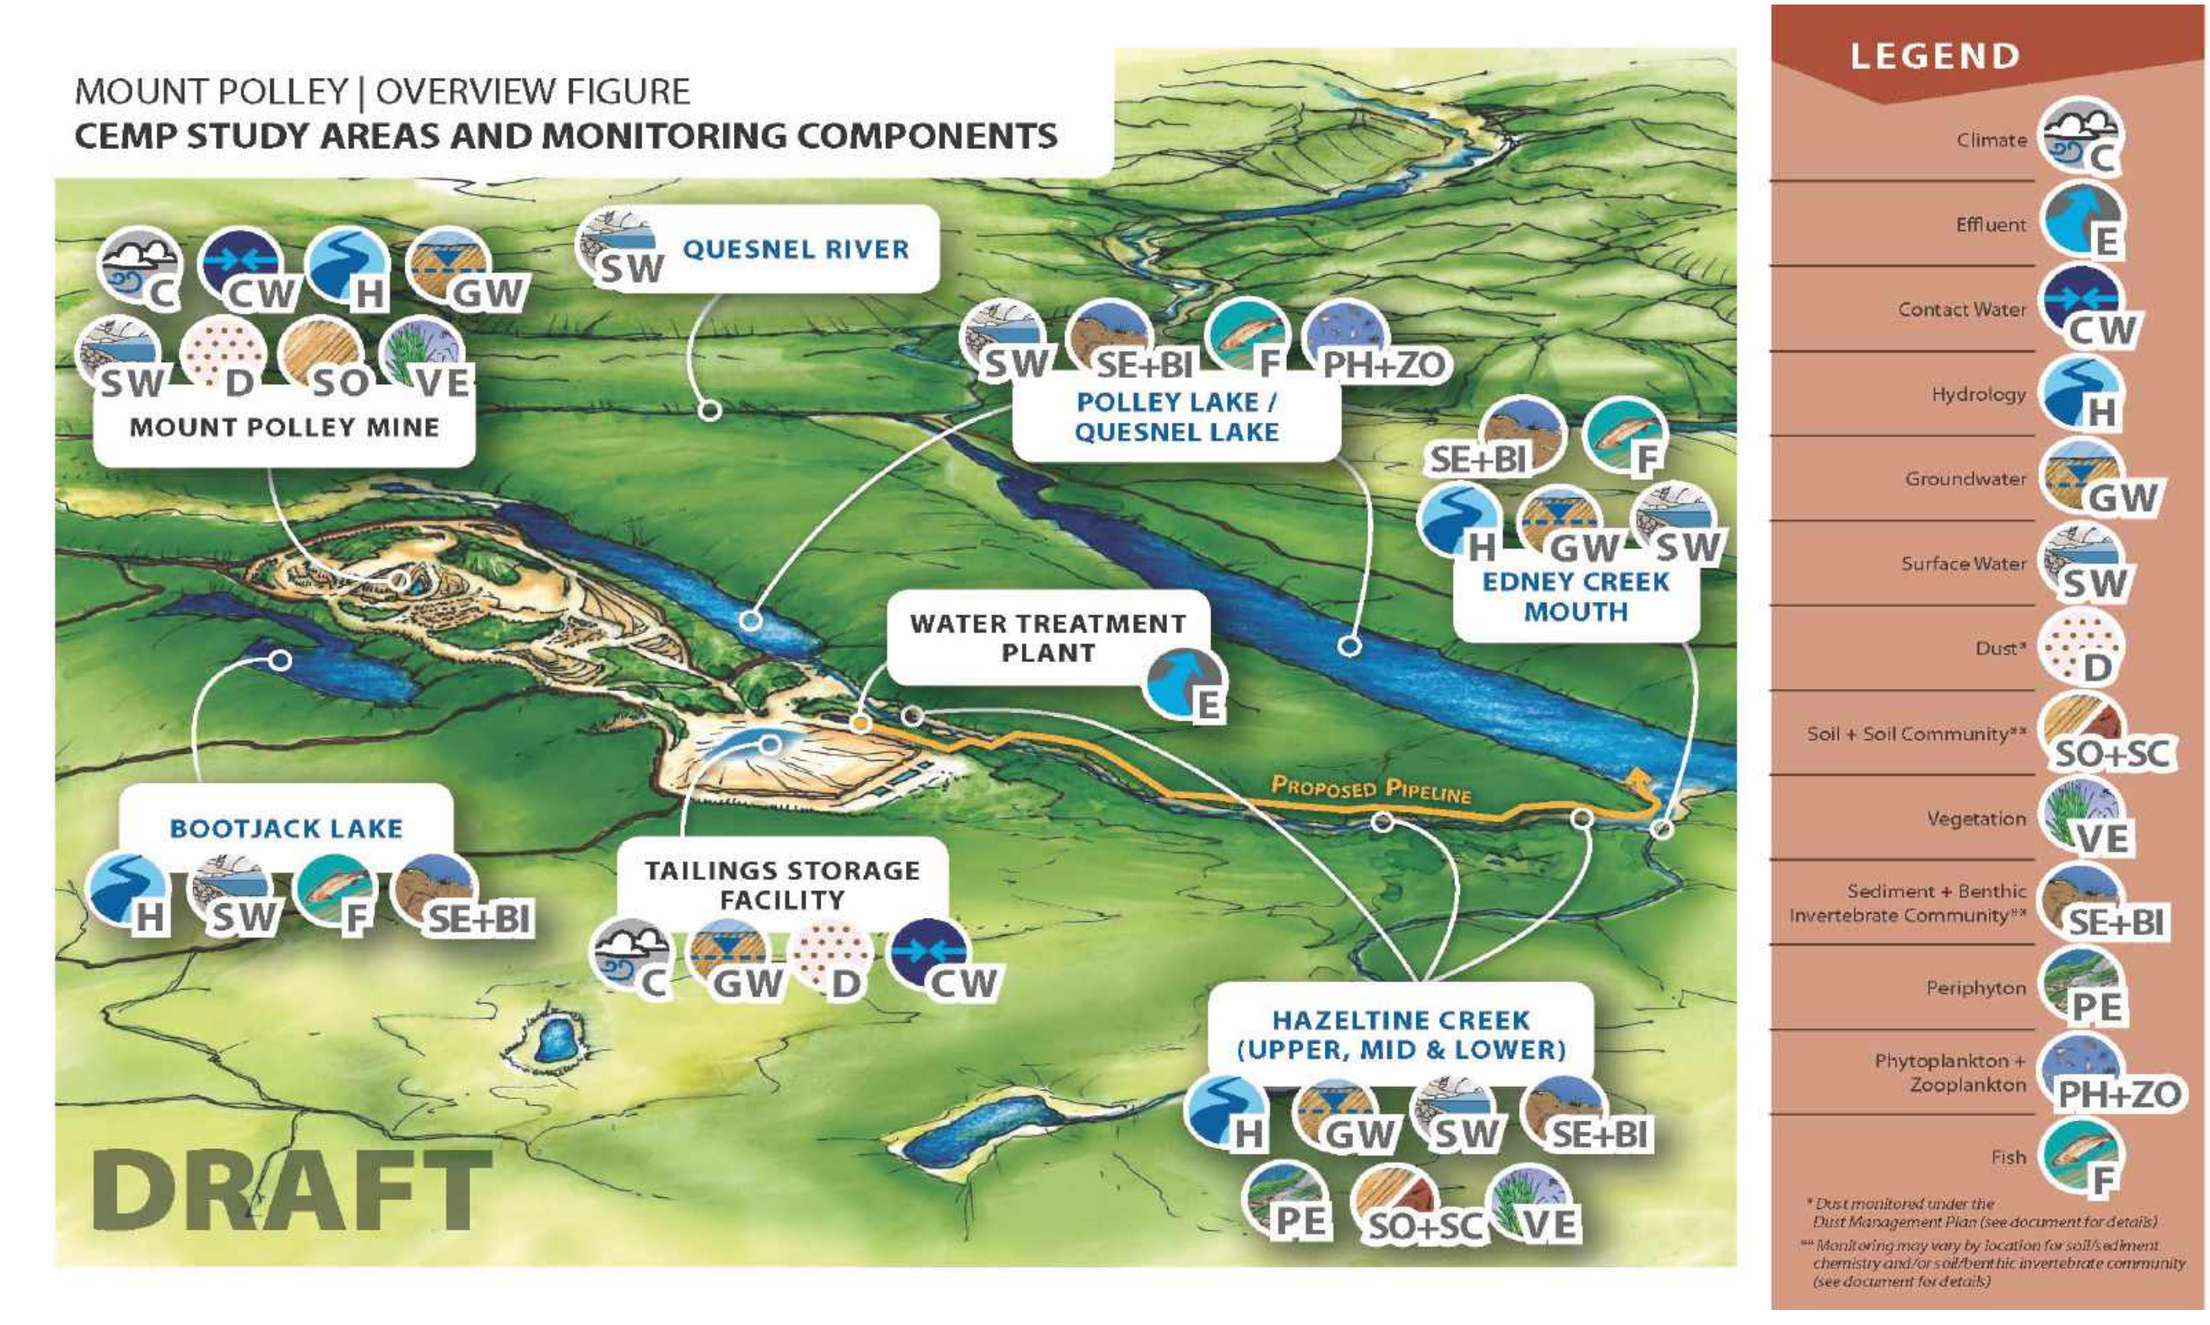

Figure 2.2 CEMP Study Areas and Monitoring Components

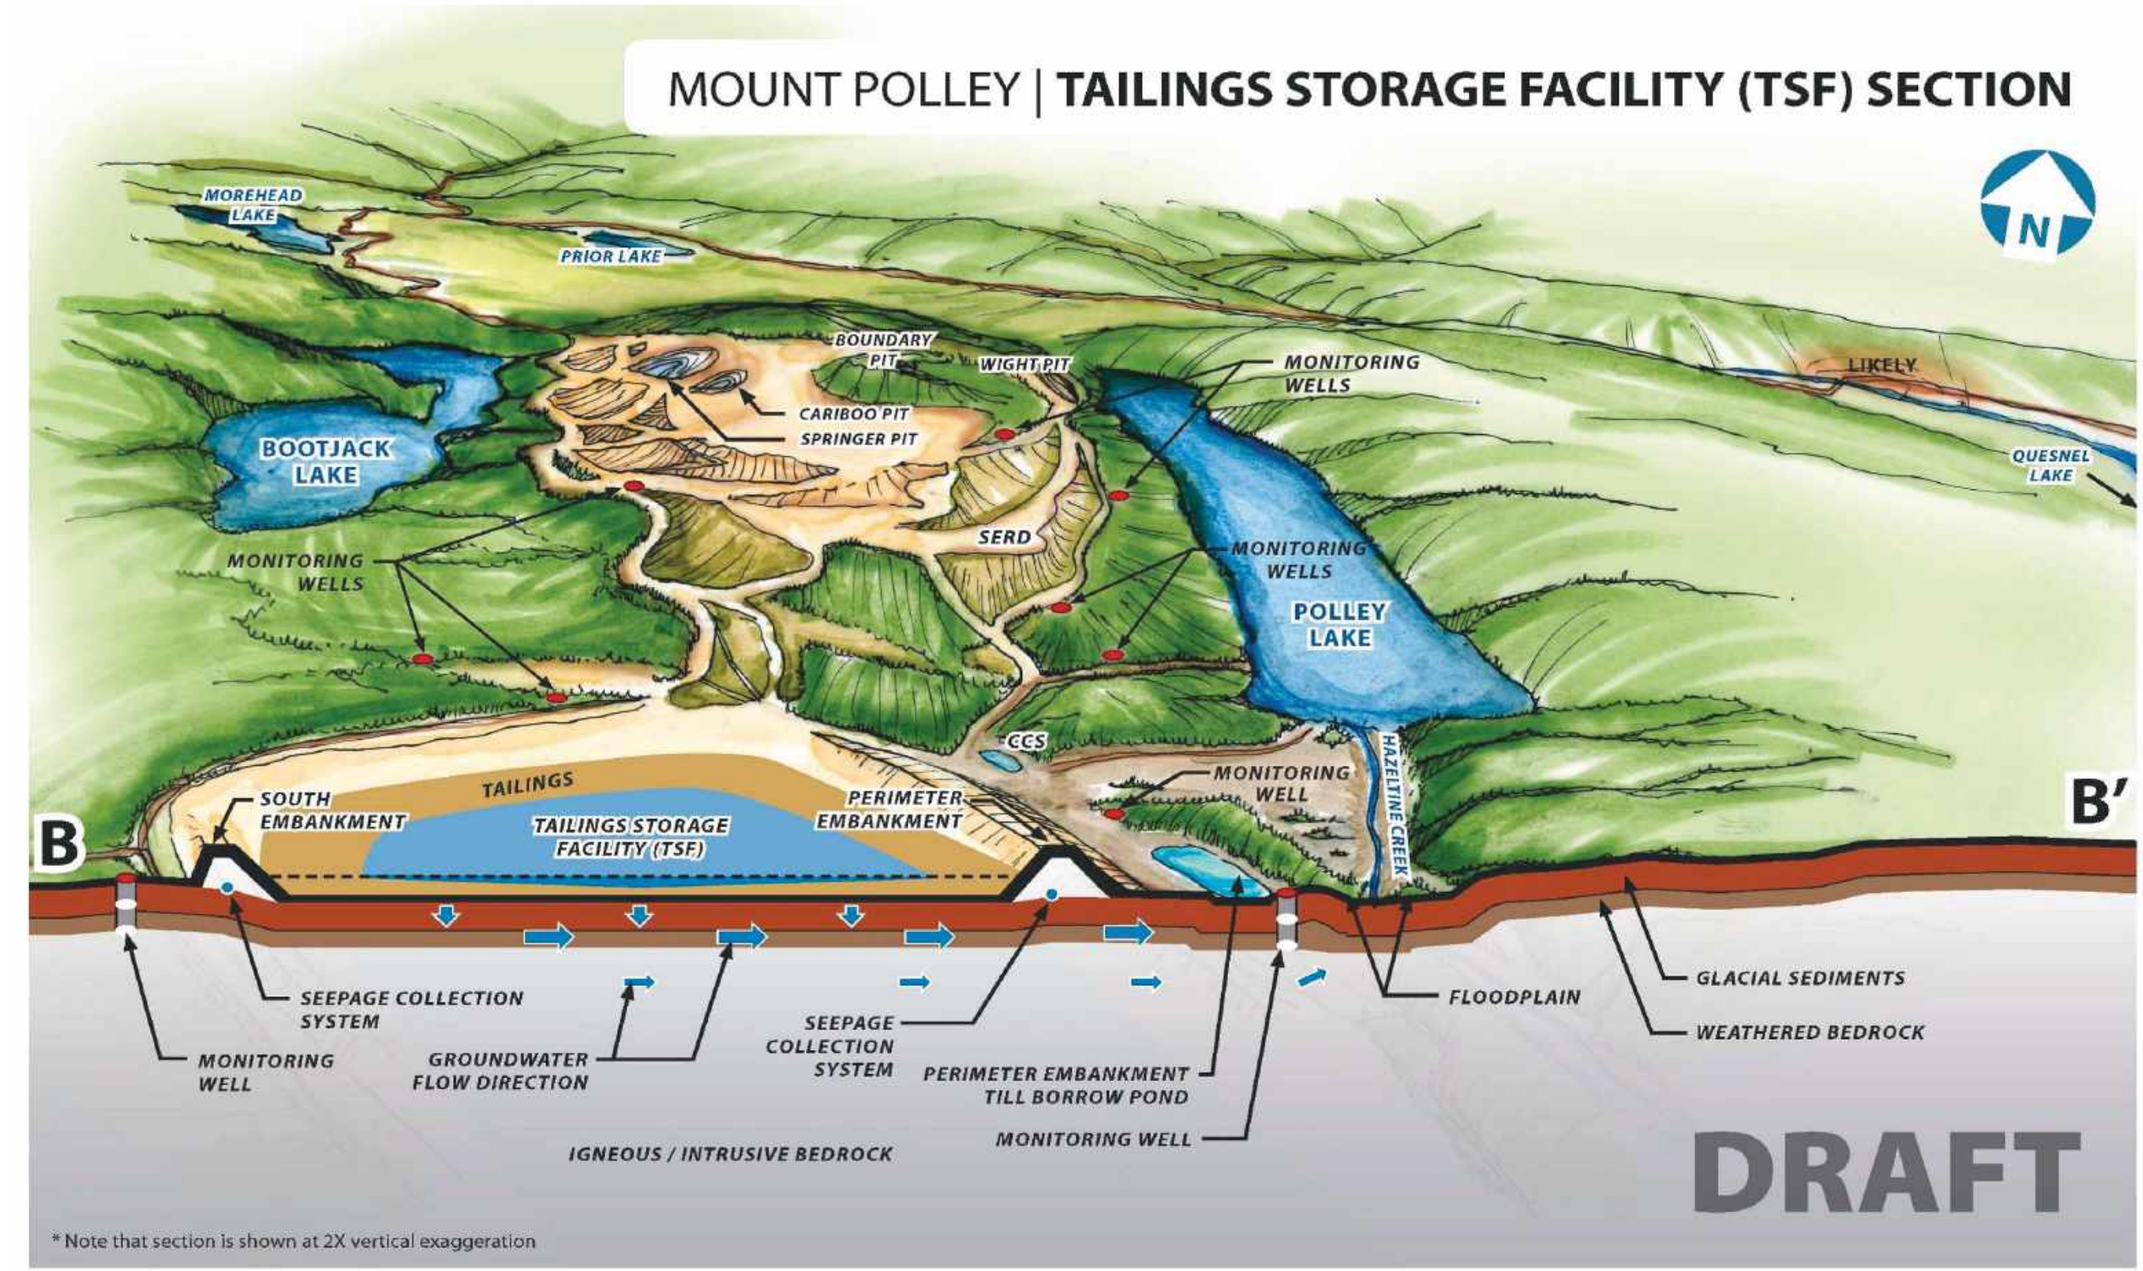

Figure 2.3 Tailings Storage Facility Section

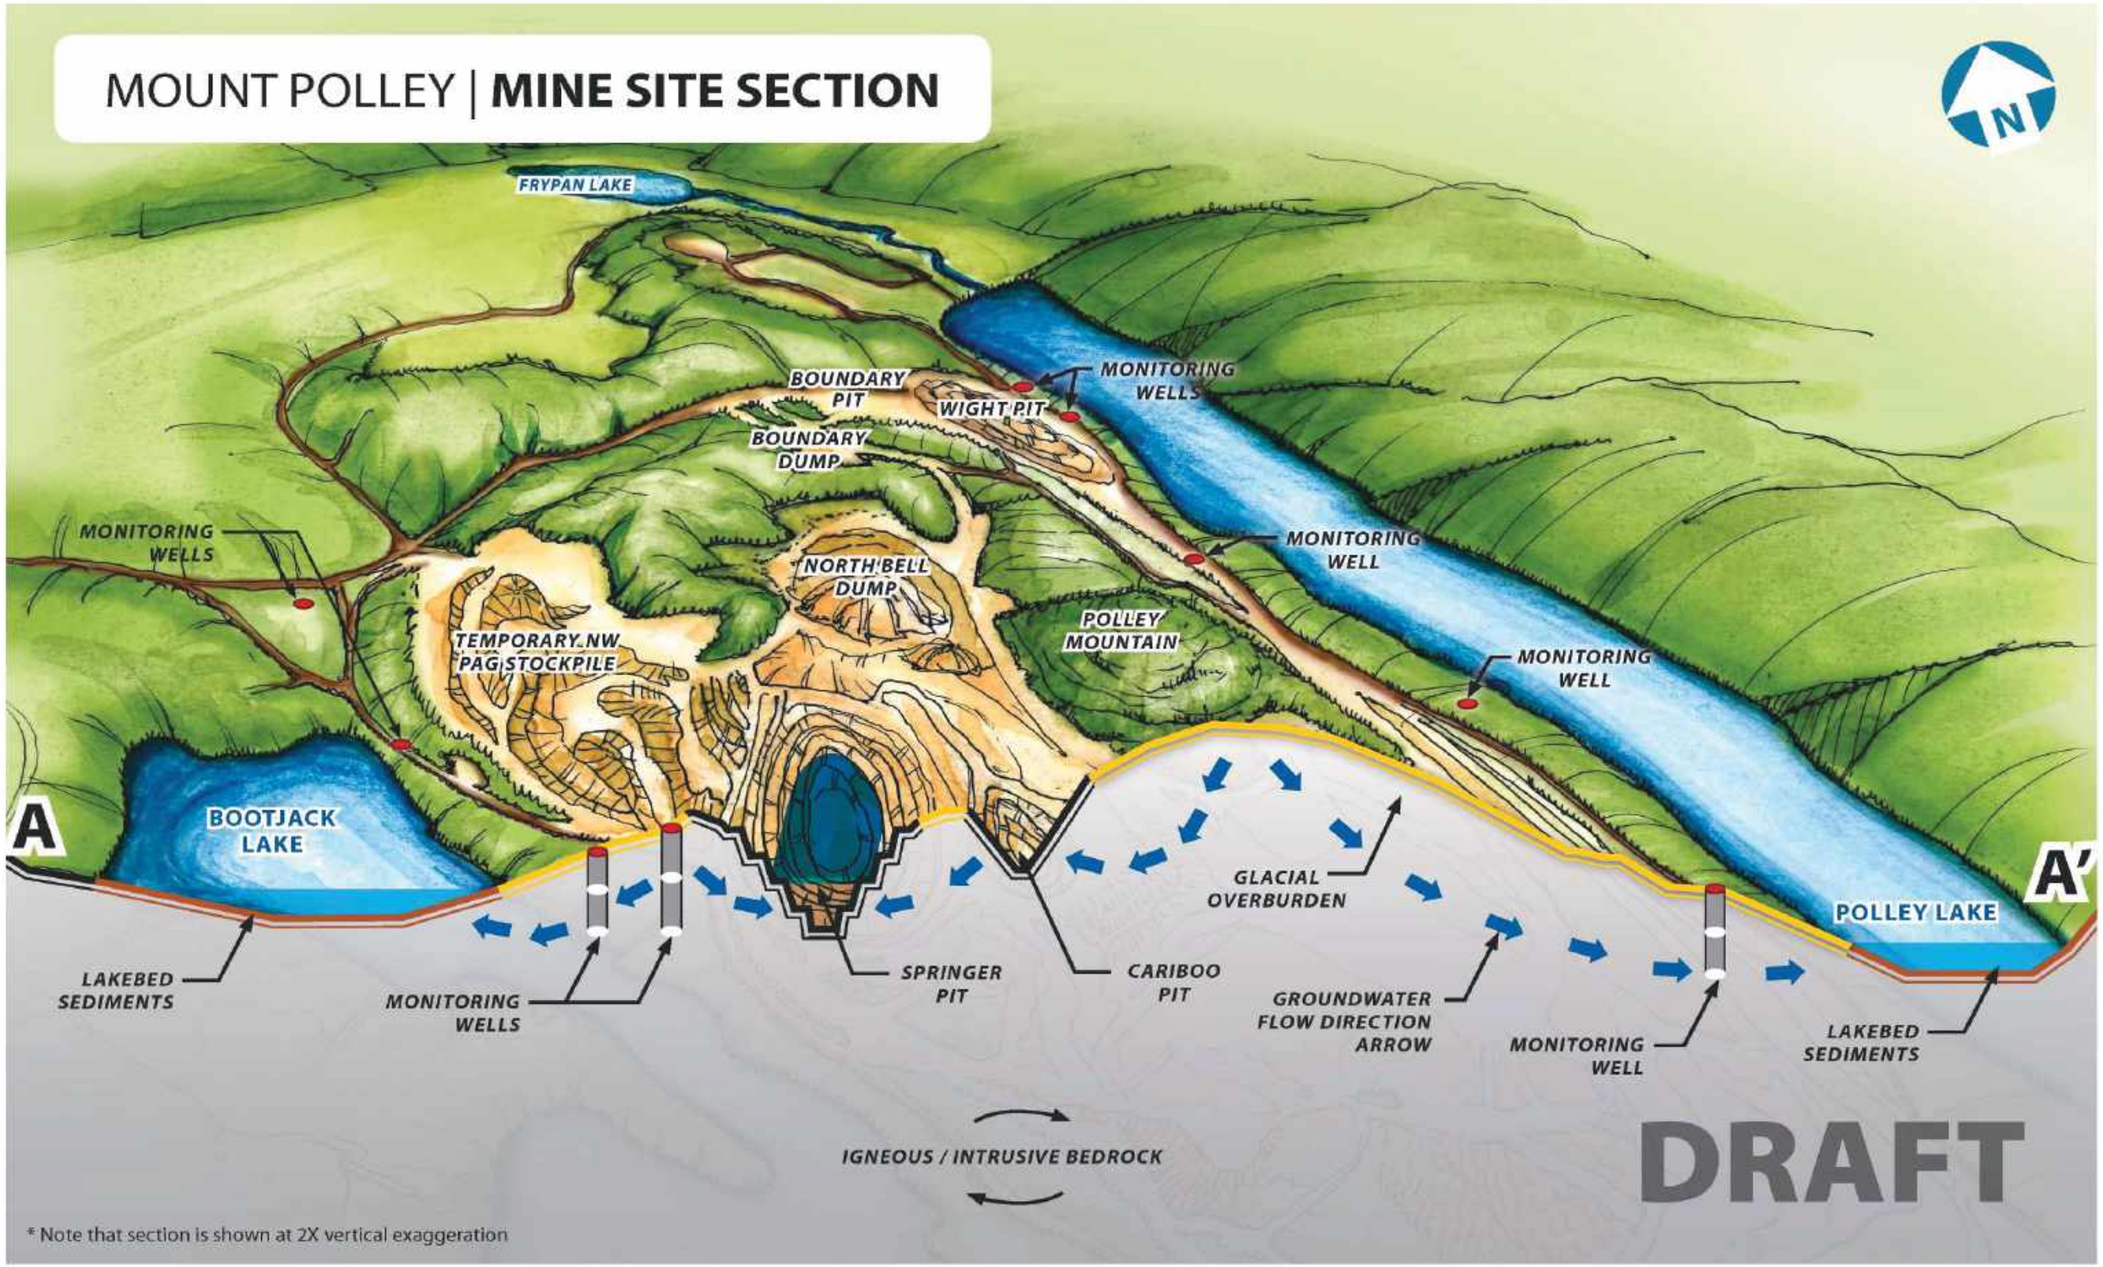

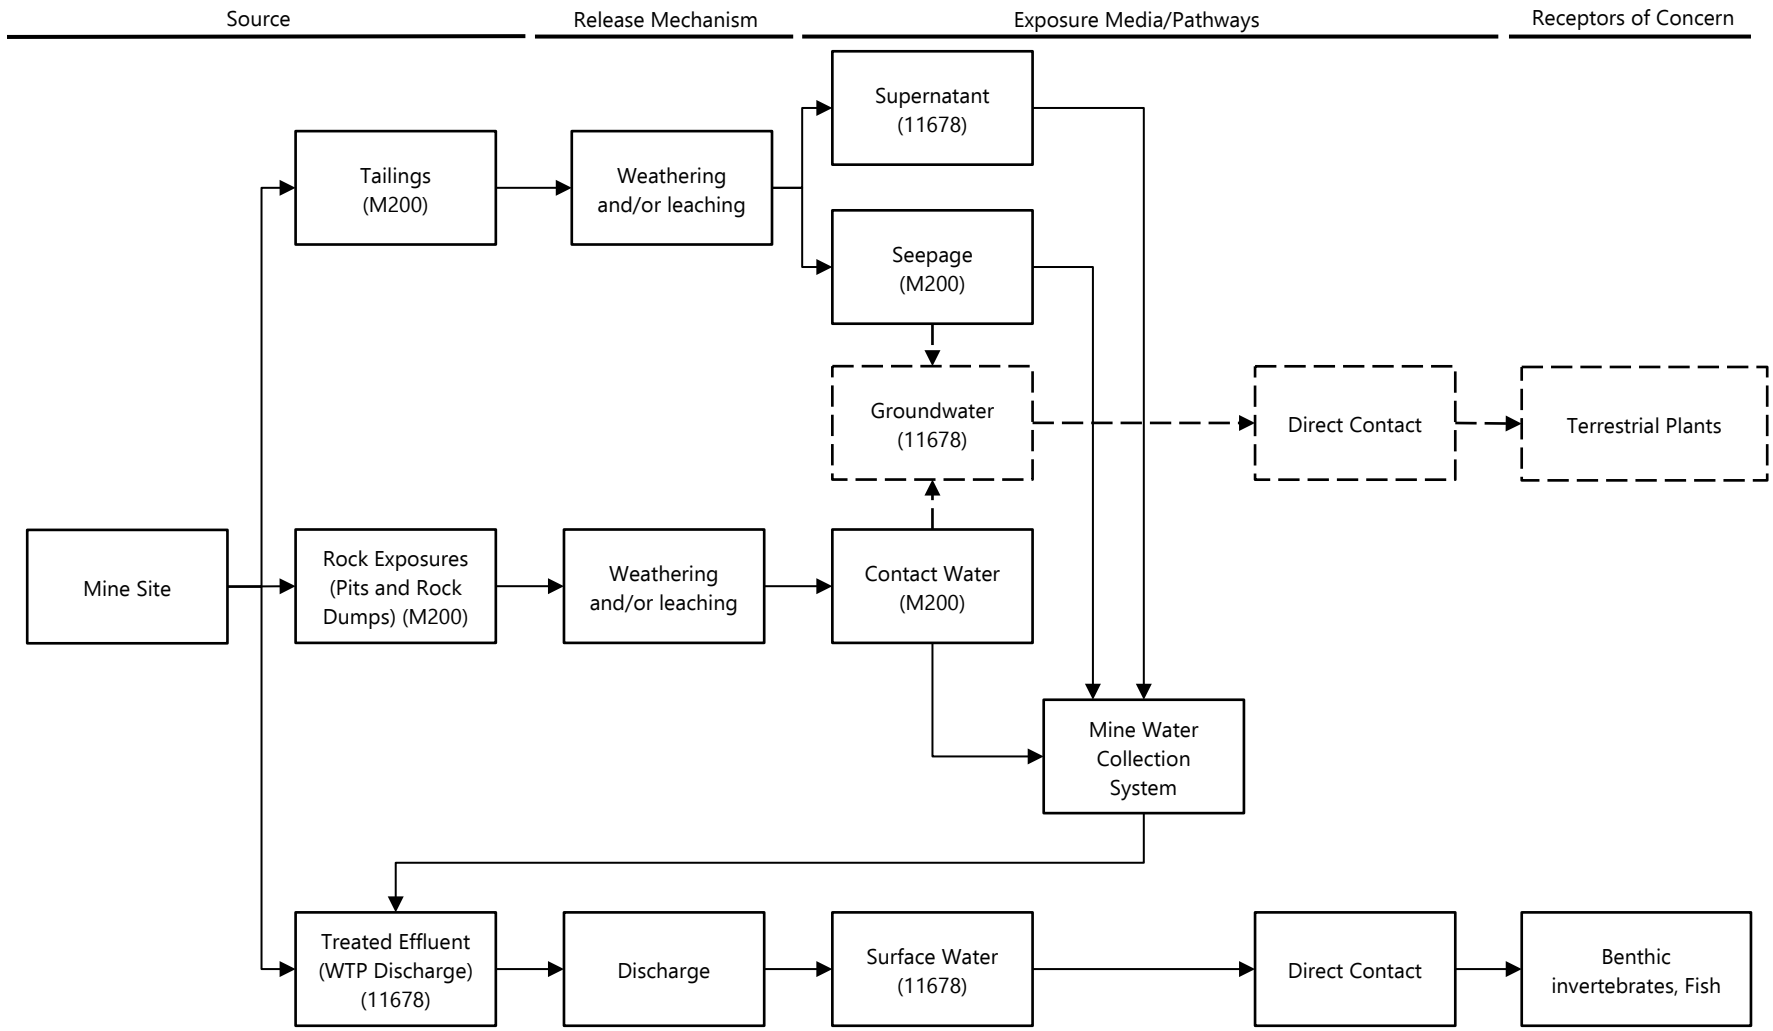

Figure 2.4 Mine Site Section

A CSM helps provide the basis for selecting appropriate monitoring components and suitable locations for those measurements. A CSM provides a graphical articulation of the understanding upon which the CEMP is based including movement of substances, pathways by which organisms (receptors) might become exposed to and interact with those substances in the environment. CSMs are often used in risk assessments to communicate similar concepts; however, in this CEMP, the focus of the study on specific constituents of potential concern (COPCs) has not been an objective because the monitoring program includes broader purposes and will include, for example, the full commercial analytical package for elemental analysis (frequently called "metals analysis"). Groups of substances that will be analyzed for, however, are those related to the potential sources. A CSM specific to the mine site was developed and is shown in Figure 2.5. A CSM for the TSF breach affected areas was developed for the Ecological Risk Assessment (ERA; Golder 2017) and is shown in Figure 2.6.

As discussed in Section 2.1.1, the mine has ongoing operational monitoring needs that centre on permit compliance that include management of site water and ultimately treated water discharges. The mine also needs to address disturbed ground through dust management in the short term. The measurable characteristics or components that contribute information to the stated monitoring objectives can then be identified as variables such as: precipitation and temperature (i.e., climate); dust; mine contact water, groundwater, and surface water quantity and quality; and influent and effluent quantity and quality. These are considered "Site" monitoring components (Figure 2.1). This information contributes to understanding the site water balance, function of site water collection systems, and management of the water treatment plant (WTP; e.g., capacity and treatment efficacy). This information is also useful in understanding the groundwater and seepage flow pathways to Bootjack and Polley lakes.

Ongoing operational activities at the site also have the potential to influence aquatic receiving environments related to effluent discharges. Under the long-term water management plan effluent is discharge from the WTP to Quesnel Lake. Relevant monitoring components for "Aquatic Habitat" include receiving water and sediment chemistry and toxicity, as well as biotic (e.g., plankton, benthos, fish) communities and tissue chemistry as summarized in Figure 2.1.

Following the TSF embankment failure in 2014, the environmental monitoring program was expanded to either incorporate additional monitoring components or increase the frequency of sampling. Many of the same existing operational monitoring components applied to this program and others were added. Additional measurements, related to physical impacts from the event, were collected to contribute to the Post-event Environmental Impact Assessment Report (PEEIAR) and to contribute to the Human Health Risk Assessment (HHRA) and the ERA. This "special purpose" monitoring information is relevant to the Remediation Plan for which an annotated table of contents has been submitted to ENV. As noted in the Risk Monitoring Considerations section of the ERA, further sample collection and evaluation of monitoring data will be done to further refine toxicity reference values for wildlife and confirm bioavailability of copper continues to be low and does not present a risk to wildlife.

Notes:
Solid lines indicate pathways that are likely to be complete or operative.
Dotted lines indicate pathways that are likely to be incomplete or inoperative.

Figure 2.5 Conceptual Site Model for the mine site

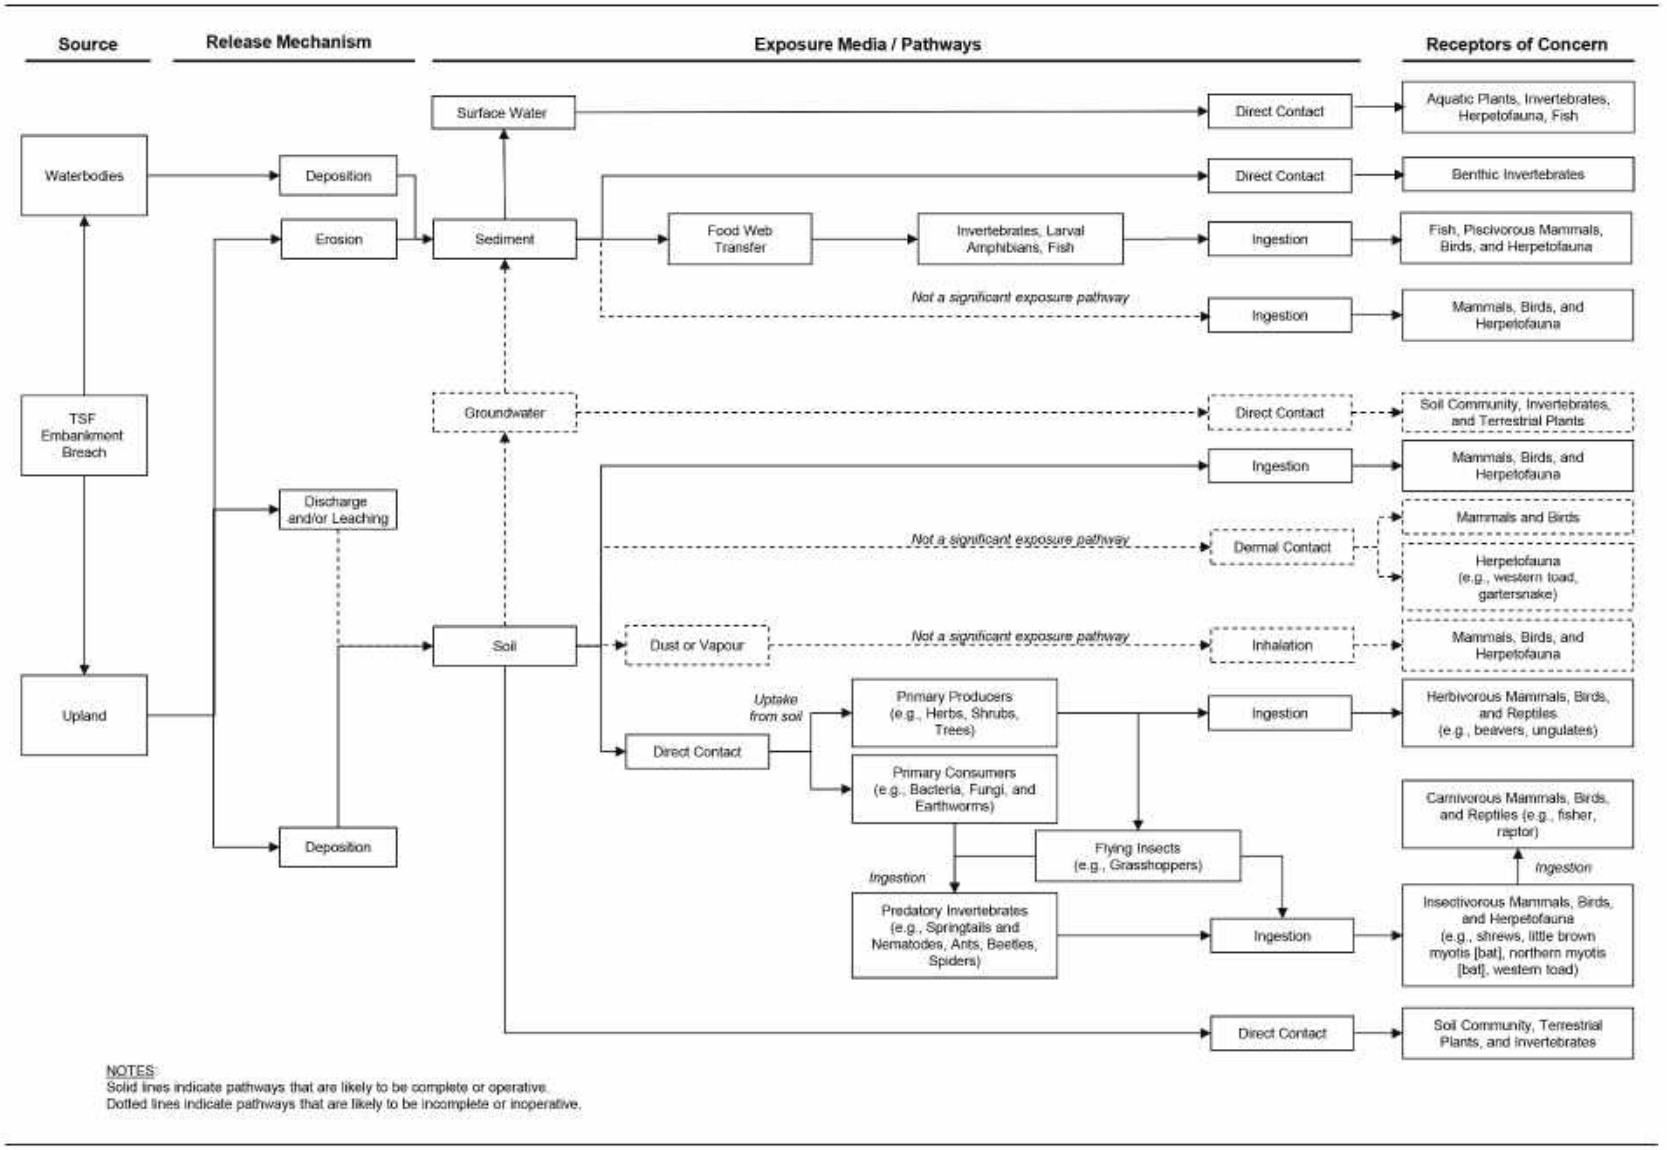

Figure 2.6 Conceptual Site Model for TSF breach affected areas, as developed for the ERA (from Golder 2017)

2.3 Adaptive Management Framework

The CEMP will be adaptive based on the results of ongoing operational and special purpose monitoring (illustrated in Figure 2.7) and based on the developing RCP. The adaptive framework recognizes that studies and monitoring can lead to new information that should be used to inform future monitoring. The framework provides feedback of this new information into the decision-making process that links monitoring and management actions that may need to be implemented to keep MPMC in compliance. For example, more immediate management actions may need to be undertaken in response to pre-defined triggers for unexpected changes in condition. The progressive implementation of the adaptive management framework will also include an annual review of the monitoring program to determine the potential need for revisions to planned sampling and analysis tasks. This review could include cessation of monitoring components that data show may no longer be necessary, or increase of monitoring based on changing conditions or monitoring results. Recommendations for monitoring related to the findings of post-breach-related studies have been included in this CEMP with the intention of forecasting monitoring that may be undertaken in the next three years. Monitoring for a specific year will be verified in monitoring program work plans following the adaptive management framework.

Figure 2.7 Adaptive Management Framework

3 FIRST NATIONS AND STAKEHOLDERS

3.1 FIRST NATIONS ENGAGEMENT

First Nations with recognized claimed traditional territory for the Mount Polley Mine are the T'exelc (Williams Lake Indian Band; WLIB) and the Xatśūll First Nation (Soda Creek Indian Band; SCIB). In 2011 and 2012, MPMC executed Participation Agreements with the WLIB and the SCIB, respectively. Through these respective Participation Agreements, Implementation Committees were formed to facilitate open dialogue between each of the First Nations and MPMC, providing a formalized and regular venue to discuss environmental, social, and economic matters related to mine development, operation, reclamation, and closure (e.g., mine updates, permitting, environmental protection, reclamation, employment opportunities, and potential joint ventures). Meetings with the WLIB have taken place since March 16, 2012 and since July 19, 2012 with the SCIB. Effective October 18, 2012, Joint Implementation Committee meetings have been held with representatives from MPMC, the WLIB, and the SCIB, replacing the previous MPMC/SCIB and MPMC/WLIB Implementation Committee meetings. Joint Implementation Committee meetings are held at minimum quarterly, but typically more frequently. These meetings and associated documentation (TOR, minutes, and action items) provide a well-defined, constructive forum in which issues, reviews, and comments relating to the current and anticipated future operations of the Mount Polley Mine may be discussed. This CEMP and the AERR will be provided in their current form to the SCIB and the WLIB for review, and discussion regarding any comments or concerns will be facilitated through the Joint Implementation Committee.

3.2 PUBLIC LIAISON COMMITTEE

The Public Liaison Committee (PLC) for the Mount Polley Mine was formed in 1999, and meetings have been maintained through the operating years of the Mine. Meetings were historically scheduled in conjunction with updates on proposed developments and projects, with a minimum frequency of one meeting per year. An annual PLC meeting became a requirement of the Permit in 2013 and quarterly meetings became a requirement in 2015. The PLC is intended to provide an opportunity for MPMC to share information about mine activities and the results of monitoring programs with its members, and for members to share such information with their respective membership. The PLC does not replace or diminish the use of other communication procedures that MPMC will use regularly to inform the public, including but not limited to: public meetings, newsletters, emails, and internet websites. The PLC is seen as a medium to add value to parties with interest in the Mount Polley Mine, including, but not limited to: MPMC and its personnel, the public and public interest groups, local communities, First Nations, and regulators.

3.3 COMMUNICATION PLAN

The Permit requires a Communication Plan between MPMC and the WLIB, SCIB, Cariboo Regional District, and the Community of Likely to be in place. The original Communication Plan was submitted to the Director (ENV Statutory Decision Maker) on March 20, 2016 and was approved by the Director on May 11, 2016. The amended Permit required that an updated Communication Plan be submitted by June 30, 2017. The final Communication Plan was submitted to ENV on March 20, 2016.

4 MOUNT POLLEY MINE PROJECT OVERVIEW

4.1 PROJECT HISTORY

Mount Polley Mine, operated by MPMC (a wholly-owned subsidiary of Imperial Metals Corporation), is an open pit copper/gold mine with an underground component, and has the capacity to process 20,000 to 22,000 tonnes per day (tpd) of ore. The Mount Polley property covers 18,892 hectares (ha), which consist of seven mining leases totaling 2,007 ha, and 43 mineral claims encompassing 16,855 ha, as of March 2018.

Clearing of the site and construction of the entire facility began in 1995, with the mill being commissioned in June 1997. In May 1997, the Mine received an ENV (known as the Ministry of Water, Land and Air Protection at that time) Effluent Permit, issued under the provisions of the provincial EMA. This permit authorized the discharge of concentrator tailings, mill site runoff, mine rock runoff, open pit water, and septic tank effluent to a tailings impoundment. Approval of the "Mount Polley Mine Reclamation and Closure Plan" by the EMPR resulted in the issuance of Permit M-200 in July 1997. The first full year of mining and milling at Mount Polley Mine took place in 1998. The mine suspended operations in October 2001 due to low metal prices, then reopened in December 2004 with mill production commencing again in March 2005. A summary of Permit 11678 amendments is provided in Table 4.1.

Table 4.1 Summary of Permit 11678 amendments

Date	Scope of Amendment
30-May-1997	Original permit
20-Oct-1997	Amended authorized tailings discharge rate (10,000 tpd increase)
12-Jun-1998	Amended reporting requirements
08-Sep-1999	Amended monitoring requirements
01-Feb-2000	Amended authorized tailings discharge rate (4,500 tpd increase)
07-Feb-2002	Approval to discharge effluent from the PESCP and MESCP; approval to store TSF supernatant and Mine Site contact water in the Cariboo and Bell Pits
04-May-2005	Amended authorized tailings discharge rate (5,000 tpd increase); discharge of groundwater to Polley Lake; updates to reference analytical procedures and monitoring program
17-Apr-2009	Amended monitoring, water level and supernatant characteristic requirements for the Cariboo and Bell Pits
07-Nov-2012	Approval to discharge to Hazeltine Creek
07-Jun-2013	Sulphate guidelines
09-Jul-2015	Tailings discharge to the Springer Pit
29-Nov-2015	Approval to discharge to Hazeltine Creek
04-Apr-2016	Discharge of additional tailings to the Springer Pit
09-Sep-2016	Hazeltine Creek discharge total suspended solids limit change
07-Apr-2017	Approval to discharge directly to Quesnel Lake

Notes: tdp: tonnes per day; PESCP: Perimeter Embankment Seepage Collection Pond; MESCP: Main Embankment Seepage Collection Pond; TSF: Tailings Storage Facility

As a result of a foundation failure of the perimeter embankment of the TSF on August 4, 2014 (see Section 2.1.2), the mine was placed in care and maintenance until August 5, 2015, when restricted operations under a short-term permit commenced. This restricted operations permit allowed processing of up to 4 million tonnes of ore over a one-year period, with tailings deposition into the Springer Pit.

The Mount Polley Mine became subject to the MDMER on April 10, 2014, following a planned discharge of mine effluent into Hazeltine Creek. The MDMER are also applicable to the long-term discharge approved for the Mount Polley Mine.

4.2 CURRENT OPERATIONS

MPMC was granted full restart permits on June 23, 2016 and has been operating at full capacity since June 27, 2016. The Mount Polley Mine site includes a crusher and mill (includes office spaces), a TSF, waste rock disposal sites, seepage collection ponds, haul roads, access roads, and various small buildings and storage areas (Figure 4.1). Concentrate is transported by truck from the site to the Port of Vancouver, where it is shipped to smelters overseas.

4.3 ENVIRONMENT

4.3.1 TOPOGRAPHY AND CLIMATE

The Mount Polley property is located on the eastern edge of the Fraser Plateau physiographic sub-division, characterized by rolling topography and moderate relief. Elevations range from 920 metres above sea level (masl) at Polley Lake to 1266 masl at the summit of Mount Polley. Volcanic rocks generally underlay this part of the plateau with inclusions of intrusive rocks. Most of the area is covered by a deposit of unconsolidated till which contains fluvial, lacustrine, and colluvial deposits. Some patches of organic soils are present in poorly drained areas (i.e., wetlands). The property is located in an alkali porphyry copper-gold deposit hosted in the Central Quesnel Belt along the Intermontaine Belt of BC.

The site is located within the Interior Cedar Hemlock biogeoclimatic zone. Local forests consist of Western red cedar, Douglas-fir, hybrid spruce, and subalpine fir, with a lesser presence of trembling aspen, black cottonwood, and paper birch. Much of the area has been harvested in commercial logging operations and is also used for cattle grazing.

Average annual precipitation in the study area is 670 millimetres (mm). Precipitation typically occurs as snowfall from November through March, with an average maximum of snowpack of 178 mm snow water equivalent occurring at the end of March (Golder 2015b). Average monthly temperatures at the Mount Polley Mine range from -6.0 degrees Celsius (°C) in January to 15.3°C in July and August (MPMC 2016b). Prevailing winds are from the north-north-east and from the south-south-west near the TSF, and from the northwest (and to a lesser extent the southeast) near the mill, with a predominance of winds designated as calm (below 3 metres per second; Golder 2015b).

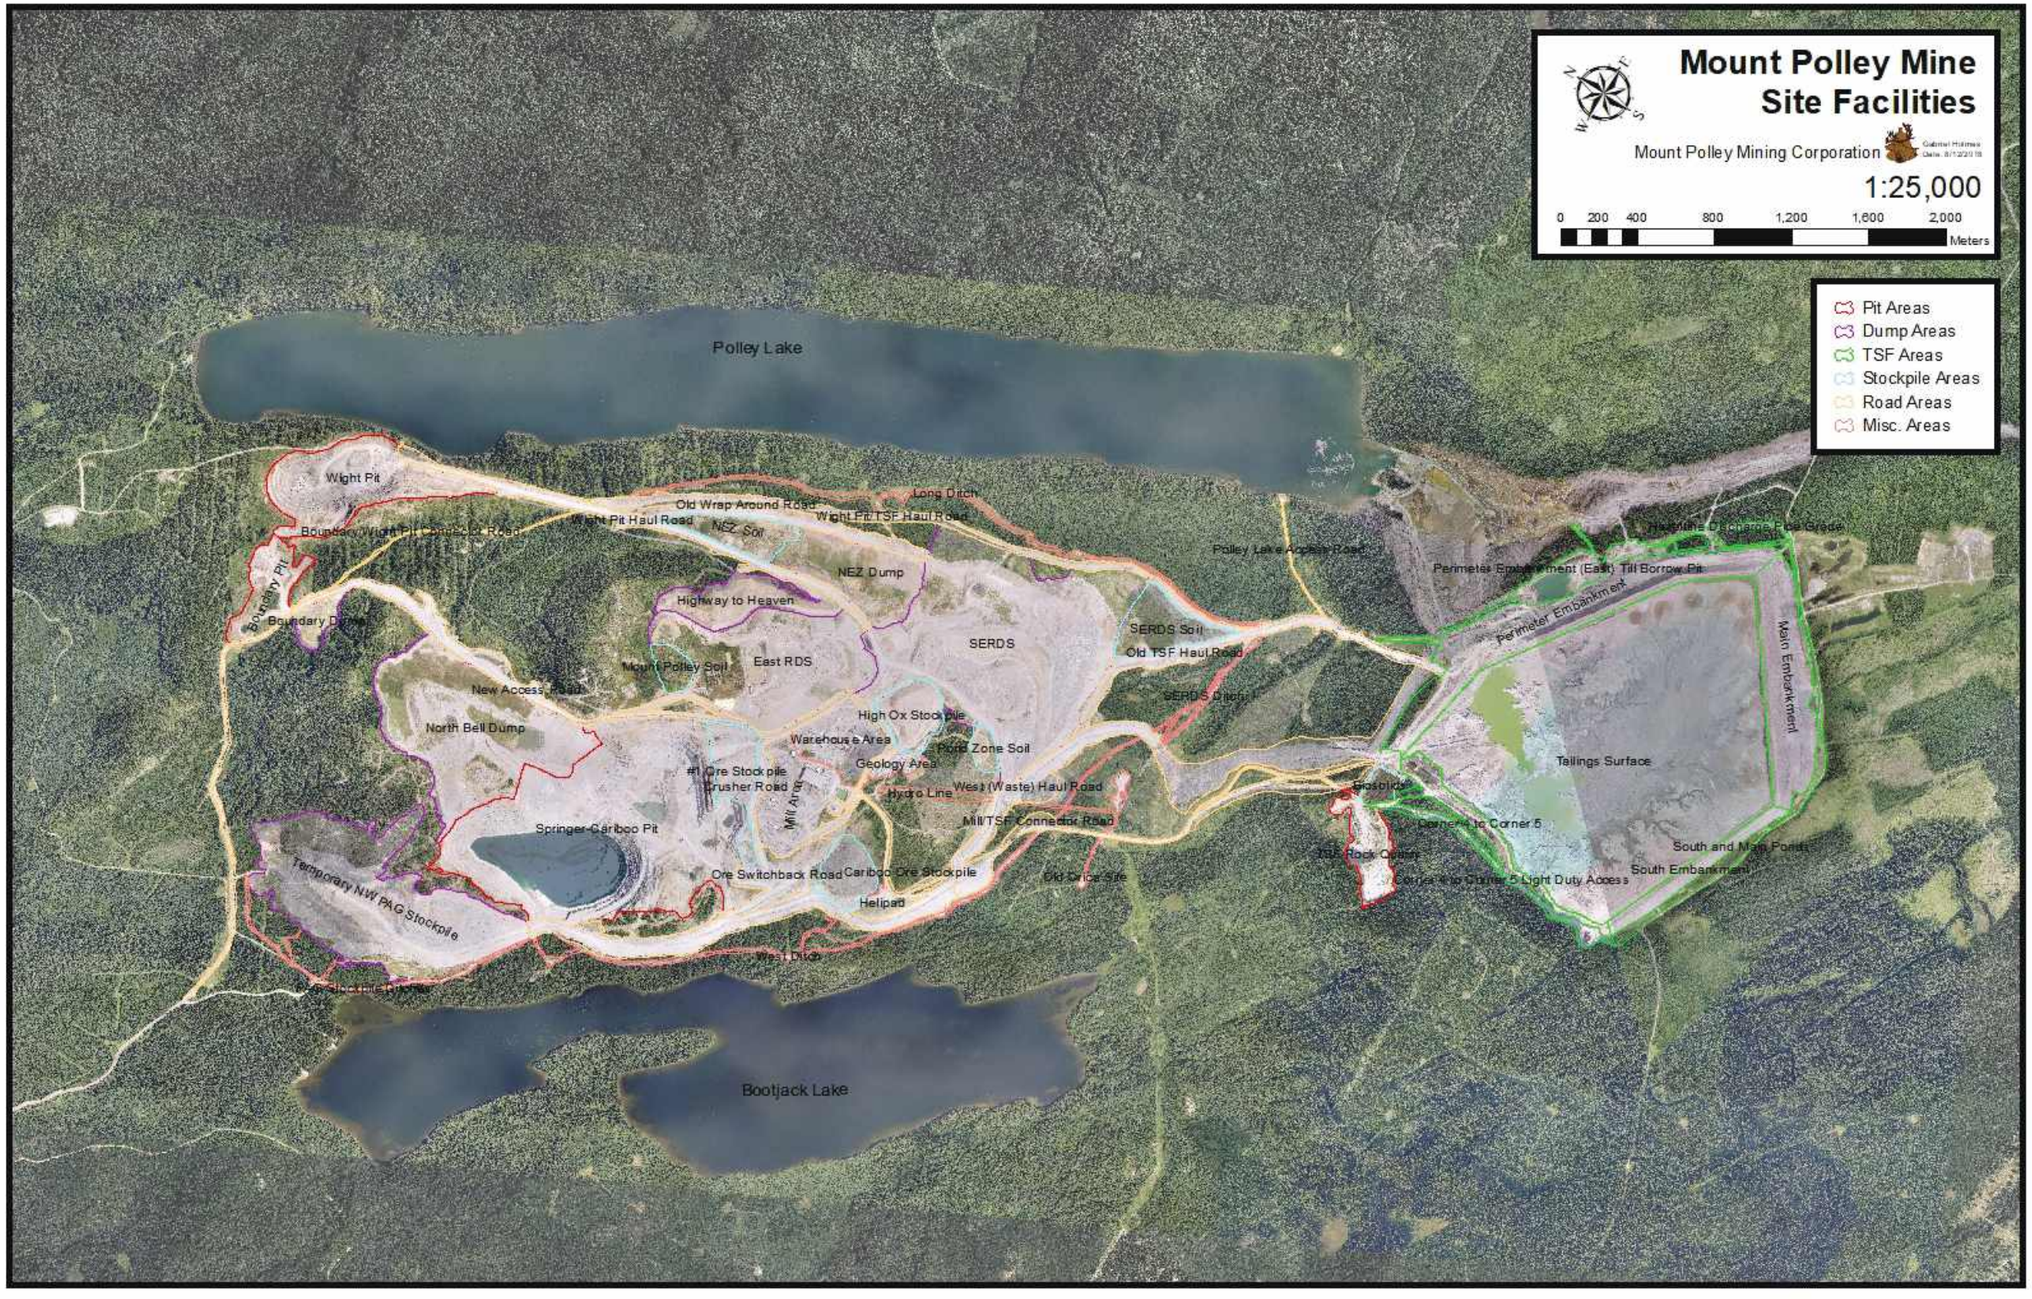

Figure 4.1 Mount Polley Mine site facilities

4.3.2 HYDROGEOLOGY

The groundwater flow at the site occurs primarily in the bedrock units in response to recharge from precipitation in the area between Polley Lake and Bootjack Lake. Flow in the overburden is less significant due to its limited thickness and discontinuous nature. Prior to mining, the water table at the site generally followed the surface topography, but the water table was deeper below the topographic heights and shallower in the low areas. At that time, the direction of groundwater flow was inferred to be from the top of the ridge between the Polley Lake and the Bootjack Lake towards the low lying areas associated with these lakes northeast and southwest from the ridge.

Mine dewatering has altered the groundwater flow pattern at the site, with the open pit and underground workings acting as sinks for groundwater flow. Mine dewatering lowered the water table elevation and created radial patterns of groundwater flow towards these facilities. Following the formation of the pit lake in the Cariboo Pit, seepage from this pit started to provide a contribution to groundwater inflow to the Springer Pit. At present, Springer Pit and Cariboo Pit continue to act as groundwater sinks. The currently available information suggests that some seepage from the Springer Pit lake towards Bootjack Lake occurred when the pit lake level exceeded 1030 m elevation in 2016 (Golder 2016b).

4.3.3 DRAINAGE AND HYDROLOGY

The mine is located on the divide of two sub-watersheds within the Quesnel Lake watershed. Quesnel is a large, deep fjord lake with a surface area of 255 square kilometres (km^2), and is composed of East, West, and North Arms. It is the deepest fjord-type lake in the world, with a maximum depth of more than 511 m in the East Arm (Laval et al. 2008). The West Basin is a shallower (113 m maximum depth) portion of the west arm that is demarcated in the east by a shallow sill near Cariboo Island that is approximately 35 m deep (Laval et al. 2008). The lake drains to the west via the Quesnel River to the Fraser River. The Horsefly River, Mitchell River, and Niagara Creek are the main tributaries to Quesnel Lake, entering from east of the sill.

The western watershed, which includes drainage from Bootjack Lake, Trio Lake, and Morehead Lake, discharges to Quesnel River via Morehead Creek and drained approximately 60% of the Mount Polley area prior to mine construction.

The eastern watershed includes Polley Lake (surface area of 3.8 km^2), which discharges to the east via Hazeltine Creek and then to the western arm of Quesnel Lake. The Hazeltine Creek and Edney Creek watershed areas at Quesnel Lake are currently approximately 30.2 km^2 and 87.4 km^2, respectively. Approximately 10.5 km^2 that historically reported to this watershed is now within the mine contact water runoff collection system catchment.

Bootjack Creek is a small tributary that previously flowed into Hazeltine Creek downstream of Polley Lake. Following the TSF embankment breach, Bootjack Creek was re-routed to Polley Lake; fish access is currently restricted. Historically, Bootjack Lake (surface area of 1.2 km^2) discharged into Hazeltine Creek via Bootjack Creek, but in 1913 a dam was constructed at the south end of Bootjack Lake and the flow direction was reversed in order to direct water into Morehead Lake for hydropower production. This resulted in 14 km^2

being diverted from the Hazeltine Creek catchment. The Morehead Creek watershed, including the Bootjack Lake catchment area, is approximately 11.2 km^2. Approximately 2.3 km^2 that historically reported to this watershed is now within the mine contact water runoff collection system catchment.

Pre-mining watersheds are shown in Figure 4.2. In general, the hydrology of the Mount Polley area is snowmelt driven, with the majority of annual runoff occurring in April and May during snowmelt (i.e., freshet; Knight-Piésold 2014).

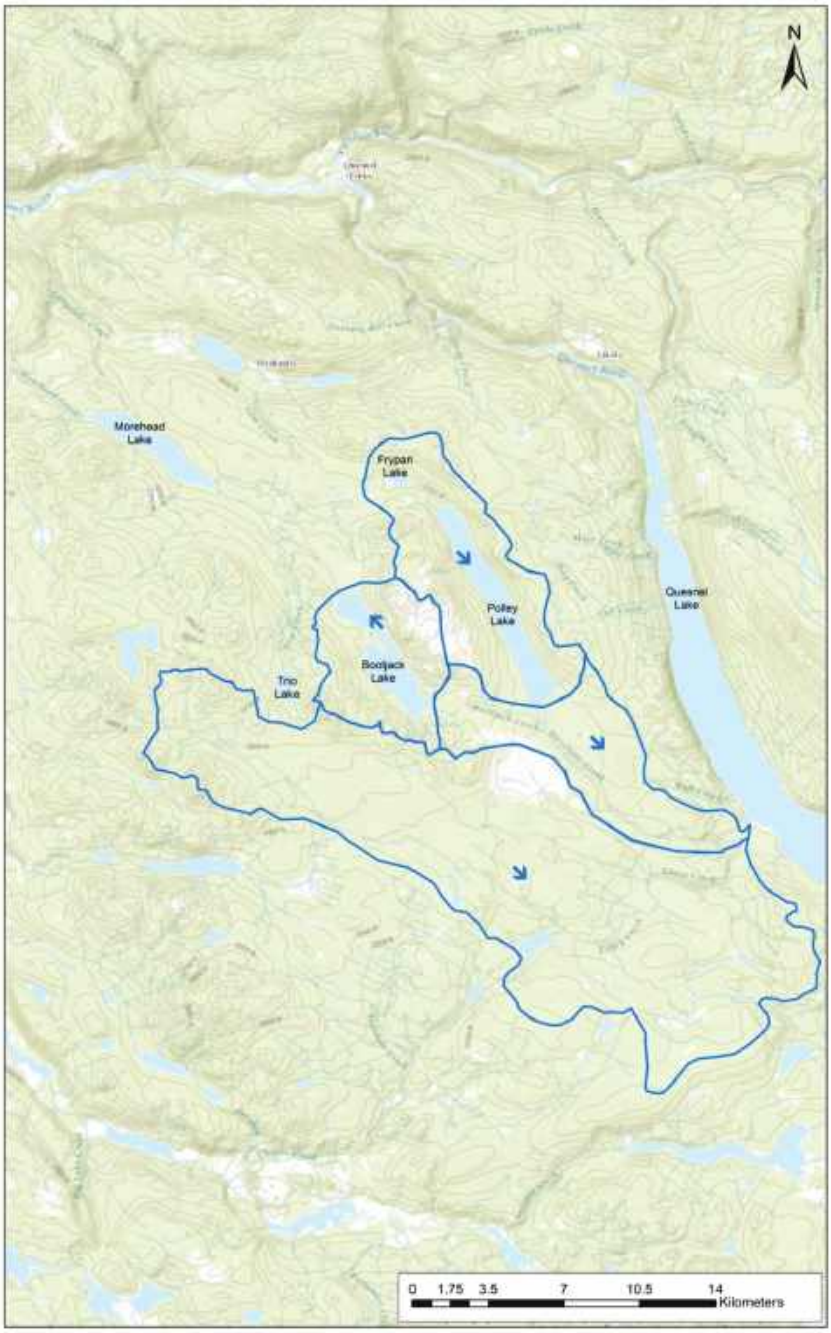

Figure 4.2 Mount Polley area pre-mining watersheds

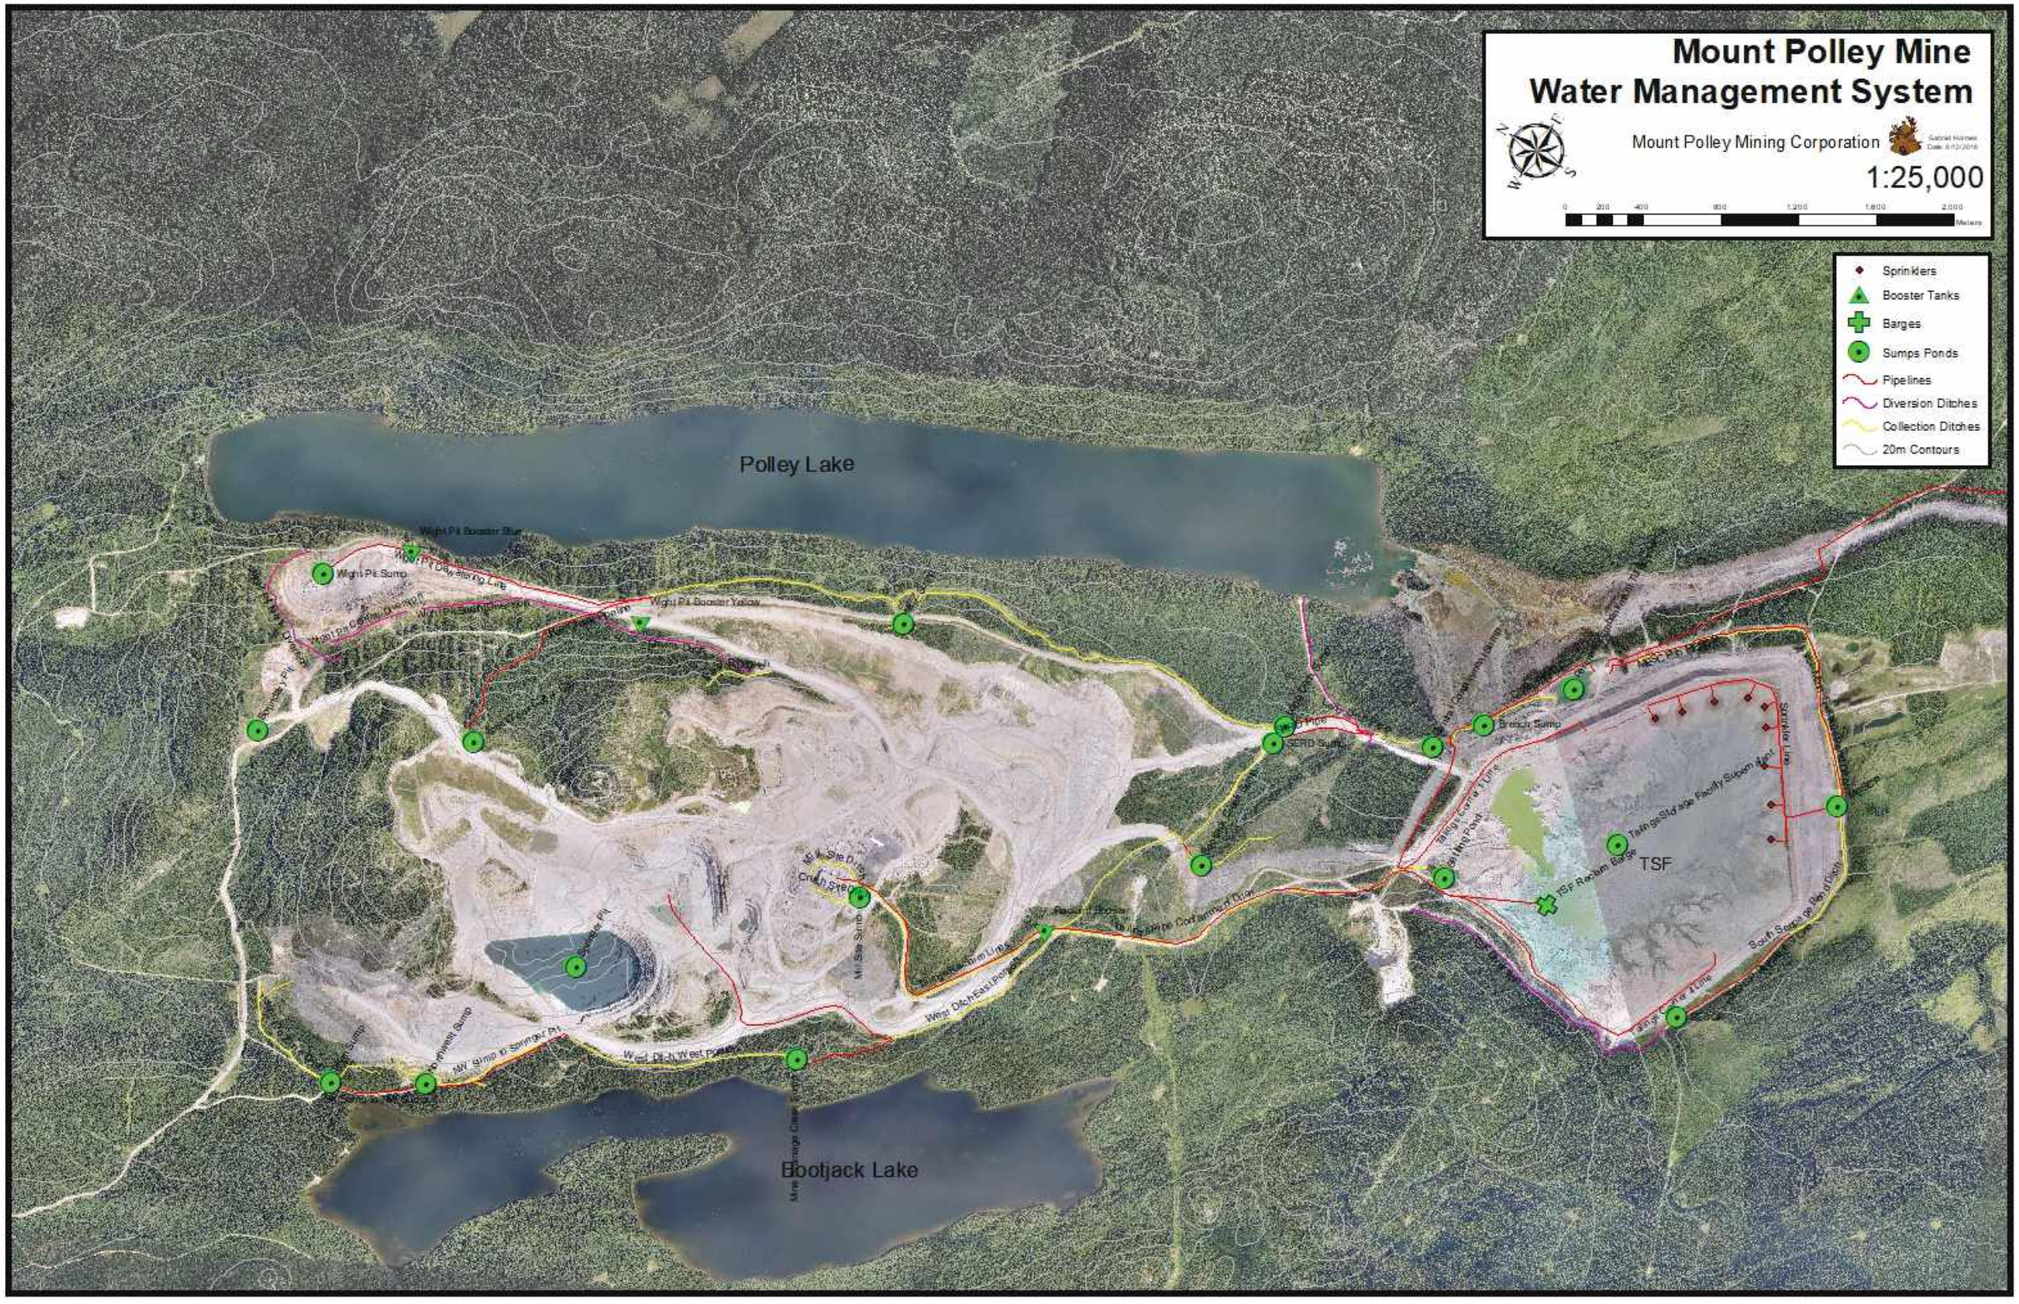
5 ENVIRONMENTAL MANAGEMENT

5.1 WATER MANAGEMENT

To protect natural watercourses from mine-influenced contact water from roads, haul roads, waste rock piles, and other Mine areas, water is collected in a system of ditches and sumps located around the Mine site. Based on site water management objectives, site contact water is either pumped directly to the TSF or reports to the gravity-driven sections of the West Ditch or Long Ditch, the latter two of which both flow to the Central Collection Sump (CCS). Water in the CCS is currently allowed to overflow to the Perimeter Embankment Till Borrow Pond (PETBP) where it is pumped to the WTP or can be returned to the TSF. Pumping infrastructure also exists at the CCS such that it can be directed to the TSF. Water from the TSF is primarily pumped to the Mill via the Booster Station to meet process requirements, but can also be diverted to the CCS. A map of water collection infrastructure, including site collection ditches (including flow direction) and sumps, is shown in Figure 5.1. All water, primarily rain and snow melt, ultimately reports to the PETBP from which it is pumped to the WTP. At the time of writing, any contact water that requires temporary storage on site (i.e., when flows exceed those able to be treated and discharged) is pumped to the TSF. Tailings and process water from the Mill reports by gravity from the Mill to the TSF.



The Mount Polley site has a positive water balance, and a permit for a long-term water discharge system was received on April 7, 2017. Treatment is conducted for removal of suspended solids and associated metals using a Veolia ACTIFLO® system, which is described in detail in Section 5.1.2. Under the long-term water management strategy, treated mine effluent is discharged to Quesnel Lake via a direct pipeline to the submerged diffusers installed in the lake. A continuous discharge of up to 0.6 m^3/s, with an annual average of 0.33 m^3/s is currently permitted until December 31, 2022.

5.1.1 ANNUAL DISCHARGE PLAN

Permit 11678 requires the yearly submission of an Annual Discharge Plan (ADP). The intent of the plan is to identify the specific sources and quantities of water that will be discharged; however, the discharge system (which is described in Section 5.1.2) at Mount Polley is not designed to be able to solely discharge from specific sources and it is not realistic for MPMC to estimate the volumes of precipitation that will occur from year to year. The overall water management at the mine is described in detail in the Long-Term Water Discharge Technical Assessment Report (TAR) that was submitted to ENV October 17, 2016 (Golder 2016e).

5.1.2 DISCHARGE SYSTEM

The WTP sources water from the PETBP. During treatment, the feed water of the WTP undergoes suspended solids removal using Veolia ACTIFLO® water treatment technology. The WTP doses the raw water with coagulant to a tank where a polymer is injected to create floc particles. Microsand is added to ballast the flocculants, which move on to another tank that allows them to swell and mature. The water flows to the next stage, which uses lamella to clarify the water and promote fast settling of the microsand ballasted sludge. The clarified water is discharged and the sludge is separated from the microsand, which is reused.

An on-line turbidity meter measures the turbidity every ten seconds, where the WTP human-machine interface calculates the total suspended solids (TSS) using a calibrated factor based on a site-specific correlation between turbidity and TSS for the treated effluent. If the calculated on-line TSS is greater than 13 mg/L for 10 minutes, or greater than 14 mg/L instantaneously, an alarm sounds to alert the operator and the WTP automatically goes into recirculation mode and ceases discharge.

Treated water from the WTP is discharged, by gravity, to Quesnel Lake via a pipeline (installed as of November 2017) connected to two submerged diffusers. Effluent discharge to the Hazeltine Creek channel ceased as of September 30, 2017.

5.2 Sediment and Erosion Control Management Plan

MPMC has developed a RCP that has been submitted to EMPR under the *Mines Act* Permit M-200. This plan includes several Environmental Management Plans including a Sediment and Erosion Control Plan.

5.3 Invasive Plant Management Plan

MPMC developed an Invasive Plant Management Plan in 2010 and has regularly updated this plan to include newly disturbed areas and to follow the Cariboo Regional District Strategic Plan for Invasive Plant Management. This plan is included in the RCP.

5.4 Dust Management Plan

MPMC maintains a Dust Management Plan that is also included in the RCP.

5.5 Project Environmental Monitoring Plans

MPMC develops a project specific Environmental Monitoring Plans (EMPs) for any development project that has potential to impact the environment. The requirement for these EMPs is outlined in the Erosion and Sediment Control Plan (Section 5.2).

5.6 Waste Management

MPMC recognizes the value of responsible waste management and recycling. MPMC Recycling and Waste Management Awareness presentations are given to Mount Polley employees annually and MPMC promotes several recycling programs for used materials including waste oil, scrap steel, batteries, plastic pails, electronic waste, light bulbs and associated fixtures, paper, cardboard, and beverage containers. Waste management information is also presented to employees and contractors during site orientation. Each year, Mount Polley donates the funds generated by its beverage container recycling program to local charities.

In the course of its ongoing operations, Mount Polley utilizes potentially hazardous chemicals, reagents, and other products. Sumas Environmental Services Ltd. routinely removes and disposes of these waste products in an environmentally safe manner compliant with all relevant waste management legislation. Products removed include: aerosol cans; contaminated gasoline and diesel; waste oil (in drums); waste oil filters; waste grease fuel or oil soaked rags, debris, and floor dry; and leachable liquid toxic waste, such as

glycol/anti-freeze mix. The site waste oil tanks are emptied and the oil removed from site by a third party contractor. MPMC is registered (BCG-01559) with the ENV under the *Hazardous Waste Regulation* for generation and temporary storage of these materials.

5.7 INCIDENT REPORTING

All non-compliance incidents are reported to the Director or to Emergency Management BC. All incidents are recorded and tracked, and are included in the AERR. As outlined in the Communication Plan (see Section 3.3) and required by Section 2.5 of the permit, incidents or emergencies that have the potential to have adverse impacts on the environment will be reported to the SCIB, WLIB, Cariboo Regional District and community of Likely.

5.8 INSPECTIONS

MPMC Environmental Department staff conduct weekly inspections on the site with a focus toward regulatory compliance and waste management (Section 5.6). These inspections are documented and communicated regularly to the site management and their respective departments. Guidance is provided by the Environmental Department for proper internal reporting and follow-up. The goal of these inspections is to provide all departments the capability to engage in proper environmental management practices and open lines of communication with the Environmental Department.

6 MONITORING

The subsections below outline general procedures at MPMC for scheduling of environmental monitoring and data review and management. Field methods, laboratory analysis, data quality control and objectives, as well as data analysis methods are included in the following sections with their respective monitoring components. Note that frequencies may change due to weather conditions or construction work and will be dependent on accessibility and, most importantly, safety of the field crews. Declarations of Competency for relevant Qualified Professionals are provided in Appendix E.

6.1 SCHEDULING

To coordinate sampling and schedule all planned monitoring, as per the CEMP, MPMC prepares internal monthly sampling schedules. An example monthly sampling schedule has been included as Appendix C.

6.2 FIELD METHODS

Monitoring procedures that will be used in carrying out the CEMP are consistent with the *BC Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples* (2013 or most recent version, herein referred to as the "BC Field Sampling Manual"; MoE 2013a). As appropriate, monitoring procedures will also be consistent with the *Metal Mining Technical Guidance for Environmental Effects Monitoring* (Environment Canada 2012) and the *Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators* (MoE 2012). MPMC's procedures are also consistent with applicable sections of the *British Columbia Environmental Laboratory Manual* (MoE 2015), such as sample collection and preservation requirements.

Quality assurance/quality control (QA/QC) methods will follow procedures outlined in the *MPMC Environmental Department QA/QC Manual* (most recent version: MPMC 2016c, herein referred to as the "QA/QC Manual", developed for the Mount Polley Mine. This manual provides detailed Standard Operating Procedures (SOPs) and Work Methods (WMs) of the protocols for environmental monitoring at MPMC and is a requirement of the Permit (April 7, 2017: Section 3.8). Procedures described in the manual are consistent with the BC Field Sampling Manual (MoE 2013a). The QA/QC Manual is reviewed and updated as appropriate (at minimum annually) to reflect changes to the ENV procedures and recommendations, and industry best practices. Should the manual be updated, the ENV Environmental Protection Division will be notified within 30 days of implementation as required by the Permit.

The QA/QC Manual protocols include collection of samples by trained personnel using standardized procedures, and use of field notebooks and chain of custody forms for sample documentation and tracking. These protocols are summarized for the different CEMP monitoring components below, where appropriate.

6.3 LABORATORY ANALYSIS

Sample analysis will be conducted at a laboratory registered for the designated parameter under the *Environmental Data Quality Assurance Regulation*. MPMC will participate in QA audits as required by the regulation.

6.4 Data Quality Review and Data Management

A data quality review of results will be conducted, including screening of laboratory QA/QC data, sample integrity issues, detection limits achieved, and metadata accuracy, as well as potential outliers/extreme values. This information will be catalogued in the MPMC sample tracking spreadsheets and the laboratory is contacted if any problem is identified. Water, soil, sediment, and tissue chemistry data as well as weather station data will be uploaded into the MP-5 database using files generated by the analytical laboratory. Accompanying field data will be manually entered and uploaded into the MP-5 database. Original laboratory-produced results files are filed on the MPMC network by date, and are linked to the data stored in the MP-5 database. Field data undergo a QC screening prior to upload and parameter restrictions are in place to reduce the likelihood of a typographical or laboratory reporting error being uploaded.

Non-chemistry data, including toxicity testing results, benthic invertebrate and plankton taxonomy data, and hydrology data (logger downloads and FlowTracker exports) are filed according to year and site on the MPMC network.

6.5 Climate Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.5.1 Section Authors and Study Component Design Professionals

This section was written by MPMC and is guided by Section 3.6 of the Permit (April 7, 2017).

6.5.2 Monitoring Objectives

The objective of the climate monitoring program is to track site weather data to support maintenance of the site water balance, water flow and accumulation predictions, and the design of water management infrastructure. Climate data are also considered important basic site characterization information that inform a number of other activities, such as reclamation revegetation prescriptions or building snow load requirements. Climate monitoring is also required under the Permit Section 3.6 (April 7, 2017).

6.5.3 Monitoring Overview

MPMC maintains two automated HOBO weather stations. Both stations are connected via telemetry allowing real time viewing of weather conditions. Four snow course sites are located around the mine site to target different exposure conditions. Table 6.1 provides an overview of the climate monitoring. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.1 shows monitoring locations of the meteorological monitoring locations.

Table 6.1 Climate monitoring overview

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
Weather Station #1	N/A	Continuous monitoring weather station beside tree plots near Mill Site	Logged every 5 minutes	Temperature, wind speed and direction, solar radiation, relative humidity, rainfall	N/A
Weather Station #2	N/A	Continuous monitoring weather station adjacent to the TSF	Logged every 5 minutes	Temperature, wind speed and direction, solar radiation, relative humidity, rainfall	N/A
JCP	N/A	Snow course site located east of the start of the Long Ditch in a clearing	End of month and after major snowfall and melting events	Snow depth, snow volume	N/A
Weather Station #1	N/A	Snow course site located near Weather Station #1	End of month and after major snowfall and melting events	Snow depth, snow volume	N/A
PAG Stockpile	N/A	Snow course site located beside the NW sump	End of month and after major snowfall and melting events	Snow depth, snow volume	N/A
TSF	N/A	Snow course site located near Weather Station #2, near the TSF	End of month and after major snowfall and melting events	Snow depth, snow volume	N/A

Notes: N/A: not applicable, TSF: tailings storage facility, JCP: Joe's Creek Pipe, PAG: potentially acid generating; NW: Northwest

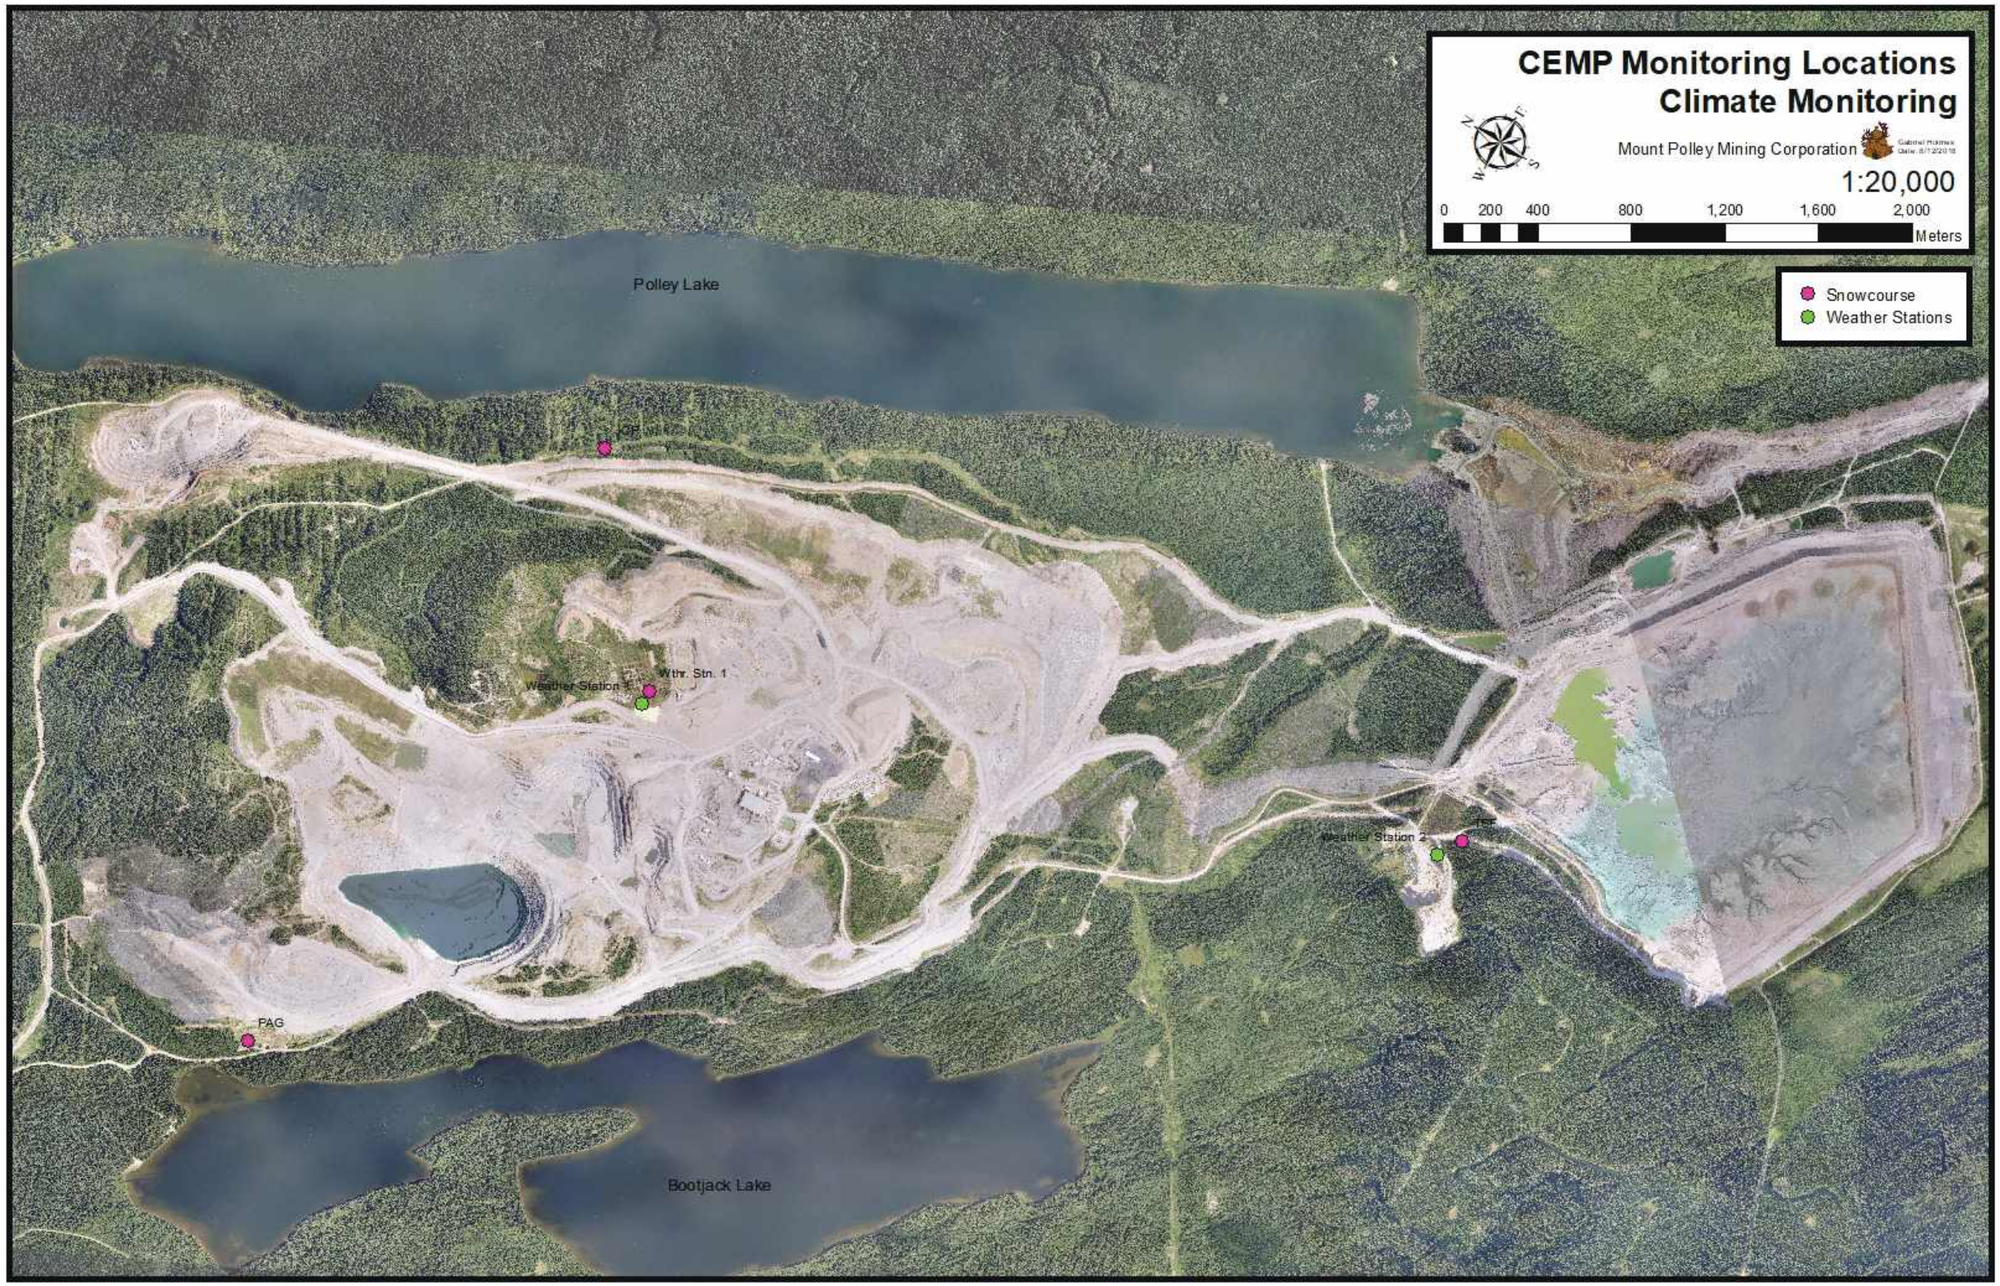

Figure 6.1 CEMP monitoring locations: Climate monitoring

6.5.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Meteorological monitoring will occur as per the SOPs and WMs for Meteorological Data Collection and Snowpack Measurements in the QA/QC Manual. There are two automated HOBO weather stations located on the mine site that continuously record wind speed and direction, precipitation, solar radiation, relative humidity, and temperature. Evaporation is calculated based on data collected from these stations. The data are downloaded from the automated weather stations monthly or as required by remote radio telemetry. If necessary, data are also stored for 30 days on the weather logger and can be downloaded manually using a data shuttle.

The snowpack measurement method will change in 2018 to align with the *Snow Survey Sampling Guide* written by ENV (MoE 2016). A workshop will be given to the Environmental Staff at first snowfall in fall 2018. The SOP and WM for Snowpack Measurements will be updated at this time and submitted to ENV for review.

Table 6.2 is a summary of previous climate monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.2 Summary of climate monitoring

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Two weather stations collect temperature, wind speed and direction, solar radiation, and precipitation data. Snowpack data was collected at four representative snow course sites. The weather and snow course stations are situated to encompass the topographical and geographic range of the mine site.	N/A	N/A
Summary of findings	Weather data collected were compared to site averages. Evaporation was calculated using measured parameters.	N/A	N/A
Recommendations for 2018-2020 monitoring	The snowpack measurement method will be changed to align with the *Snow Survey Sampling Guide*. The program will otherwise continue unchanged because the two current weather stations and snow course sites provide adequate information for the conditions on site.	N/A	N/A

Notes: N/A – not applicable

6.5.5 Data Quality Control, Objectives, and Review

Data ranges are set in the MP-5 database to detect erroneous data collected during station malfunctions. Weather station data that are erroneous (e.g., sensor malfunctions) will be investigated.

6.5.6 Laboratory Analysis

No laboratory analysis is required for climate monitoring.

6.5.7 Data Analysis and Reporting

Climate statistics, including mean, minimum, and maximum temperature, will be calculated and reviewed monthly. Daily evaporation is calculated using the Penman-Monteith equation for open water in the WaSIM software (developed by Cranfield University), based on data collected from the weather stations and site-specific factors, such as weather station elevation. These data are reported annually in the AERR.

6.6 Surface Water Monitoring

Surface water monitoring is characterised below into the following locations: Hazeltine Creek, streams and creeks adjacent to the mine site (receiving environment of the mine site), Bootjack Lake, Polley Lake, Edney Creek, Quesnel Lake, and Quesnel River.

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.6.1 Section Authors and Study Design Professionals

The mine site environmental monitoring was developed during the Environmental Assessment process in 1995, which included input from several QPs. For the purpose of the CEMP, MPMC will continue to monitor with the understanding that this program is well-established to monitor any mine-related effects. The mine site monitoring described below was written by MPMC.

6.6.2 Monitoring Objectives

The objective of water chemistry monitoring in Hazeltine Creek is to evaluate the Hazeltine Creek aquatic environment following the TSF embankment breach and track changes to the aquatic environment over time and/or as a result of implementation of rehabilitation and sediment and erosion control work.

The objective of water chemistry monitoring in streams and creeks adjacent to the mine site, as well as Bootjack Lake and Polley Lake, is to identify water quality changes in waterbodies that run through or are adjacent to the mine site to assess efficacy of the mine water management systems and to stimulate applicable management actions.

The objective of water chemistry monitoring in Polley Lake, Quesnel Lake, and Quesnel River is to support ongoing evaluation of water chemistry following the TSF embankment breach in the downstream environments.

The objective of water chemistry monitoring in Quesnel Lake at the boundary of the initial dilution zone (IDZ) is to verify that the discharge of treated effluent is not causing an exceedance of the applicable ambient BC Water Quality Guidelines at the edge of the IDZ, as required by the Permit, and to verify the discharge model, as described in the ADP.

Monitoring of the far-field receiving environment in Quesnel Lake in the West Basin will be carried out downstream and upstream (for reference) of the mouth of Hazeltine Creek for the verification of the discharge model as described in the ADP.

6.6.3 MONITORING OVERVIEW

Table 6.3 summarizes the parameters analysed for surface water quality. The lake field parameters are measured at each sampling depth and for each limnological profile (excluding Secchi depth, which is taken from the surface of each lake sampling point). Table 6.4 provides an overview of the surface water monitoring. The location "Mine Site" refers to the streams and creeks adjacent to the mine site. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.2 shows monitoring locations of the surface water sampling locations.

Quesnel Lake	QUL-2a	E303020	Quesnel Lake far-field, upstream of Hazeltine Creek (reference)	Four times annually[7, 11]	Limnological profile, 0 m, 20 m, 40 m, 60 m	Field parameters - lake, physical tests, anions and nutrients, DOC, total and dissolved metals, EEM parameter (total mercury)[8]	BC WQG - AL

Location	Station Name	EMS Code	Description	Frequency	Depths	Parameters Measured	Guidelines
Quesnel Lake	QUL-ZOO-1	E306455	Quesnel Lake in centre of West Basin (zooplankton station)	Three times annually [10, 11]	Limnological profile, surface	Field parameters - lake, physical tests, anions and nutrients, DOC, total and dissolved metals	BC WQG - AL
Quesnel Lake	QUL-ZOO-7	E306456	Quesnel Lake near Cariboo Island (reference zooplankton station)	Three times annually [10, 11]	Limnological profile, surface	Field parameters - lake, physical tests, anions and nutrients, DOC, total and dissolved metals	BC WQG - AL

Notes: [1] In June and October due to access; [2] May to November only due to restricted access in winter; [3] At spring overturn and late summer; [4] Between spring and fall overturn; [5] Monitoring will depend on closure conditions; [6] if ice and weather conditions meet safety requirements; [7] Taken at evenly spaced time series plus or minus one month; [8] Total mercury will be collected at MID or BT for QUL-58 and at 40 m for QUL-2a as part of EEM four times per year (no less than 1 month apart). Parameter only reported to MDMER; [9] QUL-18 is approximately 110 m deep. 100 m sample depth is collected for historical consistency; [10] Taken in conjunction with plankton sampling (see Section 6.14); [11] When sampling is less frequent than monthly, sampling at Quesnel Lake operational surface water monitoring stations (as identified in Table 6.6) will be undertaken when effluent discharge to Quesnel Lake is discharging. In the event of an unexpected shutdown of the water treatment plant, reasonable efforts will be made to re-sample within the timeframe of the quarterly or other specified time period sampling upon restart of effluent discharge to Quesnel Lake; [12] Samples will be taken at HAD-3 on the same day as samples collected from QUL-57, -58, and -59.

DOC: dissolved organic carbon; BC WQG: British Columbia Water Quality Guidelines; AL: aquatic life; FSR: Forest Service Road; EEM: Environmental Effects Monitoring; IDZ: initial dilution zone

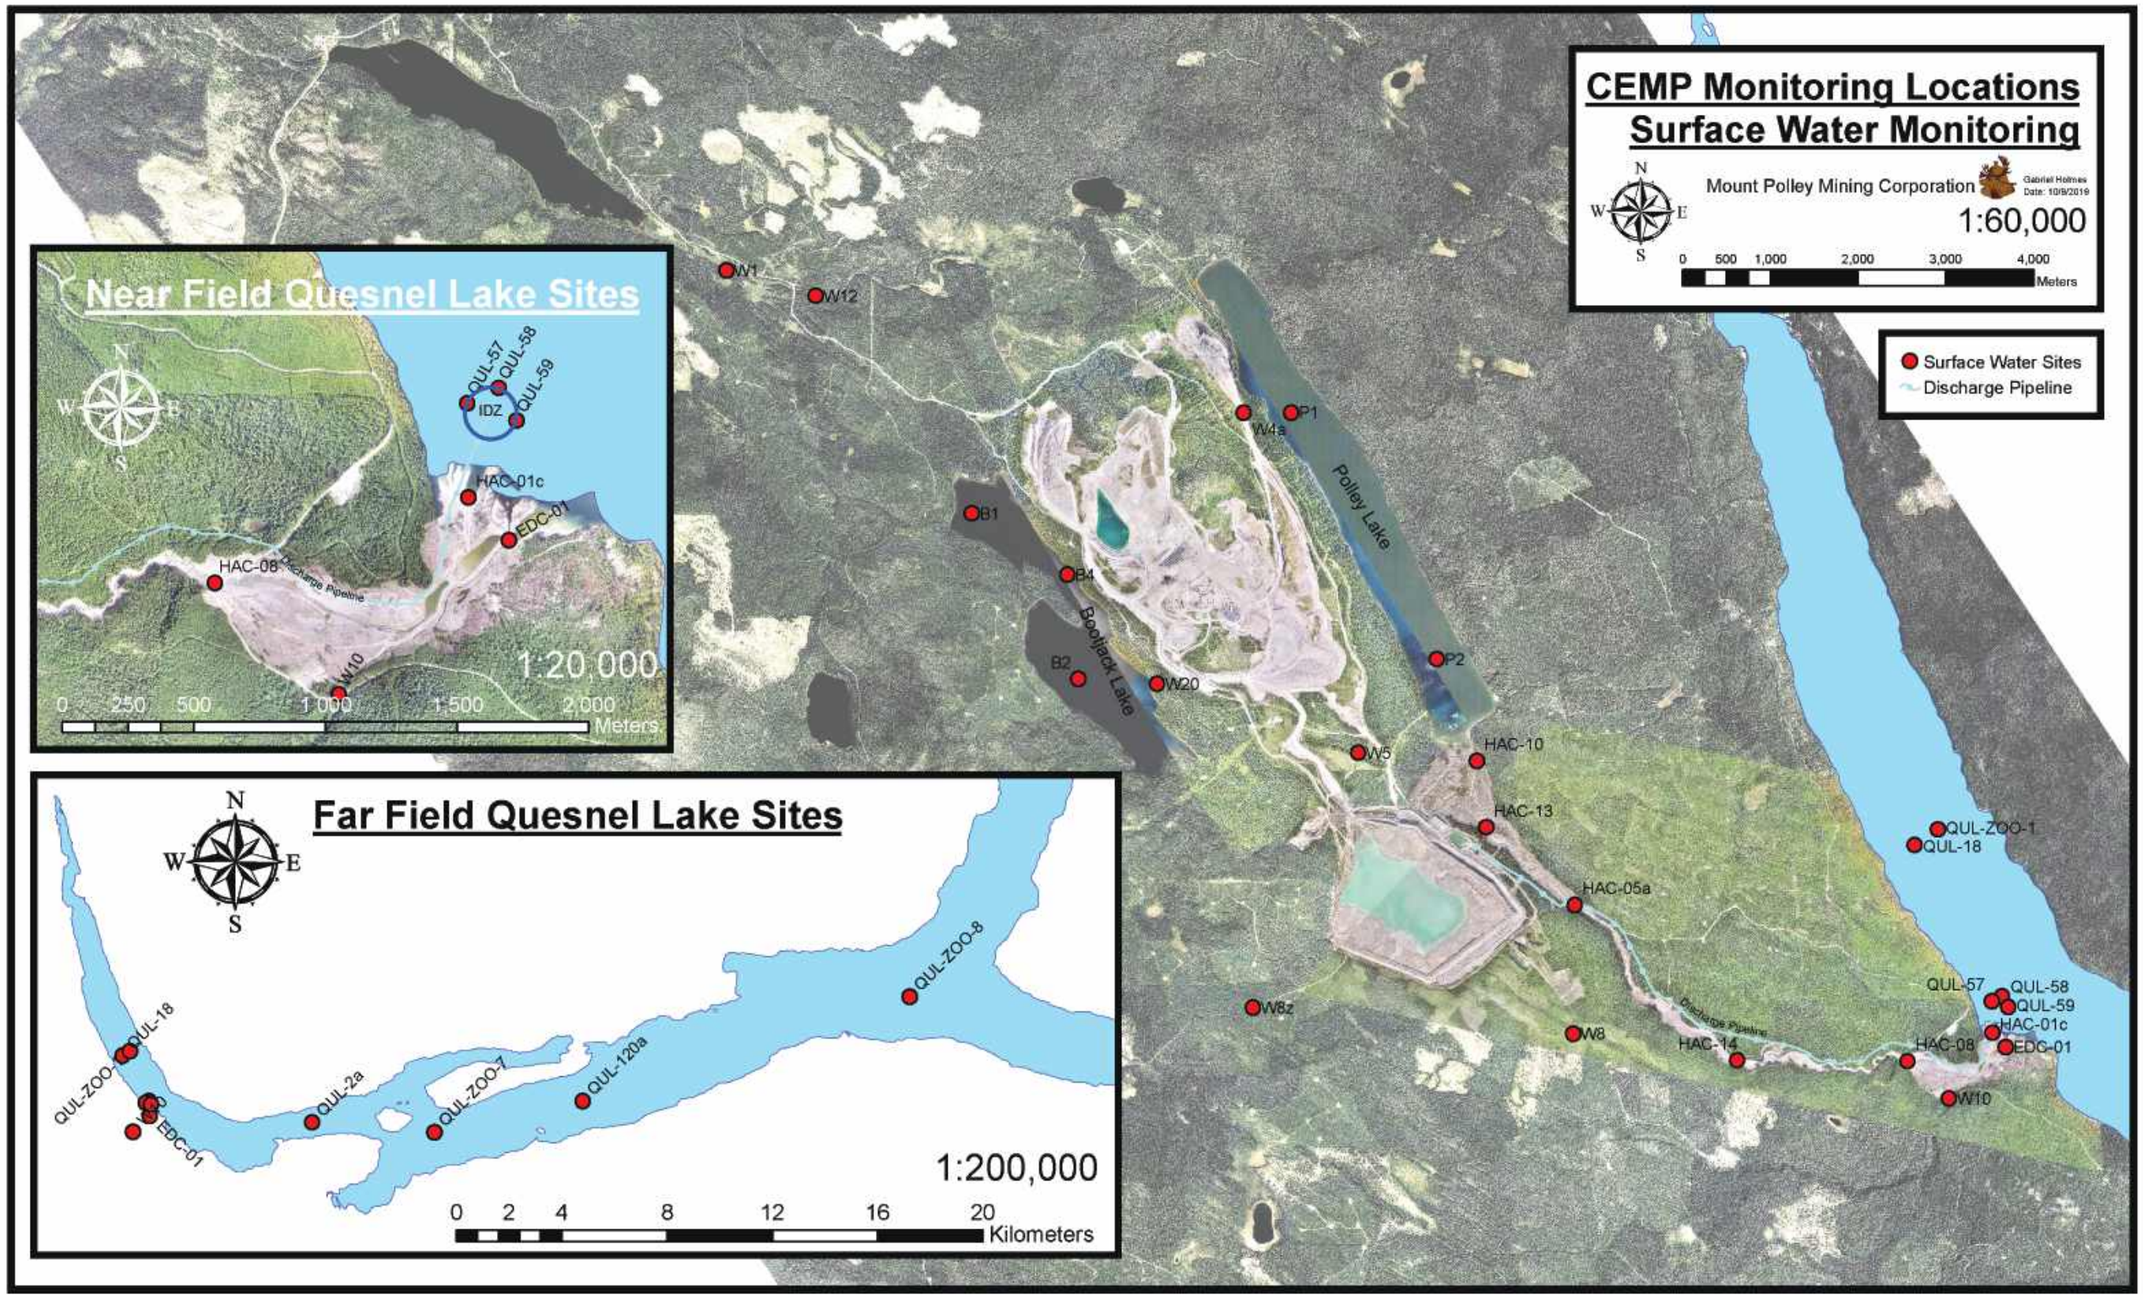

Figure 6.2 CEMP monitoring locations: Surface water monitoring

6.6.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Field parameter collection, sample collection, preparation, and shipping will be conducted following the SOPs and WMs for the associated field meters, Surface Water Quality Monitoring and Lake Water Monitoring, as appropriate as described in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.6.3. Limnological profiles of field parameters will be conducted where described in Table 6.4.

For the edge of the IDZ sampling, limnological profiles of field parameters (specific conductance, temperature, and turbidity) will be carried out in an attempt to identify the location of the plume from the outfall (i.e., direction of flow). MPMC is committed to spending a reasonable level of effort and time to detect the plume and direction of flow. The reasonable level of effort and time will vary depending on the health and safety risks associated with the weather conditions and season. Vertical profiles of field measurements and water chemistry samples will be taken at the inferred centerline of the plume at the edge of the IDZ (station QUL-58).

A plume dispersion model was developed by Golder for the nearfield (i.e., in the vicinity of the IDZ), and a hydrodynamic model of Quesnel Lake has been developed and calibrated by Tetra Tech EBA to predict effluent transfer throughout the West Basin of Quesnel Lake and potential for buildup (Golder 2015b). Monitoring at the near-field station, along with monitoring of other Quesnel Lake receiving environment stations, will be used to verify the near-field and lake-wide hydrodynamic models. It should be noted that the nearfield and the hydrodynamic models, as described in the Long Term Water Management Plan, serve as the basis for the Trigger Response Plan incorporated into the 2018 ADP.

Table 6.5 is a summary of previous surface water monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.5 Summary of surface water monitoring

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Monitoring included streams adjacent to the mine site to determine if there are any changes in water quality. Bootjack and Polley lakes were monitored as receiving environment of the mine. Bootjack Lake was monitored to evaluate potential for exfiltration from Springer Pit. The monitoring sites in Bootjack Lake were moved to two deeper monitoring locations in 2017, as described in the 2016 AERR. For the discharge receiving environment, Quesnel Lake and Quesnel River were monitored.	Post-breach monitoring overlapped with operational monitoring in Polley Lake, Quesnel Lake, and Quesnel River. Monitoring occurred at sites selected to capture major inputs and mixing of Hazeltine Creek. Supplemental sampling of 3 stations flowing into Hazeltine Creek in the Polley Flats area was undertaken to support a geochemical conceptual model in 2016 (SRK and Minnow 2016).	N/A
Summary of findings	The results for the creeks and lakes from 2016-2017 identified no significant trends. No indication of exfiltration from the Springer Pit was found in Bootjack Lake.	Results from Quesnel River show no indications of further effects post-breach since 2016. The 2016 and 2017 results showed that the lower sedimentation pond was effective at decreasing the TSS concentration of Hazeltine Creek. The modelling concluded that 93 to 99% of copper was organically complexed and generally not bioavailable.	N/A
Recommendations for 2018-2020 monitoring	A summary of all changes from the 2016 CEMP is provided in Section 6.6.4.1.	A summary of changes from the 2016 CEMP is provided in Sections 6.6.4.1 and 6.6.4.2.	N/A

Notes: AERR: Annual Environmental and Reclamation Report; N/A: not applicable; TSS: total suspended solids

6.6.4.1 OPERATIONAL MONITORING

Table 6.6 summarizes all changes in operational surface water monitoring form the 2016 CEMP.

Table 6.6 Operational monitoring changes since the 2016 CEMP

Sample Site(s)	Change from 2016 CEMP	Purpose/Justification
W1	Reduced frequency from monthly to quarterly	W1 monitors water quality in Morehead Creek, the outflow of Bootjack Lake. As of time of writing, Springer Pit water level is below 990 masl and no indication of exfiltration from the Springer Pit was found in Bootjack Lake. The monitoring frequency will be reviewed by a QP if Bootjack Lake shows any mine-related changes in the future.
W10	Reduced frequency from monthly to semi annually (in June and October)	The monitoring of this site overlaps with Post-Breach Monitoring as it acts as a reference location for the remediated section of Edney Creek. The reduced frequency aligns with frequency of EDC-01 (see Section 6.6.4.2).
W20	Reduced frequency from quarterly to semi-annually	This creek is not directly influenced by mine activities as mine-affected water is diverted away from this creek catchment. Less intense monitoring is required. The frequency will be reviewed by a QP if Bootjack Lake water quality shows any mine-related changes.
QUL-58	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	Monitoring As per the ADP, QUL-58 monitoring is for model verification.
QUL-57	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	As per the ADP, QUL-57 monitoring is for model verification.
QUL-59	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	As per the ADP, QUL-59 monitoring is for model verification.
QUL-18	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month)	As per the ADP, QUL-18 monitoring is for model verification.
QUL-2a	Reduced frequency from monthly to 4 times per year (taken at evenly spaced time series plus or minus one month) Considered Quesnel Lake reference site	As per the ADP, QUL-2a monitoring is for model verification and is now considered the Quesnel Lake reference site.

Sample Site(s)	Change from 2016 CEMP	Purpose/Justification
QUL-120a	Reduced from seasonally to semi-annually (taken at evenly spaced time series plus or minus one month) No longer considered Quesnel Lake reference site	As per the ADP, QUL-120a monitoring is for model verification.
QUR-1	Continuous monitoring removed	Continuous monitoring was conducted at this site from August 12, 2014 to May 30, 2016. In consultation with ENV, given the lack of variation in the results, continuous monitoring was deemed to be no longer necessary.
QUR-11	Removed	This site is regularly monitored by the provincial and federal government agencies with financial support from MPMC. An annual side-by-side sample will be collected by MPMC at the request of the regulator.
P1, P2	Reduced sampling from monthly to spring overturn, twice in summer, fall overturn, and once in winter under ice Change in sampling depths	The monitoring of these sites overlap with Post-Breach Monitoring. The reduction in monitoring frequency (both sampling and limnological profiles) is because the water quality in Polley Lake appears to be stable. If changes are observed in water quality reflecting breach- or mine-related impacts, frequency of monitoring will be reviewed by a QP. These sample depths align with pre-breach monitoring as agreed upon with ENV staff biologist.
B1, B2	Reduced monitoring of limnological profile from semi-monthly to monthly Change in sampling depths	The reduction in monitoring frequency is because the water quality in Bootjack Lake appears to be stable. If changes are observed in water quality reflecting mine-related impacts, frequency of monitoring will be reviewed by a QP. These sample depths align with pre-breach monitoring as agreed upon with ENV staff biologist.

Notes: CEMP: Comprehensive Environmental Monitoring Plan; masl: meters above sea level; QP: Qualified Professional; ADP: Annual Discharge Plan

6.6.4.2 POST-BREACH MONITORING

Table 6.7 summarizes all changes in operational surface water monitoring form the 2016 CEMP.

Table 6.7 Post-breach monitoring changes since the 2016 CEMP

Sample Site(s)	Change from 2016 CEMP	Purpose/Justification
HAC-13	Reduced from weekly to monthly	This site used to be upstream of the Hazeltine Creek Discharge and was monitored under the EEM. Currently, this site monitors water quality in Hazeltine Creek after Reach 1. Monitoring frequency has been reduced to align with other Hazeltine Creek samples.
HAC-14	Added	This site was added to monitor effects of remediation activities on Hazeltine Creek water quality. The frequency aligns with other Hazeltine Creek samples.
HAC-12	Removed	In consultation with ENV (C. Danyluk, personal communication, February 8, 2018), this site has been removed as it is no longer necessary with the connection of the pipeline from the WTP to the diffusers.
HAC-01c	Added	This site represents Hazeltine Creek water quality before entering Quesnel Lake. The frequency aligns with other Hazeltine Creek samples.
EDC-01	Reduced from monthly to semi-annually	No significant trends have been identified at EDC-01. Because of reduced site access in winter and stable water quality, sampling frequency has been reduced to semi-annually.

Notes: CEMP: Comprehensive Environmental Monitoring Plan; EEM: Environmental Effects Monitoring; ENV: BC Ministry of Environment and Climate Change Strategy; WTP: Water Treatment Plant

6.6.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all surface water monitoring (i.e., operational, post-breach, reclamation) is summarized in Table 6.8.

Table 6.8 Water chemistry QC sample frequencies for surface water monitoring

QC Samples	Frequency
Duplicate samples	10% of surface water samples
Equipment blanks	Monthly per piece of equipment (when used)
Trip blanks	Twice per month
Field blanks	Twice per month
Filter blanks	Quarterly
Deionized water blanks	Annually
Laboratory replicate[1]	Annually

Note: [1] Split sample

For results greater than five times the method detection limit (MDL), a relative percent difference (RPD) will be used to identify differences between original and duplicate samples. These data quality objectives (DQOs) are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

6.6.6 Laboratory Analysis

Samples will be submitted to and processed by a Canadian Association of Laboratory Accreditation (CALA) accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.6.7 Data Analysis and Reporting

In Hazeltine Creek, data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, maximum, and 95th percentile values over the period of interest) and evaluation of any spatial (e.g., down the creek) and temporal changes or trends. Results will also be compared to the BC aquatic life WQGs.

In the other surface water monitoring sites, statistical analysis will be carried out to compare data to reference sites and to assess trends over time. Results will also be compared to the BC aquatic life WQGs.

6.7 Hydrology Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.7.1 Section Authors and Study Design Professionals

This section was written by MPMC, and is guided by Section 3.4 of the Permit (April 7, 2017).

6.7.2 MONITORING OBJECTIVES

The objective of hydrological monitoring in Hazeltine Creek is to characterize the hydrology of the Hazeltine Creek system, assess fish habitat (only in reaches accessible to fish), interpret water quality and water balance, and evaluate changes over time as rehabilitation works are carried out and system recovery occurs (e.g., establishment of riparian vegetation).

The objective of hydrological monitoring in Edney Creek is to characterize the hydrology of Edney Creek in the remediated section, asses fish habitat, interpret water quality, and evaluate changes over time as rehabilitation works are carried out and system recovery occurs (e.g., establishment of riparian vegetation).

The objective of the hydrological monitoring of the streams and creeks that run through or adjacent to the mine site is to characterize the hydrology of the drainages, interpret water quality, and evaluate any changes over time.

6.7.3 MONITORING OVERVIEW

MPMC maintains eight hydrology stations as required by the Permit. Table 6.9 provides an overview of the hydrology monitoring. No large changes have been made from the 2016 CEMP, but wording has been changed to more align with the wording in Section 3.4 in the Permit. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.3 shows monitoring locations of the hydrology monitoring locations.

Staff gauges will be benchmarked (calibrated) once per year between June 15 and August 31, as defined by the Permit. Staff gauge readings will be recorded during water chemistry sampling events at the associated stations and each manual flow measurement. Note that there is currently no staff gauge installed at station W4a (North Dump Creek), as it is a very low flow creek; however, as recommended by WaterSmith Research Inc. (WaterSmith; Appendix K in MPMC 2016e), MPMC will endeavor to install a staff gauge at this location that provides adequate information. Continuous stage monitoring equipment (pressure transducers) will be installed at hydrometric locations specified in Table 6.9 during non-freezing conditions.

Manual flow gaugings will be conducted at all sites during high, moderate, and low flows in non-freezing conditions. These measurements will be conducted at minimum three times per year for validation of the stage-discharge rating curves. If stage-discharge stability is not demonstrated, the frequency of monitoring will be increased to five times per year during the non-freezing period (across the spectrum of high to low flows) to meet Resources Information Standards Committee Grade A standards for hydrometric monitoring (MoE 2009). Due to site characteristics and difficult operating conditions, often the sites meet Grade B/C standards. MPMC will continue to work with a QP to move toward meeting Grade A standards for all hydrological stations. A stage discharge curve that encompasses the non-freezing period flows will be maintained for all hydrological stations with staff gauges.

Table 6.9 Hydrology monitoring overview

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
H4	-	Upper Hazeltine Creek at Polley Lake outlet	Continuous[1]	Water head pressure, temperature	N/A
			Weekly (daily during high runoff periods)	Stage (staff gauge)	Permit 11678
			Monthly[1]	Manual flow gauging	
H1	-	Upper Hazeltine Creek hydrometric station (at Gavin Lake FSR Bridge)	Continuous[1]	Water head pressure, temperature	Permit 11678
			Monthly[1]	Stage (staff gauge)	
			Monthly[1]	Manual flow gauging	
H2	-	Lower Hazeltine Creek hydrometric station (downstream of the Ditch Road Bridge)	Continuous[1]	Water head pressure, temperature	Permit 11678
			Monthly[1]	Stage (staff gauge)	
			Monthly[1]	Manual flow gauging	
W1b	E291449	Morehead Creek	Water quality sample and when flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated)	
W4a	E298551	North Dump Creek below Wight Pit Road	Monthly[1]	Manual flow gauging	Permit 11678
W5	E208039	Bootjack Creek Above Hazeltine Creek	Water quality sample and when flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate, and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated); only when sufficient flow	

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
W12	E216744	6 km Creek at Road	Water quality sample; when flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated)	
H3	-	Lower Edney Creek	Continuous[1]	Water head pressure, temperature	N/A
			When flows are measured[1]	Stage (staff gauge)	Permit 11678
			High, moderate and low flows[1]	Manual flow gauging (3 time/year; 5 times if rating curve stability not demonstrated)	

Notes: [1] In non-freezing conditions; N/A: not applicable

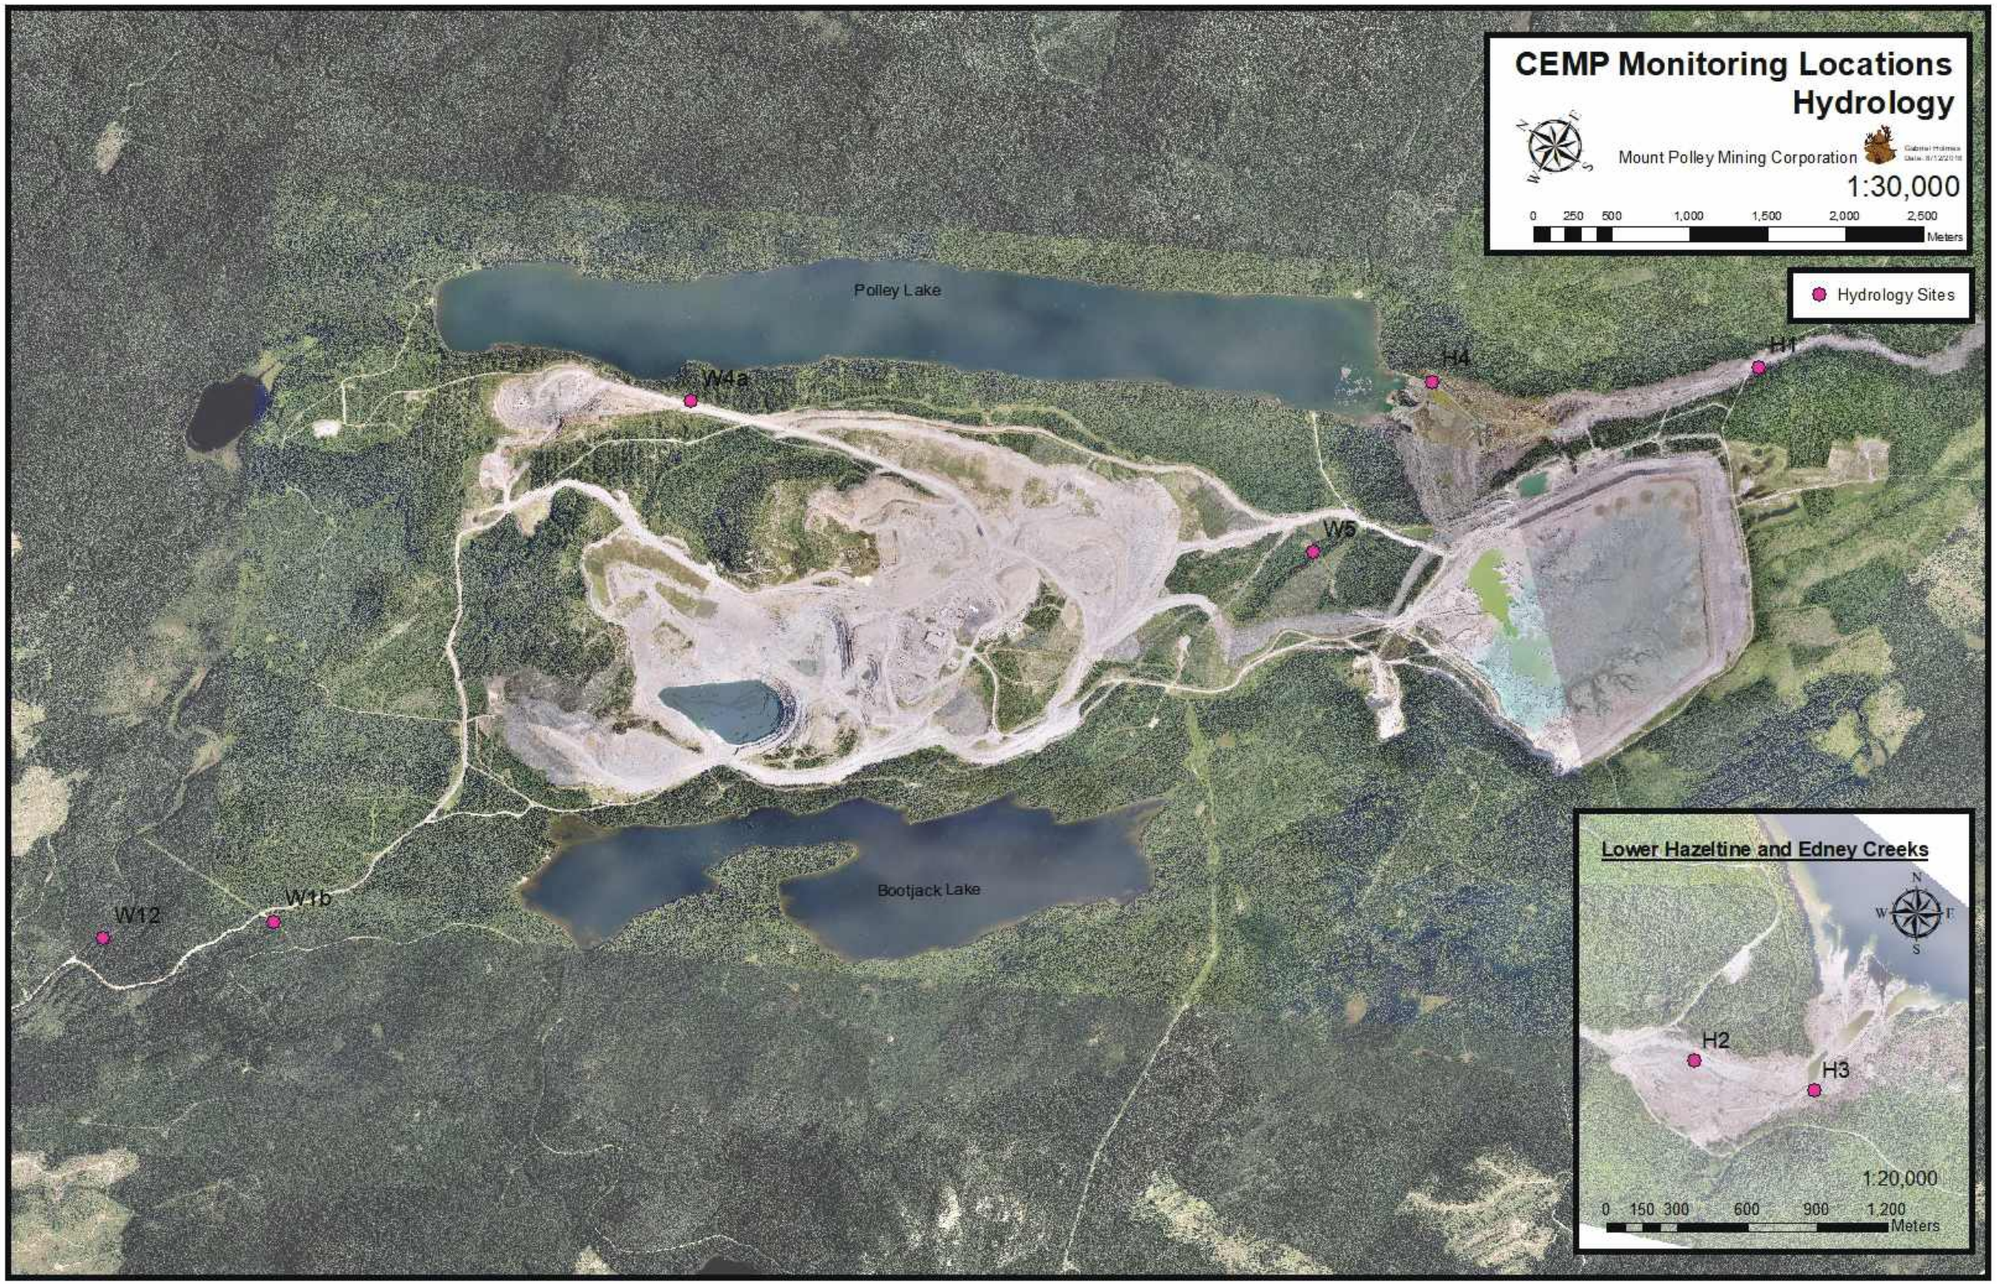

Figure 6.3 CEMP monitoring locations: Hydrology monitoring

6.7.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Hydrological monitoring will be conducted as per the SOPs and WMs for Hydrological Monitoring (which includes installing and downloading continuous loggers) and Benchmarking, as well as the specific WM for operating the FlowTracker acoustic Doppler velocity meter.

Note that some streams do not flow year-round; if there is no flow and a sample or measurement cannot be taken as scheduled, the attempt will be documented in the field notebook.

To verify the accuracy of established rating curves (i.e., confirm that the channel morphology at the station and outflow control point have not changed) and, where possible, extend the upper and lower bounds of the curves, manual flow gaugings will be taken according to Table 6.9 in non-freezing conditions. Manual flow monitoring requirements will be re-evaluated each year, following refinement of the stage-discharge rating curves.

Table 6.10 is a summary of previous hydrology monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.10 Summary of hydrology monitoring and findings

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	W1b, W5, and W12 were established prior to 2014. W4a was established in 2014. More detail for each site is provided in Section 6.7.4.1.	H1 and H2 hydrology sites were established in 2015, when channeling of Hazeltine Creek was completed. H4 hydrology site was established in 2016 in the remediated section of upper Hazeltine Creek. H3 hydrology site in the remediated section of Edney Creek was established in 2015. More detail of each station is provided in Section 6.7.4.2.	N/A
Summary of findings	Manual measurements were used to confirm and refine rating curves.	Manual measurements confirmed the rating curves for H1, H2, and H3. Increased manual measurements for H4 will confirm the ratings curve.	N/A

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	Post-Breach	Reclamation
Recommendations for 2018-2020 monitoring	Manual measurements will be collected to confirm the rating curves. One hydrology station is not configured for staff gauge and its establishment will be explored.	Continuous monitoring of levels will continue using the established rating curve. Manual measurements will be collected to confirm the rating curves.	N/A

Notes: N/A: not applicable

6.7.4.1 Operational Monitoring

Table 6.11 summarizes the operational hydrology sites. Flows around the MPMC site are freshet driven; therefore, many hydrology stations are low flow during the rest of the year and cannot be measured. No continuous monitoring devices are installed at these sites due to the very low flow nature of the creeks.

Table 6.11 Summary of operational hydrology sites

Site	Comment
W1b	Site W1b was established in 2012. Benchmarking of this station has occurred annually. In 2016, WaterSmith made significant changes to the site and a new stage-discharge curve was developed. MPMC will continue to conducted manual measurements to confirm the rating curve.
W4a	Site W4a was established downstream, and replaced site W4 in 2014. Only manual bucket flow measurements are recorded from a constructed pipe weir at this site and will continue until recommendations for installation of a staff gauge are explored.
W5	Site W5 at Bootjack Creek was re-established in 2008. Benchmarking of this station has occurred annually. A new staff gauge was installed in 2016 by WaterSmith and a new stage-discharge curve was developed. MPMC will continue to conducted manual measurements to confirm the curve.
W12	Site W12 was established in 1990. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. MPMC will continue to conducted manual measurements to confirm the curve.

Notes: WaterSmith: WaterSmith Research Inc.; MPMC: Mount Polley Mining Corporation

6.7.4.2 Post-Breach Monitoring

Table 6.12 summarizes the post-breach hydrology sites.

Table 6.12 Summary of post-breach monitoring hydrology sites

Site	Comment
H1	Site H1 was established in upper Hazeltine Creek in 2015. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the rating curve.
H2	Site H2 was established in upper Hazeltine Creek in 2015. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the rating curve.
H3	Site H3 was established in the remediated area of lower Edney Creek in 2015. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the curve.
H4	Site H4 was established in upper Hazeltine Creek at the Polley Lake Weir in 2016. Benchmarking of this station has occurred annually. A new stage-discharge curve was developed in 2016. A continuous monitoring device will be installed at this station to provide continuous water head pressure measurements during non-freezing periods. In addition, MPMC will continue to conducted manual measurements to confirm the curve.

Notes: MPMC: Mount Polley Mining Corporation

6.7.5 Data Quality Control, Objectives, and Review

The FlowTracker has built in error messages associated with measurements that are outside of set QC bounds, and reports an International Standard Calculation error and statistical (US Geological Survey calculation) error output following each discharge measurement as a QC measure.

Benchmarking, as described above and as per the protocol in the QA/QC Manual, will occur annually between June 15 and August 31 as per the Permit, or as described by the Permit.

Routine monitoring includes inspections of equipment, including stilling wells and loggers (e.g., to identify sedimentation inside the stilling well or debris build up in logger ports). Identification of potential station changes or issues also occurs through data analysis when data are inconsistent or unusual in comparison with previously collected data.

6.7.6 Laboratory Analysis

No laboratory analysis is required for hydrology monitoring.

6.7.7 Data Analysis and Reporting

Data analysis will include building and validating the stage-discharge rating curves, as well as production of annual hydrographs. These will be presented in the AERR.

6.8 GROUNDWATER MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.8.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC.

6.8.2 MONITORING OBJECTIVES

The primary objective of the groundwater monitoring program on the mine site is to determine the direction, volume, and quality of groundwater flow from the mine site and other disturbed areas to receiving environment.

6.8.3 MONITORING OVERVIEW

Groundwater monitoring wells around the mine site are installed in the area around the TSF, the Springer Pit, downstream of waste rock dumps and haul roads, and in other areas on or surrounding the mine. The monitoring program was developed on the recommendation of the groundwater program review by Golder conducted in March 2016. This review was submitted to ENV on March 31, 2016. An annual review of the groundwater monitoring program was also conducted by Golder in March 2017 and was submitted as Appendix F in the 2017 AERR (MPMC 2018). Recommendations from the 2017 review have been incorporated into the monitoring program outlined below. Sampling events at times of maximum and minimum hydrologic conditions to account for seasonal variability will be conducted when appropriate (i.e., spring and late summer/fall). Static water level (SWL) of all wells will be monitored on the same day at minimum once annually to allow for comparison across the site.

Groundwater monitoring wells were also installed along the Hazeltine Creek in 2015 and 2016. From Golder (2017), groundwater "was not screened for the terrestrial risk assessment because wildlife do not consume groundwater". Monitoring of surface water in Hazeltine Creek captures the potential effects of groundwater discharged to the Hazeltine Channel system (Golder 2017; see Section 6.6). No further monitoring is planned at these groundwater wells.

Table 6.13 summarizes the parameters analysed for groundwater quality. Table 6.14 provides an overview of the groundwater monitoring. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.4 shows monitoring locations of the groundwater sampling locations.

Notes: [1] Wells show stable chemistry. If an unexpected change in SWL is observed, well water will be sampled; [2] Wells provide domestic water for personnel; BC WQG – British Columbia water quality guideline; SWL: static water level; CSR: Contaminated Sites Regulations; AL: aquatic life; [3] Leveloggers have been removed from GW15-1a and 1b as wells are dry. Leveloggers will be reinstalled once water is above well screen.

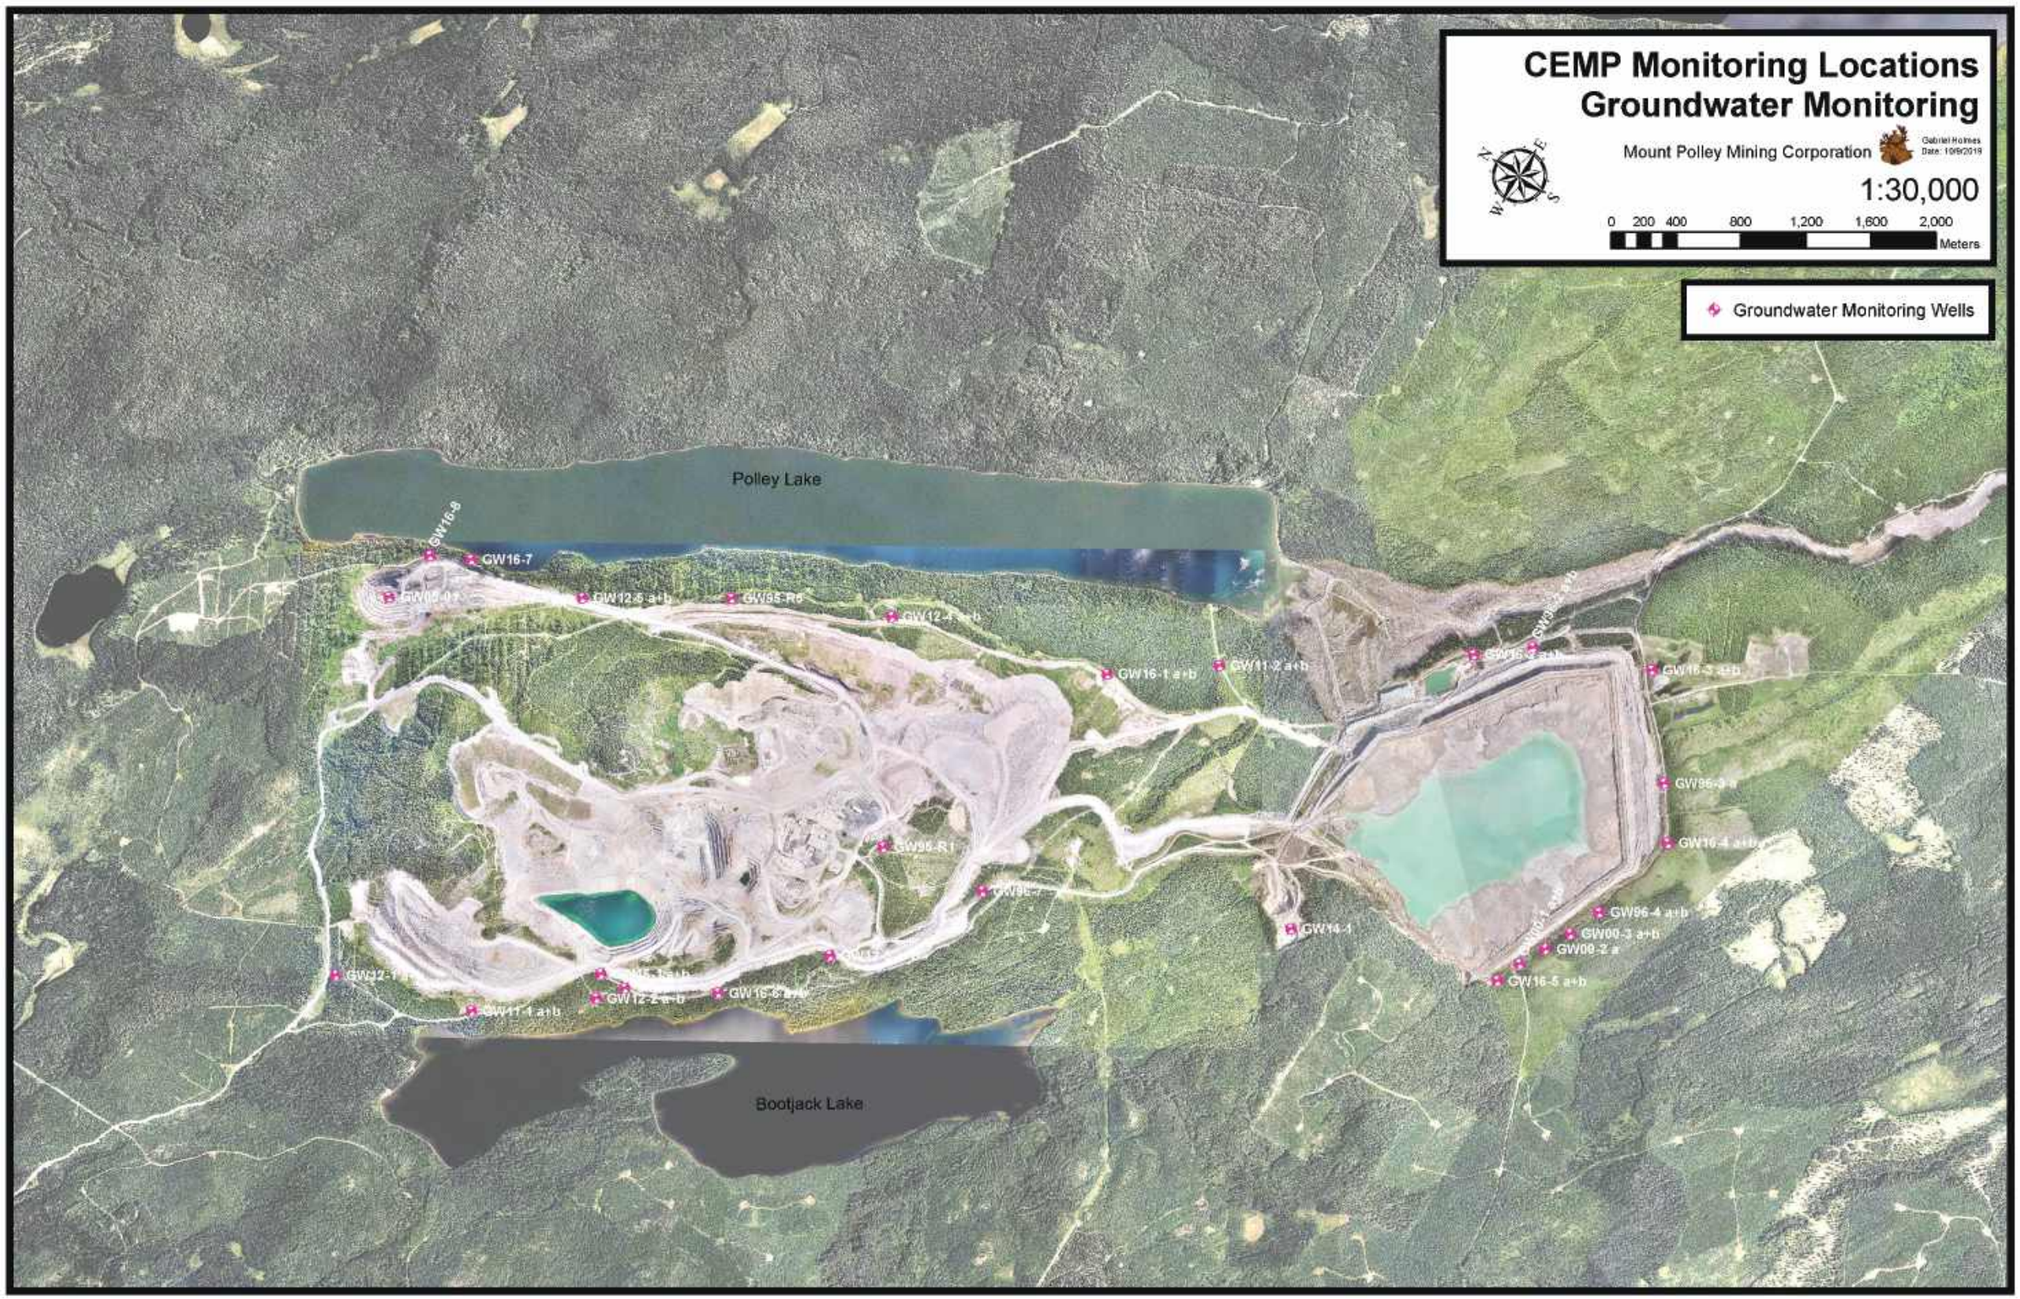

Figure 6.4 CEMP monitoring locations: Groundwater monitoring

6.8.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

As outlined in the SOPs, groundwater monitoring involves use of an automated depth to water meter to measure SWL and a submersible pump powered by a generator for sampling. These protocols also require routine inspections of the well housing.

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Groundwater Monitoring and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.8.3.

Table 6.15 is a summary of previous groundwater monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.15 Summary of groundwater monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Groundwater locations in both shallow and deep bedrock downstream of mine activities. Higher frequency monitoring occurred at wells near the Springer Pit in 2015, 2016, and 2017 because the pit water level was above 1025 masl. Dredging of the Springer Pit commenced in 2017, and the water level in the pit is less than 1000 masl at the time of writing.	An updated groundwater program was implemented for the ERA (Golder 2017). Wells installed in 2015 were resampled and additional wells were installed along the creek in 2016. Groundwater was analyzed for dissolved metals, TSS, pH, anions, nutrients, hardness and acidity.	N/A
Summary of findings	Monitoring of the groundwater wells near the Springer Pit showed exfiltration from the Springer Pit towards Bootjack Lake occurred during 2016. This exfiltration was reversed after the Springer Pit was dewatered, which was confirmed by continued monitoring of these wells. No groundwater leakage from Springer Pit to Bootjack Lake in 2107 was inferred based on the levels measured. No significant changes to groundwater quality were identified in the 2017 annual groundwater review (MPMC 2018).	Although copper was the primary metal of concern in the tailings outwash material deposited in Hazeltine Creek, groundwater copper concentrations were lower than the CSR standard. Other substances that exceeded CSR standards are believed to be associated with natural conditions and were not derived from the tailings.	N/A
Recommendations for 2018-2020 monitoring	New groundwater wells were drilled at the end of 2016 as per recommendations in the Groundwater Program Review. These wells were incorporated into the current program in 2017. One pair of wells was removed due to likely contamination and were replaced (see Golder 2016c). See Section 6.8.4.1 for more detail on the recommendations for future monitoring.	No further sampling is planned for groundwater in Hazeltine Creek. If the water quality declines in the creek, monitoring of these wells will be reviewed and considered.	N/A

Notes: masl: metres above sea level; CSR: Contaminated Sites Regulation; ERA: ecological risk assessment; TSS: total suspended solids

6.8.4.1 OPERATIONAL MONITORING

The monitoring frequencies of the Springer Pit wells were decreased from monthly to quarterly due to the ongoing dewatering at Springer Pit, which has resulted in a significant drop in water levels in some of these wells. For example, dataloggers have been removed from GW15-1a and b as these wells are now dry (J. Foley, personal communication, August 10, 2018). According to J. Foley, "due to the ongoing dewatering at Springer Pit, Golder would consider it acceptable to move to quarterly monitoring, if groundwater is present within the wells." Once dewatering stops and the pit is refilled, consideration to move back to monthly monitoring for a period of time will be given.

A further change to the recommendations put forth in Appendix F of MPMC (2018) is that "quarterly groundwater monitoring should continue at GW16-6 a and b, but semi-annual monitoring can be completed at the remaining GW16 well series. Note that some of the remaining 2016 well series (other than GW16-6 a/b) were monitored one to three times in the 2017 calendar year" (J. Foley, personal communication, August 10, 2018).

6.8.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all the groundwater monitoring is summarized in Table 6.16.

Table 6.16 Water chemistry QC sample frequencies for groundwater water monitoring

QC Samples	Frequency
Duplicate samples	10% of groundwater samples
Equipment blanks	Quarterly per piece of equipment (when used)
Trip blanks	Quarterly/semi-annually[1]
Field blanks	Quarterly/semi-annually[1]

Notes: [1] Quarterly for quarterly groundwater samples, semi-annually for semi-annual groundwater samples (i.e., six per year)

For results greater than five times the MDL, an RPD will be used to identify differences between original and duplicate samples. These DQOs are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

6.8.6 LABORATORY ANALYSIS

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC for chemistry samples, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.8.7 Data Analysis and Reporting

Data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, maximum, and 95th percentile values over the period of interest) and evaluation of water chemistry or water level changes and/or trends. Groundwater chemistry will be compared to the Schedule 3.2, Column 3 (Aquatic Life) standards in the ENV Contaminated Sites Regulation (CSR) under the EMA, and BC WQGs per Technical Guidance 15 (MOE 2017a). These data will also be used by a third party qualified professional for the three-year groundwater monitoring program review, and updates to hydrogeological models, including the Springer Pit groundwater model. Hazeltine Creek groundwater data will be used to support the geochemical characterization of materials in the Hazeltine Creek corridor.

6.9 Contact Water Quality Monitoring

Monitoring in this subsection falls under BC *Mines Act* M-200 and is only described here for completeness. Monitoring is summarized and changes will be presented in the CEMP, but changes to this monitoring are subject to BC *Mines Act* Permit M-200 and not Section 7 in the CEMP or Section 5 in the CEMP TOR (Appendix A).

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.9.1 Section Authors and Study Design Professionals

This section was written by MPMC.

6.9.2 Monitoring Objectives

The objective is to monitor trends in contact water quality on site, including runoff and mill process water, specifically at locations that represent the WTP source water. These data are applied to understand trends in site water chemistry and inform water management planning, including water discharge strategies.

6.9.3 Monitoring Overview

Table 6.17 summarizes the parameters analysed for contact water quality. Table 6.18 provides an overview of the contact water monitoring. Figure 6.5 shows monitoring locations of the contact water sampling locations.

Table 6.17 Contact water chemistry parameters

Parameter	LOR	Unit

These clean water ditches are monitored to ensure water quality is maintained; N/A: not applicable; TSF: Tailings Storage Facility; PAG: potentially acid generating

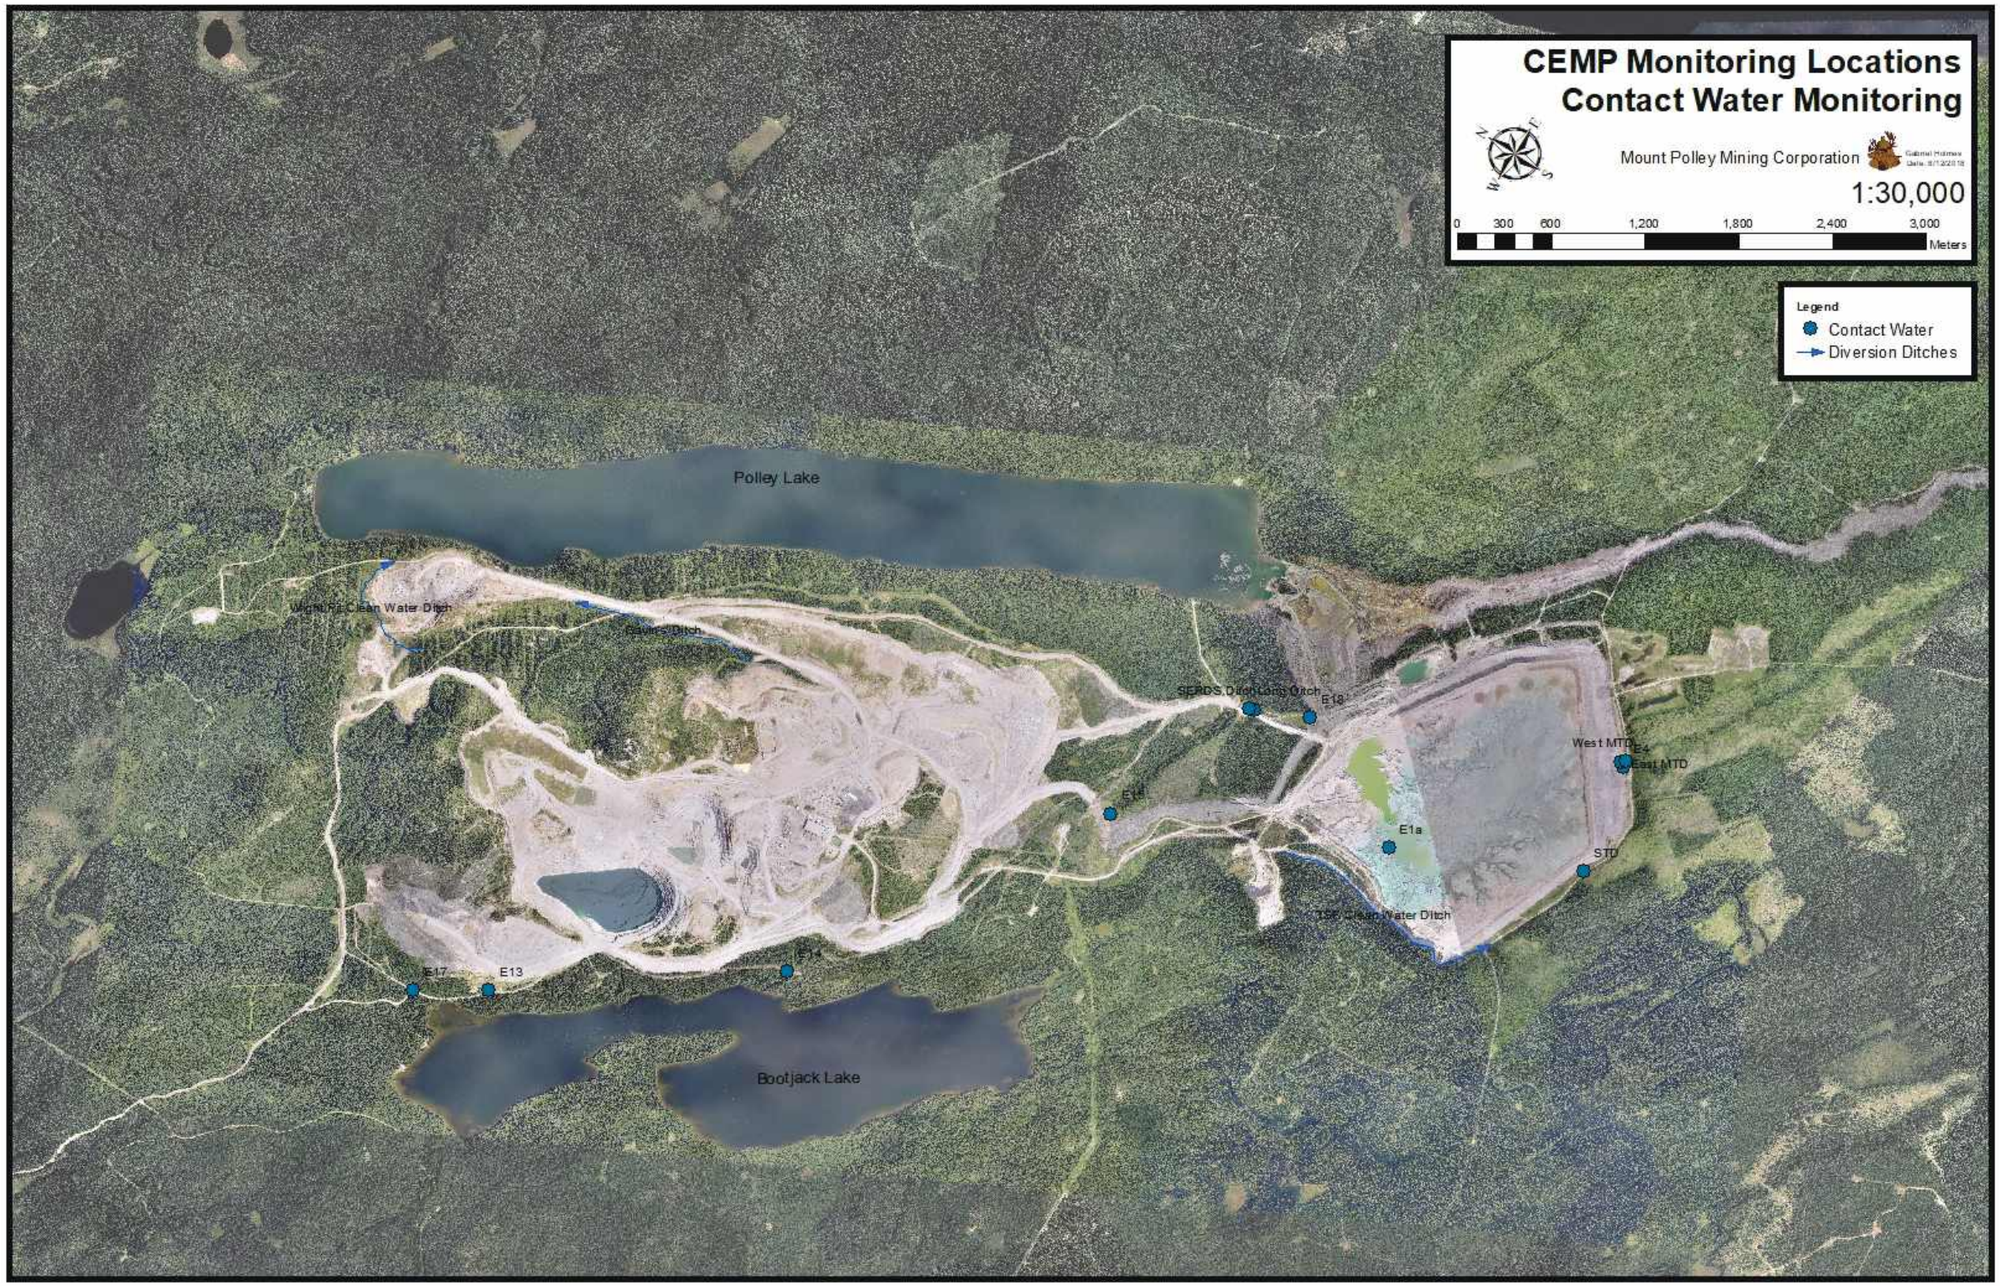

Figure 6.5 CEMP monitoring locations: Contact water monitoring

6.9.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Surface Water Quality Monitoring, and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.9.3.

Table 6.19 is a summary of previous contact water monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.19 Summary of contact water monitoring and findings

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Sumps that collect and temporarily store water as well as ditches that convey water from many different sources were monitored.	N/A	N/A
Summary of findings	There were no notable trends in 2017 contact water monitoring that suggested the monitoring program needs to be changed.	N/A	N/A
Recommendations for 2018-2020 monitoring	The Springer Pit Sump (E11) is no longer representative of the pit lake water quality and has not been the source of influent for the WTP since 2016. Tailings supernatant (E1a) is also not the source for the WTP. Therefore, these sites has been removed from monitoring under the Permit; E11 continues to be monitored under the *Mines Act* Permit M-200 (see Section 6.10).	N/A	N/A

Notes: N/A: not applicable; WTP: Water Treatment Plant

6.9.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all contact water monitoring is summarized in Table 6.20. For results greater than five times the MDL, an RPD will be used to identify differences between original and duplicate samples. These DQOs are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

Table 6.20 Water chemistry QC sample frequencies for contact water monitoring

QC Samples	Frequency
Duplicate samples	10% of contact water samples
Trip blanks	Combined with surface water QC schedule
Field blanks	Combined with surface water QC schedule

6.9.6 Laboratory Analysis

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.9.7 Data Management and Analysis

Data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, maximum, and 95th percentile values over the period of interest). These data, including spatial and temporal trends in relation to mine features and their geochemistry, will be used in long-term water management planning (Section 5.1).

6.10 Seep Monitoring

Monitoring included in this subsection fall under BC *Mines Act* Permit M-200 and is only described here for completeness. Monitoring is summarized and changes will be presented in the CEMP, but changes to this monitoring are subject to BC *Mines Act* Permit M-200 and not Section 7 in the CEMP or Section 5 in the CEMP TOR (Appendix A).

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.10.1 Section Authors and Study Design Professionals

This section was written by MPMC.

6.10.2 Monitoring Objectives

An important component in determining and monitoring long-term chemical stability of drainage from the pits and waste rock dumps is water quality monitoring. The seep sampling is conducted under the BC *Mines Act* Permit M-200.

6.10.3 MONITORING OVERVIEW

Under the BC *Mines Act* Permit M-200 seepage monitoring program, monitoring of waste rock dump seepages is conducted under a bi-annual seep survey program of all waste rock dumps on site, with representative seeps being monitored more frequently when possible (numerous seeps stop flowing during dry periods). Table 6.21 summarizes the parameters analysed for seepage water quality. A list of dumps and pits that are sampled, along with the representative sample locations, is provided in Table 6.22 and Table 6.23, respectively. Figure 6.6 shows monitoring locations of the seepage sampling locations.

6.10.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Surface Water Quality Monitoring, and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed as described in Section 6.10.3.

Table 6.24 is a summary of previous seep monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.24 Summary of seep monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	N/A	N/A	Seeps were sampled at the toe of waste rock piles and from pits that are not storing water from other locations.
Summary of findings	N/A	N/A	The results are used to inform long-term planning for reclamation and closure. It has been identified that two seeps from the NEZ Dump have elevated metal concentrations. See Section 6.10.4.1 for more detail.
Recommendations for 2018-2020 monitoring	N/A	N/A	The program will continue unchanged because bi-annual monitoring (i.e., in spring and fall) captures representative conditions.

Notes: N/A: not applicable; NEZ: North-East Zone

6.10.4.1 RECLAMATION AND CLOSURE MONITORING

NEZ Seep 1 and NEZ Seep 2 have elevated metal concentrations compared to other seeps on site. To address this, research into the source of the elevated metals has been launched, as well as possible treatment options. A new collection system for these two seeps has been constructed to isolate the water from the mine site collection infrastructure; this water will be pumped to the mill for the short-term while the research is conducted.

6.10.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. A combined QC schedule for all seep monitoring is summarized in Table 6.25.

Table 6.25 Water chemistry QC sample frequencies for seep monitoring

QC Samples	Frequency
Duplicate samples	10% of seep monitoring samples
Trip blanks	Quarterly/Semi-annually[1]
Field blanks	Quarterly/Semi-annually[1]

Notes: [1] Quarterly for quarterly sampling events; semi-annually for semi-annual sampling events

For results greater than five times the MDL, an RPD will be used to identify differences between original and duplicate samples. These DQOs are the same as the RPDs used by the lab. If one or both results are less than five times the MDL, a difference between original and duplicate samples greater than two times the MDL is used to identify differences. Blanks in which any parameters exceed the reported MDL will be flagged.

6.10.6 Laboratory Analysis

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

6.10.7 Data Analysis and Reporting

Collection of this data is used in long-term effluent water quality predictions. These results are presented in the AERR and are applied to understand long-term ML/ARD potential, develop site source terms, and inform water management planning.

6.11 Effluent Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.11.1 Section Authors and Study Design Professionals

This section was written by MPMC.

6.11.2 MONITORING OBJECTIVES

The objective of the effluent monitoring program is to verify the water chemistry complies with the applicable regulatory limits at the point of discharge (MDMER Schedule 4 and the Permit limits in Table 6.26; see Section 1.2.3 in the Permit), and that the discharge flow rate does not exceed the permitted rates of a maximum of 52,000 m^3/day and an annual average of 29,000 m^3/day (see Section 1.2.1 in the Permit). The influent is also sampled to allow for analysis of treatment efficacy.

6.11.3 MONITORING OVERVIEW

The flow rate, temperature, and TSS of the effluent will be continuously monitored and recorded in the Veolia WTP HMI. MPMC may consider less frequent sampling (MDMER minimum is quarterly) if the monthly mean concentrations of parameters are <10% of the MDMER guidelines for 12 months, as described Section 13 (1) of the MDMER. To make this change if these conditions are met, MPMC will follow the process outlined in Section 7. Table 6.27 summarizes the parameters analysed for effluent quality and Table 6.28 provides an overview of the effluent monitoring. Further details of monitoring sites, including site access descriptions, access or safety concerns, and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.7 shows monitoring locations of the effluent sampling locations. Reporting of the monitoring data is outlined in Section 9.

Table 6.26 Permit 11678 and MDMER Schedule 4 treated effluent compliance limits for direct discharge to Quesnel Lake

		Permit Limit		MDMER Schedule 4: Authorized Limits	
Constituent	**Units**	**Interim [1]**	**Final [2]**	**MAX Monthly Mean**	**MAX Grab Sample**

Zinc	mg/L	0.059		-	-
Dissolved Metals					
Aluminum	mg/L	0.75		-	-
Cadmium	mg/L	0.00034		-	-
Iron	mg/L	0.35		-	-
Acute Toxicity Testing Results					
96h LC50 Rainbow Trout	Mortality in 100% effluent	50%		-	LC50 >100%
48h LC50 *D. magna*		50%		-	LC50 >100%

Notes: [1] Maximum discharge limits until toxicity testing on final effluent concentrations is conducted; [2] Maximum discharge limits applicable after ENV is satisfied that toxicity testing demonstrates that the final effluent will not cause mixture toxicity. This requirement has been met; [3] MDMER requirement only; if cyanide is not used in the mining/milling process, then it does not have to be analysed. Since cyanide is not used in the mining/milling process at Mount Polley, the effluent is not analysed for cyanide; [4] MDMER requirement only; if 10 consecutive samples show radium 226 as less than 0.037 Bq/l then frequency of sampling for radium 226 can be reduced to once a quarter. This has been satisfied, and radium 226 analysis is currently conducted quarterly.

			Semi-annually[5]	Chronic toxicity tests: - Biological Test Method: *Toxicity Tests Using Early Life Stages of Salmonid Fish* (Rainbow Trout) (Reference Method EPS 1/RM/28) - Invertebrate species: *Biological Test Method: Test of Reproduction and Survival Using the Cladoceran Ceriodaphnia dubia* (Report EPS 1/RM/21) - Plant species: *Biological Test Method: Test for Measuring the Inhibition of Growth Using the Freshwater Macrophyte, Lemna minor* (Reference Method EPS 1/RM/37) - Algal species: *Biological Test Method: Growth Inhibition Test Using Freshwater Alga Selenastrum capricornutum* (Report Method EPS 1/RM/25)	MDMER

Notes: [1] Only when discharging; [2] MDMER requirement only; if 10 consecutive samples show radium 226 as less than 0.037 Bq/l then frequency of sampling for radium 226 can be reduced to once a quarter. This has been satisfied and radium 226 analysis is currently conducted quarterly; [3] EEM requirement only; can be discontinued if concentration is less than 0.10 µg/L in 12 consecutive samples. This has been satisfied and mercury analysis has been discontinued; [4] MDMER June 2018 Part 2 Division 2 16 (1): frequency may be reduced to quarterly if discharge is determined not to be acutely lethal for 12 consecutive months; [5] Chronic/sub-lethal toxicity tests are conducted semi-annually for 3 years. MDMER June 2018 Schedule 5, 6 (1-3): after 3 years, frequency will be increased to once per calendar quarter on the sub lethal species whose results of sub lethal tests produce the lowest geometric mean, taking into account the inhibition concentration that produces a 25% effect or effective concentration of 25%; N/A: not applicable; TSS: total suspended solids; DOC: dissolved organic carbon; MDMER: Metal and Diamond Mining Effluent Regulations; EEM: Environmental Effects Monitoring

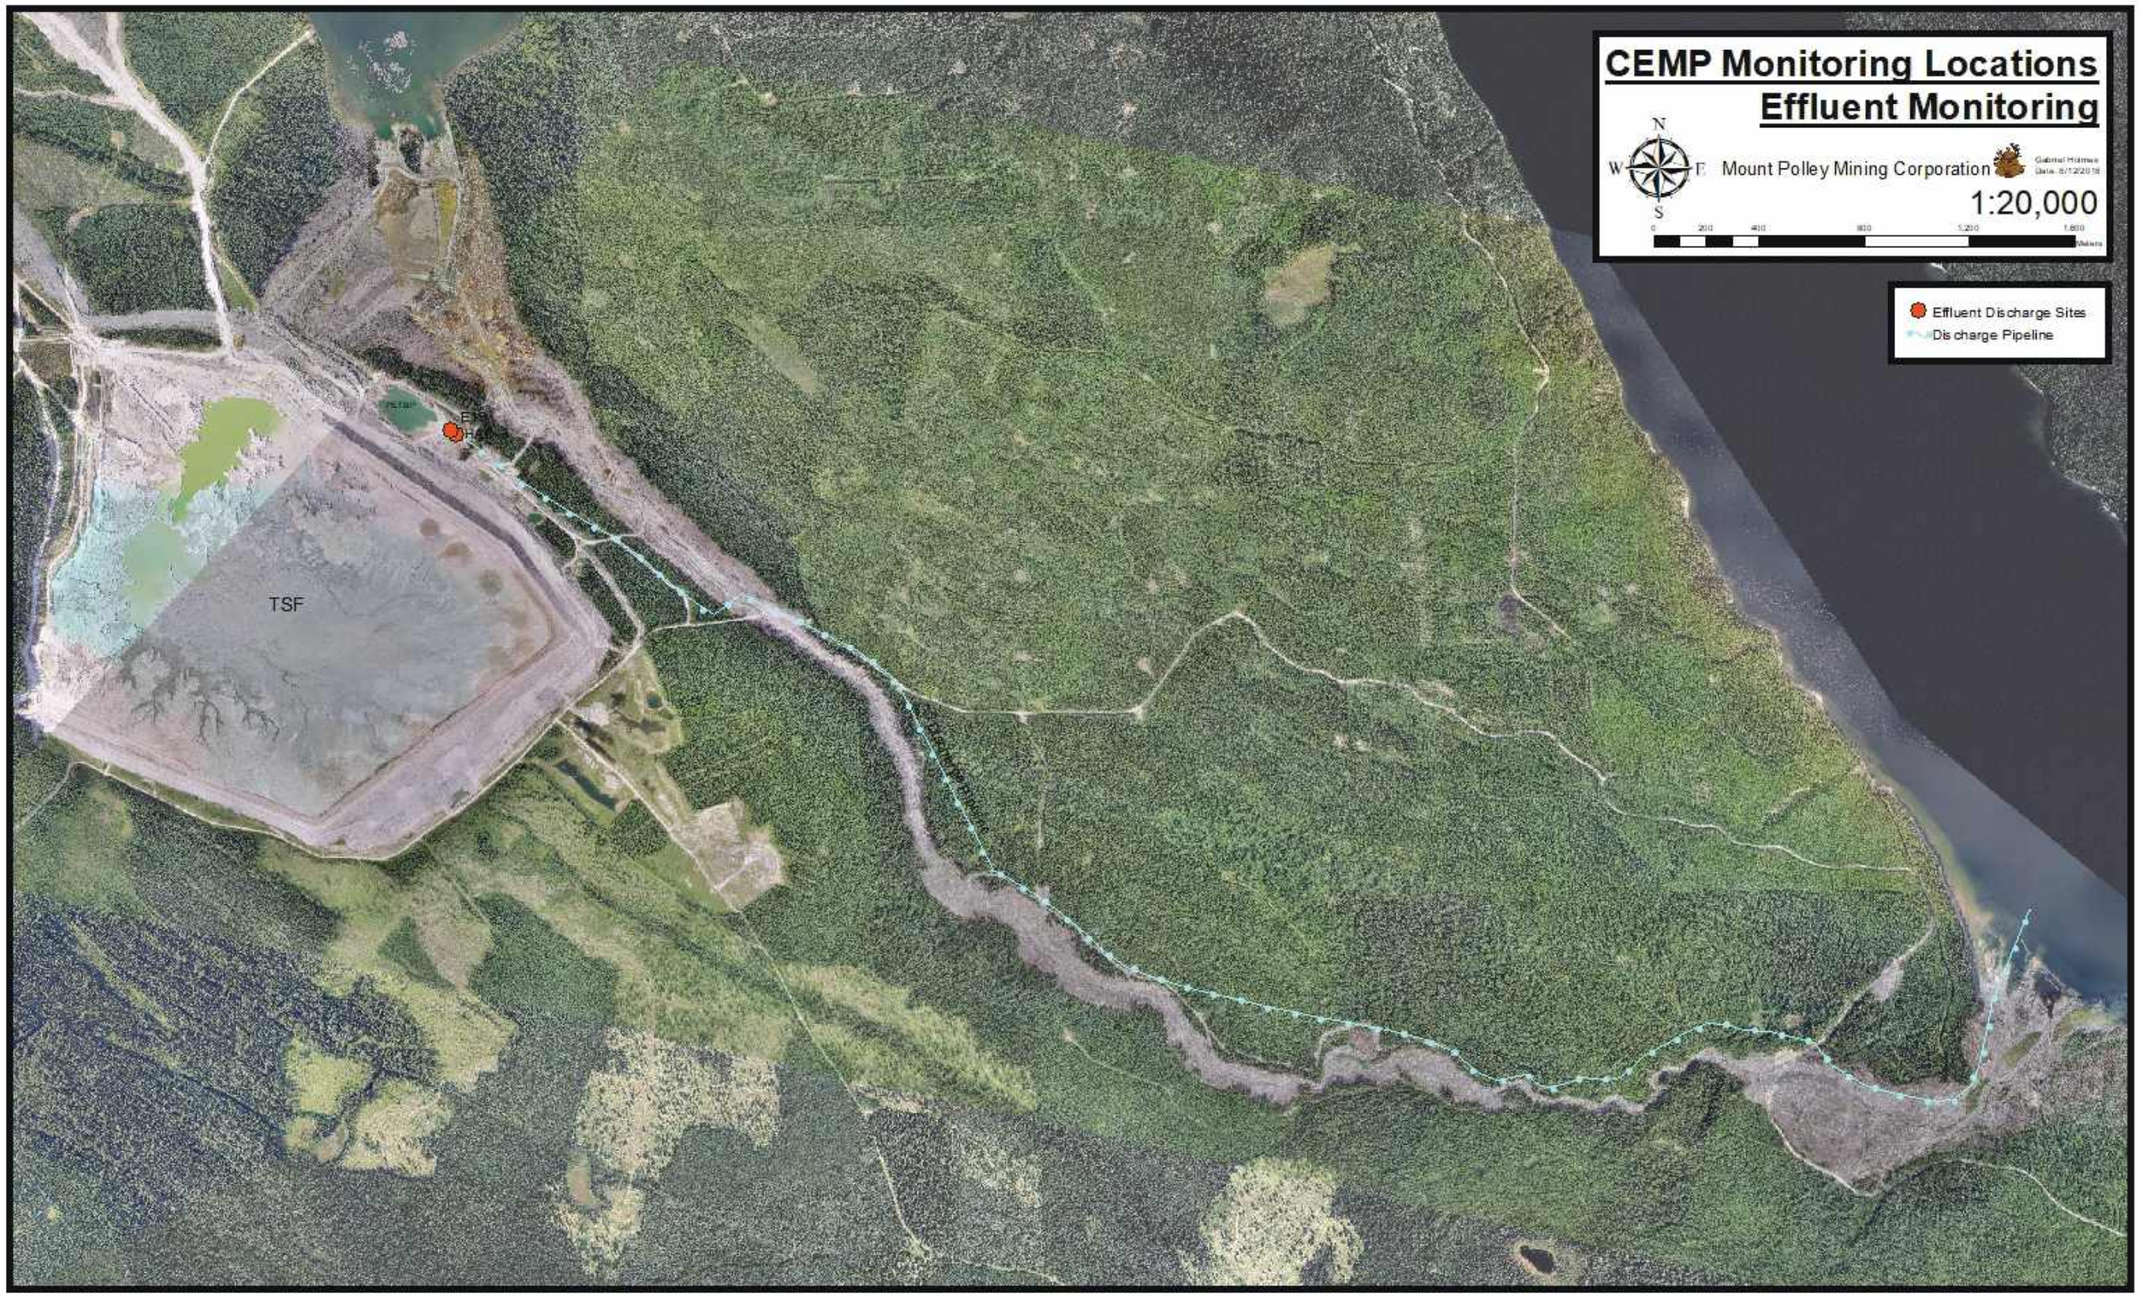

Figure 6.7 CEMP monitoring locations: Effluent monitoring

6.11.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following the SOPs and WMs for Surface Water Quality Monitoring, and use of associated field meters in the QA/QC Manual. These procedures include use of lab-verified clean or appropriately rinsed sampling bottles and steps to reduce risk of sampling contamination. *In-situ* parameters will be measured when samples for chemistry are collected. Water samples will be analyzed for the parameters described in Section 6.11.3.

Table 6.29 is a summary of previous effluent monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.29 Summary of effluent monitoring and findings

Summary of Monitoring and Findings	**Monitoring Objective**		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Discharge monitoring included the influent and treated effluent.	N/A	N/A
Summary of findings	All samples were at or below permit limits for the treated effluent in 2017; in 2016, the majority of samples were at or below the permit limits. When samples did not meet permit limits, ENV was notified and an investigation into the cause was undertaken. Comparing the influent concentrations to treated effluent concentrations verified reduction in parameters interest. See Section 6.11.4.1 for more details.	N/A	N/A
Recommendations for 2018-2020 monitoring	Monitoring of the influent (E19) will be increased from monthly to weekly to align with monitoring of HAD-03 for better efficiency analysis of the WTP.	N/A	N/A

Notes: N/A: not applicable; ENV: Ministry of Environment and Climate Change Strategy; WTP: water treatment plant

Should there be an extreme weather event or equipment failure in the WTP that could affect water quality in the effluent, MPMC has the ability to request rush analysis from the analytical lab (ALS). MPMC maintains an Emergency Response Plan for the effluent discharge as required by the MDMER and the Permit.

6.11.4.1 OPERATIONAL MONITORING

Figure 6.8 shows total copper concentrations and Figure 6.9 shows TSS in the influent (E19) and effluent (HAD-03) in 2017. No exceedances were recorded in 2017 in the effluent.

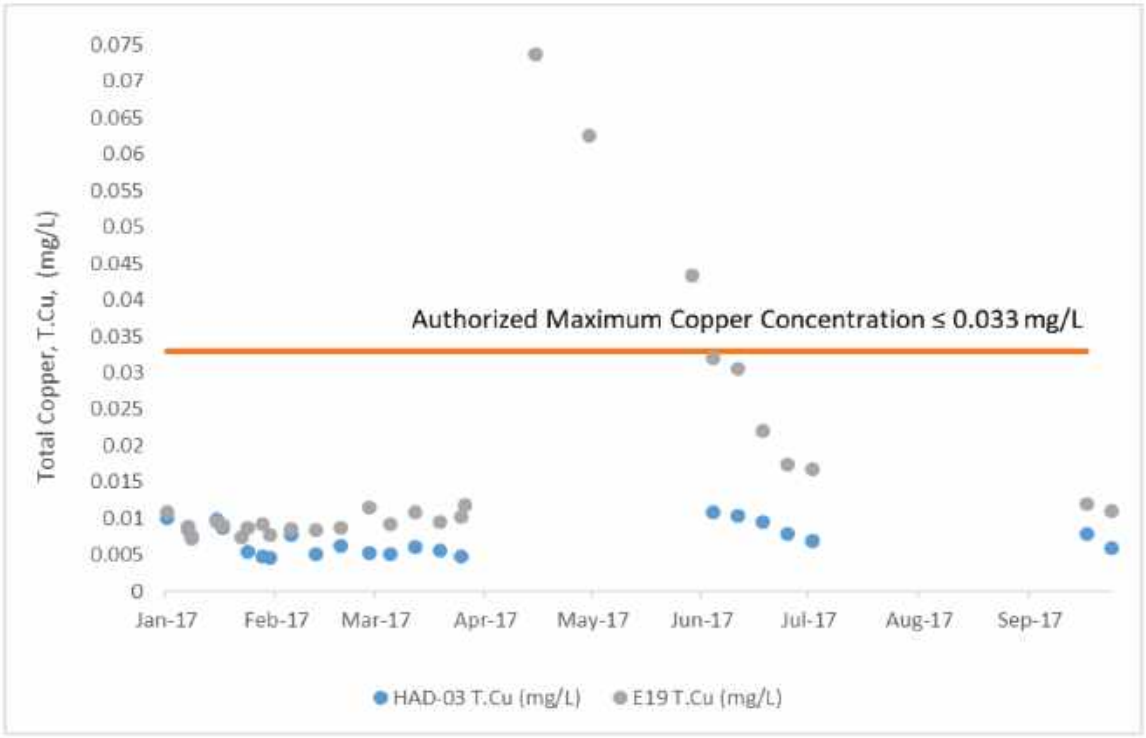

Figure 6.8 Total suspended solids concentrations in influent (E19) and effluent (HAD-03) in 2017

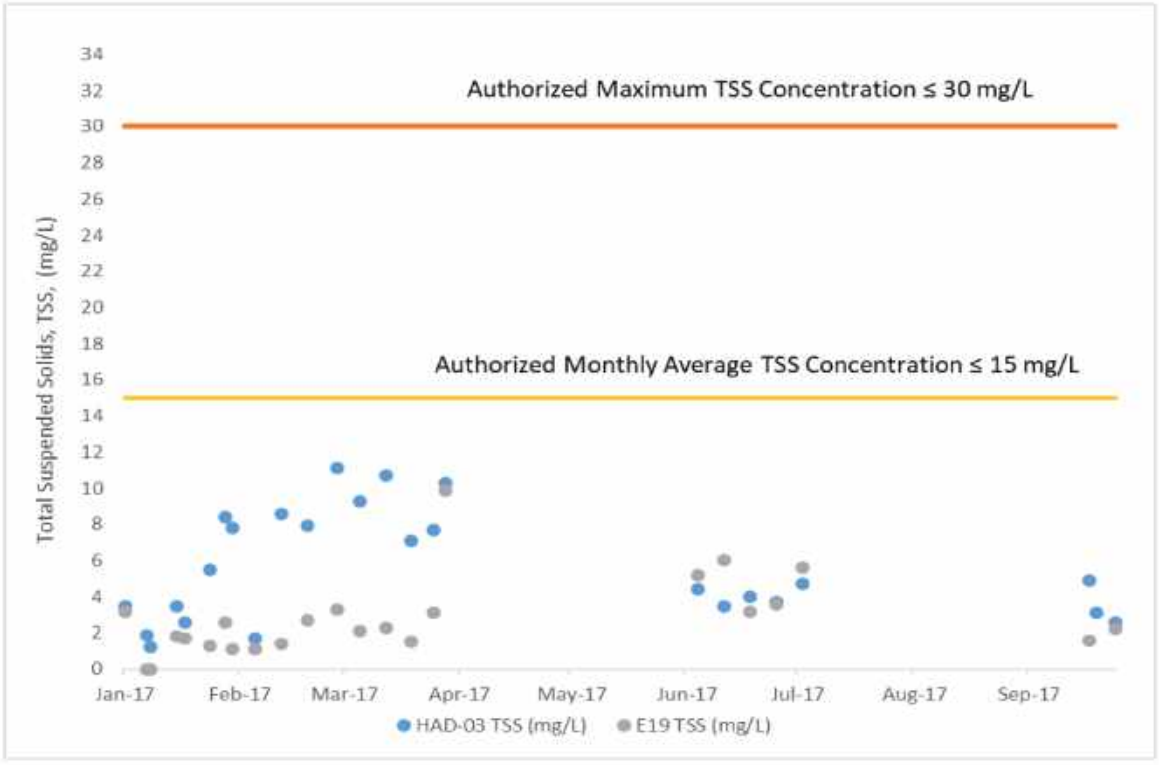

Figure 6.9 Total copper concentrations in influent (E19) and effluent (HAD-03) in 2017

MPMC conducts acute toxicity tests monthly for LC50 Rainbow trout and LC50 *Daphnia magna*. Under the new MDMER, *D. magna* is now a compliance parameter. MPMC will continue to conduct these acute lethality tests as required.

MDMER has changed the frequency of acute toxicity tests for effluent discharge. In accordance with Part 2, Division 2, paragraph 16 (1), acute lethality tests at the final discharge point (HAD-3) will become quarterly if the effluent is determined to be non-lethal for 12 consecutive months (Government of Canada 2018). Effluent at HAD-3 since discharge has started (December 2015) has been shown to be non-lethal.

MPMC has conducted chronic toxicity tests on the effluent discharge since December 7, 2015 on a quarterly and semi-annual basis. Under MDMER requirements, after three years (after December 2018 at HAD-3), the chronic toxicity tests results will be reviewed by a QP and will be streamlined to one test only. This test will be based on the most sensitive organism to the effluent according to historical geometric means and will be tested quarterly. The reduction of frequency from the 2016 CEMP for the chronic toxicity tests, as described in Table 6.28, aligns with the MDMER, as no actionable effects have been recorded at HAD-03 and the MDMER protocol is established to characterise the impacts on the most sensitive aquatic life.

6.11.5 Data Quality Control, Objectives, and Review

For water chemistry, QC samples will be collected as a component of the monitoring program as per the MPMC QA/QC Manual. Effluent monitoring samples are combined in the surface water QC schedule (see Section 6.6.5), as laid out in Table 6.8.

6.11.6 Laboratory Analysis

Samples will be submitted to and processed by a CALA accredited analytical laboratory, typically ALS Environmental Inc. in Burnaby, BC for chemistry samples and Nautilus Environmental in Burnaby, BC for toxicity testing, where standard testing procedures will be used as specified in the most recent editions of the *BC Environmental Laboratory Manual* (MoE 2015) and the MDMER (where applicable; i.e., discharge water toxicity testing).

Laboratory precision will be assessed on the basis of laboratory duplicate results and laboratory accuracy will be assessed using certified reference materials (CRMs) and matrix spikes. Potential laboratory contamination will be assessed using a DQO of ≤ 2 times the laboratory MDL in laboratory method blank results.

QC monitoring for toxicity testing will be carried out at the laboratory, as per the test methods, with requirements to meet criteria such as test organism health history, and control acceptability. Uncertainty associated with test results will be described by the standard deviation around the mean and/or the confidence limits around the point estimate.

6.11.7 Data Analysis and Reporting

Data analysis and interpretation for reporting purposes will include calculation of summary statistics (e.g., mean, minimum, max, and 95th percentile values over the period of interest) and screening of results

against applicable regulatory benchmarks (see Table 6.26). Screening will include evaluation of results at the treated effluent discharge against MDMER and the Permit limits. Alerts are set up in the MP-5 database so that MPMC Environmental Department staff receives an email if specified benchmarks are exceeded.

6.12 SEDIMENT QUALITY MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.12.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow Environmental Inc. (Minnow). The detailed study design is provided in Appendix B.1. Golder prepared the study design for selecting an alternate reference lake for Polley Lake (Appendix B.7).

6.12.2 MONITORING OBJECTIVES

As outlined in Appendix B.1, the objectives of sediment quality monitoring are to:

- "Evaluate the influence of mine activities on the receiving environments (e.g., Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions";
- "Determine potential implications to aquatic life by applying a variety of interpretive tools";
- "Provide data to support exposure assessment as part of the ERA and HHRA";
- "Provide supporting information for benthic invertebrate community monitoring"; and,
- "Advance technical understanding of the stability or mobility and potential bioavailability of metals and metalloids in lake sediments affected by the TSF Breach".

6.12.3 MONITORING OVERVIEW

Sediment quality monitoring under the CEMP is proposed to meet the combined needs of:

1) Operational monitoring (including the discharge of treated effluent to Quesnel Lake);
2) Monitoring of the impact of the 2014 perimeter embankment failure; and
3) Monitoring of response to reclamation activity following the perimeter embankment failure.

An overview of the proposed sediment quality monitoring program is provided in Table 2 and Figures 5 and 6 of Appendix B.1. Sediment quality monitoring is focused on Polley Lake, Hazeltine Creek, and Quesnel Lake, with reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake for Polley Lake, unaffected areas of Quesnel Lake for impacted areas of Quesnel Lake). Table 3 in Appendix B.1 summarizes the analytes and laboratory reporting limits for the sediment quality monitoring program.

The monitoring program is divided into lake monitoring and creek monitoring and will include physical and chemical characterisation of deposited sediments. Sediment quality sampling will be supported by

measurements of temperature, dissolved oxygen, pH, and specific conductance near the sediment-water interface at all sampling stations. Some additional monitoring of the stability and potential bioavailability of metals associated with sediments impacted by the TSF Breach may be undertaken (e.g., deployment of Diffusive Gradients in Thin Films [DGT] devices to monitor labile metal concentrations; toxicity testing using *Hyalella azteca*). More detail is provided in Appendix B.1.

6.12.4 High-Level Monitoring Design Description

Appendix B.1 provides a summary of sediment monitoring history previously conducted in the vicinity of the mine in the surrounding lakes and creeks, including baseline, and pre- and post-breach monitoring. The sample collection methods are also summarized in Appendix B.1 for lake sediment sampling, creek sediment sampling, and DGT sampling. A study design for evaluating alternate reference lakes for Polley Lake is provided in Appendix B.7.

6.12.5 Data Quality Control, Objectives, and Review

Appendix B.1 summarizes the QAQC program for the sediment monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. As described in Appendix B.1, "comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD <40% for concentrations that are >5 times the detection limit, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective detection limits." See Appendix B.1 for more details.

6.12.6 Laboratory Analysis

Chemical analyses will be completed at a CALA accredited analytical laboratory and will include moisture content, pH, particle size distribution, total organic carbon (TOC), total nitrogen, total sulphur, and total metal concentrations, as summarized in Table 3 in Appendix B.1.

Toxicity testing will be conducted at a CALA accredited testing laboratory using a 10 day test of the survival and growth of *Chironomus dilutus.* DGT analysis is described in detail in Appendix B.1 in Section 4.3.

6.12.7 Data Analysis and Reporting

As described in Appendix B.1, data will be provided to the QP and summarized by calculating mean, median, standard deviation, standard error, minimum, maximum, 5^{th} percentile, and 95^{th} percentile for each analyte for all replicated data. Appendix B.1 describes how "sediment quality data will then be evaluated in comparison to British Columbia Working Sediment Quality Guidelines for the protection of aquatic life (WSQGs; MOE 2017b) and reference concentrations. Reference 95^{th} percentile values will be used to screen exposed-area mean concentrations to efficiently identify analytes with concentrations that are beyond the range of reference.

"The overall interpretation of sediment quality data will include integration of a weight-of-evidence that includes other components of the MPMC CEMP (e.g., benthic invertebrate community data). Thus, within

the CEMP, sediment quality data interpretation will specifically include the integration of data on sediment quality, the results of specialized evaluations (e.g., DGT results), and the results of bio-assessment (e.g., sediment toxicity testing and benthic invertebrate communities).

"An interpretive report based on the sediment quality data will be prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an Appendix and will include the data quality review, the results of the screening against BCWSQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots."

6.13 BENTHIC INVERTEBRATE MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.13.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow. The detailed study design is provided in Appendix B.2. Golder prepared a study design for selecting an alternate reference lake for Polley Lake (Appendix B.7).

6.13.2 MONITORING OBJECTIVES

As outlined in Appendix B.2, the objectives of benthic invertebrate monitoring are to:

- "Evaluate the influence of Mount Polley Mine activities on benthic invertebrate communities, productivity, and tissue quality in receiving environments (e.g., Polley Lake, Hazeltine Creek, Edney Creek, and Quesnel Lake) in comparison to baseline and/or reference conditions";
- "Determine potential implications to aquatic life (e.g., through assessment of benthic invertebrate community and productivity endpoints, and comparison of benthic tissue quality results to available guidelines; MoE 2014) and to aquatic ecosystem health by providing supporting information for the assessment of potential effects to higher trophic levels (e.g., fish and fish habitat quality; Section 6.16)"; and,
- "Provide data to support exposure assessment as part of the ERA and HHRA."

Benthic invertebrate community monitoring is also required as part of EEM under the MDMER. The objective of the MDMER EEM benthic invertebrate monitoring identified in Appendix B.2 is to "evaluate whether there are effects to benthic invertebrate community characteristics between the area of Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012)."

6.13.3 MONITORING OVERVIEW

Benthic invertebrate monitoring under the CEMP is designed to meet the combined needs of:

1) Operational monitoring (including the discharge of treated effluent to Quesnel Lake);
2) Monitoring of the impact of the 2014 TSF embankment breach; and
3) Monitoring of the response to reclamation activity following the TSF embankment breach.

An overview of the proposed benthic invertebrate monitoring program is provided in Table 3 of Appendix B.2, and includes benthic invertebrate community, productivity, and tissue quality. Benthic invertebrate monitoring is focused on Polley Lake, Hazeltine Creek, lower Edney Creek, Quesnel Lake, and associated reference areas (Figures 6 and 7 of Appendix B.2). Table 4 in Appendix B.2 summarizes the analytes and laboratory reporting limits for the benthic invertebrate monitoring program. The sampling frequency at this time is once every three years.

6.13.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Appendix B.2 provides a summary of benthic invertebrate monitoring history previously conducted in the vicinity of the mine in the surrounding lakes and creeks, including baseline, and pre- and post-breach monitoring. The sample collection methods are also summarized in Appendix B.2 for community and productivity sampling, and tissue quality sampling. A study design for evaluating alternate reference lakes for Polley Lake is provided in Appendix B.7.

6.13.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Appendix B.2 summarizes the QAQC program for the benthic invertebrate monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. As stated in Appendix B.2, "for benthic invertebrate tissue quality samples, comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD <25% for concentrations that are >5 times the detection limit, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective detection limits.

"For benthic invertebrate community samples, reanalysis for quality control endpoints (organism sorting efficiency, subsampling precision and accuracy error, and taxonomic identification error) will be performed on 10% of samples, and results of quality control measures will be evaluated relative to pre-established DQOs." See Appendix B.2 for more details.

6.13.6 LABORATORY ANALYSIS

As described in Appendix B.2, "taxonomic identification of benthic invertebrate community samples will be completed by a qualified laboratory certified under the Taxonomic Certification Program of the Society for Freshwater Science (SFS). Benthic invertebrate tissue quality samples will remain frozen until overnight shipment on ice with completed COCs to ALS Environmental, Burnaby BC, which is an analytical laboratory accredited by the CALA."

6.13.7 DATA ANALYSIS AND REPORTING

As described in Appendix B.2, data will be provided to the QP and summarized by calculating mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile for each endpoint for all replicated data. Data analysis will be completed for each monitoring component (community, productivity, and tissue quality). More detail for each monitoring component is provided in Section 4.5 of Appendix B.2.

As stated in Appendix B.2, "an interpretive report based on the benthic invertebrate data will be prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an appendix and will include the date quality review, the results of the screening against BCWQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots."

6.14 PLANKTON AND CHLOROPHYLL *A* MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.14.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC.

6.14.2 MONITORING OBJECTIVES

The objective of phytoplankton and zooplankton monitoring at lake stations is to assess potential changes in plankton community abundance and diversity, as well as temporal and special changes in zooplankton metal concentrations. Chlorophyll *a* sampling will be conducted and analyzed to provide support data that can be interpreted with other biological monitoring and water chemistry data in a broader analysis of lake productivity.

This monitoring will be conducted to aid in assessing lake productivity following the TSF embankment breach (Post-Breach Monitoring: Polley Lake and Quesnel Lake) and to identify any changes related to the chemistry of the discharged treated effluent (Operational Monitoring: Quesnel Lake).

6.14.3 MONITORING OVERVIEW

Table 6.30 summarizes the parameters analysed for plankton and chlorophyll *a* monitoring. Chlorophyll *a*, phytoplankton taxonomy and biomass, and zooplankton taxonomy and metal tissue samples will continue to be collected concurrently with water chemistry samples (including field parameters) three times per year to capture early and late growing seasons as outlined in Table 6.31. Growing seasons were determined after monthly sampling was conducted in 2015; data analysis of zooplankton community is presented in Golder (2016d). Further details of monitoring sites, including site access descriptions, access or safety concerns,

and a brief rationale for monitoring, is provided in the Site Matrix in Appendix D. Figure 6.10 shows monitoring locations of the plankton and chlorophyll *a* sampling locations.

Table 6.30 Plankton and chlorophyll *a* parameters

Parameter	LOR	Unit
Taxonomy		
Phytoplankton	-	-
Zooplankton	-	-
Total Metals in Tissue		
Aluminum (Al)	2	mg/kg

Table 6.31 Plankton and chlorophyll *a* monitoring overview

Station Name	EMS Code	Description	Frequency	Parameters Measured	Guidelines
P2	E307975	Polley Lake deepest area at south end	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A
B2	E215897	Bootjack Lake deepest area at south end	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A
QUL-ZOO-1	E306455	Quesnel Lake zooplankton station at Hazeltine	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A
QUL-ZOO-7	E306456	Quesnel Lake zooplankton station at Horsefly	Three times between June 15 and September 15, at least 30 days apart	Chlorophyll *a*, Phytoplankton taxonomy and biomass Zooplankton metals, taxonomy, and biomass	N/A

Notes: N/A: not applicable; IDZ: initial dilution zone

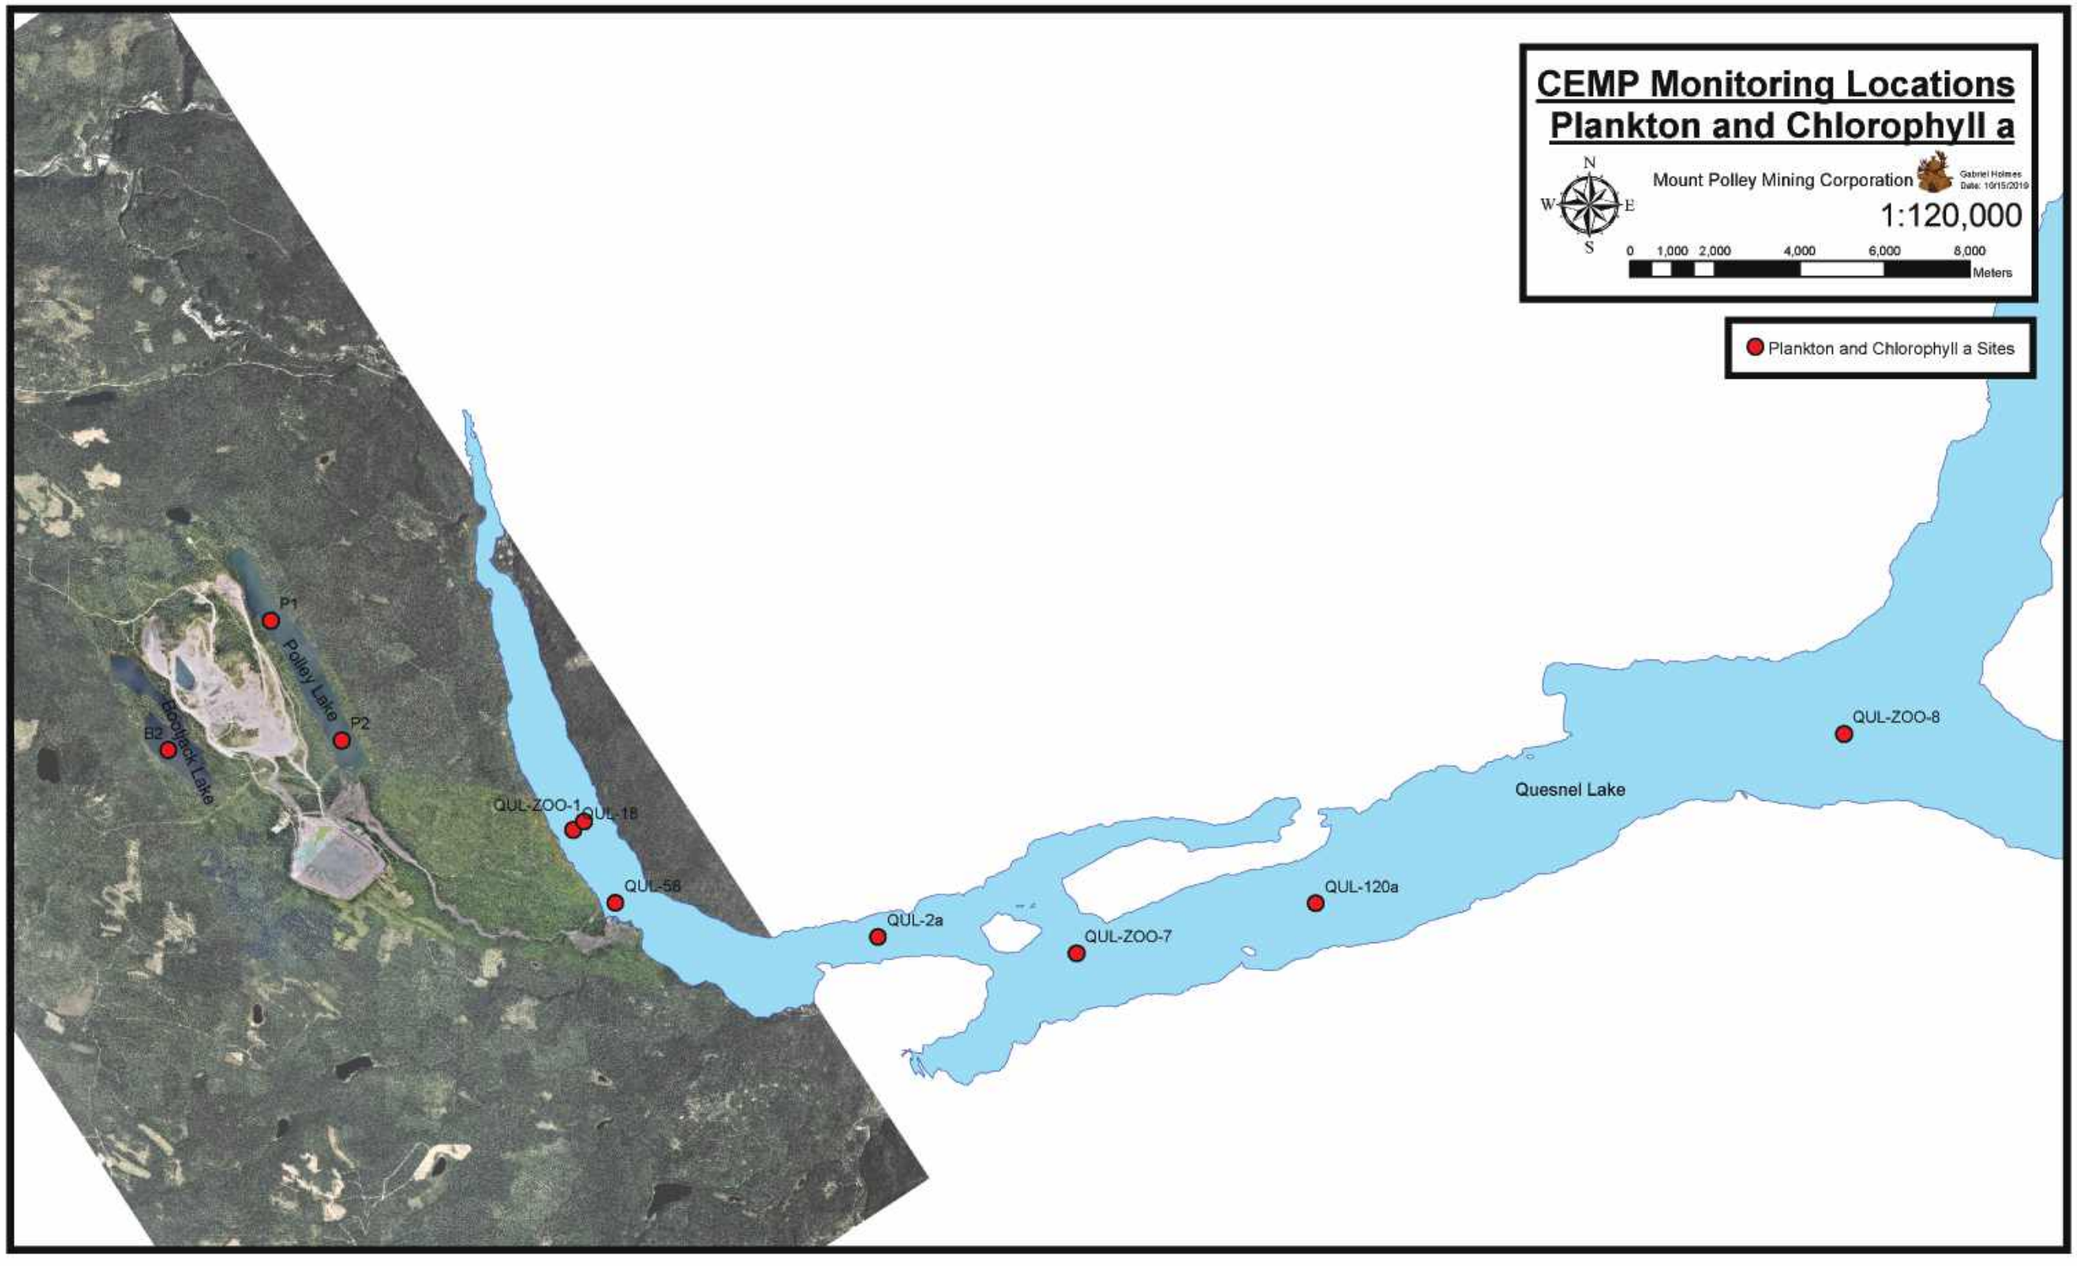

Figure 6.10 CEMP monitoring locations: Plankton and chlorophyll *a* monitoring

6.14.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Sample collection, preparation, and shipping will be conducted following procedures outlined in the SOPs and WMs on Lake Water Monitoring and Zooplankton Sampling in the MPMC QA/QC Manual.

In brief, sampling at all stations will be conducted as follows:

- Zooplankton samples:
  - will be collected using 50 µm mesh nets with a mouth diameter ≥0.5 m, and equipped with a flow meter. In 2019, for stations previously sampled with a 150-µm mesh net, samples will be collected with both a 50- and a 150-µm mesh net to enable an assessment of the difference between the two net mesh sizes and to facilitate comparison with historical data.
  - will be collected using a modified horizontal tow.
  - for taxonomy/biomass will be transferred to a Nalgene container and preserved with buffered formalin.
  - for tissue chemistry will consist of a composite of multiple tows to achieve a minimum required tissue mass for analysis (i.e., 1.5 g).
- Phytoplankton samples
  - will be collected as a depth-integrated sample. Water will be collected from at least four discrete depths at each station (surface, one-third Secchi depth, two-thirds Secchi depth, total Secchi depth), with a grab sampler (e.g., Kemmerer, Van Dorn) or with a length of flexible tubing modified for this purpose, with or without a peristaltic pump.
  - will be collected as surface and depth-integrated samples in 2019 to allow for an assessment of the difference between the two methods and to facilitate comparison with historical data.
  - for Chlorophyll *a* analysis will be transferred to a container wrapped in aluminum foil.
  - for taxonomy/biomass will be preserved with Lugol's solution

One replicate will be collected in each of June and August, and five replicates will be collected during the July sampling event, and samples for zooplankton and phytoplankton will be collected on the same day for each lake. Secchi depth and *in situ* water-chemistry supporting data will be collected concurrently at each station.

Table 6.32 is a summary of previous plankton and chlorophyll *a* monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable. Monitoring for plankton and chlorophyll *a* overlaps with operational monitoring in Quesnel Lake, as described in Section 6.14.2.

Table 6.32 Summary of plankton and chlorophyll *a* monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	Plankton (phyto and zoo) taxonomy and chlorophyll *a* sampling frequency was semi-annually in 2016 and 2017 (June/July and August) at two stations in Polley Lake and three stations in Quesnel Lake. Some sampling events were missed in 2017 due to safety concerns.		N/A
Summary of findings	Zooplankton and phytoplankton results will be analysed in the three-year interpretive report (see Section 9.4) and recommendations for changes may be made, if required, in this report. Some chlorophyll *a* data were collected prior to the TSF breach. Results from 2013 – 2017 are shown in Section 6.14.4.1.		N/A
Recommendations for 2017-2020 monitoring	The sampling program outlined in Table 6.31 will be repeated annually.		N/A

Notes: N/A: not applicable

6.14.4.1 POST-BREACH MONITORING

Figure 6.11 shows chlorophyll *a* data collected from Polley Lake from 2013 – 2017. Data from P2 will continue to be collected to analyse potential trends.

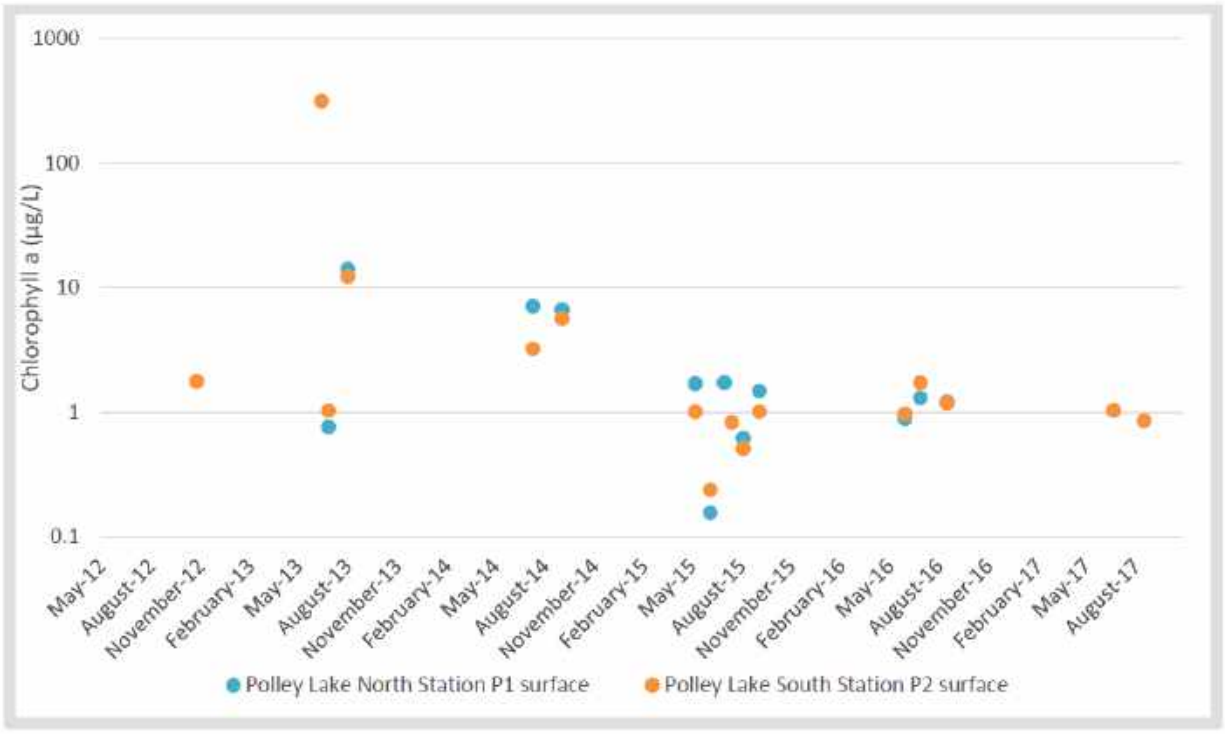

Figure 6.11 Chlorophyll *a* data collected from Polley Lake from 2013 - 2017

6.14.5 Data Quality Control, Objectives, and Review

QA/QC procedures will consist of re-analysis of 10% of phytoplankton and zooplankton taxonomy samples, and analysis of a duplicate metals sample for tissue chemistry once annually. For taxonomy, replicate counts should meet the DQO of within 20% of the original count. For metals, the RPD data quality of greater than 40% for concentrations greater than or equal to five times the MDL will be used to identify differences between original and duplicate samples for metals.

6.14.6 Laboratory Analysis

Plankton taxonomy samples will be shipped to the following laboratories for processing[2]:

- Biologica environmental Services Ltd., Victoria, BC: plankton taxonomy.
- ALS Environmental Inc., Burnaby, BC[3] – chlorophyll *a* and zooplankton tissue chemistry.

6.14.7 Data Analysis and Reporting

Statistical analysis will be carried out to evaluate trends over time by comparing results with data collected annually. In Quesnel Lake, near-field data will be compared with far-field and reference data to evaluate

[2] No accreditation program exists for plankton taxonomy

[3] Accredited by the Canadian Association of Laboratory Accreditation (CALA)

potential mine impact and spatial trends. These data will also be used to assess implications for lake productivity and fish populations.

6.15 PERIPHYTON MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.15.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow. The detailed study design is provided in Appendix B.3.

6.15.2 MONITORING OBJECTIVES

As outlined in Appendix B.3, the objectives of periphyton monitoring are to:

- "Evaluate the influence of mine activities (related to mine operations, the TSF breach, and/or rehabilitation activities) on Hazeltine Creek (the creek receiving environment directly influenced by mine activity) and lower Edney Creek (a creek environment directly influenced by the TSF breach)";
- "Serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (benthic invertebrates and fish; Sections 6.13 and 6.16, respectively)";
- "Provide supporting information for the assessment of benthic invertebrate tissue quality, benthic invertebrate community condition, and fish habitat productivity"; and,
- "Provide data to support exposure assessment as part of the ERA and HHRA".

Periphyton monitoring will include assessment of productivity, community composition, and tissue quality, with comparison to previous and/or reference conditions, to applicable guidelines (i.e., chlorophyll *a*; MoE 2018), and to literature-based criteria (or classification ranges) for productivity.

6.15.3 MONITORING OVERVIEW

Periphyton monitoring under the CEMP is proposed to meet the combined needs of:

1) Operational monitoring (including the previous discharge of treated effluent to Hazeltine Creek);
2) Monitoring of the impact of the 2014 TSF breach; and
3) Monitoring of the response to reclamation activity following the TSF breach.

An overview of the proposed periphyton monitoring program is provided in Table 1 and Figure 4 of Appendix B.3. Periphyton monitoring is focused on Hazeltine Creek and lower Edney Creek with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and an unaffected area of lower Edney Creek for rehabilitated areas of lower Edney Creek

and lower Hazeltine Creek). Table 2 in Appendix B.3 summarizes the analytes and laboratory reporting limits or the periphyton monitoring program.

6.15.4 High-Level Monitoring Design Description

Appendix B.3 provides a summary of periphyton monitoring history previously conducted in the vicinity of the mine in the surrounding creeks, including pre- and post-breach monitoring. The sample collection methods are also summarized in Appendix B.3 for biomass and chlorophyll *a* sampling, community sampling, and tissue quality sampling.

6.15.5 Data Quality Control, Objectives, and Review

Appendix B.3 summarizes the QAQC program for the periphyton monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. As stated in Appendix B.3, "comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD < 25% for concentrations that are > 5 times the detection limit, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective detection limits. Specific QC sampling and associated reporting will for tissue quality and periphyton productivity endpoints be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). QC reporting will also be requested of the laboratory performing taxonomic analysis of the periphyton community samples, including organism enumeration checks for a minimum of 10% of samples." See Appendix B.3 for more details.

6.15.6 Laboratory Analysis

The laboratory responsible for the physical or chemical analyses will be accredited by the CALA for these analyses.

6.15.7 Data Analysis and Reporting

For all replicated data (typically based on a sample size of five or eight stations per area), data will be provided to the QP and summarized by calculating mean, median, standard deviation, minimum, and maximum for each analyte. Data analysis will be completed for each monitoring component (productivity, community, and tissue quality). More detail for each monitoring component is provided in Section 4.5 of Appendix B.3.

As outlined in Appendix B.3, "an interpretive report based on the periphyton monitoring data will be prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an appendix and will include the data quality review, the results of the screening against BCWSQG and other guidelines or classification schemes, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots."

6.16 FISH MONITORING

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.16.1 SECTION AUTHORS AND STUDY DESIGN PROFESSIONALS

This section was written by MPMC, and is a summary of the study design provided by Minnow. The detailed study design is provided in Appendix B.4.

6.16.2 MONITORING OBJECTIVES

As outlined in Appendix B.4, the objectives of fish monitoring are to:

- "Evaluate the influence of Mount Polley Mine activities on fish communities, populations, and tissue quality in receiving environments (Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions";
- "Determine potential implications to aquatic ecosystem health and human health (e.g., relative to available fish tissue quality guidelines [MoE 2014; CFIA 2015])";
- "Provide data to support exposure assessment as part of the ERA and HHRA"; and,
- "Document fish habitat utilization in creek and lake areas that were physically impacted by the TSF breach (most notably Hazeltine Creek and the lower segment of Edney Creek), thereby documenting the effectiveness of fish habitat rehabilitation efforts".

From Appendix B.4, the objective of the MDMER EEM fish monitoring is to "evaluate whether there are differences in population endpoints (survival, growth, and reproduction) of sentinel fish species between the area of Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012)." Evaluation of selenium in fish tissues is also triggered under the MDMER on the basis of current selenium concentrations in effluent.

6.16.3 MONITORING OVERVIEW

Fish monitoring under the CEMP is designed to meet the combined needs of:

1) Operational monitoring (including the discharge of treated effluent to Quesnel Lake);
2) Monitoring of the impact of the 2014 TSF embankment breach; and
3) Monitoring of the response to remediation following the TSF embankment breach.

As previously indicated, fish monitoring includes fish tissue quality monitoring, sentinel fish population monitoring, fish habitat characterization and fish usage monitoring, and fish community monitoring. An overview of the proposed fish monitoring program is provided in Table 8 and Figures 5 and 6 of Appendix B.4. Table 9 in Appendix B.4 summarizes the fish tissue analytes and laboratory reporting limits for the fish monitoring program.

6.16.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Appendix B.4 provides a summary of fish monitoring history previously conducted in the vicinity of the mine in the surrounding creeks, including baseline monitoring, and pre- and post-breach monitoring. The sample collection methods and monitoring are also summarized in Appendix B.4 for tissue sampling, sentinel fish population monitoring, fish community monitoring, and fish habitat characterization and usage monitoring.

In addition to the monitoring outlined in Appendix B.4, visual spawning surveys of upper Hazeltine Creek to evaluate the success of re-introduction of spawning access by Polley Lake rainbow trout, and at the mouth of Hazeltine/Edney Creek to confirm access to that stream reach following a monitoring program developed in conjunction with the Habitat Remediation Working Group (HRWG). The surveys consisted of two field staff walking the bank of the creek channel and documenting visual observations of species, life stage, and behaviour of fish in the creek, and in lower Hazeltine/Edney, the presence of redds was noted. In upper Hazeltine Creek 25 surveys were conducted through the 2018 ice-free period and in the Hazeltine/Edney Creek mouth, 12 surveys were conducted. Spawning surveys were conducted in Hazeltine/Edney again in 2019.

6.16.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Appendix B.4 summarizes the QAQC program for the fish monitoring plan. It includes specific QA/QC protocols, including collection of QC samples and collection of replicate samples to allow for statistical calculations and to capture within-area variability. For fish tissue samples, comparisons between duplicate samples will be made by calculating the RPD between concentrations of paired duplicates. If the RPD <25% for concentrations that are >5 times the detection limit, then the duplicate sample results will be considered acceptable. Specific QC samples will include laboratory blanks, laboratory replicates, and laboratory accuracy samples (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). The QC sample results will be assessed as part of the data quality review. See Appendix B.4 for more details.

6.16.6 LABORATORY ANALYSIS

All chemical analyses will be completed by a laboratory that is accredited by CALA, and will be required to include specific QC samples and report associated results.

6.16.7 DATA ANALYSIS AND REPORTING

Catch-per-unit-effort and summary statistics for meristic measurements taken in the field will be calculated. Although community and population data is collected during every phase or component of the fish monitoring program, the sample size will be defined by the study objectives and may be insufficient to address corollary questions. For example, the sample size required for tissue quality analyses (n = 8) is not large enough to support formal contrasts of population endpoints. To this end, evaluation of fish community data will rely on qualitative comparisons, and conclusions regarding fish populations will be supported by non-lethal measurements and sampling under the MDMER EEM (with larger sample size), as described in Appendix B.4. Analysis methods for the MDMER EEM fish population data, as described in Appendix B.4 will be "consistent with EEM technical guidance (Environment Canada 2012). Summary statistics, including mean, median, minimum, maximum, standard deviation, standard error, and sample

size, will be calculated for fish age, fork length, total length, body weight, condition, liver weight, gonad weight, and fecundity; calculations will be completed according to species and area. All data sets will be assessed for normality and equality of variance in order to determine the suitability of parametric statistical procedures. An effect on the fish population will be evaluated for each of these measures and is defined as a statistically significant difference between the effluent-exposed area and the reference area (Environment Canada 2012). For each endpoint, statistically significant differences between effluent-exposed and reference areas (by species and sex) will be assessed using ANOVA, Analysis of Covariance (ANCOVA), or non-parametric equivalents, as appropriate, following technical guidance (Environment Canada 2012).

"For the fish tissue data sets, statistical comparisons of age, length, weight, and concentrations of metals in fish tissues (n = 8) will be completed among years and locations. The sample size, mean, median, standard deviation, standard error, minimum, maximum, 5^{th} percentile, and 95^{th} percentile will be calculated for each analyte. Means will be calculated using the Kaplan-Meier (K-M) method. The standard deviation and the median for each analyte will also be calculated using the K-M method. When a standard deviation cannot be estimated (i.e., when an analyte has a high proportion of censored values), it will be reported as "not calculated".

"Results of the fish habitat characterizations for Upper Hazeltine, Lower Hazeltine, and Lower Edney creeks will be summarized, along with fish usage results, according to season (spring, summer, and fall) and year. Fish habitat characterization measures will be summarized by season, reach, and area (rehabilitated and reference), with summary statistics (mean and standard deviation) calculated for all numerical parameters."

More detail for each monitoring component is provided in Section 4.5 of Appendix B.4.

An interpretive report based on the fish monitoring data was prepared to be integrated into the AERR for the Mount Polley Mine that is prepared annually by MPMC (see Section 9.3). The interpretive report will provide all data in an appendix and will include the data quality review, the results of the screening against BCWQGs, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

With respect to the spawning surveys, rainbow trout were observed spawning in upper Hazeltine Creek, confirming that the fish were successfully re-introduced to the reconstructed channel. A majority of spawning activity occurring from May 10 to 25, 2018, when 488 rainbow trout redds were counted, and emergence of young-of-year trout began in late June (Minnow 2019). In 2018, rainbow trout, longnose sucker and redside shiner were observed lower Hazeltine/Edney (Minnow 2019) and in fall 2019, sockeye salmon were observed using the reconstructed habitat (data will be reported in 2020).

6.17 WILDLIFE MONITORING

Wildlife monitoring described below includes observational monitoring and monitoring using wildlife cameras. A study design for wildlife monitoring in the Hazeltine Creek corridor will be provided in 2020. This subsection will be updated accordingly.

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.17.1 Section Authors and Study Design Professionals

This section was written by MPMC (wildlife observations) and Golder (tissue collection and food chain model – related to follow up tasks for the ERA).

6.17.2 Monitoring Objectives

The current objective of the wildlife monitoring is to document the presence of mammals and birds using or migrating through the mine site and adjacent areas. This information is used for land use planning and to monitor the potential for effects of mine-related activities on animals in the area.

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017).

6.17.3 Monitoring Overview

Operational Monitoring - Wildlife occurrences will be recorded throughout the year by MPMC Environmental Department staff, and by other MPMC employees and contractors, when possible. Observations will include wildlife sightings and evidence of wildlife, such as tracks and droppings. Documentation will include the date, initials of the observer, location of the observation, wildlife observed, and comments (such as size of group, sex, or activity of an animal).

Data files from wildlife cameras installed in three locations (Hazeltine Creek, Mine Site, Reference site) are downloaded and reviewed monthly. Any changes to the location of the cameras are documented. Details including frequency of use by wildlife near each camera and variety of wildlife are documented. These details will be included in the AERR.

Supplemental Tasks - A tiered approach was been recommended, as outlined in Appendix B.5. Only Tasks 1A, 2A, 2B and 3 will be undertaken as part of the current CEMP. If risks are found to be unacceptable at the end of Step 2, further investigation following the proposed tiered approach described in Appendix B.5 will be conducted, which may include a development of a study design.

6.17.4 High-Level Monitoring Design Description

Table 6.33 is a summary of previous wildlife monitoring undertaken and includes recommendations for future monitoring. Further rationale is provided in the following sub-sections, if appropriate, and is referenced in the table where applicable.

Table 6.33 Summary of wildlife monitoring and findings

Summary of Monitoring and Findings	Monitoring Objective		
	Operational	**Post-Breach**	**Reclamation**
Previous monitoring undertaken	General wildlife observations (animals, scat, and tracks) documented.	N/A	N/A
Summary of findings	734 observations of wildlife were documented in 2017.	N/A	N/A
Recommendations for 2018-2020 monitoring	General wildlife observations will continue to be made per Permit requirements. A study design for wildlife monitoring in the Hazeltine Creek corridor will be provided in 2020.	Reconnaissance-level field surveys to support updated food chain modelling for potential bioaccumulation in wildlife.	N/A

Notes: N/A: not applicable

6.17.4.1 Operational Monitoring

This section will be updated when a study design is submitted in 2020.

6.17.4.2 Post-Breach Monitoring

In 2018, a reconnaissance-level survey was undertaken to support an update of the food chain model first presented in the ERA. Soil sampling is presented in Section 6.19, soil invertebrate sampling in Section 6.20, and vegetation monitoring in Section 6.21. An additional component considered in the food chain model was flying insects.

Samples of flying invertebrates (bees/wasps [order Hymenoptera], moths [order Lepidoptera], and crickets/grasshoppers [order Orthoptera]) were collected from the impacted area and background areas. Information about the tissue chemistry of this important food item for insectivorous birds and bats was not previously available in Golder (2017). The samples were collected through a combination of manual foraging and trapping. Manual foraging generally involved surveying flowering plants for bees or the ground surface for grasshoppers and using a sweep net to capture target invertebrates. Moths were predominantly collected using black light traps. Terrestrial invertebrate trapping was conducted using methods adapted from the RISC guidelines for terrestrial arthropod inventory (RIC 1998), guidance from the Biological Survey of Canada (Marshall et al. 1994; Danks 1996) and the US Department of Agriculture (Schauff 1998). Terrestrial invertebrate trapping methods employed on the Site included malaise traps, black light traps, pan/window traps and Berlese funnels.

Irrespective of the specific capture method, the following steps consistent with the *BC Field Sampling Manual* (BC ENV 2013) were followed to process the flying invertebrate samples:

- Samples were collected using nitrile gloves and transferred to clean Ziploc bags.
- Flying invertebrates of the same order from a single sample location (limited to 25 meters squared [m2]) were composited.
- Flying invertebrates were left in sample containers stored at ambient temperature overnight to allow samples to depurate.
- Flying invertebrate samples were rinsed using DI water and blotted dry with lint-free wipes before being transferred to clean Ziploc bags.
- Samples were transferred to a freezer to kill the invertebrates.
- Samples were kept frozen until they were submitted to the laboratory for analysis.

The invertebrate tissue samples were submitted for analysis of metals and moisture content, and the data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.7.

6.17.5 Data Quality Control, Objectives, and Review

Wildlife observations data will undergo a QC screening prior to upload to the network.

Twelve duplicate flying invertebrate samples were collected and laboratory QC samples consisted of duplicates, method and equipment blanks, and certified reference materials. RPDs exceeded DQOs for most metals in at least one duplicate sample. A higher variability in flying invertebrate samples is expected because the field duplicates are not splits of a composite—they are two composites of different individual organisms. In terms of copper, RPDs of 58 and 86% were noted in two of twelve duplicate pairs for wet weight concentrations and in one of twelve (RPD = 50%) of dry weight concentrations For vanadium, RPDs of 65 to 126% were noted in three of twelve duplicate sample pairs for wet weight concentrations and in zero of twelve duplicate sample pairs for dry weight. The data were considered reliable and suitable for there intended purpose

6.17.6 Laboratory Analysis

Laboratory analyses of the invertebrate tissue samples were undertaken by a CALA-accredited laboratory.

6.17.7 Data Analysis and Reporting

Number of wildlife observations will be tabulated and reported in the AERR.

The flying insect chemistry data (Golder 2019a) and updated food chain model (Golder 2019b) were submitted to ENV as an attachment to the 2018 Annual Report.

The wildlife food chain model presented in the ERA (Golder 2017) provided screening-level risk estimates for receptors exposed to copper and vanadium (the only contaminants of concern identified in the ERA),

which were based on calculated area-weighted hazard quotients (HQs) of <1 to 2.8, and a maximum HQ of 5.1 (for masked shrew in the Polley Flats area). Although the HQs were considered not to represent an unacceptable risk to wildlife, the food chain model was refined in 2018 by:

- Adding bats (*Myotis* sp.) as a receptor.
- Improving the quality of information with respect to tissue concentrations in invertebrates and plants by expanding the existing bioaccumulation sampling (as part of the reconnaissance-level survey conducted in 2018).
- Replacing the conservative assumption that flying insects have the same tissue concentrations as soil-dwelling insects by collecting site-specific data (as part of the reconnaissance-level survey conducted in 2018).
- Refining the toxicity reference values (i.e., the denominator in the HQ) to consider more than a highly conservative threshold

Revised screening-level risk estimates resulted in lower HQs. Screening-level HQs were <1 for all receptors except robin, shrew, and bat exposed to copper. The aggregate area-weighted HQs for those three receptors ranged from 1.0 to 1.7, and the maximum observed HQ for a sub-area was 2.1 for robin in the Polley Flats area. When a refined TRV was used to provide an additional level of protection to listed species, no HQs greater than 1 were identified and therefore, risks to wildlife associated with copper and vanadium in soils at the site are considered to be acceptable.

6.18 Amphibian and Reptile Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.18.1 Section Authors and Study Design Professionals

This section was written by Golder. The detailed study design concept is provided in Appendix B.6. Note that Appendix B.6 is a study design concept; a study design may be submitted at a later date depending on results of a preliminary review (Steps 1 and 2 as outlined in Figure 1 in Appendix B.6).

6.18.2 Monitoring Objectives

The study design concept in Appendix B.6 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.6, the objectives of amphibian monitoring will be to "continue the risk assessment process by proceeding through tiers to the point needed to support an informed risk management decision". More detail is provided in Appendix B.6.

6.18.3 Monitoring Overview

A tiered approach has been recommended, as outlined in Appendix B.6. Only Steps 1 and 2 will be completed as part of the current CEMP, with Step 1 undertaken in 2018. If risks are found to be unacceptable

at the end of Step 2, further investigation following the proposed tiered approach described in Appendix B.6 will be conducted, which may include a development of a study design.

6.18.4 High-Level Monitoring Design Description

In 2018, Step 1 of the study design concept was undertaken, specifically, a hazard evaluation. Existing soil, sediment and surface water chemistry data were screened for different habitat units against a conservative amphibian-specific screening value, as follows:

1. Review of existing guidelines: the purpose of the review was to determine if existing guidelines, criteria or standards contained sufficient amphibian-specific data to allow their use as a screening value for this assessment.
2. Derivation of screening values: the existing guidelines were determined to be unsuitable for the amphibian hazard assessment, and therefore screening values were developed through the review of scientific literature. Toxicity testing data were compiled, an uncertainty analysis was conducted on the compiled data, and safety factors were applied as applicable to mitigated identified uncertainties.
3. Application of derived screening values to site data: site monitoring data for water, sediment and soils were compared to the screening values for water and hydric soils/sediment.

6.18.5 Data Quality Control, Objectives, and Review

The study was a desktop review of guideline derivation documents and scientific literature.

6.18.6 Laboratory Analysis

No laboratory analysis were undertaken as part of the amphibian hazard assessment.

6.18.7 Data Analysis and Reporting

The amphibian hazard assessment (Golder 2019c) was submitted to ENV as an attachment to the 2018 Environmental and Reclamation Report (the "2018 Annual Report"), prepared in fulfillment of *Mines Act* permit M-200, and *Environmental Management Act* permit 11678. In summary, a toxicity reference value of 0.018 mg/L dissolved copper was derived for evaluating hazards associated with surface water, and 800 mg/kg copper for evaluating hazards associated with hydric soils or sediment. The available surface water and soil data for the Mount Polley site were compared to these conservative screening values, and overall, there was no evidence that environmental concentrations were routinely or notably higher than those screening value on a site-wide basis. Hazards to amphibians as a result of exposure to soil or surface water are considered to be low under these circumstances.

6.19 Soil Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description;

data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.19.1 Section Authors and Study Design Professionals

This section was written by Golder, and the detailed study design concept is provided in Appendix B.5.

6.19.2 Monitoring Objectives

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.5, the objective of soil monitoring will be to "refine site-specific relationships between copper concentrations in soil and copper concentrations in various soil invertebrate and plant tissues". More detail is provided in Appendix B.5.

6.19.3 Monitoring Overview

Monitoring of soil stockpiles on the mine site for reclamation and closure is outlined in the Soil Management Plan included in the RCP. It is covered under BC *Mines Act* Permit M-200.

In 2018, Task 1A of the study design concept was undertaken, specifically, a reconnaissance-level sampling program.

6.19.4 High-Level Monitoring Design Description

Operational Sampling - Monitoring of soil stockpiles on the mine site for reclamation and closure is outlined in the Soil Management Plan included in the RCP. It is covered under BC *Mines Act* Permit M-200.

Supplemental Sampling - Soil samples were collected from 69 locations (co-located with tissue samples – described in Sections 6.20 and 6.21) to refine the exposure estimate for post-breach rehabilitated areas. The soil chemistry data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.

Each sample was a composite of three aliquots of soil collected from within a 5 m radius of the tissue sample. The aliquots were collected from the top 20 cm of soil using a hand shovel, and then homogenized in a stainless-steel bowl prior to transfer to clean, laboratory-supplied 125-mL, glass sample jars with Teflon™ lined lids. Samples were kept on ice in a cooler after collection and kept cool until submitted to ALS for analysis of metals and pH.

6.19.5 Data Quality Control, Objectives, and Review

Supplemental soil sampling was undertaken using methods consistent with those used for the HHRA and ERA. Eight field duplicates were collected and laboratory QC consisted of duplicates, method blanks and matrix spike recovery. Copper and vanadium (the metals of interest for the food chain model) met the field DQOs. The soil sample results met the laboratory DQOs for precision, accuracy, method blanks, duplicate sample analysis and matrix spike recovery, with the exception of a method blank that had a detected

concentration of copper. This could be a potential bias in samples that are near the limit of reporting but was not an issue in the current samples because all copper results were substantially higher than detection limits. Overall, the data were considered representative and suitable for their intended use.

6.19.6 Laboratory Analysis

Laboratory analyses were undertaken by a CALA-accredited laboratory.

6.19.7 Data Analysis and Reporting

The results of the reconnaissance survey (Golder 2019a) were submitted to ENV as an attachment to the 2018 Annual Report. Data from the 2018 soil sampling were integrated with the relevant historical data to update the soil concentrations used in the food chain model. All samples were compared to the applicable CSR standards, and an overview of those findings is provided below for each of the different rehabilitated areas that were sampled in Tables 1 through 3. Overall, the results of the soil chemistry were consistent with results from previous sampling in those areas and no new contaminants of concern were identified. The use of the soil chemistry data is further discussed in Section 17 (vis-à-vis the food chain model update).

6.20 Soil Invertebrate Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.20.1 Section Authors and Study Design Professionals

This section was written by Golder, and the detailed study design concept is provided in Appendix B.5.

6.20.2 Monitoring Objectives

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.5, the objectives of soil invertebrate monitoring will be to:

- "Focus on establishing a long-term trend analysis of soil invertebrate community rather than to support a multitude of pair-wise comparisons that would have limited value for making site management decisions";
- "Refine site-specific relationships between copper concentrations in soil and copper concentrations in various soil invertebrate tissues"; and,
- "Improve the quality of data with respect to tissue concentrations in invertebrates, particularly for flying insects."

6.20.3 Monitoring Overview

In 2018, Task 2A of the study design concept was undertaken, specifically, a reconnaissance-level sampling program.

6.20.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Additional sampling was conducted to improve the spatial coverage of soil invertebrate samples, and to obtain sufficient samples of each main invertebrate type from the range of soil concentrations present at the site. Invertebrate (i.e., ants, beetles, spiders and worm) samples were collected through a combination of manual foraging and trapping. Manual foraging involved surveying the ground surface and searching below woody debris. Sampling was conducted if sufficient volume of soil invertebrates were noted or if a larger soil invertebrate (e.g., a large beetle) was found.

Terrestrial invertebrate trapping was conducted using methods adapted from the RISC guidelines for terrestrial arthropod inventory (RIC 1998), guidance from the Biological Survey of Canada (Marshall et al. 1994; Danks 1996) and the US Department of Agriculture (Schauff 1998). These documents guided the selection of the trapping method, locations of samples, sampling design and trapping protocols. Terrestrial invertebrate trapping methods employed on the Site included pitfall traps and Berlese funnels. Irrespective of the specific capture method, the following steps consistent with the *BC Field Sampling Manual* (BC ENV 2013) were followed to process the soil invertebrate samples:

- Samples were collected using nitrile gloves and transferred to either clean, laboratory supplied glass jars or clean Ziploc bags.
- Invertebrates of the same order from a single sample location (limited to 25 m^2) were composited.
- Soil invertebrates were left in partially open sample containers stored at ambient temperature overnight to allow samples to depurate.
- Invertebrate samples were rinsed using DI water and blotted dry with lint-free wipes before being transferred to clean Ziploc bags.
- Samples were transferred to a freezer to kill the invertebrates.
- Samples were kept frozen until they were submitted to the laboratory for analysis.

The soil invertebrate tissue samples were submitted for analysis of metals and moisture content, and the data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.

6.20.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Soil invertebrate sampling were undertaken using methods consistent with those used for the HHRA and ERA. Eight field duplicates were collected and laboratory QC consisted of duplicates, method blanks and certified reference materials. RPDs were greater than 50% for most metals in at least one duplicate sample. A higher variability in soil invertebrate samples is expected because the field duplicates are not splits of a composite—they are two composites of different individual organisms. In terms of copper, an RPD of 65% was noted for the wet weight concentration in one duplicate pair, but the dry weight data had an acceptable RPD (48%). There was less variability in copper results than most other metals, and Golder concludes that the data are reliable and suitable for its intended purpose. RPDs of 55 to 106% were noted in four of eight duplicate sample pairs for wet weight concentrations and in two of eight duplicate sample pairs for dry

weight with respect to vanadium. However, this variability does not impact the overall conclusion that vanadium bioaccumulation is limited, nor does it change the conclusion that vanadium risks to wildlife from consumption of dietary items was low. The tissue samples met the laboratory DQOs with respect to copper and vanadium (the parameters of interest for the food chain model).

6.20.6 Laboratory Analysis

Laboratory analyses were undertaken by a CALA-accredited laboratory.

6.20.7 Data Analysis and Reporting

The results of the reconnaissance survey (Golder 2019a) were submitted to ENV as an attachment to the 2018 Annual Report. The use of the soil chemistry data is further discussed in Section 17 (vis-à-vis the food chain model update).

6.21 Vegetation Monitoring

The following sections give a synopsis of the objectives; sample locations along with parameters measured, site description, sampling frequency, and applicable guidelines; a high-level monitoring design description; data quality control, objectives, and review; laboratory analysis; and data analysis and reporting, where applicable.

6.21.1 Section Authors and Study Design Professionals

This section was written by MPMC, and is a summary of the study design concept provided by Golder. The detailed study design concept is provided in Appendix B.5. Note that Appendix B.5 is a study design concept; a study design will be submitted in Q1 2019 after completion of tasks outlined in Figure 2 in Appendix B.5.

6.21.2 Monitoring Objectives

The study design concept in Appendix B.5 focuses on reducing the sources of uncertainty from the terrestrial ERA (Golder 2017). As outlined in Appendix B.5, the objectives of vegetation monitoring will be to:

- "Focus on establishing a long-term trend analysis of plant community rather than to support a multitude of pair-wise comparisons that would have limited value for making site management decisions"; and,
- "Refine site-specific relationships between copper concentrations in soil and copper concentrations in various plant tissues."

More detail is provided in Appendix B.5.

6.21.3 Monitoring Overview

In 2018, Task 2A of the study design concept was undertaken, specifically, a reconnaissance-level sampling program.

6.21.4 HIGH-LEVEL MONITORING DESIGN DESCRIPTION

Samples of the edible portions of plants (were collected following the same approach used in 2015 and 2016. The focus of plant sampling was on rehabilitated areas to increase sample density in these areas and to provide more information about plants growing in soils that have lower copper concentrations than the non-reclaimed areas. The following plant tissue samples were collected in 2018:

- Berry—Berry samples were collected from raspberry [*Rubus occidentalis]*, high bush cranberry [*Viburnum trilobum*], and thimbleberry [*Rubus parviflorus*]) plants that were rooted in soil.
- Leaf—Willow (*Salix* sp.) and alder (*Alnus crispa*) leaf samples were collected from shrubs planted in the impacted area. Only shrubs planted in the floodplain before spring 2016 were sampled. Plants sampled included willow planted in lower Hazeltine Channel in early 2015, above the canyon in late 2015, and in upper Hazeltine Channel late 2015 (near Gavin Lake Bridge).
- Grass— Slender wheatgrass *(Elymus trachycaulus*) samples were collected from a variety of areas. The objective of the sampling was to reduce the uncertainty in the existing soil-to-grass bioaccumulation relationship, and therefore, sampling was limited to a single species which was commonly found across the entire site. Only the edible, above-ground portion of grass was collected.

Sampling methods were consistent with the *BC Field Sampling Manual* (MoE 2013) and consisted of the following steps:

- Plant tissue was hand-picked by field staff using nitrile gloves from an area of 25 m^2 or less. Plant tissue was composited from multiple plants within the area if sufficient volume could not be collected from one plant.
- Plant samples were rinsed using DI water and blotted dry with lint-free wipes before being transferred to clean Ziploc bags.
- Samples were placed in a cooler containing ice until they could be transferred to a freezer for storage prior to shipping to the laboratory for analysis.

The plant tissue samples were submitted for analysis of metals and moisture content, and the data were used, with other data collected as part of the reconnaissance survey, to update the food chain model developed to evaluate the potential for bioaccumulation of metals in wildlife. The food chain model update is described in Section 6.17.

6.21.5 DATA QUALITY CONTROL, OBJECTIVES, AND REVIEW

Vegetation sampling was undertaken using methods consistent with those used for the HHRA and ERA. Five replicate plant samples were collected and laboratory QC consisted of duplicates, method blanks and certified reference materials. Data quality objectives were met for copper and vanadium (the parameters of interest for the food chain model) in vegetation samples for both field and laboratory QC samples.

6.21.6 Laboratory Analysis

Laboratory analyses were undertaken by a CALA-accredited laboratory.

6.21.7 Data Analysis and Reporting

The results of the reconnaissance survey (Golder 2019a) were submitted to ENV as an attachment to the 2018 Annual Report. The use of the soil chemistry data is further discussed in Section 17 (vis-à-vis the food chain model update).

6.22 Biosolids Monitoring

MPMC is in possession of an EMA permit (15968) for the use of biosolids. This permit requires that MPMC retain the services of a qualified professional to develop a monitoring plan for the biosolids application program. MPMC will submit this plan to ENV and EMPR prior to receiving any additional shipments of biosolids to the mine site.

7 CEMP UPDATES AND REVISIONS

When possible, MPMC will provide written notice of planned changes to the CEMP to the ENV Director a minimum of 30 days prior to implementation to allow for review and feedback on the revision. Proposed changes will be shared with First Nations and stakeholders, as per MPMC's Communication Plan (MPMC 2016d). Additionally, changes that occur but are unplanned, such as the collection of additional samples, will be discussed with the ENV Director as soon as possible after the sampling occurs. When changes are made to the monitoring, this amended plan (or relevant replacement pages) will be resubmitted to the Director.

Given the dynamic nature of environmental investigation, rehabilitation, and water management plan development at Mount Polley Mine, it is anticipated that the CEMP will evolve in alignment with site activities and findings, as described in Section 2.3, and will be updated as required. It is anticipated that larger CEMP revisions in response to these activities and findings will be made with consideration of maintaining continuity in spatial and temporal coverage to meet the global objectives of the CEMP, as described in Section 1.1.

As required by the Permit, following the three-year detailed monitoring program interpretive report to the Director, MPMC will submit a summary of proposed changes to the CEMP to the Director by April 30 of that year (one month following the interpretive report deadline). In order to incorporate recommended changes in a timely fashion, MPMC would appreciate feedback on the proposed changes from the ENV by May 31 of that year.

8 RECLAMATION AND REMEDIATION

Rehabilitation of the aquatic and terrestrial receiving environments that were impacted by the TSF embankment breach and associated remediation activities is continuing as outlined in the Rehabilitation Strategy (November 2015 update; MPMC 2015f), as required by the PAO 107461. Under this broader Rehabilitation Strategy:

- Terrestrial rehabilitation works are being conducted as per the *Planning Concepts for Rehabilitation of Terrestrial Ecosystems at Mount Polley* technical memorandum prepared by Golder (2015e). The reclamation and monitoring steps described in this memorandum are based on the TSF embankment breach environmental impact assessment results to date.
- Rehabilitation of aquatic systems is being conducted under guidance of the Habitat Remediation Working Group, which includes representatives of DFO, ENV, the BC Ministry of Forest, Lands and Natural Resource Operations, the SCIB, and the WLIB. This group provides recommendations and feedback on aquatic ecosystem rehabilitation plans developed by MPMC's consultants.

Monitoring associated with the Hazeltine Creek channel rehabilitation construction activity is undertaken under the *Post-Breach Rehabilitation Work Environmental Management Plan* (Golder 2015f), which pertains to monitoring of any construction works and associated construction specifications. While the lower reaches of Hazeltine Creek remain non-fish bearing (with the exception of the lower sedimentation pond), the *MPMC Fish Exclusion and Response Plan* (MPMC 2015f) is in effect. MPMC will conduct monthly visual inspections for fish in the non-fish bearing areas of the creek when the creek is free of snow and ice (in case any fish have evaded the barriers), as well as weekly inspections of fish exclusion structures. The plan outlines response actions in the event that fish are observed.

As Hazeltine Creek is rehabilitated and returned to fish-bearing status, this environmental management plan will be phased out and be replaced by routine monitoring for evaluating performance of the works as a component of the CEMP.

The Habitat Remediation Working Group made up of provincial and federal regulators, qualified professionals and First Nations representatives, agreed upon a monitoring plan for the return of rainbow trout in Hazeltine Creek in 2018. This plan includes week fish surveys, detailed habitat usage surveys, benthic, sediment, water (quality and quantity), and fish tissue sampling. Reporting on these results will be included in the AERR.

The steps in the aforementioned terrestrial rehabilitation plan include establishment of permanent monitoring plots for ongoing assessment, feedback (to inform adaptive management) and demonstration. As terrestrial rehabilitation works progress, monitoring to this end will be implemented.

A Conceptual Remediation Plan (CRP) was submitted to ENV on January 31, 2018 (Golder 2018) and following receipt of comments on the CRP, a Remediation Plan submitted on March 29, 2019 (Golder 2019d). The Remediation Plan identifies remedial options for the sites impacted by the TSF breach, including creek habitats, lake habitats, and terrestrial habitats, as well as proposed monitoring components to verify the success of the planned remediation. The Remediation Plan was approved by ENV on July 3, 2019.

9 REPORTING

9.1 MONTHLY REPORTING

As required by Section 3.9 in the Permit (April 7, 2017) a monthly report will be submitted to the Director in each month that discharge occurs. The report will summarize the volume of treated effluent discharged, a summary of continuous turbidity readings of the treated effluent discharged, and the most recently available water quality results for the effluent discharged, including a summary of acute and/or chronic toxicity testing results.

9.2 QUARTERLY REPORTING

All data and information collected under the CEMP will be provided to the Director, in electronic format, on a quarterly basis or as required by the Permit.

Under the most recent version of PAO 107461 (June 9, 2017) Section 6.0, a quarterly report detailing the implementation status of requirements of the order, a summary of communications with stakeholders and public relating to the breach, and any remediation activities undertaken in Hazeltine Creek, Polley Lake and Quesnel Lake for the previous and upcoming three months must be submitted to the director.

9.3 ANNUAL REPORTING

As required by the Permit Section 3.9, MPMC will continue to submit an AERR on or before March 31 of each year. This report is combined with the Annual Reclamation Report prepared for the EMPR, with the combined document submitted to both agencies. These reports will include the details required by the permit, as well as an analysis of the linkages between program components, where appropriate. MPMC will refer to *Technical Guidance 4, Environmental Monitoring under the Environmental Management Act* such that the ENV's expectations for reporting are achieved.

The AERR will continue to be in a format suitable for public release and will be deposited at the Cariboo Regional District Library as well as submitted to the SCIB and WLIB within 30 days of being submitted to the ENV.

As required by the Permit (April 7, 2017) Section 2.5, MPMC will continue to submit an annual Environmental Emergency Response Plan and will include updated procedures and notification protocols. MPMC will also continue to submit an Annual Discharge Plan on or before April 15 of each year and include the details required by the Permit Section 2.7.

9.4 THREE-YEAR REPORTS

Under the Permit, a detailed monitoring program interpretive report is required every three years with the first report due on March 31, 2019 and every three years thereafter. The March 2019 interpretive report will include data collected in 2016, 2017, and 2018. This report will be completed by one or more qualified professionals and will be more comprehensive than the synoptic review of data presented in the annual reports. It will include recommendations for changes to the CEMP.

In addition, a groundwater monitoring program review including, but not limited to, sampling, well locations, site water balance, interpretation of data trends, and suitable recommendations is required every three years, with the first presented in March 2016. The next report will be submitted on March 31, 2019. Monitoring data and the analysis of those data presented in the report will be reviewed by a third party qualified professional.

10 FUTURE OUTLOOK

This CEMP represents a unique and specialized variation of a typical mine environmental monitoring plan. This plan seeks to integrate all environmental monitoring programs that are carried out on the Mount Polley mine site and in the local area related to:

(a) Ongoing mine operations (including EMA and *Mines Acts* permit requirements and MDMER requirements of the *Fisheries Act*);
(b) TSF embankment breach-related impacts and remediation; and,
(c) Reclamation and closure planning (*Mines Act* permit requirement).

The overall goals of this CEMP are to provide science-based evidence: for evaluation of environmental impacts of mine operations; for evaluation of the effects of any ongoing impacts of, and remediation measures undertaken in response to, the TSF embankment breach; and to inform ongoing reclamation and closure planning. These goals are guided by an intent to return the impacted areas of the mine site and its surroundings to viable and diverse ecosystems that reflect pre-breach land uses, or those identified by Communities of Interest as representing values of importance. These values of importance are identified through ongoing consultation with local Communities of Interest.

Mount Polley fosters a culture of research and innovation. In addition to the extensive monitoring and research work that was undertaken as part of the impact and risk assessments of the TSF embankment breach, there are a number of research projects underway (and several recently completed) that the mine has supported. The results of these projects may contribute directly to improving the mine's understanding of breach impacts (Cuervo et al, 2017; Garris et al, 2018; Byrne et al, 2018), new approaches to remediation, reclamation and closure (McMahen, PhD in progress, UBC; Litke MASc in progress, UBC), and to mitigating environmental impacts of ongoing operations.

With respect to mitigating environmental impacts of ongoing operations and planning for reclamation and closure, Mount Polley is embarking on passive water treatment research and pilot projects to test the suitability of constructed wetland water treatment systems for dispersed water treatment and discharge on the mine site. These research projects will include lab and site testing, monitoring of water quality, vegetation, and microbial communities, and will be reported annually in the AERR or in a technical memo.

As the results of monitoring programs and environmental research projects are generated, analyzed, and interpreted, this CEMP will be reviewed and updated where warranted. MPMC will aim to review the requirements of the CEMP on a quarterly basis and will submit a list of proposed changes based on the review to the Director within 45 days from the end of the quarter.

Terms of Reference

Comprehensive Environmental Monitoring Plan – 4 July 2017

1 BACKGROUND AND CONTEXT

Mount Polley Mining Corporation (MPMC) is the owner and operator of the Mount Polley Mine, a property comprising, among other things, a copper-gold mine and mill complex located near Likely, British Columbia (BC).

MPMC is authorized by the BC Ministry of Environment (MoE) to discharge effluent to the land and to surface water from the Mount Polley Mine, subject to the terms and conditions of *Environmental Management Act* (*EMA*) Permit 11678. *EMA* Permit 11678 was originally issued to MPMC by the MoE on 30 May 1997, and has been the subject of numerous amendments since.

As is typical of owners of mines in BC, MPMC undertakes extensive environmental monitoring for a variety of purposes and objectives. In many instances, data collected as part of one monitoring program are beneficial to other programs, even though programs may have been established specifically for unique purposes.

Under Section 3.2 of *EMA* Permit 11678, MPMC is required to implement a Comprehensive Environmental Monitoring Plan (CEMP). In previous versions of *EMA* Permit 11678, MPMC was required to implement a number of individually defined monitoring plans for various aspects of Mount Polley Mine operations to which this MoE authorization was subject. As stated in Section 3.2 of *EMA* Permit 11678, the CEMP is intended to consolidate and integrate all such pre-existing monitoring programs.

2 OBJECTIVES AND DRIVERS

As described in Section 3.2 of *EMA* Permit 11678, the objective of the CEMP is to evaluate the effects of mining-related activities on the physical, chemical and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas.

Environmental monitoring has the broad objective of verifying that environmental controls are in place that protect the environment and are sufficient to confirm compliance with applicable statutory requirements to which operations are subject. Environmental monitoring also has the broad objective of providing data to support evidence-based communication to parties who might be affected by the Mount Polley Mine.

For the Mount Polley Mine, the main drivers (which govern the objectives) are:

- Regulatory Drivers;
    - Federal (e.g., *Metal Mining Effluent Regulation* [MMER])
    - Provincial (e.g., *EMA, Mines Act*)
- MPMC Commitments:
    - The respective Participation Agreements (PAs) that MPMC have in place with the Soda Creek Indian Band (SCIB; Xatśūll First Nation) and the Williams Lake Indian Band (WLIB).

Subject to the requirements of the various drivers, the CEMP is intended to be an adaptive plan. This means that the CEMP is anticipated to change over time, as it is informed by findings obtained from preceding stages of work.

3 SCOPE AND CONTENT

The scope of the CEMP will be built around the Objectives and Drivers, will provide an appropriate level of scientific robustness, and will utilize provincially and federally acknowledged methodology. It is noted that failing to utilize methods common to the various objectives undermines the value of a comprehensive monitoring program. The scope of the CEMP will not include studies of general research (e.g., academic), nor will it include collection of regional data that are not directly linked to the Objectives and Drivers.

As per Section 3.2 of *EMA* Permit 11678, the scope of the CEMP must be such that it consolidates and integrates monitoring programs that are being conducted in the vicinity of the Mount Polley Mine site. At minimum, the CEMP must consider programs addressing surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.

As described in Section 3.2 of *EMA* Permit 11678, the CEMP must address, at minimum, a three-year time span, as well as, at minimum, include all sampling sites, frequency of sampling, variables to be analyzed, method detection limits, sampling methods, sample analysis methods, and data analysis methods.

As noted in the Background and Context of this Terms of Reference, environmental monitoring is a tool used by mining companies (and others) to inform them (and other parties), of the adequacy of their source control efforts. The content of the CEMP will be reflective of its use as such a monitoring tool. The CEMP will serve as the document that provides the context and linkages demonstrating how the monitoring program developed provides an appropriate mechanism by which to meet the Objectives and Drivers of the CEMP. In providing this purpose, the CEMP's content is anticipated to provide: a statement of its objectives; an overview of its subject (the Mount Polley Mine); a discussion of the various components that comprise environmental management in the context of the Mount Polley Mine; presentation of monitoring procedures and considerations (e.g., previous data) specific to each environmental monitoring component; and, an outline for control of the CEMP (e.g., updating and revising) and its reporting outputs.

A comprehensive monitoring plan requires a response framework as the monitoring program is the linkage between monitoring plan design, implementation, and effective use. The level and urgency

of response will have due regard to the level of potential risk to the environment (which includes people). The CEMP response framework will be updated in parallel with the CEMP, or as otherwise appropriate.

4 DEPENDENCIES AND ASSUMPTIONS

The CEMP is intended to support an interdependent program. The dependencies across the monitoring programs will be evaluated with the benefit of a conceptual site model (CSM). The CSM will aid in understanding and addressing the dependencies by allowing a visual representation of release and transport mechanisms (e.g., sources and water flow) and exposure by environmental receptors. The CEMP is predicated on the understanding that people (i.e., humans) are part of the environment. The CEMP response framework will have due regard to linkages and dependencies, and the CSM.

The CSM will be reviewed for dependencies in the context of:

- The Objectives and Drivers and Scope for the CEMP, as described in this Terms of Reference.
- The basal understanding of sources, pathways, contaminants of potential concern (COPC), and receptors.
- An analysis of the linkages between program components, in a tabular format.
    - Linkages will include a rationalization of methods used across program components to make the methodology as consistent as possible.
- Current and planned activities at the Mount Polley Mine site, especially how those activities might impact on the CSM.

The following assumptions guide the continued development and implementation of the CEMP required under Section 3.2 of *EMA* Permit 11678:

- The CEMP is developed, reviewed and revised by Qualified Professionals (QPs), QPs being as defined by the Province of BC (e.g., R.P.Bio.).
    - MPMC notes that there are certain aspects of CEMP scoping (particularly in defining the objectives and drivers), where a QP is not necessary. For example, the reasonable study questions from members of the public are outside of the domain of expertise for a QP who would develop a CEMP; however, the scientific approach by which those questions would be answered are within the QP's domain of expertise.
- The CEMP will be based on information that is available, verifiable and can be relied upon by a QP.
- With the exception of regulatory requirements, a pattern of decrease or stasis in environmental condition is a suitable basis for gradual decrease in monitoring locations, frequencies, or parameters.

5 REVISION

The Mount Polley Mine is an operating site, changes to which are anticipated to transpire as development and closure activities co-occur; thus, an adaptive approach is both necessary and appropriate for documents such as the CEMP. Review of the CEMP content is an integral aspect of its effectiveness. In this application, 'effectiveness' means that the CEMP delivers on the regulatory drivers, some of which have rigid statutory obligations (e.g., MMER), satisfies the Objectives and Drivers for the CEMP, and undertakes that work with due regard to financial impact (without limiting the ability to meet the Objectives and Drivers established) and the adaptive nature of the CEMP.

To fulfill the adaptive approach, the CEMP will be reviewed and revised considering data collected in previous years (as interpreted by QPs). Such data will include that collected and interpreted directly under the CEMP, or as may be available from other assessments, studies or reports commissioned by MPMC as relating to the Objectives and Drivers for the CEMP. In the case of the latter, the CEMP will be modified, as appropriate, in consideration of the results and recommendations of such assessments, studies or reports. Based on collected data (and subsequent interpretation by QPs), the CEMP will include rationale for existing monitoring as well as any changes to the monitoring plan. It is anticipated that larger CEMP revisions in response to these activities will be made with consideration of maintaining continuity in spatial and temporal coverage to meet the Objectives and Drivers of the CEMP.

When possible, MPMC will provide written notice of planned changes to the CEMP to the MoE Director a minimum of 30 days prior to implementation to allow for review and feedback on the revision. Such written notice shall describe the planned changes as well as the rationale for the changes, including a summary of relevant data considered.

Under Section 3.2 of *EMA* Permit 11678, MPMC must submit a three-year detailed monitoring program interpretive report and updated CEMP to the MoE Director, for approval, by 31 March 2019, and every three years thereafter. Following the three-year detailed monitoring program interpretive report to the Director, MPMC will submit a summary of proposed changes to the CEMP to the MoE Director by April 30 of that year (one month following the interpretive report deadline).

A key component of the CEMP will be the monitoring program itself. The monitoring program will be designed, reviewed and revised by QPs such that, in their professional opinion, it satisfies the Objectives of the Drivers for the CEMP and allows MPMC to be informed of the adequacy of their source control efforts. Changes to the monitoring program that occur but are unplanned, such as the collection of additional samples, will be formally submitted with the MoE Director as soon as possible after the sampling occurs. Such written notice shall describe the planned changes as well as the rationale for the changes.

Notification of any CEMP or CEMP monitoring program changes must be provided to the MoE Director in writing for approval.

Notwithstanding the above, as per Section 3.2 of *EMA* Permit 11678, the MoE Director may require revisions to the CEMP or monitoring program based on review of monitoring data and/or any other relevant information.

6 CONSTRAINTS AND PROJECT RISKS

In the context of the CEMP and the content of this Terms of Reference, the following constraints and project risks have been identified by MPMC:

- The Mount Polley Mine, and by it, MPMC as owner and operator of the mine, is constrained to comply with applicable laws and statutory requirements.
- The health and safety of persons engaged in the monitoring work is a paramount consideration. Samples that cannot be obtained safely, using practical methods, will not be obtained. Certain seasonal conditions may preclude safe sampling.
- MPMC has voluntarily entered into (respective) PAs with the SCIB and the WLIB. MPMC will honour the respective PAs in full, and expects the SCIB and WLIB to reciprocate. Certain aspects of the CEMP pertain to subjects that fall within the bounds of the PAs.

7 ROLES AND RESPONSIBILITIES

In the context of the CEMP and the content of this Terms of Reference, the following roles and responsibilities are established:

- The MPMC Environmental Superintendent (or designate) will be responsible for implementing the CEMP, and revising it as appropriate.
    - Deliverables will be prepared by, or under the direct supervision of, QPs.
- Monitoring that is part of the CEMP will be coordinated by MPMC.
- All parties' reviewers of technical elements of the CEMP are required to be QPs if they are providing recommendations on the content or implementation of its subject matter.
- Participants involved in the design and review of the CEMP acknowledge that study designs, monitoring methods, and interpretation will be carried out in accordance with federal and provincial laws, policy and guidance.

Appendix B

Detailed Study Designs for CEMP Components

Appendix B - Addendum

Subsequent to the Issuance of the August 2018 CEMP, the following changes were made to study programs described in Appendix B:

Study	Change
Appendix B.1: Diffusive Gradient in Thin Film (DGT) sampling and toxicity testing with *Hyalella azteca*.	Sampling was conducted in 2019 and laboratory results are pending. When received, the data will be reviewed and recommendations for additional sampling, if any, will be presented to ENV in 2020.
Appendix B.2: Replication of tissue samples at Edney Creek location E1	Eight replicates of periphyton and benthic invertebrate tissues for chemistry were collected from E1 in 2019. The results are pending from the analytical laboratory.
Appendix B.4: Monitoring frequency	Monitoring frequencies applicable from 2018 to 2019, will be reviewed following data interpretation and modifications may be made in response to QP recommendations, subject to approval by the Director.
Appendix B.4: Spawning surveys	Visual spawning surveys (counts of adults and redds) were conducted in Upper Hazeltine Creek (2018) and lower Hazeltine/Edney Creek (2018 and 2019) per a monitoring plan developed in conjunction with the Habitat Remediation Working Group.

1 INTRODUCTION

1.1 Background

Sediment is an important sink and potential source of metals, metalloids, and nutrients[1] in aquatic environments (e.g., Horowitz 1991; Ingersoll et al. 1997; Simpson and Batley 2016). Sediment quality of receiving environments adjacent to mine sites can be influenced by the direct input of solids as well as by the introduction of dissolved constituents (e.g., metals) into water that subsequently associate with reactive materials on sediment surfaces (e.g., oxides, organic carbon) by surface complexation (Santschi et al. 1990; Stumm and Morgan 1996; Sposito 2004). Sediment also represents a pathway for the exposure of aquatic life to metals and other substances (e.g., nutrients, organic substances). Therefore, sediment quality is an important component of the CEMP.

The influence of the Mount Polley Mine on sediment quality can occur (or, at some locations, has occurred) by several key mechanisms: 1) general mine influence from physical impingement, dustfall, and/or uncontained surface or groundwater flows: 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to December 2017, and directly since January 2018]); 3) the TSF embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Sediment quality in waterbodies adjacent to the Mount Polley Mine has been monitored since baseline investigations in 1989, 1995, and 1996 (Imperial Metals 1990; HKP 1996, 1997). Results of sediment quality monitoring are reviewed in Section 2 and provide context for a CEMP sediment quality monitoring program that is guided by a combination of historical findings, representative locations downstream of Mount Polley Mine operations, representative reference locations, and considerations for a statistically-based design that will facilitate the detection of spatial and temporal differences in addition to providing data to evaluate concentrations relative to effects-based guidelines (e.g., British Columbia Working Sediment Quality Guidelines [BCWSQG]; BCMOE 2017). In addition to sediment quality monitoring required as part of the Mount Polley CEMP, sediment quality monitoring is required to support benthic invertebrate community monitoring conducted as part of Environmental Effect Monitoring (EEM) under the Metal Mining Effluent Regulations (MDMER) of the federal *Fisheries Act*.

The following sections of the CEMP Sediment Quality Monitoring Plan provide the objectives of sediment quality monitoring, a summary of historical sediment quality findings, an overview of the CEMP study design and associated rationale (including sampling locations, replication,

[1] Through the remainder of this section, the term “metals” will be used to include metals, metalloids, and nutrients for ease of communication

frequency, and analytes), and detailed methodology for sediment quality monitoring (quality assurance/quality control [QA/QC], sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting).

1.2 Monitoring Objective

The objective of sediment quality monitoring is to evaluate the influence of Mount Polley Mine activities on receiving environments (Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions, and to determine potential implications to aquatic life by applying a variety of interpretive tools (e.g., Working Sediment Quality Guidelines [BCMOE 2017], biological assessment). Sediment quality monitoring also provides supporting information for benthic invertebrate community monitoring, and to support exposure assessment as part of ecological risk assessment (ERA) and human health risk assessment (HHRA). An additional objective is to advance the technical understanding of the stability or mobility and the potential bioavailability of metals in lake sediments affected by the TSF embankment breach.

2 SUMMARY OF HISTORICAL FINDINGS

Sediment has been monitored in the vicinity of the Mount Polley Mine since 1989, with most of the sediment quality samples collected in Polley Lake, Bootjack Lake, Hazeltine Creek, and Edney Creek (Table 1). Hazeltine Creek and Edney Creek are primarily comprised of erosional habitat, with few locations of sediment deposition. This has made sediment sampling challenging relative to lake environments, and some unconventional methodologies were applied in baseline studies.

Sediment quality sampling in the vicinity of the Mount Polley Mine has spanned four distinct time periods:

1. Baseline monitoring (1989, 1995, 1996);
2. Pre-breach operational monitoring (1999, 2009, 2012);
3. Post-breach operational monitoring (2014, 2015); and
4. Post-breach and post-discharge monitoring (2016).

Data collected prior to the breach were summarized in an Aquatic Environmental Description Report prepared concurrent with an application for water discharge to Polley Lake in 2014 (Minnow 2014), and general findings of the historical sampling, as well as sediment monitoring data collected from 2014 to present, are provided, by sampling area to support the design of the sediment quality monitoring plan.

2.1 Polley Lake

Baseline sediment quality of Polley Lake was characterized by concentrations of a number of metals that were naturally elevated above sediment quality guidelines, including arsenic, chromium, copper, iron, manganese, nickel, and selenium (Minnow 2014). Concentrations of copper, iron, and manganese were particularly elevated, with concentrations naturally exceeding upper sediment quality guidelines (also known as probable effect levels) in some samples (HKP 1996, 1997).

Sediment quality monitoring in Polley Lake during operations but before the TSF embankment breach in 2014 indicated that concentrations of most of the elevated analytes remained similar to baseline. One apparent exception was selenium, which increased from 1.7 – 2.6 mg/kg dry weight (dw) in baseline to 2.5 – 3.7 mg/kg dw in 2009, and 5.0 to 6.9 mg/kg dw in 2012 (Minnow 2014). This increase was considered to be due to uncontrolled surface runoff from a north waste rock dump which reported to Polley Lake via North Dump Creek. This runoff contained elevated concentrations of selenium from 2006 until control in 2009 with the construction of the Long Ditch.

Table 1: History of Sediment Quality Monitoring in Waterbodies in the Vicinity of the Mount Polley Mine

A) Lakes

Year	Locations	Report
1989	Polley Lake, Bootjack Lake	Imperial Metals 1990
1995	Polley Lake, Bootjack Lake	HKP 1996
1996	Polley Lake, Bootjack Lake	HKP 1996
1999	Polley Lake, Bootjack Lake	Beak 2000
2009	Polley Lake	Minnow 2011
2012	Polley Lake	Minnow 2013a
2014	Polley Lake, Bootjack Lake, Quesnel Lake	Minnow 2015a
2015	Polley Lake, Bootjack Lake, Quesnel Lake	Minnow 2015b
2016	Polley Lake, Bootjack Lake, Quesnel Lake	Minnow 2016

B) Creeks

Year	Locations	Report
1995	Upper Hazeltine, Lower Hazeltine, Edney	HKP 1996
1996	Upper Hazeltine, Lower Hazeltine, Edney	HKP 1997
1999	Upper Hazeltine, Lower Hazeltine, Edney	Beak 2000
2007	Upper Hazeltine, Lower Hazeltine	Minnow 2009
2009	Upper Hazeltine	Minnow 2011
2010	Upper Hazeltine, Lower Hazeltine	Minnow 2011
2011	Edney	Minnow 2012
2012	Upper Hazeltine, Lower Hazeltine, Edney	Minnow 2013a
2013	Upper Hazeltine	Minnow 2013b
2014	Upper Hazeltine, Lower Hazeltine	Minnow 2015a
2015	Sedimentation Pond	Minnow 2015b
2016	Sedimentation Pond	Minnow 2016

Following the TSF embankment breach, sediment quality monitoring in Polley Lake indicated that concentrations of arsenic, copper, and iron were elevated at one or more monitoring locations relative to guidelines and baseline concentrations (Minnow 2015a). Changes in sediment quality were greatest for copper, with concentrations increasing from a baseline range of 262 – 370 mg/kg dw to 630 – 722 mg/kg dw in September 2014 (Minnow 2015a). Due to very low organic content of the breach-derived materials, sediment organic carbon content was also lower following the breach (Minnow 2015a). Sediment quality monitoring completed in 2015 and 2016 indicated very similar sediment quality from 2014 to 2016 (Minnow 2015b; 2016a; Figures 1 and 2). Evaluation of sediment deposition rates have indicated relatively low rates of sediment deposition in Polley Lake (average 0.66 mm/yr; 15 years for the accumulation of 1 cm of sediment; Minnow 2018). Sediment toxicity testing completed in 2014 and in 2016 indicated no effects to survival or growth of *Chironomus dilutus* and *Hyalella azteca* in standard tests completed on sediments from the Polley Lake basins (the deepest locations of the lake, known as P1 and P2), but a moderate reduction in growth of *H. azteca* at mid-depth areas (Minnow 2015a; Minnow 2017a). The benthic invertebrate community of the two deep basins in Polley Lake showed consistent recovery from 2014 to 2016 to a condition similar to the reference area in terms of density and richness in 2016 (Minnow 2017b). Lastly, a variety of sediment quality investigations conducted to characterize the potential mobility and bioavailability of sediment-associated metals (humidity cell tests, shake flask tests, selective extractions, ratios of simultaneously extracted metals to acid volatile sulphides [SEM/AVS], porewater chemistry, and Diffusive Gradients in Thin Films [DGT] devices) have all supported low mobility and bioavailability of sediment-associated metals (e.g., SRK 2015a,b; Minnow 2015a, 2016c, 2016d, 2017c, 2017d)

2.2 Hazeltine Creek

Baseline sediment quality of Hazeltine Creek was characterized in 1995 and 1996 (HKP 1996, 1997), but the latter included suspected errors (i.e., sampling in 1996 yielded unusually high concentrations of some metals [e.g., up to 2.2% copper] that were not observed in 1995 and have not been observed since). Based on the sampling conducted in 1995 (HKP 1996) and consistency with sampling conducted in 1999 (Beak 2000), concentrations of arsenic, copper, iron, and manganese (although reported as much lower than in 1996) were naturally elevated above lower sediment quality guidelines (Minnow 2014).

Sediment quality monitoring in Hazeltine Creek during operations but before the TSF embankment breach in 2014 indicated that concentrations of most of the elevated analytes remained similar to baseline. One possible exception was selenium, which, despite some uncertainty associated with different sampling methods and locations, had concentrations that were slightly greater than the sediment quality guideline of 2 mg/kg dw (i.e., up to 3.14 mg/kg dw

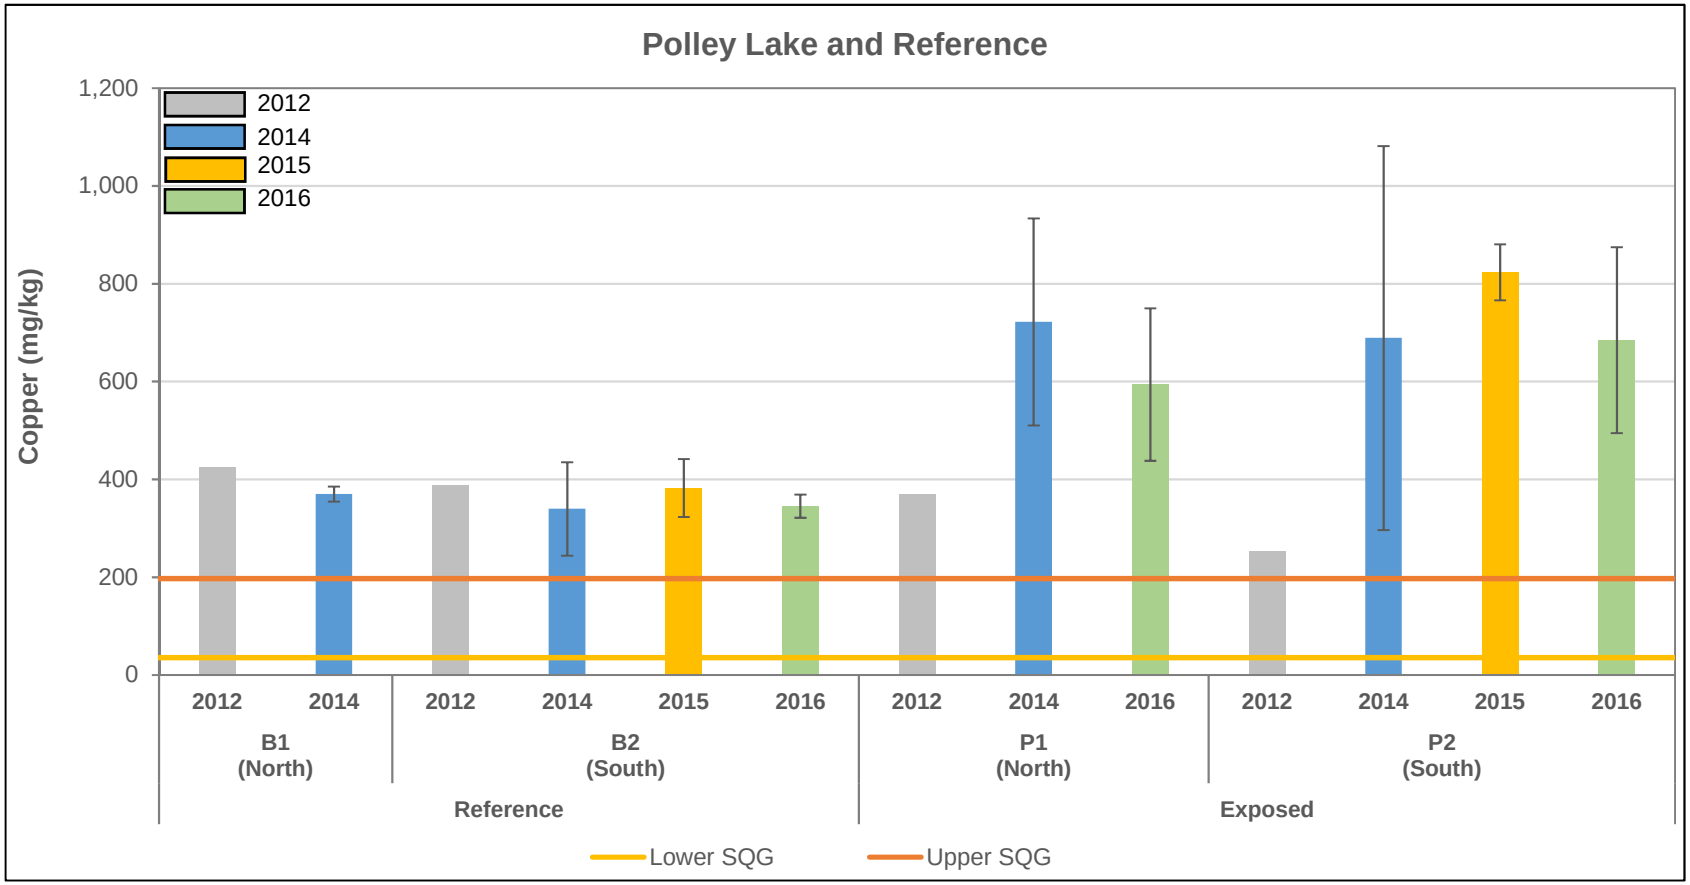

Figure 1: Concentrations of Copper in Polley Lake and Reference Sediment, 2012 to 2016

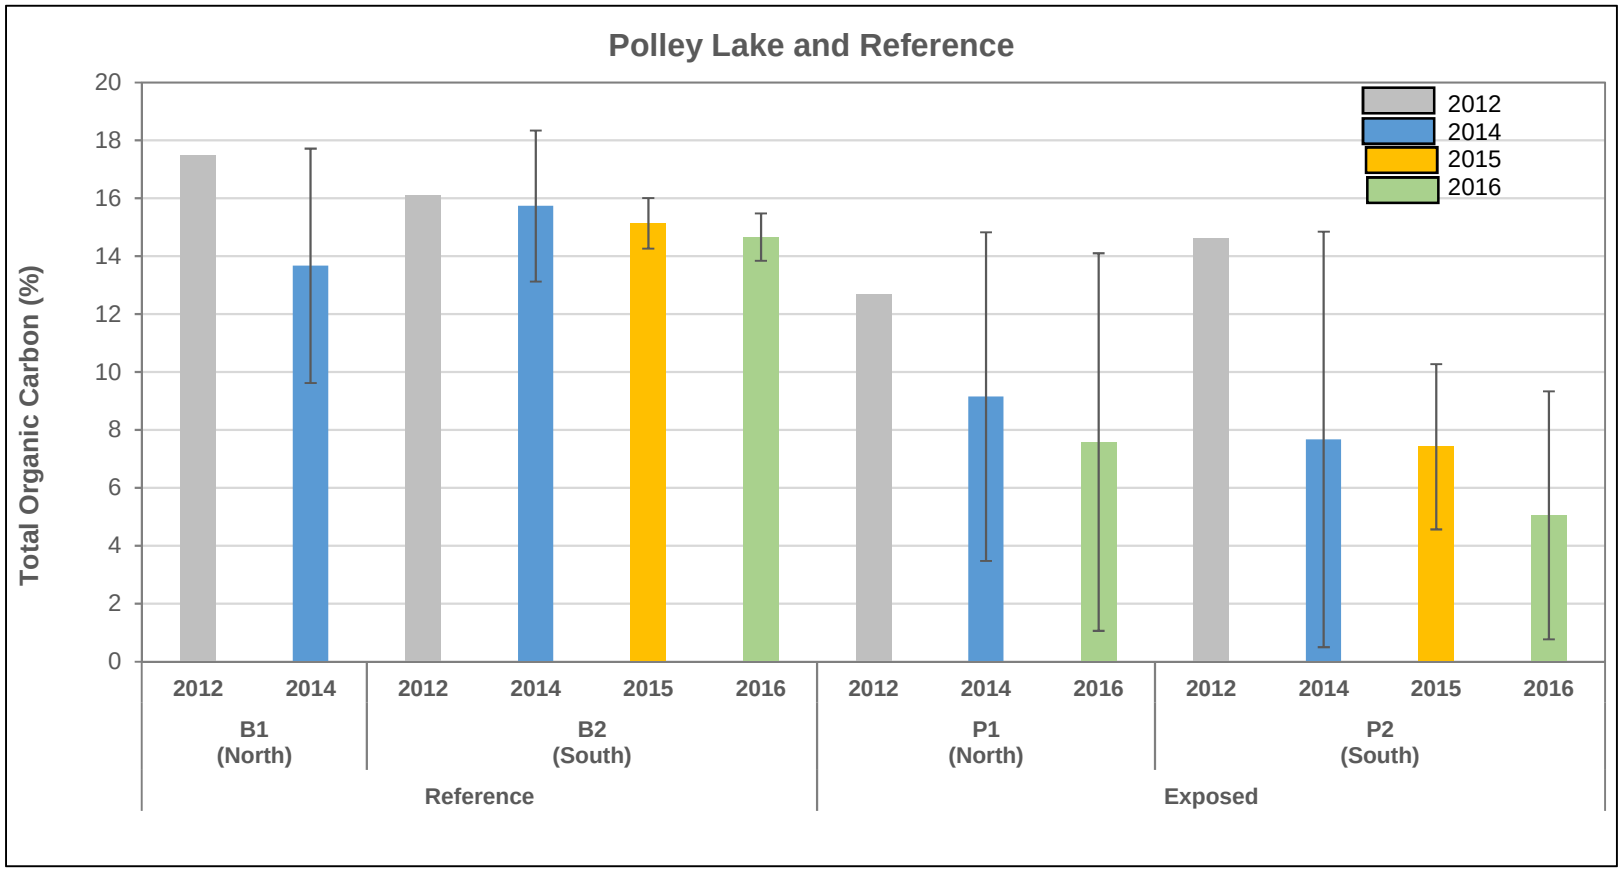

Figure 2: Concentrations of Total Organic Carbon in Polley Lake and Reference Sediment, 2012 to 2016

in a beaver pond in the fall of 2013; Minnow 2014). It is uncertain whether this difference was associated with the uncontrolled surface runoff that occurred from 2006 to 2009 (as described in Section 2.1) or if it was associated with the exclusive availability of fine sediment (that would naturally be expected to have higher metal concentrations) at a beaver pond sampled in 2013.

Following the TSF embankment breach, sediment quality monitoring was conducted in Hazeltine Creek in 2014. This sampling was prior to substantial rehabilitation from 2015 to 2017 and represented breach-material, believed to be mostly tailings. Accordingly, these "sediments" had very low organic carbon content, concentrations of copper and iron greater than upper sediment quality guidelines, and concentrations of arsenic and nickel greater than lower sediment quality guidelines (Minnow 2015a). Sediment quality monitoring of the Hazeltine Creek upper sedimentation pond completed in 2015 and 2016 indicated that concentrations of arsenic and nickel occurred at concentrations greater than reference and lower sediment quality guidelines, and concentrations of copper and iron occurred at concentrations greater than reference and upper sediment quality guidelines (Minnow 2015b; 2016).

2.3 Quesnel Lake

Sediment quality data for Quesnel Lake collected prior to the TSF embankment breach are limited to a few samples collected in the north arm near the mouth of the Mitchell River in 2012. These data documented a mean selenium concentration of 0.37 mg/kg dw (Minnow 2015a).

Following the TSF embankment breach, sediment quality monitoring in Quesnel Lake was completed at impacted areas and reference areas. A total of 121 sediment samples were collected from deep habitat of Quesnel Lake and 60 sediment samples were collected from shallow habitat of Quesnel Lake between 2014 and 2016 to characterize sediment quality (Minnow 2015a, 2015b, 2016). These sediment quality investigations indicated that the majority of breach-derived material was deposited to deep habitat. As with other habitats (i.e., Polley Lake and Hazeltine Creek), the chemical influence of the breach was most evident in copper concentrations greater than reference and upper sediment quality guidelines in impacted areas. Arsenic, iron, and manganese were elevated to concentrations greater than lower sediment quality guidelines, but concentrations of these metals were not elevated relative to reference or far-field concentrations. The influence of the breach was also evident in very low organic carbon content in impacted areas relative to reference. Sediment quality monitoring completed in 2015 and 2016 indicated very similar sediment quality from 2014 to 2016 (Figures 3 and 4; Minnow 2015b; 2016b), although the repositioning of two stations in area PNF in 2016 resulted in higher mean concentrations and lower variability. Some sediment consolidation (i.e., compaction) appears to be occurring in Quesnel Lake. Temporal change is expected to be primarily associated with deposition (i.e., covering of impacted sediment with non-impacted

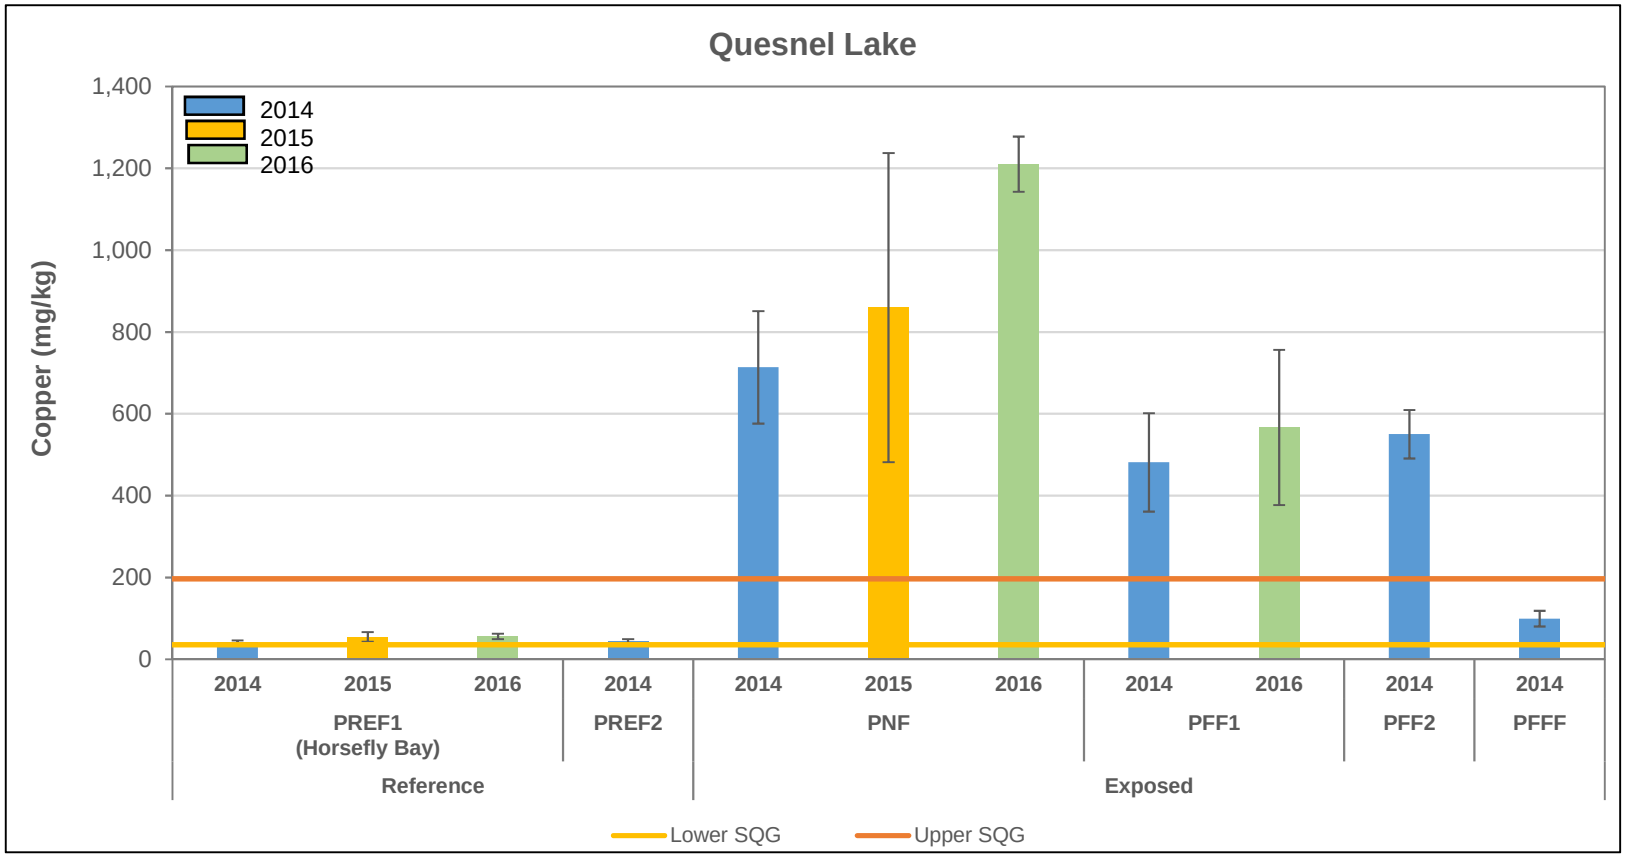

Figure 3: Concentrations of Copper in Quesnel Lake Sediment, 2014 to 2016

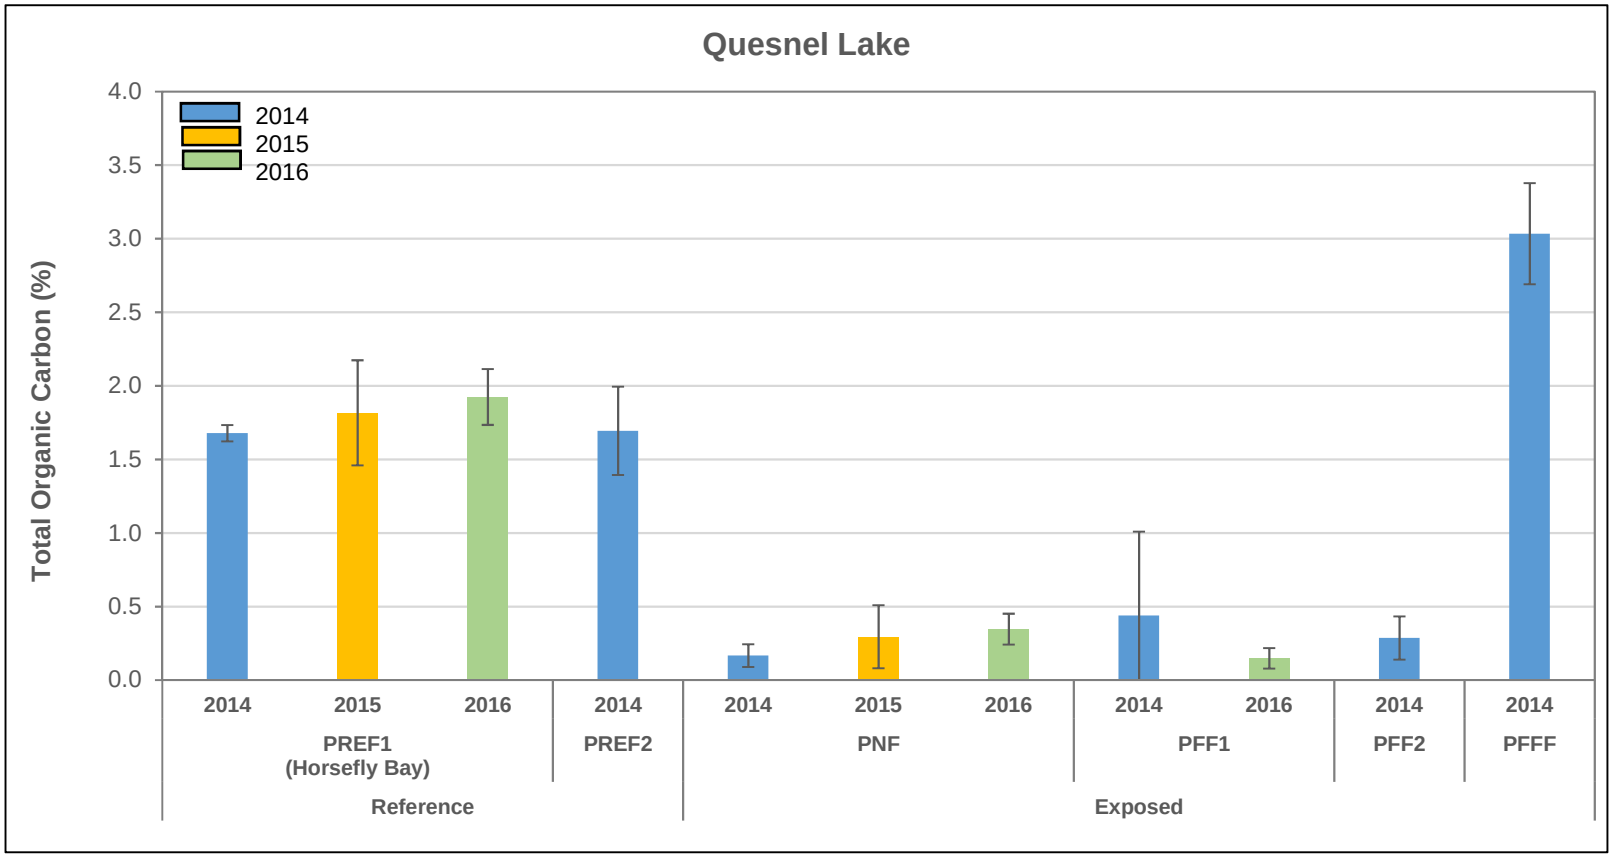

Figure 4: Concentrations of Total Organic Carbon in Quesnel Lake Sediment, 2014 to 2016

sediment), and evaluation of sediment deposition rates have indicated relatively low rates of sediment deposition in Quesnel Lake (range 1.4 to 1.7 mm/yr; 6 to 7 years for the accumulation of 1 cm of sediment; Minnow 2018).

Sediment toxicity testing completed in 2014, 2015, and 2016 indicated no responses to *C. dilutus* survival, but clear reductions in growth (Minnow 2017a). Clear responses to *H. azteca* survival and growth were observed, but *H. azteca* has low site-relevance as it is not present in deep areas of local lakes. Evaluation of relationships between observed responses and sediment quality indicated that combinations of high copper concentrations and low sediment organic carbon content were the best determinants of the observed responses (Minnow 2017a). Despite the observed responses in sediment toxicity tests, benthic invertebrate community monitoring, which is considered to be a measure of greater ecological relevance than toxicity testing (due to the fact that it evaluates in-situ habitat use by site organisms), indicated consistent recovery of organism density and taxon richness from 2014 through 2016. Although these endpoints remain lower than reference and the exposed area communities are not identical to reference, the observed increases are indicative of continued recolonization of these impacted areas. Lastly, a variety of sediment quality investigations conducted to characterize the potential mobility and bioavailability of sediment associated metals (humidity cell tests, shake flask tests, selective extractions, ratios of simultaneously extracted metals to acid volatile sulphides [SEM/AVS], porewater chemistry, and DGT devices) have supported low mobility and bioavailability of sediment-associated metals (e.g., SRK 2015a,b; Minnow 2015a, 2016c, 2017c).

3 STUDY DESIGN OVERVIEW AND RATIONALE

Sediment quality monitoring under the CEMP is designed to meet the combined needs of: 1) operational monitoring (including the discharge of treated effluent to Quesnel Lake); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to reclamation activity following the TSF embankment breach. An overview of the proposed sediment quality monitoring program is provided in Table 2 and Figures 5 and 6. Sediment quality monitoring is focused on Polley Lake, Hazeltine Creek, and Quesnel Lake, with reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake [and Jacobie Lake in 2018] for Polley Lake, unaffected areas of Quesnel Lake for impacted areas of Quesnel Lake). In Polley Lake, sediment sampling will focus on the two basins (deepest locations in Polley Lake, representing locations of sediment accumulation/fate), with the deepest location in Bootjack Lake (and Jacobie Lake in 2018) serving as reference. In Quesnel Lake, sediment quality monitoring for MDMER EEM will focus on the area near the point of effluent discharge (per Minnow 2016b) with two reference areas serving as reference (one unaffected by the breach and one affected by the breach but outside of the influence of effluent discharge). Additional sediment sampling in Quesnel Lake will focus on the deep areas that were previously monitored as near-field areas, with concurrent sampling of suitable reference areas. Hazeltine Creek is an erosional creek, and sediment sampling will be opportunistic, focussed on the collection of fines deposited on the declining hydrograph. All sediment quality monitoring includes sediment physical condition and sediment chemistry at all proposed sampling locations, as well as supporting sediment toxicity testing at a subset of areas (Table 2). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) concentrations relative to sediment quality guidelines for the protection of aquatic life (BCMOE). Accordingly, five stations per area are proposed for each to provide replication for the statistical contrasts.

Sediment quality monitoring will include physical and chemical characterization of deposited sediments, including particle size distribution, organic matter content, nutrients, and metals (see Section 4.2 below for greater detail). In accordance with BCMOE (2016) and in consideration that lake samples analyzed at the <63 µm fraction and <2.0 mm fraction yielded similar results (Minnow 2015a), sediment organic matter content, nutrients, and metals will be determined in the <63 µm fraction (silt and clay). Sediment toxicity testing (at Polley Lake, Quesnel Lake deep habitat, and associated references) will focus on larvae of the non-biting midge *Chironomus dilutus*. This organism is an ideal test organism for these sediments due to the ubiquitous presence of Chironomidae in these areas (Minnow 2015a) and the in-benthic habit of these organisms (in contrast to the epi-benthic habitat of other test organisms such as the amphipod

Table 2: Mount Polley CEMP Sediment Quality Monitoring Program Overview

A) Lakes

Water Body	Sampling Area	Type	Components [1]	Replication [2]	Rationale
Polley Lake	POL - P1 (Northwest Basin)	Exposed	C, T	5	immediately adjacent to mine and breach-influenced
	POL - P2 (Southeast Basin)	Exposed	C, T, D	5	immediately adjacent to mine and breach-influenced

Hyalella; Wang et al. 2004). Lastly, DGT devices will be deployed above the sediment water interface in areas most impacted by the TSF embankment breach (Polley Lake and Quesnel Lake deep areas) to provide annual feedback on whether there has been any change in the concentrations and/or proportion of labile metals above the sediment water interface (which would be suggestive of the potential instability or the temporal stability of sediment-associated metals).

Sediment quality and toxicity sampling will be supported by measurements of temperature, dissolved oxygen, pH, and specific conductance near the sediment-water interface at all sampling stations. Additional information to be collected includes GPS coordinates of each station and supporting photographs of the sampling location and samples. Some additional monitoring of the stability and potential bioavailability of metals associated with sediments impacted by the TSF embankment breach will be undertaken (e.g., deployment of Diffusive Gradients in Thin Films [DGT] devices to monitoring labile metal concentrations), as recommended by a QP and approved by ENV.

Sediment sampling will be completed in August or September consistent with previous data collections (HKP 1996, 1997; Beak 2000; Minnow 2015a,b; 2016). The frequency of sediment quality monitoring at the federal EEM sampling areas (where sediment is collected to support a benthic invertebrate community survey to evaluate potential effects of effluent discharge) is initially at a prescribed frequency of every three years, subject to modification based on the findings of at least two EEM phases (Environment Canada 2012). The frequency of sediment sampling at the lake areas is also guided by the results of sediment quality monitoring undertaken from 2014 to 2017. Evaluation of sediment deposition rates have indicated relatively low rates of sediment deposition in Polley Lake (average 0.66 mm/yr; 15 years for the accumulation of 1 cm of sediment) and Quesnel Lake (range 1.4 to 1.7 mm/yr; 6 to 7 years for the accumulation of 1 cm of sediment; Minnow 2018). This is consistent with limited change in sediment quality of these lakes which were sampled annually from 2014 to 2016 (e.g., Figures 1 to 4; Minnow 2016). Therefore, sediment sampling in lakes will be completed in 2018 and then every three years concurrent with EEM (2018, 2021, etc.). It is anticipated that a three-year frequency will be sufficient to track recovery associated with the deposition of approximately 2.0 mm of new sediment in Polley Lake and approximately 4.7 cm of new sediment in Quesnel Lake over the three-year period. As sediment samples are composed of the top 3 cm (30 mm) of deposited sediment (to represent exposure to benthic organisms and consistent with technical guidance; BCMOE 2016), this is equivalent to approximately 6.6% and 16% of the sample volume being comprised of new material. Water quality above the sediment water interface will be monitored in 2018-2020, including the deployment of Diffusive Gradients in Thin Films (DGTs). If monitoring of labile metal concentrations using DGT devices indicate increases above the sediment-water

interface, design modification (e.g., changes to monitoring frequency or locations) will be made in response to QP recommendations in future interpretive reports.

The initial frequency of sediment quality monitoring at the creek areas (Hazeltine and Edney Creeks) is annual. This is because post-breach / post-rehabilitation conditions have not been established. Frequency should be reviewed following interpretation of the data collected in 2020, with particular consideration of whether sediment, which is quantitatively rare in these erosional creeks, provides value as an independent monitor given the intensive monitoring of water, periphyton, and benthic invertebrates.

Sediments will be sampled, processed, analyzed, and associated data interpreted using methodology consistent with previous assessment at Mount Polley (e.g., Minnow 2015a,b; 2016), which is also consistent with technical guidance (e.g., Environment Canada 2012; BCMOE 2013, 2016). Detailed methodology is provided in Section 4, including: quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting.

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be performed by qualified field staff experienced in the implementation of sediment quality monitoring programs. Quality assurance and quality control measures will be consistent with requirements outlined in the BC Field Sampling Manual (BCMOE 2013), and will include program review prior to implementation, adequate resources for all field teams including field checklists and field data sheets, the availability and maintenance of clean sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination.

Quality control (QC) samples will be collected to support the sediment quality monitoring program. Five replicate samples (samples from 5 separate stations to represent the sampling area) will be collected from each sampling area in order to capture within-area variability. Specific field QC samples will include duplicates (i.e., splits) collected at a frequency of 10% of the total number of samples to assess field precision as part of the Data Quality Review (DQR; Section 4.4). Duplicate water samples will be collected at a frequency of 10% to assess field precision associated with the water samples that support DGT monitoring. In addition to field QA/QC, any laboratory conducting the physical or chemical analyses will be accredited by the Canadian Association for Laboratory Accreditation (CALA) for these analyses. Specific QC sampling and associated reporting will be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). These results will be assessed as part of the DQR (Section 4.4).

All raw field data will be transcribed from field sheets into an electronic spreadsheet. Data will then checked by a separate individual for data entry errors as part of routine Quality Assurance/Quality Control (QA/QC) procedures.

4.2 Sample Collection Methods

4.2.1 Lakes

Sampling of lake sediments will be consistent with previous monitoring (Minnow 2015a,b; 2016a). In Polley Lake (and the associated reference – Bootjack Lake [and Jacobie Lake in 2018]), sediments will be collected at five replicate stations per area, with sediments for the analysis of total organic carbon, total sulphur, total nitrogen, and metals collected using a Kajak-Brinkhurst corer or a Tech Ops corer in accordance with technical guidance for gravity coring outlined in the BC Field Sampling Manual (BCMOE 2013) and the Metal Mining Technical Guidance for EEM

(Environment Canada 2012). Sediment samples for particle size distribution will be collected using a Petite Ponar grab sampler. Briefly, the KB corer is a gravity corer that collects samples in 2" (5.08 cm) diameter core tubes. Core collection relies on a combination of surface tension within the core and suction supplied by a plunger that seals the top of the core tube after being deployed by a messenger. The Tech Ops corer is a gravity corer that collects samples in 4" (10.16 cm) diameter core tubes. Core collection relies on a combination of surface tension within the core and suction supplied by an automatic seal (plunger assembly) that shuts in response to sampler retrieval (upward pull). Success rates for each of the core devices tend to vary with sampling location in accordance with sediment characteristics and both devices may be used in the program.

Collection of sediment by coring requires careful application and experience to obtain good quality sediment samples (i.e., sediment samples that capture an undisturbed sediment-water interface). During coring, care will be taken to control the rate at which the coring device is lowered, to maintain the corer in a vertical position during descent, and to allow the corer to penetrate the sediment with minimal sediment disturbance. The corer will then be carefully retrieved to surface. At surface, an extruder head-piece will be inserted into the bottom of the core tube to prevent sediment slippage. Core samples will be rejected if there was evidence of slippage, that the core did not penetrate the substrate vertically, or that the sediment-water interface was disturbed within the core. Accepted samples will then be processed by removing the core tube from the corer and using the extruder to push the sediment upwards towards the top of the core tube in a controlled fashion with care taken to minimize suspension of fines. In the event of suspension, momentum will be stopped, allowing the suspended solids to re-settle. Once the sediment is extruded to near the top of the tube, an extrusion collar marked in 1-cm intervals will be carefully aligned on the top of the tube and the sediment will be extruded upwards into the extrusion collar to the 3-cm mark. A core slicer will then be carefully inserted between the tube and the collar to collect the top 3-cm of sediment, which will then be transferred into a 250 mL glass sampling jar labeled with the project number, sample location, and collection date. The procedure will then be repeated twice more (at minimum) in order to provide a composite sample of sufficient volume for the required analyses. All sampling equipment will be rinsed between stations using site water. As indicated above, duplicate (split) sediment samples will be collected at a target frequency of 10% for quality assurance/quality control (QA/QC) purposes (associated composite samples will be composed of twice the number of grabs to support the split samples). In addition, supporting information will be collected at each sampling site as outlined below. Immediately after collection, sediment samples will be placed into a cooler with ice packs, where they will be maintained cool prior to transport to the field laboratory where they will then be transferred to a refrigerator and held until shipment to the analytical laboratory.

Sediment samples for particle size analysis in Polley Lake, Bootjack Lake, and Jacobie Lake will be collected using a stainless steel Petite Ponar grab sampler in accordance with technical guidance outlined in the BC Field Sampling Manual (BCMOE 2013) and the Metal Mining Technical Guidance for EEM (Environment Canada 2012). Briefly, the Petite Ponar is a 6" x 6" (15.24 cm x 15.24 cm) grab sampler with jaws that can be held open by shear-pressure on a spring-loaded pin. The grab sampler is lowered to the substrate at which point shear-pressure is eliminated and the pin springs out. Upon upward pull at the initiation of retrieval, the jaws of the ponar close to grab surficial sediment. As with coring, care must be taken to control the rate at which the ponar is lowered to allow appropriate sediment penetration and to minimize sediment disturbance. The ponar will then be carefully retrieved to surface and each grab will be placed into a plastic tote and observed for completeness and any unusual characteristics. If the sample is deemed acceptable (i.e., the sampler is full to each end and is representative of surface sediment), surficial material to a depth of 3 cm will be transferred to a second tote using a stainless steel spoon, and the remaining sediment discarded. At each station, composite samples of the top 3 cm of surficial sediment of three acceptable grabs will be collected. The sediment within the tote will then be homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars labeled with the project number, sample location, and collection date. Sampling equipment will be rinsed between stations using site water.

Sediment samples for toxicity testing of *Chironomus dilutus* will also be collected using a Petite Ponar grab sampler. The same methodology as above will be applied, with the exception that, at stations that require both sediment chemistry and toxicity testing, a composite sample will be composed of a minimum of five grabs and will be placed into a 250 mL glass sampling jar for chemical analysis (as above) and another 500 mL jar for toxicity testing. As noted above, all jars will be labelled with the project number, sample location, and collection date.

In Quesnel Lake, all sediment samples (for total organic carbon, total sulphur, total nitrogen, and metals) will be collected using a stainless steel Petite Ponar (15.24 cm x 15.24 cm; 0.023 m^2 sampling area) or a stainless steel standard ponar (22.86 cm x 22.86 cm; 0.052 m^2 sampling area) in accordance with federal and provincial technical guidance (Environment Canada 2012; BCMOE 2013). Attempts to collect sediment from Quesnel Lake by gravity coring have yielded poor success rates due to the substantial depth of sampling (approximately 100 meters) and the non-cohesive nature of the sediment. Samples will be retrieved with the assistance of a coMDMERcial line hauler (Ace Line Hauler - Brutus Plus 40) using methodology consistent with that described above for collection of the Polley Lake (and Bootjack Lake) sediment particle size samples. Composite samples of the top three centimeters of surficial sediment of a minimum of three acceptable grabs (i.e., full to each edge of the sampler) will be collected at stations where toxicity testing is not required, and composite samples of the top three centimeters of surficial

sediment of a minimum of five acceptable grabs (i.e., full to each edge of the sampler) will be collected at stations where toxicity testing is required (Table 2 and Figure 5). Sediment homogenization and transfer to sampling jars will be as described above. All sampling equipment will be rinsed between stations using site water. Duplicate (i.e., split) sediment samples will be collected at a target frequency of 10% for quality assurance/quality control (QA/QC) purposes (associated composite samples will be composed of twice the number of grabs to support the split samples). In addition, supporting information will be collected at each sampling station as outlined below. Immediately after collection, sediment samples will be placed into a cooler with ice packs, where they will be maintained cool prior to transport to the field laboratory where they will be placed in a refrigerator and held until shipment to the analytical laboratory.

Supporting information collected at each of the lake sediment monitoring stations will include GPS (Geographic Positioning System) coordinates, sampling depth, Secchi depth, field meter measurements of temperature, specific conductance, dissolved oxygen and pH, photographs of sediment samples, notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). In addition, one full vertical profile of the field meter measurements will collected at one station per area.

4.2.2 Creeks

Hazeltine Creek and the associated reference creek (Edney Creek) are predominantly erosional (HKP 1996, 1997; Minnow 2007) and there are few locations of true sediment deposition. The limited sediment within these creeks tends to wash through during spring freshet and deposit as a thin layer of fines in quiescent areas on the lowering hydrograph. Thus, collection of true sediment (i.e., fines in the silt and clay size category) cannot be completed by conventional grab sampling as applied in lakes (as described above) and typically applied in depositional creeks (i.e., due to the dominant presence of sand, gravel, and cobble). An alternative method will therefore be applied – sampling by spoon. This sampling will target the fine sediment fraction (i.e., silt and clay). Sampling will be undertaken in late suMDMER when low flows support some sediment deposition, even if only as a thin layer over sand, gravel, or cobble. As with lake sampling, sediments will be collected at five replicate stations per area. However, due to the non-uniform nature of sediment deposition in erosional creeks, the actual sampling stations will be determined opportunistically with each field sampling campaign and may vary slightly over time (i.e., a priority will be placed on the quality of the five replicate sediment samples collected within each area rather than the precise location of each sample within each area).

Sediment samples from creeks will be collected using a clean stainless steel spoon. All samples will be collected from wetted sampling stations that support the accumulation of fine materials (i.e., small pools or backwaters). Sampling locations will be approached by foot in a manner that

does not disturb sediment prior to sampling. At locations of sediment deposition, surficial sediment will be carefully collected by slowly placing the spoon on the sediment surface in a manner that minimizes disturbance. The spoon will then be inserted into the sediment to capture sediment to a depth of no greater than 3 cm and moved horizontally to fill the spoon. In reality, the collection depth may be much less than 3 cm, as fines often settle in a thin layer over coarser material (and sampling seeks to avoid coarse material as indicated above). The spoon will then be slowly retrieved to surface to avoid sample washout. The content of the spoon will then be inspected to ensure that it represents fine sediment (i.e., is predominantly silt and clay) and, if accepted, will be placed into a 250 mL glass sampling jar labeled with the project number, sample location and collection date. This procedure will be repeated a minimum of four more times to form a composite sample representative of the sampling station. Sampling equipment will be rinsed between stations using site water. Duplicate sediment samples will be collected at a target frequency of 10% for quality assurance/quality control (QA/QC) purposes (associated composite samples will be composed of twice the number of spoons to support the split samples). In addition, supporting information will be collected at each sampling site as outlined below. Immediately after collection, sediment samples will be placed into a cooler with ice packs, where they will be maintained cool prior to transport to the field laboratory where they will then be transferred to refrigerator and held until shipment to the analytical laboratory.

Supporting information collected at each of the creek sediment monitoring stations will include GPS (Geographic Positioning System) coordinates, average water depth at the sample locations, average sediment depth collected, field meter measurements of temperature, specific conductance, dissolved oxygen and pH, photographs of sediment samples, notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.).

4.2.3 DGT Sampling

Diffusive Gradients in Thin Films (DGT) sampling devices (DGT model C-LSNX; DGT Research, Lancaster, UK) as described in Minnow (2017a) will be installed in the lower water column at one sediment sampling area in Polley Lake (POL-P2; with an area in Bootjack Lake [BOL-2] as reference) and at one sediment sampling area in Quesnel Lake (QUL-PNF; with an area in Quesnel Lake [QUL-PREF1] as reference; Table 2). Five replicate DGT devices will be placed in exposed areas and three replicates will be placed in reference areas. The purpose of the DGT device monitoring is to provide data on the concentrations of DGT-labile metals above of the sediment-water interface, and most importantly to monitor DGT-labile metals above the sediment-water interface to determine if those concentrations are changing over time. Low and unchanging concentrations of DGT-labile metals would be indicative of stability of metals and metalloids in

lake sediments affected by the TSF embankment breach. Conversely, increasing concentrations of DGT-labile metals would be indicative of instability of metals and metalloids in lake sediments.

The DGT devices will be installed in the lower water column approximately one meter above the sediment surface. This will be achieved by placing a line with anchor and float at each sample location. The DGT devices will be deployed with care (including not touching the DGT window) while wearing metal free disposable nitrile gloves and will be left in place for a total period of 35 to 50 days. Upon retrieval, DGT devices will be handled with care while wearing metal free disposable nitrile gloves. Upon retrieval, each DGT device will be gently rinsed with metal free water (provided by the laboratory) and placed into a labelled glass soil jar with a few drops of metal free water to prevent desiccation. Jars will then be placed into clean Ziploc™ bags and then into a dedicated cooler with ice packs, where they were maintained cool prior to transport.

Supporting information collected at each DGT deployment location will include GPS (Geographic Positioning System) coordinates, sampling depth, field meter measurements of temperature, specific conductance, dissolved oxygen and pH, site photographs (including photographs of the DGT devices), and notes on the presence or absence of any fouling of the DGT devices. Supporting water samples will also be collected from each sampling area, including samples for total and dissolved constituents (including metals), the latter prepared by field filtration using a 0.45 µm syringe filter. Water samples will be placed into a dedicated cooler with frozen ice packs, and kept cool prior to transport to the field laboratory.

4.3 Sample Handling and Laboratory Analysis

At the termination of the field program or at intervals of no more than seven days, sediment samples will be shipped in coolers with ice packs to the analytical laboratory and/or toxicity testing laboratory. Shipment transit time will be less than one day.

Chemical analyses will be completed at an analytical laboratory accredited by the Canadian Association for Laboratory Accreditation (CALA) using methods that are consistent with those specified in the British Columbia Environmental Laboratory Manual (BCMOE 2015) and will include moisture content, pH, particle size distribution, total organic carbon (TOC), total nitrogen, total sulphur, and total metal concentrations (Table 3). All analyses except for particle size distribution will be completed on the silt/clay fraction (<63 µm diameter) in accordance with recent recommendations by BCMOE (2016) and because sediment quality characterization conducted in 2014 indicated similar results in <63 µm and <2 mm sediments (Minnow 2015a). Analysis of metals will be based on the BC Strong Acid Leachable Metals digestion (SALM; BCMOE 2016). Analyses of pH will be completed by electrode, particle size analysis will be completed by sieve and pipette, total organic carbon will be completed by combustion and titration (total carbon minus total inorganic carbon), total nitrogen and total sulphur will be completed by combustion, metals

Table 3: Analytes and Laboratory Reporting Limits for Mount Polley CEMP Sediment Quality Monitoring

[2] British Columbia Sediment Quality Guidelines; from British Columbia Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture (BCMOE 2017)

[a] approximately 2%

[b] approximately 4%

will be completed by collision reaction cell inductively coupled plasma – mass spectrometry (ICP-MS [USEPA Method 6020A; USEPA 1998]), and mercury will be completed by cold vapor atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (USEPA Method 245.7; USEPA 2005).

Toxicity testing will be completed at a testing laboratory accredited by CALA. Testing will be completed using a standard 10 day test of the survival and growth of *Chironomus dilutus* (a midge larva; Environment Canada 1997). In accordance with recent recommendations for toxicity testing, test replicates (n = 5) will be field-collected replicates. In addition to the exposed area field replicates and the reference area field replicates, a laboratory control (beach sand in accordance with the standard biological test methods) will also be included (also to be set up with five laboratory replicates).

At the termination of the DGT device collections or at intervals of no more than four days, DGT devices will be shipped in coolers with ice packs to the analytical laboratory. Laboratory analysis of the DGT devices will involve dismantling the devices followed by digestion of the resins to determine total metal concentrations in the resin by ICP-MS (USEPA Method 6020A; USEPA 1998). DGT-labile metal concentrations will subsequently be calculated by the analytical laboratory based on total metal in the resin, mean water temperature during deployment at each area, total deployment time, and manufacturer-supplied peer-reviewed diffusion coefficients, which, in turn, are based on Fick's first law of diffusion (Zhang and Davison 1995; Panther et al. 2014). Supporting water samples will be treated in a manner identical to the routine water quality samples collected as part of the CEMP (Section 6.6).

Each of the laboratories will provide a sample receipt confirmation when the samples are received and logged. These receipts will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. Upon completion of the analyses, each laboratory will provide a data report in Microsoft (MS) Excel™ and as an Adobe Acrobat Portable Document Format (PDF). Reporting will include the results of the laboratory QC sample results.

4.4 Data Quality Review

Upon receipt of sediment quality data and supporting water quality data from the analytical laboratory, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs have been achieved. The DQR will also include an evaluation of differences between duplicate samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the sediment quality data will ensure timely communication with the laboratory should any issues be identified.

Comparisons between duplicate samples will be made by calculating the relative percent difference (RPD) between concentrations between paired duplicates. If the RPD is <40% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping).

4.5 Data Handling, Interpretation, and Reporting

Upon receipt of data from the analytical laboratories, all laboratory data files will be managed by the Mount Polley Mining Corporation (MPMC) Environment Department. In addition, data provided by the primary analytical laboratories as an Electronic Data Deliverable (EDD) will be imported directly into the MPMC's database following completion of the DQR. Following the completion of the DQR, all sediment quality data and supporting data will be managed in Microsoft (MS) Excel™. For all replicated data (typically based on a sample size of five stations per area), data will be provided to the QP and summarized by calculating mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile for each analyte. Sediment quality data will then be evaluated in comparison to British Columbia Working Sediment Quality Guidelines for the protection of aquatic life (WSQGs; BCMOE 2017) and reference concentrations. Reference 95th percentile values will be used to screen exposed-area mean concentrations to efficiently identify analytes with concentrations that are beyond the range of reference. Analytes with concentrations greater than guidelines and reference will be the focus of more detailed interpretation, which may include, as required for data interpretation: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations and/or over time.

WSQGs are numerical criteria that are protective of sediment-dwelling organisms based on long-term exposure. Most British Columbia WSQGs have been adopted from the CCME (CCME 1999) or from Ontario (OMOE 1993) and have two levels – a Lower WSQG (also known as a Threshold Effect Level [TEL] or a Lowest Effect Level [LEL]) and a Higher WSQG (also known as a Probable Effect Level [PEL] or a Severe Effect Level [SEL]). The Lower WSQG is intended to represent a concentration that will protect aquatic life from adverse effects of a toxic substance in most situations (BCMOE 2017). The Upper WSQG is intended to represent a concentration that, if exceeded, will likely cause severe effects on aquatic life (BCMOE 2017). However, WSQGs – even the Upper WSQGs - are often naturally exceeded in mineralized areas, as was the case for copper, iron, and manganese in Polley Lake (Section 2.1). In addition, SQGs were developed based on co-occurring bulk surficial sediment data and biological effect data (CCME 1995). Bulk

sediment chemistry can differ substantially from the <63 µm fraction, and this discrepancy between measurement (<63 µm fraction) and exposure (to bulk sediment to which SQGs are most applicable) should be considered in interpretation as "caution should be used in interpreting the biological significance of chemical concentrations in sediments for different types based on these guidelines" (CCME 1995).

Multivariate statistical tools may also be applied to assist with sediment quality data interpretation. Specifically, ordination techniques such as Principal Components Analysis (PCA), Correspondence Analysis (CA), or Nonmetric Multidimensional Scaling (NMDS) may be applied to assist in the identification of key spatial or temporal differences in sediment chemistry. Perhaps more importantly, these techniques will be used in the analysis of potential physical and/or chemical causes of differences in biological metrics (e.g., benthic invertebrate community condition) as a means of reducing data to focus on a small list of key components for correlation analysis (see Section 6.13 – Benthic Invertebrate Monitoring).

As indicated above, analytes with concentrations greater than guidelines and reference 95th percentile concentrations will be the focus of more detailed interpretation, which may include, as required for data interpretation: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations and/or over time. This will include the following: graphical plots in relation to all guidelines, reference values, and historical values and examination of relationships to physical variables. Plots of the analytes of interest (those greater than SQG and reference) will be prepared in MSExcel. At a sample size of 5, plots will include of each replicate by area. Available guidelines (BCWSQG), reference concentrations, and background concentrations (as available) will be added to the plots as lines to facilitate comparison of concentrations to these benchmarks.

Relationships between the analytes of interest and physical features (i.e., particle size) and other chemical variables (total organic carbon content) will be evaluated using correlation analysis. Spearman correlation (often referred to a Spearman Rank-Order correlation) will be completed. Following the derivation of correlation coefficients, a Bonferroni-type correction (i.e., p-value [0.05] divided by the total number of correlations examined for independent variables) will be applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected p-value of 0.05. Any significant correlations found at the Bonferroni-adjusted p-value or at a p-value of 0.01 will be further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were "leveraged" by outlying points (or groups of points).

Sediment toxicity test results (survival and growth of *C. dilutus*) will be interpreted based on a combination of effect size and statistical contrasts. Results associated with each exposed area will be contrasted against the matched reference area and against the laboratory control. Results will then be evaluated using a stepwise procedure similar to that of Southern California Coastal Water Research Project (SCCWRP) California Sediment Quality Objectives (CASQO; Bay et al. 2014):

1. mean responses (percent survival and growth [dry weight per surviving organism]) will be expressed as a percentage of the mean laboratory control result and the mean field reference result; and

2. results of the statistical contrasts of mean responses in tests of impacted sediment against the laboratory control and the field reference sediment will be compiled.

Results will then be categorized as follows:

1. no unacceptable response is a mean response within 20% of the mean field reference response (i.e., survival or growth were ≥80% of the field reference);

2. a low to moderate response is a mean response of between 20% and 50% of the mean field reference response (i.e., survival or growth were 50% to 80% of the field reference); and

3. a large response is a mean response of >50% of the mean field reference response (i.e., survival or growth were <50% of the field reference).

Low and moderate responses will be distinguished based on whether the results differ significantly from reference (moderate response) or not (low response). Application of a 20% reduction in survival relative to the field reference to define acceptability is consistent with thresholds used elsewhere (e.g., BCMELP 1998; Government of Canada 2010; Bay et al. 2014). If low, moderate, or high responses are observed in sediment toxicity testing, relationships between the effect endpoint (i.e., survival or growth) and sediment quality will be evaluated in consideration of WSQGs, effect thresholds, and the results of correlation analysis. Although it is recognized that a significant correlation or regression does not indicate causation (e.g., Norton et al. 2015), it is desirable to not only characterize the nature of a response (e.g., reduced survival or growth in sediment toxicity tests), but to also obtain evidence of cause. Correlation / regression analyses are commonly applied tools for identifying potential cause (e.g., Norton et al. 2015). Evidence of causation obtained from correlation or regression analysis will be carefully considered in light of the strength, range, and continuity of the relationships as well as mechanistic knowledge/understanding of potential cause.

The overall interpretation of sediment quality data will include integration of a weight-of-evidence that includes other components of the MPMC CEMP (e.g., water quality data, periphyton data for creeks, benthic invertebrate community data for lakes and creeks). Thus, within the CEMP, sediment quality data interpretation will specifically include the integration of data on sediment quality, the results of specialized evaluations (e.g., DGT results), and the results of bio-assessment (e.g., sediment toxicity testing and benthic invertebrate communities).

An interpretive report based on the sediment quality data will be prepared to be integrated into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWSQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

1 INTRODUCTION

1.1 Background

Benthic invertebrates are excellent biomonitors for assessing potential effects of physical and/or chemical habitat changes in aquatic systems (Barbour et al. 1999; Feltmate and Fraser 1999; Beatty et al. 2006). Due to the complexity of benthic invertebrate community structure and known tolerances and sensitivities to sediment and water quality (e.g., Barbour et al. 1999; Mandaville 2002), benthic invertebrate community analysis is typically a highly sensitive bio-monitor. Benthic invertebrate are sessile, therefore evaluation of benthic invertebrate tissue quality can provide an important measure of localized chemical conditions and of spatial extent of an effect, as well as of potential direct or indirect exposure of fish and wildlife to metals, metalloids, and nutrients[1]. Therefore, benthic invertebrate community and tissue quality monitoring is an important component of the Mount Polley CEMP.

The influence of the Mount Polley Mine on benthic invertebrate communities, productivity, and/or tissue quality can occur by several key mechanisms: 1) general mine influence from dustfall and/or uncontained surface or groundwater flows: 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to December 2017, and directly since January 2018]); 3) the TSF embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Reclamation activities in Hazeltine Creek and lower Edney Creek were initiated in 2014 following the TSF embankment breach, and were completed in lower Edney Creek in August 2015 (Golder 2017a). Construction / rehabilitation in areas of upper Hazeltine Creek (Reaches 1 and 2) were completed between July and September of 2016 and 2017, respectively (Golder 2017b,c). Reach 2 of the rehabilitation works encompassed a sampling area established prior to the TSF embankment breach (UHC; Minnow 2009). In lower Hazeltine Creek, initial channel rehabilitation was completed in 2015, and further rehabilitation has yet to be completed in this area of creek. The geomorphology of Hazeltine Creek was drastically altered as a result of the TSF embankment breach such that Fisheries and Oceans Canada considered it not to be fish habitat (Golder 2015a), and the creek was inaccessible to fish from August 2014 (following the breach) until the spring of 2018 when it was reopened as fish habitat.

Benthic invertebrate communities in waterbodies adjacent to the Mount Polley Mine have been monitored since baseline investigations in 1989, 1995, and 1996 (Imperial Metals 1990; HKP 1996, 1997). Benthic invertebrate tissue quality has been monitored since prior to the TSF

[1] Through the remainder of this section, the term “metals” will be used to include metals, metalloids, and nutrients for ease of communication.

embankment breach (2009, 2010, 2012, and 2013; Minnow 2011, 2013a,b). Results of benthic invertebrate community and tissue quality monitoring are reviewed in Section 2 and provide context for a CEMP benthic invertebrate monitoring program that is guided by a combination of historical findings, representative locations downstream of Mount Polley Mine operations, representative reference locations, and considerations for a statistically-based design that will facilitate the detection of spatial and/or temporal differences in benthic invertebrate productivity, community, and/or tissue quality, in addition to providing data to evaluate tissue quality results (i.e., tissue selenium concentrations) relative to effects-based guidelines (e.g., British Columbia Water Quality Guidelines [BCWQG]; BCMOE 2014). In addition to monitoring required as part of the Mount Polley CEMP, benthic invertebrate community monitoring is required as part of Environmental Effect Monitoring (EEM) under the Metal Mining Effluent Regulations (MDMER) of the federal *Fisheries Act*.

The following sections of the CEMP Benthic Invertebrate Monitoring Plan provide the objectives of benthic invertebrate community and tissue quality monitoring, a summary of historical benthic invertebrate findings, an overview of the CEMP study design and associated rationale (including sampling locations, replication, frequency, and analytes), and detailed methodology for benthic invertebrate community and tissue quality monitoring (quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting).

1.2 Monitoring Objective

The objective of benthic invertebrate monitoring is to evaluate the influence of Mount Polley Mine activities on benthic invertebrate communities, productivity, and tissue quality in receiving environments (Polley Lake, Hazeltine Creek, Edney Creek, and Quesnel Lake) in comparison to baseline and/or reference conditions, and to determine potential implications to aquatic life (e.g., through assessment of benthic invertebrate community and productivity endpoints, and comparison of benthic tissue quality results to available guidelines; BCMOE 2014) and to aquatic ecosystem health by providing supporting information for the assessment of potential effects to higher trophic levels (e.g., fish and fish habitat quality; Section 6.16). Benthic invertebrate monitoring also provides data to support exposure assessment as part of the ecological risk assessment (ERA) and human health risk assessment (HHRA). Benthic invertebrate community monitoring is also required as part of Environmental Effect Monitoring (EEM) under the Metal and Diamond Mining Effluent Regulations (MDMER) of the federal *Fisheries Act* (Government of Canada 2018). The objective of the MDMER EEM benthic invertebrate monitoring is to evaluate whether there are effects to benthic invertebrate community characteristics between the area of

Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012a).

2 SUMMARY OF HISTORICAL FINDINGS

Benthic invertebrate community has been monitored in the vicinity of the Mount Polley Mine since 1989, and benthic invertebrate tissue quality has been monitored since 2009. The majority of benthic invertebrate community and tissue quality samples have been collected from Polley Lake, Bootjack Lake, Quesnel Lake, Hazeltine Creek, and Edney Creek (Tables 1 and 2).

Benthic invertebrate community sampling in the vicinity of the Mount Polley Mine has spanned the four distinct time periods listed below:

1. Baseline monitoring (1989, 1995, 1996);
2. Pre-breach operational monitoring (1999, 2007, 2009, 2010, 2012, 2013);
3. Post-breach operational monitoring (2014, 2015); and
4. Post-breach and post-discharge monitoring (2016, 2017).

Benthic invertebrate tissue quality sampling in the vicinity of the Mount Polley has spanned operational time periods only (time periods 2 to 4). Data collected prior to the breach were summarized in a Technical Assessment Report (MPMC 2009) and an Aquatic Environmental Description Report (Minnow 2014a) prepared concurrently with applications for water discharge in 2009 and 2014, respectively. General findings associated with baseline, pre-breach, post-breach operational, and post-breach post-discharge monitoring are summarized, by sampling area, in the following sections.

2.1 Polley Lake

2.1.1 Community

The benthic invertebrate community of Polley Lake during baseline studies (Table 1; 1995 and 1996; HKP 1996, 1997) and pre-breach operational monitoring (1999; Beak 2000) was characterized by a dominance of Chironomidae (midges) and Oligochaeta (worms) in the two deep basins of the lake (P1 and P2). A temporal increase in density and richness at these stations was observed between baseline period and pre-breach operational monitoring, but due to unavailability of detailed sample collection and laboratory methods for baseline studies (e.g., HKP 1996, 1997) the reason for this difference is not clear (Minnow 2014a).

Following the TSF embankment breach, the benthic community in Polley Lake differed dramatically from conditions prior to the breach (1999; Beak 2000) and from reference in both deep basins of the lake (Figure 1). Specifically, no benthic organisms were present in the south basin (POL-P2) indicating an unequivocal impact, and organism density and taxon richness in the

north basin (POL-P1) was also substantially impacted (9 to 17 organisms/m^2; 1 to 2 taxa, respectively) relative to reference (1,431 to 2,551 organisms/m^2; 4 to 6 taxa, respectively) and pre-breach conditions (300 to 614 organisms/m^2; 10 to 15 taxa; Figure 1; Minnow 2015a). Benthic invertebrate community monitoring completed in 2015 and 2016 indicated substantial recovery of the benthic community in both deep basins of Polley Lake relative to 2014 conditions. Organism density (mean = 686 to 1,360 organisms/m^2) and taxon richness (mean = 7.4 to 8.4 taxa) at both areas in 2016 were similar to reference, and density was similar to pre-breach conditions as determined by Before-After/Control-Impact analysis (1999 and 2016; Minnow 2017a). Some differences in community composition relative to reference were observed in 2015 and 2016 (Minnow 2016b, 2017a); however, the primary difference (lower relative proportion of *Chaoborus* in Polley Lake in comparison to reference) was observed prior to the embankment breach (i.e., Beak 2000).

2.1.2 Tissue Quality

Benthic invertebrate tissue quality in Polley Lake was not assessed as part of baseline studies (1989-1996; Table 2). Selenium-specific aquatic environmental monitoring was initiated in 2009 after an uncontrolled surface runoff event from the north waste rock dump which reported to Polley Lake via North Dump Creek (Minnow 2011; see CEMP Sections 6.12 and 6.16). This runoff started in 2006, was controlled in 2009 with the construction of the Long Ditch, and was characterized by elevated concentrations of sulphate and selenium. Mean selenium concentrations observed during pre-breach operational monitoring (2009 and 2012; 6.0 to 7.8 mg/kg dw) were greater than reference and the interim BCWQG of 4 mg/kg dry weight, and were generally similar among sampling years (Figure 2; Minnow 2011, 2013a).

Following the TSF embankment breach, mean benthic invertebrate concentrations of selenium remained significantly higher than the BCWQG and reference, but were significantly lower in 2016 (5.4 mg/kg dw) relative to 2009 and 2012 indicating no breach-related increase (Figure 2; Minnow 2017b). Benthic invertebrate tissue quality investigations following the TSF embankment breach were also focussed on a suite of analytes identified as indicative of the chemical influence of the breach on sediment quality in the receiving environment (Minnow 2015a): Parameters of Interest (POIs: arsenic, copper, iron, manganese, nickel, and zinc), and Indicator Parameters (IPs: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium). Mean concentrations of a number these POIs and IPs were higher than reference in 2015 (manganese, tin, and titanium), in 2016 (arsenic, iron, and vanadium), and in both 2015 and 2016 (copper and molybdenum; Minnow 2016a, 2017a). In particular, mean benthic invertebrate copper concentrations were approximately 5.8 to 6.9 times higher than reference (Figure 3). These results are not unexpected, given that sediment copper concentrations were approximately

twice reference values (see CEMP Section 6.12). Although whole benthic invertebrate tissue concentrations accurately represent concentrations associated with food for higher trophic level organisms that consume benthic invertebrates, they may not accurately represent metal concentrations in the tissues of benthic organisms due to a known confounding influence of gut content on the determination of tissue metal concentrations in invertebrates, and therefore on the evaluation of potential biological effects associated with these metal concentrations (i.e., Chapman 1985, 2016). Metal concentrations were evaluated in both depurated and non-depurated benthic invertebrate samples in 2016 from Polley Lake in order to minimize the confounding influence of gut content. However, depuration made little difference to results (Minnow 2017a). Due to the uncertainties associated with depositional benthic invertebrate tissue monitoring, and similarities with results of other sampling methods (Diffusive Gradients in Thin Films [DGT] devices), DGTs will be used to monitor temporal changes in labile metal concentrations in Polley Lake (see CEMP Section 6.12).

Ratios of benthic invertebrate tissue metal concentrations to sediment concentration ([benthic invertebrate sample]/[sediment]) are referred to as Biota Sediment Accumulation Factors (BSAFs) and are often used to describe the accumulation of sediment-associated analytes in tissues of ecological receptors (i.e., Burkhard 2009). BSAFs for benthic invertebrate tissues from Polley Lake were generally higher than reference following the TSF embankment breach, however remained stable between 2015 and 2016, as did benthic invertebrate tissue chemistry results (Minnow 2016a, 2017a). The only exception was copper, with BSAF results indicative of greater bioavailability in 2016 versus 2015 (Minnow 2017a). Continued monitoring of potential temporal changes in labile metal concentrations in Polley Lake will be implemented using DGTs, which are not subject to the confounding influences (i.e., gut content) described for benthic invertebrate tissue quality monitoring.

2.2 Hazeltine and Edney Creeks

2.2.1 Community

The benthic invertebrate community of Hazeltine Creek was relatively stable between baseline studies in 1995, 1996 (HKP 1997, 1997), and operational monitoring in 1999 (Beak 2000) and 2007 (Minnow 2009), although unusual methodologies were applied to data collection in the 1996 baseline that appeared to affect results of certain endpoints such as density and the proportions of different taxon groups (MPMC 2009). Overall, benthic communities in both upper and lower Hazeltine Creek (with the exception of 1996 data) had high organism densities (25,000 to 43,000 and 6,000 to 33,000 organisms/m^2, respectively) and taxon richness (36 to 50 and 26 to 46 taxa, respectively) with a high proportion of metal sensitive taxa of the orders Ephemeroptera,

Plecoptera, and Trichoptera (EPT; mayflies, stoneflies, and caddisflies) indicating good ecosystem health (Minnow 2014a).

Monitoring in 2015 following the TSF embankment breach indicated that benthic invertebrate community recovery was incomplete and the community was dominated by pollution tolerant organisms (e.g., blackflies and oligochaete worms), particularly in the upper creek area (Minnow 2016b). In lower Hazeltine Creek, further recovery was documented in 2017, evidenced by taxon richness similar to reference (28 to 40 taxa) and a proportion of sensitive EPT taxa similar to reference and historic conditions despite significantly lower organism density (3,738 to 5,788 organisms/m^2; Figure 4). Productivity monitoring initiated in 2017 corroborated the low organism density, with biomass in lower Hazeltine Creek (0.70 to 2.5 g/m^2 dw) below that of upper Hazeltine Creek (2.9 to 20 g/m^2 dw) and reference (5.5 to 33 g/m^2 dw; Minnow 2018a). In upper Hazeltine Creek, the benthic community documented in 2017 (approximately one year following completion of final rehabilitation activities) was dominated primarily by Trichoptera (caddisflies), and to a lesser degree by Ephemeroptera (mayflies), and Chironomidae. The presence of these sensitive taxa suggests limited chemical effect on recolonization, and total organism abundances similar to reference in 2015 indicate a benthic community supportive of fish habitat productivity (Figure 4; Minnow 2018a).

Similar to Hazeltine Creek, the benthic invertebrate community of Edney Creek was evaluated during baseline studies in 1995, 1996 (HKP 1996, 1997), and during the pre-breach operational time period in 1999 (Beak 2000), 2002 (Morrow/Azimuth 2003), and again in 2007 (Minnow 2009). Benthic invertebrate communities appeared to be relatively stable over this time (with the exception of the 1996 data discussed above), with organism densities of 15,500 to 62,000 organisms/m^2 and taxon richness of 32 to 55 taxa, and a relatively high proportion of metal sensitive EPT taxa (MPMC 2009; Minnow 2014a).

Monitoring following the TSF embankment breach indicated recovery of the benthic invertebrate community between 2015 and 2017 in the rehabilitated area of lower Edney Creek. Specifically, although organism density was lower than reference in 2017 (due mainly to an increase in density at the reference area), taxon richness in 2016 and 2017 was similar to reference (Figure 4), and the relative proportion of Trichoptera increased significantly between 2016 and 2017 while the proportion of Chironomidae decreased, which is indicative of recovery (Minnow 2018a). Initial benthic invertebrate productivity sampling in 2017 indicated that total biomass in the rehabilitated area of lower Edney Creek (0.44 to 3.37 g/m^2 dw) was slightly lower than reference (0.79 to 3.44 g/m^2 dw; Minnow 2018a).

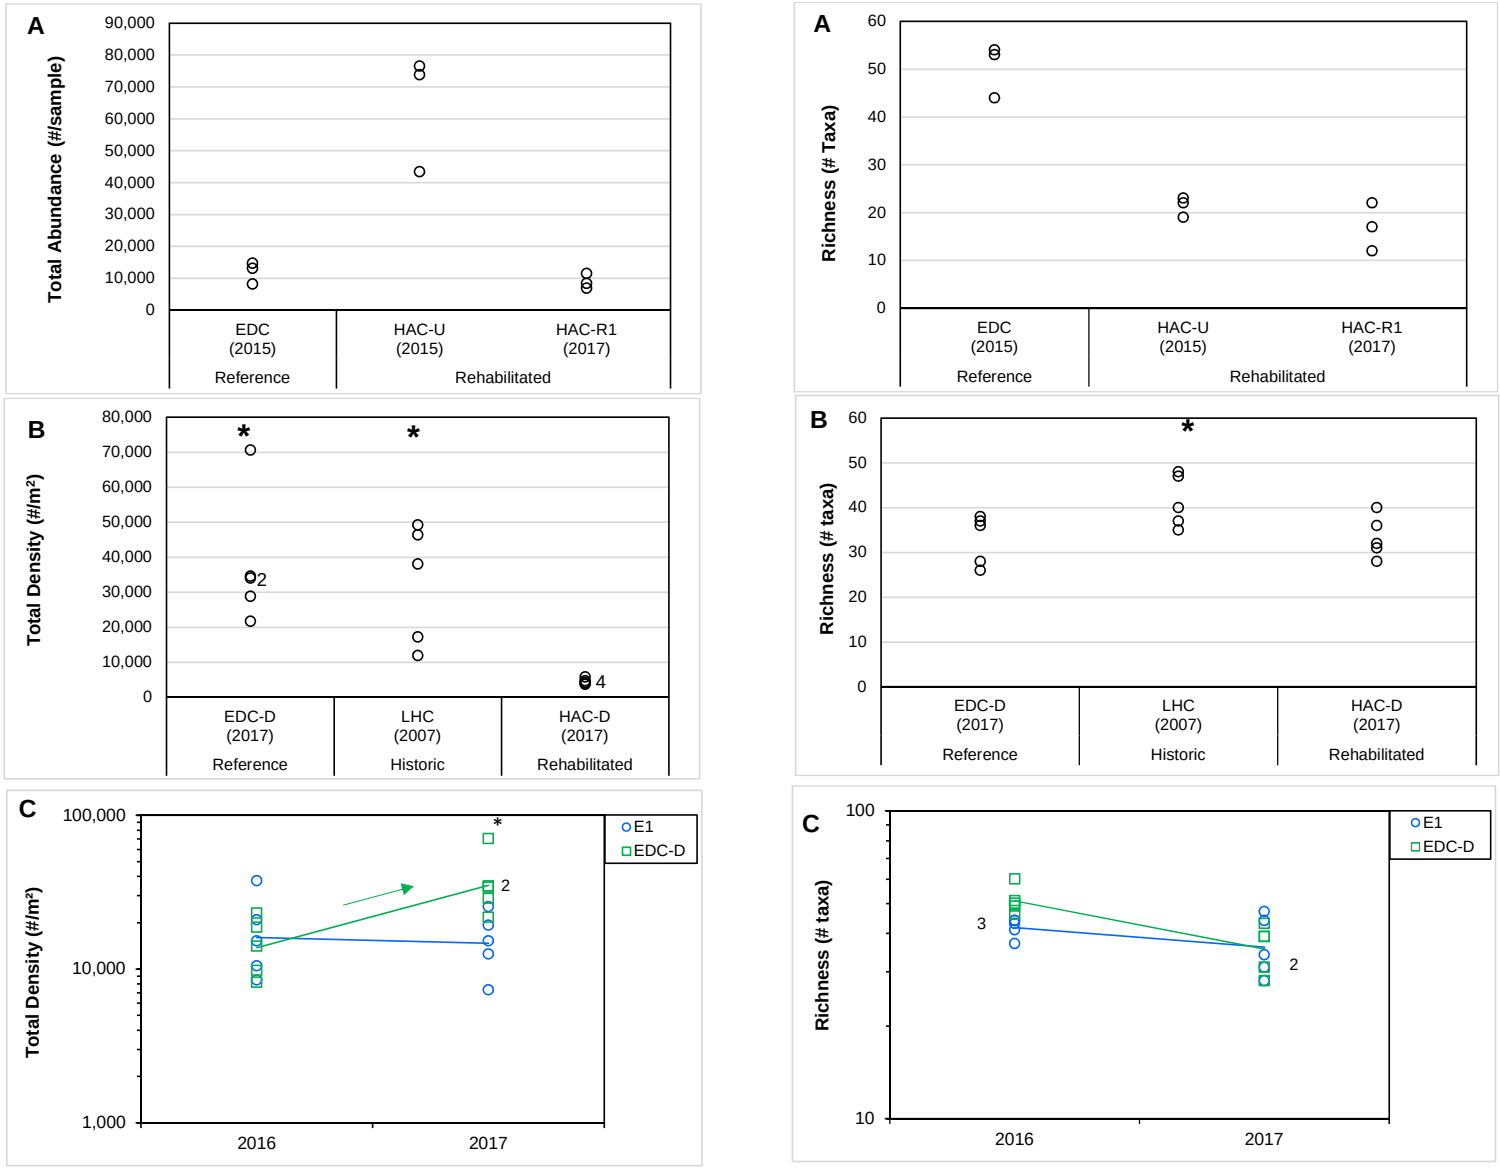

Figure 4: Benthic Invertebrate Community Endpoints for Rehabilitated Areas of A) Upper Hazeltine Creek (Kick-and-Sweep Sampling), B) Lower Hazeltine Creek (250 µm Surber Sampling), C) Lower Edney Creek (250 µm Surber Sampling), and Associated Reference Areas in the Vicinity of the Mount Polley Mine, 2007 to 2017[1]

Notes: For Lower Hazeltine Creek, areas displayed with an asterisk differed significantly from HAC-D (2017, $P < 0.1$). For Lower Edney Creek, statistical comparisons were conducted using a two-way ANOVA with factors Area and Year (* = significant difference ($\alpha = 0.1$) between areas for the given year; ** = significant difference ($\alpha = 0.1$) between areas in 2017 and magnitude of effect is different from ~~2016;~~ ► = significant ($\alpha = 0.1$) year effect ~~for E1~~► = significant ($\alpha = 0.1$) year effect for EDC-D).

[1] Values shown beside data points indicate number of stations sharing a similar result.

2.2.2 Tissue Quality

Benthic invertebrate tissue quality monitoring in Hazeltine Creek was initiated in 2009 as part of the ongoing characterization of selenium incorporation into the aquatic food chain in the vicinity of the Mount Polley Mine. Throughout the pre-breach operational period (2009 to 2013) mean benthic invertebrate tissue selenium concentrations at erosional habitats in upper Hazeltine Creek were higher than the interim BCWQG (4 mg/kg dw; BCMOE 2014) and generally higher than reference, while mean concentrations at erosional habitats in lower Hazeltine Creek were below the BCWQG (Figure 2; Minnow 2011, 2013a,b). In addition, selenium concentrations in benthic invertebrates from exposed erosional habitats were noted to be higher than those from nearby depositional areas (Minnow 2011, 2013b).

Following the TSF embankment breach, data interpretation focused on the POIs and IPs identified in Section 2.1.2 (which included selenium). In 2015 prior to initiation of effluent discharge to Hazeltine Creek, mean tissue concentrations of a number of these POIs and IPs were significantly higher in Hazeltine Creek than reference (arsenic, copper, iron, manganese, nickel, barium, calcium, cobalt, selenium, silver, sodium, strontium, titanium, and vanadium; Minnow 2016a). In addition, concentrations of copper and vanadium were higher in both upper and lower Hazeltine Creek areas relative to pre-breach conditions (3.5 and 8 times for copper, respectively; Figure 3; Minnow 2016a), whereas selenium concentrations were similar to pre-breach conditions (Figure 2). Examination of Bioconcentration Factors (BCFs; which are used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes other than diet; i.e, Arnot and Gobas 2006), indicated suggested that bioavailability did not differ from pre-breach conditions (Minnow 2016a).

Effluent was discharged directly to Hazeltine Creek between December 2015 and November 2017, however Hazeltine Creek was not considered to be fish habitat during this time by Fisheries and Oceans Canada (Golder 2015a) and was inaccessible to fish. Mean selenium concentrations in benthic invertebrates from Hazeltine Creek were higher than the majority of pre-breach results and the BCWQG in 2016 (10 mg/kg dw in both upper and lower Hazeltine Creek; Figure 2; Minnow 2017b), however these tissue concentrations corresponded with elevated mean dissolved selenium concentrations related to the conveyance of effluent that were 143-times higher than reference, and at least 46-times higher than at the same locations prior to the breach (Minnow 2013a, Minnow 2017b). Mean concentrations in 2017 were more similar to pre-breach results and were below the BCWQG in lower Hazeltine Creek (mean = 3.4 to 5.7 mg/kg dw; Figure 2; Minnow 2017b), presumably due to limited effluent discharge in 2017. Tissue concentrations of a number of POIs and IPs at effluent-exposed sampling areas were significantly

higher than reference in 2016[2] (barium, manganese, strontium, titanium), in 2017 (calcium), and in both years (arsenic, cobalt, copper, iron, molybdenum, nickel, selenium, vanadium; Minnow 2017b, 2018b). In particular, copper concentrations during this effluent discharge period (49 to 217 mg/kg dw) were elevated above reference and pre-breach concentrations but were generally similar to 2015 (prior to discharge; 158 to 254 mg/kg dw; Figure 3). Examination of BCFs indicated higher copper bioavailability relative to reference during the effluent discharge period (Minnow 2017b, 2018b), which was consistent with findings of higher labile copper concentration determined by DGTs (Minnow 2017c). Direct effluent discharge to Hazeltine Creek ceased in January 2018 prior to the reopening of upper Hazeltine Creek as fish habitat in spring 2018.

2.3 Quesnel Lake

2.3.1 Community

Benthic invertebrate community data for Quesnel Lake collected prior to the TSF embankment breach are limited to a few samples collected near the mouth of Hazeltine Creek in 2007 (Table 1). These data documented a mean density of approximately 31,100 organisms/m^2 and a mean taxonomic richness of 30 (Minnow 2009).

Benthic invertebrate community monitoring following the TSF embankment breach indicated that impacts to the community in shallow habitats were primarily limited to near-field areas and did not extend to far-field areas (Minnow 2015a). Impacts to the benthic community of the near-field area documented in 2014 included significantly lower mean organism density (159 to 294 organisms/m^2) and taxon richness (5.6 to 10 taxa) than reference (1,400 to 7,900 organisms/m^2 and 19 to 21 taxa, respectively; Minnow 2015a). Further monitoring in 2016 and 2017 confirmed these impacts, and indicated that limited recovery had occurred relative to: 1) a fine substrate reference with aquatic vegetation (2016; Minnow 2017a); and 2) two shallow sandy reference areas which more closely matching the habitat present in the near-field area in 2016 and 2017 (2017; Minnow 2018a). Benthic biomass sampling initiated in 2017 corroborated these results, with significantly lower biomass at the near-field area (mean = 0.28 g/m^2 ww) than reference (mean = 1.0 to 3.6 g/m^2 ww; Minnow 2018a).

Sediment investigations following the TSF embankment breach indicated that the majority of breach-derived material was deposited to deep habitat of Quesnel Lake (Minnow 2015a,b, 2016c). Immediately following the TSF embankment breach (2014), benthic invertebrate communities in deep exposed areas were characterized by particularly low mean organism

[2] Benthic invertebrate tissue quality results reflect single-taxon samples in 2016 and 2017 (caddisflies and/or stoneflies), and composite-taxa samples in 2015.

densities at the exposed near-field (PNF; 39.7 organisms/m^2) and far-field areas (3.4 to 22.6 organisms/m^2) relative to reference (5,840 organisms/m^2), and significantly lower mean taxon richness (0.2 to 2.6 taxa at near-field and far-field areas, 7.8 taxa at reference; Figure 5). Overall, results suggested that the biological effects were breach-related, but it was uncertain whether the effects were physical (due to smothering and/or low dissolved oxygen and low TOC content) or chemical (Minnow 2015a). Monitoring in 2015 and 2016 documented some recovery in mean organism density at the near-field (216 to 588 organisms/m^2 in 2015 and 2016, respectively), and far-field areas (266 organisms/m^2 in 2016; Figure 5), however density remained significantly lower than reference (Figure 5; Minnow 2016b, 2017a). Recovery of taxon richness was also documented (particularly at the near-field area; 4.6 to 6.2 taxa in 2015 and 2016, respectively), although differences in community composition remain (Minnow 2017a). Sediment transplant experiments indicated an increase in organism density and richness in exposed area sediment transplanted to the reference area, suggesting that sediment quality is not prohibitive of re-colonization (Minnow 2016b).

2.3.2 Tissue Quality

Benthic invertebrate tissue quality in Quesnel Lake was not assessed as part of baseline studies (1989-1996) for the Mount Polley mine (Table 2). Monitoring was initiated in 2012 as part of the ongoing characterization of selenium incorporation into the aquatic food chain in the vicinity of the Mount Polley Mine (see Sections 2.1.2 and 2.2.1). Sampling documented mean tissue selenium concentrations below the BCWQG in all areas of Quesnel Lake; 1.7 mg/kg dw near the Hazeltine Creek outlet, and 2.1 mg/kg dw at a reference area in the north arm of the lake (Minnow 2013a).

Following the TSF embankment breach, mean concentrations of all analytes identified as POIs and IPs in benthic invertebrate tissue (see Section 2.1.2) at the exposed shallow and deep areas of Quesnel Lake were similar to reference (including selenium), with the exception of copper which was significantly higher than reference at the deep exposed area in both 2015 and 2016 (147 to 178 mg/kg dw at exposed areas; 40 to 54.9 mg/kg dw at reference; Figure 3; Minnow 2016a, 2017b). As described previously (Section 2.1.2), these elevated benthic invertebrate concentrations could be attributed to higher sediment copper concentrations observed in this area and the confounding influence of gut contents (i.e., Chapman 1985; 2016). BSAFs for copper in the Quesnel Lake deep areas indicated relatively similar bioavailability between the exposed and reference areas (Minnow 2016a, 2017b), which is consistent with results of labile copper concentrations determined by DGTs (Minnow 2016d, Minnow 2017c).

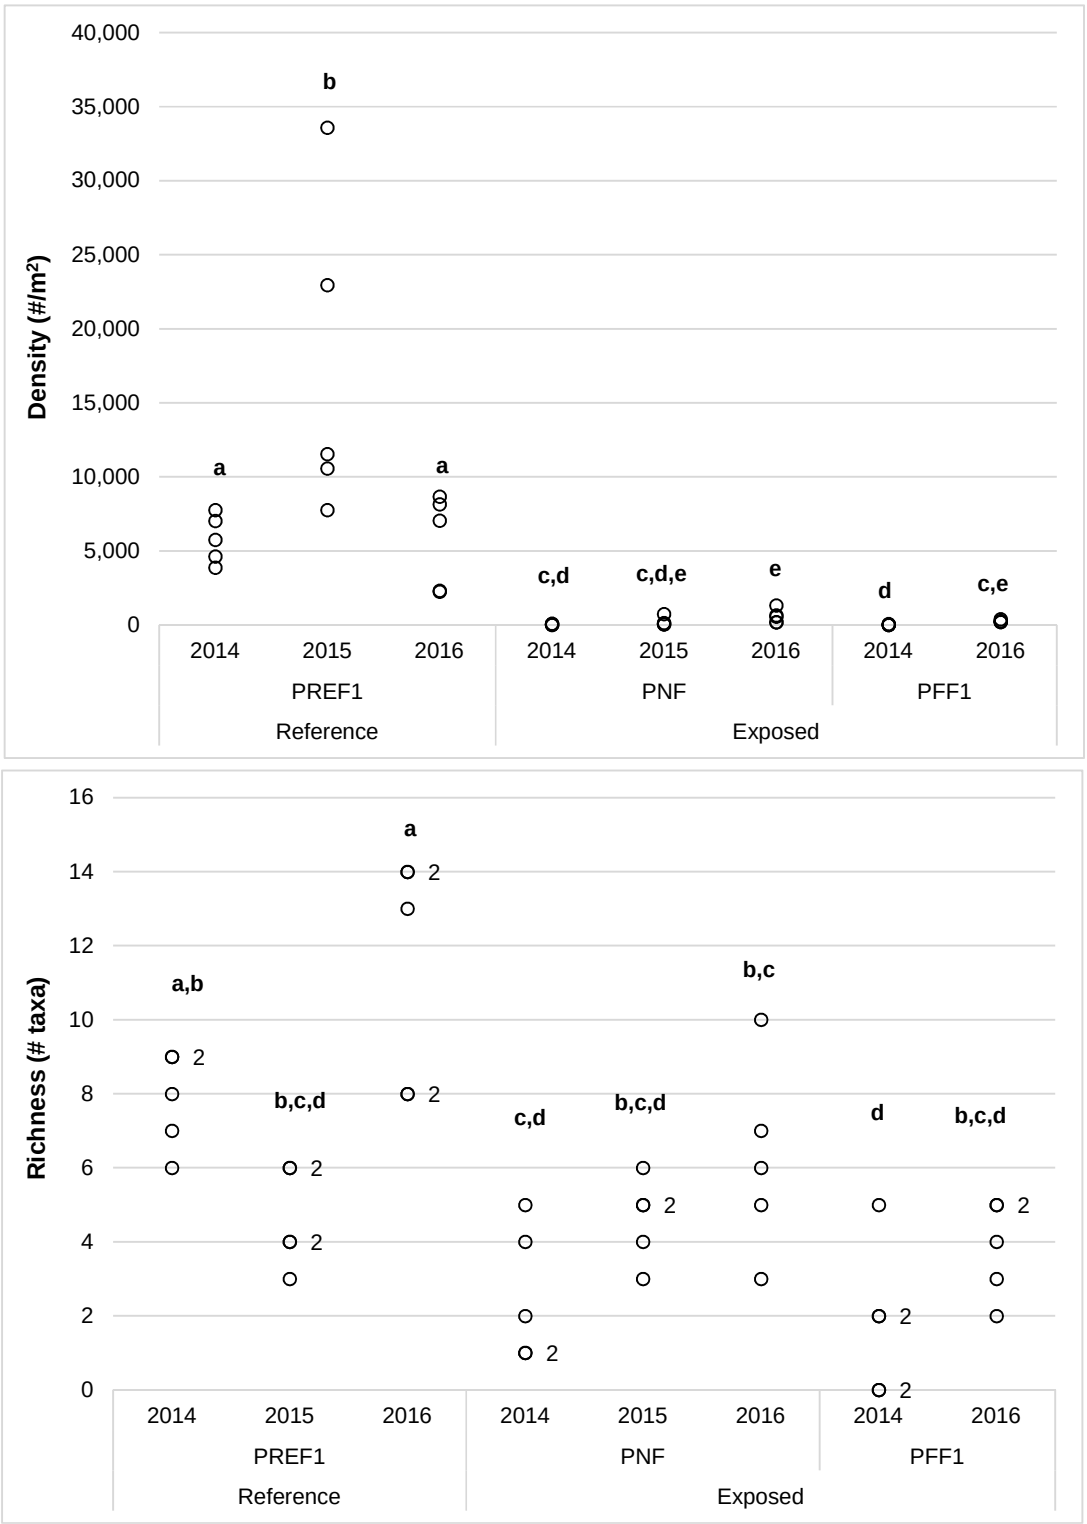

Figure 5: Benthic Invertebrate Community Endpoints in Quesnel Lake Deep Areas, Mount Polley Mine, 2014-2016 [a]

[a] Values shown beside data points indicate number of stations sharing a similar result. Areas not sharing a letter differed significantly ($p < 0.1$).

Note: Sample size = 5.

3 STUDY DESIGN OVERVIEW AND RATIONALE

Benthic invertebrate monitoring under the CEMP is designed to meet the combined needs of: 1) operational monitoring (including the discharge of treated effluent to Quesnel Lake); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to reclamation activity following the TSF embankment breach. An overview of the proposed benthic invertebrate monitoring program is provided in Table 3, and includes benthic invertebrate community, productivity, and tissue quality. Benthic invertebrate monitoring is focused on Polley Lake, Hazeltine Creek, lower Edney Creek, Quesnel Lake, and associated reference areas (Figures 6 and 7).

3.1 Community and Productivity

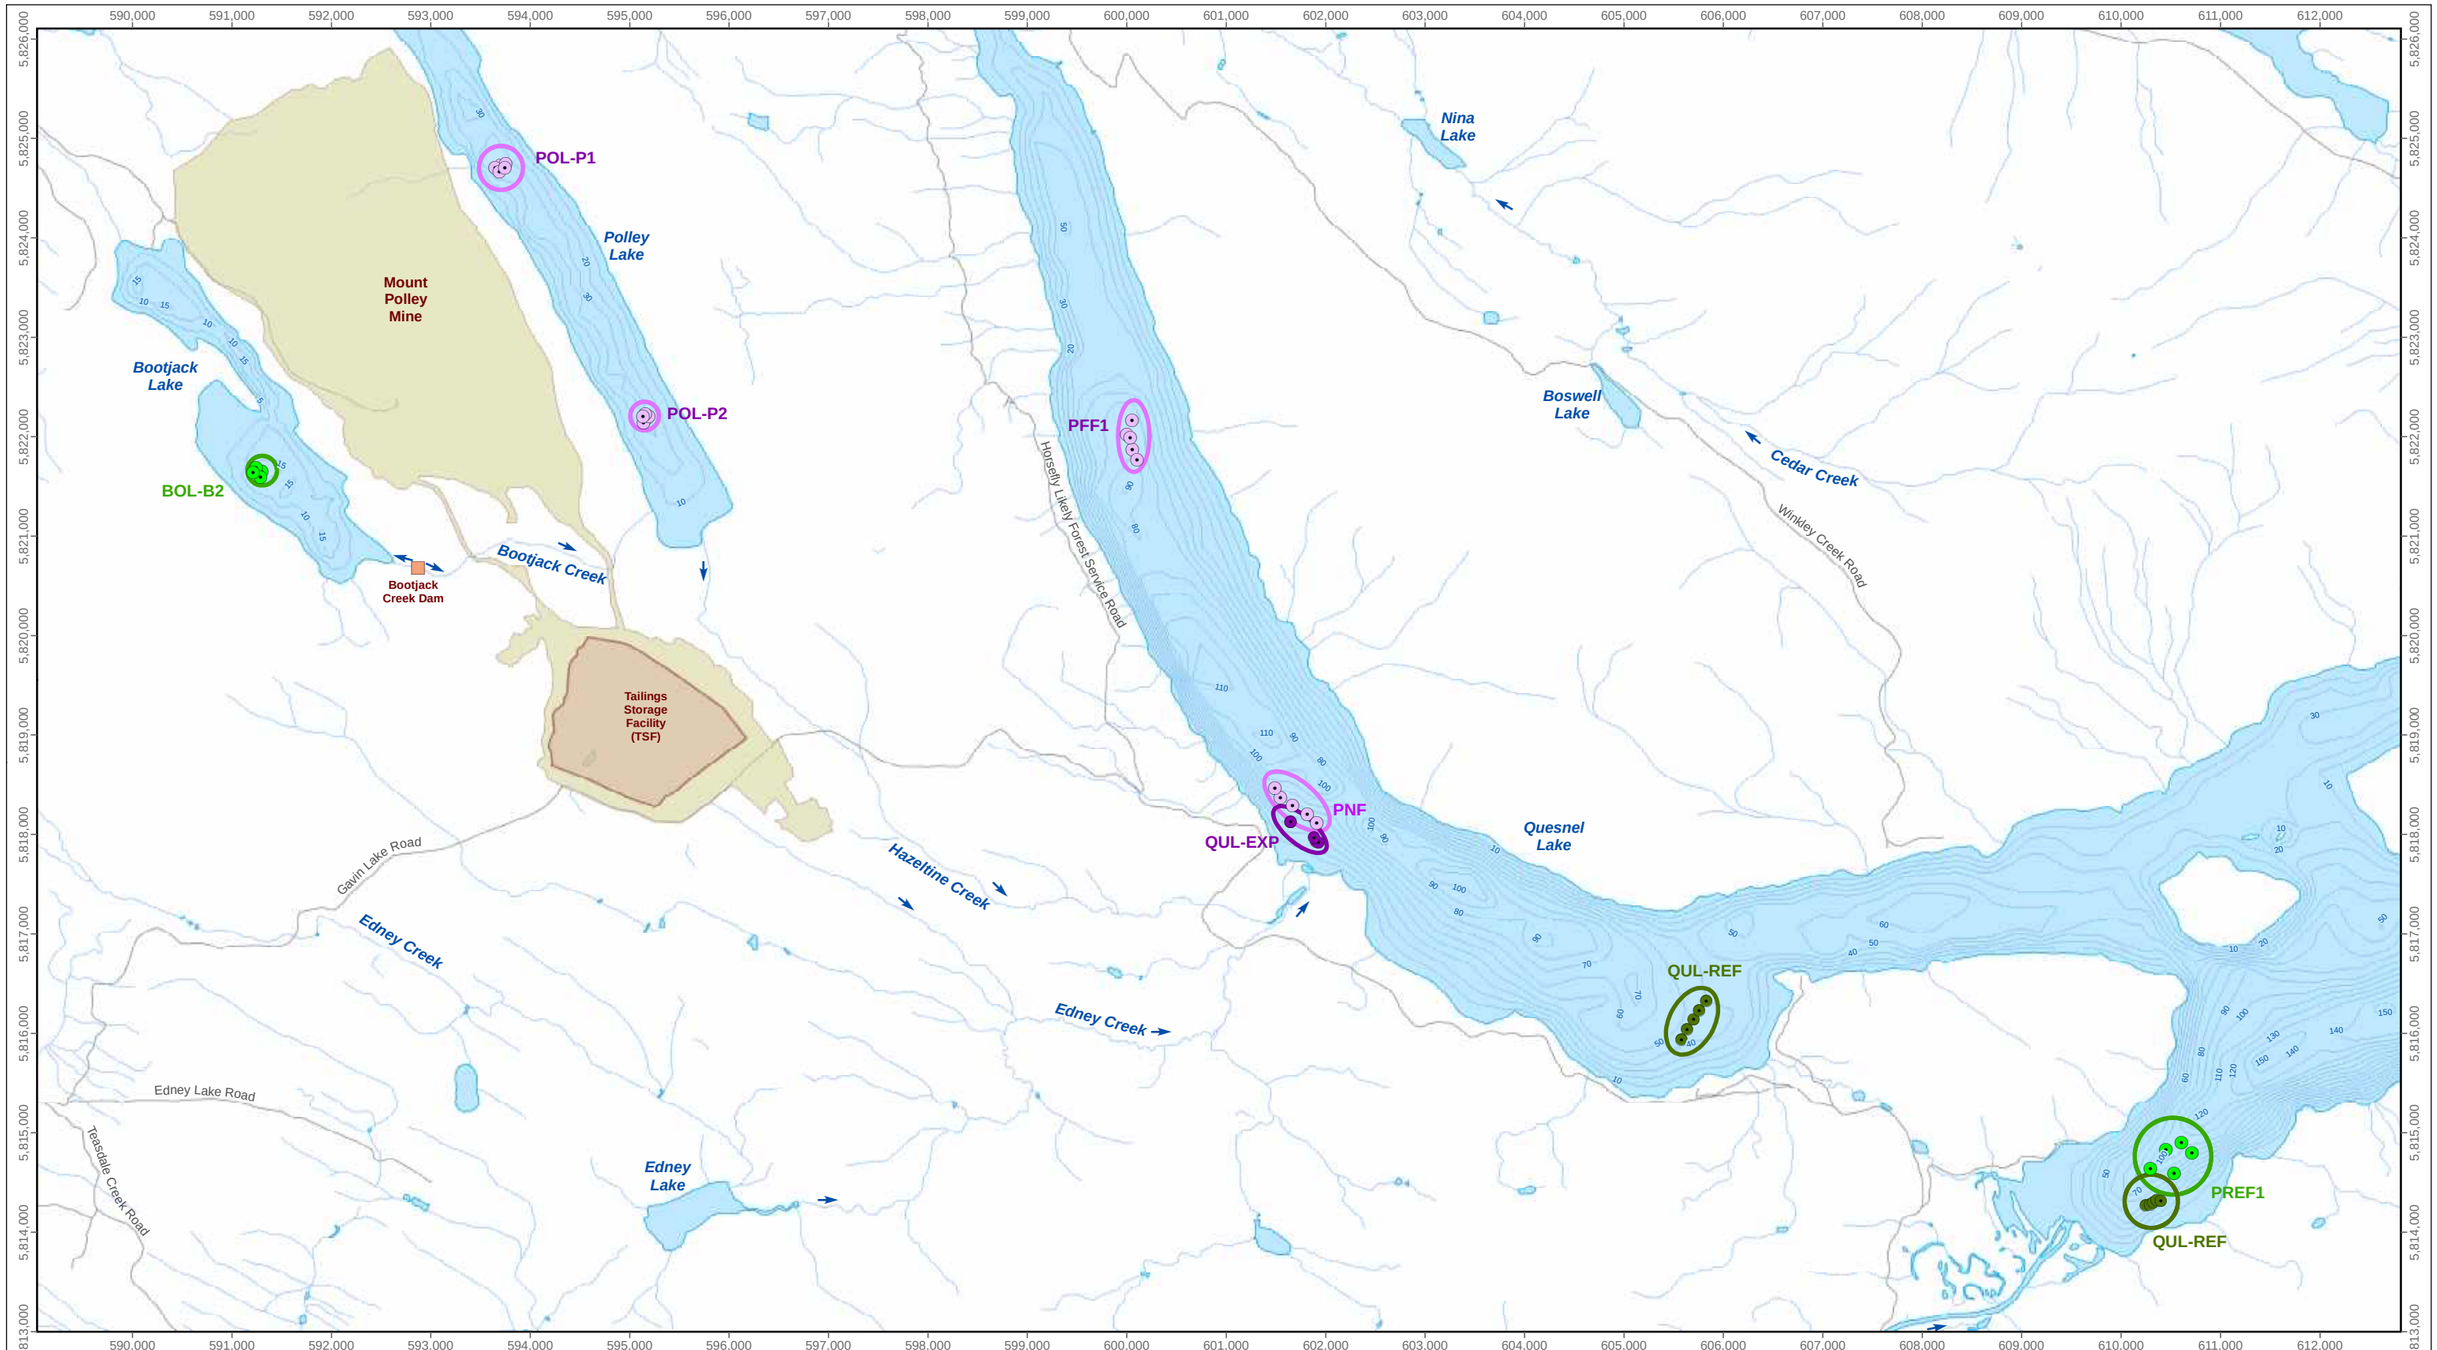
3.1.1 Lakes

Benthic invertebrate community monitoring in lakes is focused on Polley Lake and Quesnel Lake, with reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake for Polley Lake, unaffected areas of Quesnel Lake for impacted areas of Quesnel Lake; Table 3; Figure 6). In Polley Lake, benthic invertebrate community sampling will focus on the two basins (deepest locations in Polley Lake, representing locations of sediment accumulation/fate, and long-term monitoring locations), with the deepest location in Bootjack Lake serving as reference. In Quesnel Lake, benthic invertebrate community sampling for MDMER EEM will focus on the area near the point of effluent discharge (per Minnow 2016e) with two areas serving as reference (one unaffected by the breach and one affected by the breach but outside of the influence of effluent discharge; Minnow 2018c). Sediment investigations following the TSF embankment breach indicated that the majority of breach-derived material was deposited to deep habitat of Quesnel Lake (Minnow 2015a,b, 2016c), therefore benthic invertebrate community sampling in Quesnel Lake will focus on the deep areas that were previously monitored as near-field and far-field areas, with concurrent sampling of suitable reference areas.

Benthic invertebrate community sampling will be completed in August or September using a petite-ponar, consistent with previous data collections (HKP 1996, 1997; Beak 2000; Minnow 2015a, 2016b,e, 2017a), and with technical guidance (e.g., Environment Canada 2012a; BCMOE 2013, 2016). Detailed methodology is provided in Section 4, including: quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting. Sampling will be supported by sediment quality sampling (see CEMP Section 6.12), measurements of *in situ* water quality near the sediment-water interface (temperature, dissolved oxygen, pH, and specific conductance), water depth, GPS coordinates, and supporting photographs at all sampling stations. Data

Table 3: Mount Polley CEMP Benthic Invertebrate Monitoring Program Overview

A) Lakes



Water Body	Sampling Area	Type	Components [a]	Replication [b]	Rationale
Polley Lake	POL - P1 (Northwest Basin)	Exposed	T	5	immediately adjacent to mine and breach-influenced
	POL - P2 (Southeast Basin)	Exposed	T	5	immediately adjacent to mine and breach-influenced
Bootjack Lake	BOL - B2 (Southeast Basin)	Reference	T	5	reference for Polley Lake
Quesnel Lake	QUL - EEMNF	Exposed	T	5	adjacent to effluent discharge and breach-influenced
	QUL - EEMREF1	Reference	T	5	reference for EEMNF - breach-influenced reference
	QUL - EEMREF2	Reference	T	5	reference for EEMNF - non-breach-influenced reference
	QUL - PNF	Exposed	T	5	breach-influenced deep habitat
	QUL - PFF1	Exposed	T	5	breach influenced deep habitat
	QUL - PREF1	Reference	T	5	reference for exposed deep habitat areas of Quesnel Lake

[a] Core benthic invertebrate monitoring components: T = community taxonomy (Lowest-Practicable-Level).
[b] Number of replicate stations within the specified sampling area.

B) Creeks

Water Body	Sampling Area	Type	Monitoring Frequency	Components [a]	Replication [b]			Rationale
					T	P	C	
Hazeltine Creek	HAC-R1 (Upper, Reach 1)	Exposed	Annual	T,P,C	5	5	8	adjacent to mine and breach-influenced
	HAC-U (Upper)	Exposed	Annual	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
	HAC-D (Lower)	Exposed	Bi-annual [c]	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
Frypan Creek	FPC-R3 (Reach 3)	Reference	2018 only	P, C	-	5	8	reference for upper Hazeltine Creek
Edney Creek	EDC-U (Upper)	Reference	Annual	T,P,C	5	5	8	reference for upper Hazeltine Creek
	E1 (Lower)	Exposed	Bi-annual [c]	T,P	5	5	-	adjacent to mine and breach-influenced
	EDC-D (Lower, unimpacted)	Reference	Bi-annual [c]	T,P,C	5	5	8	reference for lower Hazeltine Creek [d]

[a] Core benthic invertebrate monitoring components: T = community taxonomy (Lowest-Practicable-Level), P = productivity (wet and dry benthic biomass), and C = chemistry (see Table 4 for analytes).
[b] Number of replicate stations within the specified sampling area for a given program component.
[c] Bi-annual indicates sampling will occur every other year for all parameters indicated with the exception of tissue chemistry, which will be monitored annually. The next bi-annual sampling event will occur in 2019.
[d] Lower Edney Creek reference area will be located in an unimpacted area upstream of the breach influence (see Figure 7).

interpretation will be based on a combination of: 1) statistical comparison to previous conditions; and 2) statistical comparison to reference conditions. Accordingly, five stations per area are proposed for each sampling area to provide replication for the statistical contrasts.

The frequency of benthic invertebrate community monitoring at the federal EEM sampling areas in Quesnel Lake (to evaluate potential effects of effluent discharge) is initially at a prescribed frequency of every three years, subject to modification based on the findings of at least two EEM phases (Environment Canada 2012a). Additional benthic invertebrate community sampling in Quesnel Lake and Polley Lake (not associated with EEM) will also initially be completed in 2018 and then every three years concurrent with EEM (2018, 2021, etc.). Based on results of benthic invertebrate community monitoring undertaken from 2014 to 2017 which demonstrated some recovery following the TSF embankment breach (see Section 2 for details), and on low sediment deposition rates documented in Polley Lake and Quesnel Lake (see CEMP Section 6.12), it is anticipated that a three-year frequency will be sufficient to track benthic invertebrate recovery. Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) may be made in response to QP recommendations. These may include further reduction in monitoring frequency if continued recovery of benthic community results relative to reference is demonstrated.

3.1.2 Creeks

Benthic invertebrate community monitoring in creeks is focused on rehabilitated areas of Hazeltine Creek and lower Edney Creek, with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and an unaffected area of lower Edney Creek for rehabilitated areas of lower Edney Creek and lower Hazeltine Creek; Table 3; Figure 7). Benthic invertebrate monitoring in Hazeltine Creek will focus on three areas (Figure 7)[3], including one area in Reach 1 (HAC-R1; where rehabilitation was completed in 2016), one area in Reach 2 (HAC-U; where rehabilitation was completed in 2017), and one area in lower Hazeltine Creek (HAC-D; where initial rehabilitation activities have been completed but additional rehabilitation will be conducted). The locations of sampling areas in upper and lower Hazeltine Creek (HAC-U and HAC-D) are generally consistent with those monitored prior to the TSF embankment breach, as is the location of the upper Edney Creek reference area (UER; Figure 7). Monitoring in lower Edney Creek will focus on one rehabilitated area (E1; where rehabilitation was completed in 2015). Suitable reference areas will be sampled concurrently. In Frypan Creek, the reference sampling area was selected to match habitat

[3] Note that previous creek sampling station locations are presented in Figure 7. These locations may change slightly depending on substrate, water depth, and water velocity. Similarly, conceptual station locations are displayed for Frypan Creek and Upper Edney reference areas, and will be established during the field campaign.

conditions in upper Hazeltine Creek as closely as possible, based on results of preliminary fish habitat assessment and benthic invertebrate monitoring (area selection was based primarily on substrate type and size; Minnow 2018d). The location of all benthic invertebrate community sampling stations will align with those proposed for periphyton monitoring (see CEMP Section 6.15).

Benthic invertebrate community sampling will be completed in August or September using a Hess or Surber sampler[4], consistent with previous data collections (HKP 1996, 1997; Beak 2000; Minnow 2009, 2016b, 2017a, 2018a). Detailed methodology is provided in Section 4. All benthic invertebrate community samples collected from creeks will also be evaluated for benthic invertebrate productivity (biomass; through the documentation of benthic invertebrate community sample weight by the laboratory) for the purposes of relating productivity to the assessment of fish habitat. Sampling at each station will be supported by measures of sampling depth, water velocity, in situ water quality measurements (as outlined in Section 3.1.1), GPS coordinates, notes of the presence of aquatic vegetation/bryophytes on sampled substrate and other physical observations, and supporting photographs of the sampling location and samples. Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (i.e., Frypan Creek and upper Edney reference). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; and 2) statistical comparison to reference conditions. Accordingly, five stations per area are proposed to provide replication for the statistical contrasts.

The initial frequency of benthic invertebrate community and productivity monitoring in Reaches 1 and 2 of upper Hazeltine Creek (and associated reference areas) is annual given the recent disturbance to these rehabilitated areas, and recent reopening of upper Hazeltine Creek as fish habitat to Polley Lake fish. The frequency in rehabilitated areas of lower Hazeltine Creek and lower Edney Creek (and associated reference areas) is every second year because these areas have been undisturbed since 2015 and the benthic community monitoring in these areas has demonstrated recovery (Minnow 2016b, 2017a, 2018a; see Section 2.2). Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) may be made in response to QP recommendations. If results indicate stabilizing benthic communities and productivity during this period, then a reduction of monitoring frequency to every second year will be considered for upper Hazeltine Creek areas. The Frypan Creek reference area will only be sampled in 2018 (Table 3) to provide

[4] If sufficient sampling locations with habitat attributes suitable for Hess/Surber sampling cannot be located (particularly in the recently rehabilitated areas of upper Hazeltine Creek), kick and sweep sampling consistent with CABIN guidance (Environment Canada 2012a) may be implemented instead of Hess/Surber sampling.

comparison for benthic community data from upper Hazeltine Creek following the initial reopening of upper Hazeltine Creek as fish habitat (Minnow 2018e).

3.2 Tissue Quality

Benthic invertebrate tissue quality monitoring is focused on upper and lower areas of Hazeltine Creek, with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and lower Edney Creek for lower Hazeltine Creek; Table 3; Figure 7). Benthic invertebrate tissue quality monitoring in Hazeltine Creek is undertaken to monitor the combined influence of uncontrolled surface runoff from the north dump and downstream influence on Hazeltine Creek (which occurred from 2006 to 2009), the conveyance of mine effluent between December 2015 to December 2017, and the TSF embankment breach. Benthic invertebrate tissue quality monitoring will focus on three areas of Hazeltine Creek, including one area in Reach 1 (HAC-R1) and one in Reach 2 (HAC-U) of upper Hazeltine Creek, and one area in lower Hazeltine Creek (HAC-D). As described in Section 3.1.2, the locations of sampling areas in upper and lower Hazeltine Creek are generally consistent with those monitored prior to the TSF embankment breach (Figure 7). It should be noted that sampling areas HAC-U and HAC-D were previously exposed to the discharge of treated mine effluent (December 2015 to December 2017), whereas HAC-R1 is located upstream of the previous discharge point (Figure 7). As of November 2017, treated effluent is no longer discharged into Hazeltine Creek, and upper Hazeltine Creek has been reopened as fish habitat to Polley Lake fish as of spring 2018.

Benthic invertebrate tissue quality sampling will be completed in August or September concurrent with benthic invertebrate community sample collections described in Section 3.1.2, and will be consistent with previous data collections (Minnow 2011, 2013a,b, 2016a, 2017b, 2018b). Tissue samples collected from each station will include one composite-taxa sample that contains a mixture of taxa that is proportional to biomass at the station, and one single-taxon sample[5] (e.g., a sample of only one taxon). Composite-taxa benthic invertebrate tissue samples are reflective of dietary exposure for fish, and can therefore be used in assessment of fish habitat. Alternatively, single-taxon samples are beneficial for limiting variability associated with different benthic invertebrate taxon composition. The collection of both sample types will ensure temporal comparability with previous data collections which have included both composite-taxa and single-taxon tissue samples (e.g., Minnow 2011, 2013a,b, 2016a, 2017b, 2018b). Tissues will be collected for the analytical determination of moisture content, metals, and mercury (Section 4.3.2). Supporting measures at each station will include *in situ* water quality measurements as outlined

[5] Single-taxon sampling will be completed only if adequate sample material from any one taxon can be collected with a reasonable sampling effort.

above (Section 3.1.1), GPS coordinates, physical observations, and supporting photographs. Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (i.e., Frypan Creek and upper Edney reference areas). Data interpretation for all parameters will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) comparison relative to BCWQG (i.e., tissue selenium concentrations; BCMOE 2014). A replication level of eight samples per area will be used to support the statistical contrasts.

The initial frequency of benthic invertebrate tissue quality monitoring at Hazeltine Creek (and associated reference areas) is annual given the recent disturbance of upper creek areas related to rehabilitation activities, and changes to the effluent exposure status. Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) may be made in response to QP recommendations. If results indicate stabilizing or decreasing benthic tissue concentrations during this period, then a reduction of monitoring frequency to every second year will be considered. The Frypan Creek reference area which is included for comparison with upper Hazeltine Creek will be sampled in 2018 only (see Table 3). Benthic invertebrate tissue quality sampling at this reference area will support rainbow trout tissue quality sampling in these areas only in 2018 following the initial reopening of upper Hazeltine Creek as fish habitat (Minnow 2018e).

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be performed by qualified field staff experienced in the implementation of benthic invertebrate community, productivity, and tissue chemistry monitoring programs. All sample collection, quality assurance and quality control, and laboratory analysis methods will be implemented in accordance with technical guidance (BCMOE 2013, 2015, 2016). Specifically, quality assurance and quality control measures will include program review prior implementation, adequate resources for all field teams including field checklists and field data sheets, the availability and maintenance of clean sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination.

Quality control (QC) samples will be collected to support the benthic invertebrate tissue quality monitoring program. To capture within-area variability, eight replicate composite-taxa and up to eight replicate single-taxa tissue quality samples will be collected from each sampling area. Field duplicate samples (i.e. splits samples of the benthic invertebrate tissue collected from one sampling station) will be collected for 10% of samples to assess field precision as part of the Data Quality Review (DQR; Section 4.4). Duplicate water samples will be collected at a frequency of 10% to assess field precision associated with the water samples that support benthic invertebrate community and tissue quality monitoring. In addition to field QA/QC, the laboratory responsible for chemical analyses will be accredited by the Canadian Association for Laboratory Accreditation (CALA) for these analyses. Specific QC sampling and associated reporting for tissue quality results will be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). Laboratory Reporting Limits (LRLs) will also be evaluated in comparison to targets established by the analytical laboratory.

QC samples to assess field precision (field duplicates) will not be collected for benthic community or productivity monitoring endpoints due to the high inherent natural variability of these parameters. However, composite benthic invertebrate community samples will be collected at all sampling locations to ensure that each sample is representative of the station. Taxonomic identification of benthic invertebrate community samples will be completed by a qualified laboratory certified under the Taxonomic Certification Program of the Society for Freshwater Science (SFS; formerly the North American Benthological Society). Quality control for benthic invertebrate taxonomic analyses will be consistent with federal requirements for metal mining EEM (Environment Canada 2012a). Specific QC sampling and associated reporting will be requested from the taxonomic laboratory, including an assessment of sub-sampling error, sorting

efficiency, and identification accuracy (Environment Canada 2012a, 2014). These results will be assessed as part of the DQR (Section 4.4).

All raw field data will be transcribed from field sheets into an electronic spreadsheet. Data will then checked by a separate individual for data entry errors as part of routine Quality Assurance/Quality Control (QA/QC) procedures.

4.2 Sample Collection Methods

4.2.1 Community and Productivity

Benthic invertebrate sampling in lakes for community analysis will be collected using a stainless steel petite ponar grab sampler, consistent with previous monitoring (e.g., Minnow 2015a, 2016b,d, 2017a, 2018a) and in accordance with provincial and federal technical guidance (i.e., BCMOE 2013; Environment Canada 2012a). Briefly, the petite ponar is a 6" x 6" (15.24 cm x 15.24 cm) grab sampler with jaws that can be held open by shear-pressure on a spring-loaded pin. The grab sampler is lowered to the substrate at which point shear-pressure is eliminated and the pin springs out. Upon upward pull at the initiation of retrieval, the jaws of the ponar close to grab surficial sediment. Care must be taken to control the rate at which the petite ponar is lowered to allow appropriate sediment penetration and to minimize sediment disturbance. The petite ponar will be carefully retrieved to surface and each grab will be placed into a plastic tote and observed for completeness and any unusual characteristics. In Quesnel Lake, samples will be retrieved with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). Only high quality, comparable samples will be retained. If the sample is deemed acceptable, the sample will rinsed from the ponar into the tub to ensure the complete removal of all material The sample material will then be placed into a 250 µm mesh sieve bag and sieved free of all material less than 250 µm in diameter. At each station, a composite sample of five acceptable grabs will be collected (0.116 m^2 of bottom area in total) to ensure that each sample is representative of the station. After sieving, the retained material (sample) from the five composited grabs will then be carefully transferred to 1 or 2-L wide mouth plastic jars using a wash bottle while working over a plastic tub to avoid any potential loss of organisms. Any organisms that adhere to the inside of the sieve bag will be retrieved and added to the sample jar. Each jar will receive an internal and external label with the station number, area identifier, project number, date, and the initials of the field personnel. Each sample will be preserved with a 10% buffered formalin solution within six hours of collection to eliminate the potential effects of within-sample predation, which could affect abundance estimates. Sampling will be conducted at five replicate stations in each area (see Table 3).

Supporting information collected at all lake sampling stations will include sediment quality measures (see CEMP Section 6.12), GPS (Geographic Positioning System) coordinates; water depth; *in situ* water quality near the sediment-water interface (temperature, dissolved oxygen, pH, and specific conductance), site and sample photographs, notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). In addition, a full vertical profile of the field meter measurements will collected at one station per area. Supporting water samples will also be collected from each sampling area associated with EEM (see Table 3), including samples for total and dissolved constituents (including metals), the latter prepared by field filtration using a 0.45 µm syringe filter. Water samples will be placed into a dedicated cooler with frozen ice packs, and kept cool prior to transport to the field laboratory.

Sampling of benthic invertebrates in creeks for community and productivity analysis will be consistent with previous monitoring (e.g., Minnow 2009, 2016b, 2017a, 2018a), and with technical guidance (BCMOE 2013). A Hess sampler with a 0.1 m^2 diameter and upstream (incurrent) and downstream (excurrent) openings will be used if water depth allows. The incurrent opening will be covered with a mesh to prevent contamination of the sample with organisms from upstream. The excurrent opening will consist of a conical net equipped with 250 µm mesh attached to a removable collection cup that has mesh on the downstream end to allow water to exit. If creek environments are too shallow to accommodate Hess sampling, a Surber sampler (30.5 x 30.5 cm; 0.093 m^2) equipped with 250 µm mesh will be used. Each Hess/Surber sample will be collected by firmly and carefully placing the sampler on undisturbed substrate to a depth of 5 to 10 cm. All cobble and gravel within the sampler area (to a depth of approximately 10 cm) will be scrubbed and the current will be allowed to carry all dislodged organisms into the 250 µm net. The sampler net and collection cup will be rinsed and the contents will be carefully transferred to internally and externally labelled 1 or 2 L wide mouth plastic jars. Any remaining invertebrates found clinging to the sampling equipment will be removed and placed in the sample jar. At each station, one composite sample of three sub-samples (i.e., approximately 0.3 m^2 of creek surface area if a Hess sampler is used, 0.279 m^2 if a Surber sampler is used) will be collected to ensure that each sample is representative of the station. Each sample will be preserved with a 10% buffered formalin solution as described above. Sampling will be conducted at five replicate stations in each area (see Table 3), and each station will be established at a minimum distance of approximately three bankfull widths from adjacent stations, where habitat allows. A concerted effort will be made to

ensure that water velocity, water depth, and substrate characteristics are comparable among sub-samples and among respective stations to minimize natural influences on community variability[6].

Supporting information collected at each creek sampling station will include those parameters listed above for lakes, with the addition of substrate size measurements wherein 100 randomly selected substrate pebbles per station will be measured along their intermediate axis and the percent embeddedness 10% of the pebbles will be recorded, consistent with the CABIN protocol (Environment Canada 2012b). Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (e.g., in Frypan Creek and upper Edney Creek). Water samples will be collected as described above.

4.2.2 Tissue Quality

Benthic invertebrate tissue samples will be collected using a combination of hand picking and kick-and-sweep, consistent with previous monitoring (e.g., Minnow 2011, 2013a,b, 2016a, 2017b, 2018b) and with technical guidance (e.g., BCMOE 2016). Hand picking entails overturning rocks in the streambed and collecting any of benthic invertebrates observed. The kick-and-sweep method involves a field technician moving upstream and across the stream channel (in a zig-zag pattern) while holding a kick net (a net with a triangular opening and a 400 µm mesh bag) immediately downstream, and disturbing the substrate with his or her feet to dislodge benthic organisms into the net (a method modified from the Canadian Aquatic Biomonitoring Network [CABIN] 3-minute travelling kick-and-sweep; Environment Canada 2012b). The net will then be rinsed with water to move all debris and invertebrates to the collection cup at the bottom of the net. The collection cup will be removed and its contents (i.e., invertebrates and debris) will be placed into a plastic tote. Organisms will then be picked free of debris, and transferred into a labeled scintillation vial, without rinsing, to minimize the amount of water in each sample. One composite-taxa sample (containing a mixture of taxa that is proportional to biomass at the station), and one single-taxon sample (containing one taxon only) will be collected at each station. As possible, the taxa selected for the single-taxon samples will be consistent among sampling areas, and consistent with previous monitoring (Minnow 2017b, 2018b). However, single-taxon sampling will only be completed at each station if adequate sample material can be collected with a reasonable sampling effort[7]. Sampling will be conducted at eight replicate stations in each area

[6] If five stations with closely matching habitat attributes cannot be located (particularly in the recently rehabilitated areas of upper Hazeltine Creek), kick and sweep sampling consistent with CABIN guidance (Environment Canada 2012a) may be implemented instead of Hess/Surber sampling.

[7] A reasonable sampling effort will be considered approximately 1 hour per sample. If sample collection is nearly complete within this time frame, additional sampling effort will be applied to complete the sample collection.

(see Table 3). Samples will stored in a cooler containing ice packs for transport to the mine, where they will be frozen.

4.3 Sample Handling and Laboratory Analysis

4.3.1 Community and Productivity

Preserved benthic invertebrate community samples will be stored at room temperature until shipment to the laboratory for taxonomic identification and enumeration. Samples will be shipped with completed Chain-of-Custody (COC) forms immediately after the completion of the field campaign, however there are no recommended hold times for analysis.

Taxonomic identification of benthic invertebrate community samples will be completed by a qualified laboratory using standard methods that incorporate QA/QC measures (e.g., Environment Canada 2012a; 2014). Upon sample receipt, the laboratory will provide a sample receipt confirmation which will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. All samples will be sieved and processed in the laboratory using the same mesh size as used in during field collections (250 µm), with the exception of those collected for MDMER EEM which will be identified and enumerated based on both the 250 µm and 500 µm fractions (Minnow 2018c). If the estimated number of invertebrates in a sample is greater than 600 individuals and the sample is fine and non-clumping, a subsample will be taken using a Marchant Box (Marchant 1989) as described by Environment Canada (2014). Samples (or sub-samples) will then be sorted using a gridded Petri dish under a low power stereo microscope into family/order while maintaining counts (but totals exclude Porifera, Nemata, Platyhelminthes, Ostracoda, Copepoda, Cladocera, and any terrestrial drop-ins). All samples will be processed to a minimum 300 organism count, and if 300 organisms have not been reached by the 50th cell of the Marchant Box, then the entire sample will be sorted (i.e., all 100 cells). All sorted organisms will be stored in 80% ethanol by family/order in separate labeled vials and debris will be preserved and labeled separately. Identifications of all insects to the lowest practicable level (LPL; typically genus or species) and non-insects to the genus/species level (where possible, but to a minimum of family level) will be conducted by experienced, certified taxonomists using up-to-date taxonomic keys, comparisons to an externally-verified reference collection, and effort lists compiled by CABIN, SAFIT (Southwest Association of Freshwater Invertebrate Taxonomists), and PNAMP (Pacific Northwest Aquatic Monitoring Partnership). Following identification, representative specimens may be preserved and retained for inclusion in a voucher collection for Mount Polley.

Following taxonomic identification, the wet and dry biomass of total organisms in each sample from creek environments (benthic invertebrate productivity) will be determined. For wet biomass,

samples will be poured through a piece of pre-weighed 212 µm Nitex mesh and dried gently between two pieces of absorbent paper. Each sample will then be weighed to the nearest 0.0001 g, and the weight of the mesh will be subtracted from the total weight to determine total sample wet weight. For dry biomass, wet samples will be then placed on a piece of pre-dried and pre-weighed glass fiber filter before being dried at 160^0F (71°C) for six hours. Following a short period of cooling, samples will be weighed as described above, and total sample dry weight will be calculated.

4.3.2 Tissue Quality

Benthic invertebrate tissue quality samples will remain frozen until overnight shipment on ice with completed COCs to ALS Environmental, Burnaby BC; an analytical laboratory accredited by the Canadian Association for Laboratory Accreditation (CALA). Samples will be sent to the laboratory with sufficient time to complete analyses within the recommended sample hold times. Analyses will be completed using methods that are consistent with those specified in the British Columbia Environmental Laboratory Manual (BCMOE 2015). Upon sample receipt, the laboratory will provide a sample receipt confirmation when the samples are received and logged. These receipts will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. Tissue quality samples will be analysed for metals by CRC-ICP-MS (Collision Cell Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/6020A [USEPA 2004]) or HR-ICP-MS (High Resolution Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/ 200.8 [USEPA 1994]), mercury by CVAFS (Cold Vapour Atomic Fluorescence Spectrophotometry; USEPA Method 200.3 [USEPA 1991]/Method 245.7 [USEPA 2001]), and moisture content. The method selected for metals analysis will depend on sample weight, with HR-ICP-MS employed for smaller sample sizes. Tissue quality analytes are provided in Table 4, with the associated target LRLs, detection limit objectives outlined in technical guidance (“consensus detection limits”; BCMOE 2016), and available BCWQG (i.e., selenium; BCMOE 2014). Upon completion of the analyses, the laboratory will provide a data report in Microsoft (MS) Excel™ and as an Adobe Acrobat Portable Document Format (PDF). Reporting will include the results of the laboratory QC sample results.

4.4 Data Quality Review

Upon receipt of all analytical data, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs have been achieved. The DQR will also include an evaluation of differences between duplicate (split) samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the benthic invertebrate monitoring data will ensure timely communication with the laboratory should any issues be identified

Table 4: Target Laboratory Reporting Limits (LRL) and Analytical Methods for Benthic Invertebrate Tissue Quality Analytes

[a] From Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators (BCMOE 2016).

[b] British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture (BCMOE 2018).

[c] Method for total mercury analysis will be according to USEPA (1991, 2001).

For benthic invertebrate tissue quality samples, LRLs will be evaluated relative to targets established for the analytes, to "consensus detection limits" (Table 4), and to relevant British Columbia guidelines (i.e., selenium; BCMOE 2014). Comparisons between duplicate samples will be made by calculating the relative percent difference (RPD) of metal concentrations between paired duplicates. If the RPD is <25% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Results for laboratory blanks, precision, and accuracy will be evaluated relative to Data Quality Objectives (DQO) established by the analytical laboratory that performed the analyses. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping). For benthic invertebrate community samples, reanalysis for quality control endpoints (organism sorting efficiency, subsampling precision and accuracy error, and taxonomic identification error) will be performed on 10% of samples, and results of quality control measures will be evaluated relative to pre-established DQOs. Specifically, evaluation of organism sorting efficiency will involve reprocessing previously sorted material from randomly selected samples, and then determining the number of invertebrates that were not recovered during processing of the original sample, and an efficiency of < 10% missed organisms will be considered acceptable. Evaluation of subsampling error provides a measure of analytical accuracy by comparing the numbers of benthic invertebrates recovered between at least two sub-samples, and of analytical precision by comparing sub-sample derived benthic invertebrate community numbers with the densities determined for whole benthic invertebrate community samples. An error of < 20% will be considered acceptable for subsampling accuracy and precision. Evaluation of taxonomic identification error involves an internal quality control audit of taxonomic identification results whereby blind re-enumeration and re-identification of random samples will be performed by an analyst not involved in the original sample processing, and an error of < 5% for this endpoint will be considered acceptable.

4.5 Data Handling and Interpretation

Upon receipt of data from the analytical laboratories, all laboratory data files will be managed by the Mount Polley Mining Corporation (MPMC) Environment Department. In addition, chemical data provided by the primary analytical laboratories as an Electronic Data Deliverable (EDD) will be imported directly into the MPMC's database following completion of the DQR. Following the data quality review described above (Section 4.4), all benthic invertebrate community, benthic invertebrate tissue chemistry data, and supporting data will be managed in Microsoft (MS) Excel™. For all replicated data (typically based on a sample size of five or eight stations per area), data will be provided to the QP for analysis and summarized by calculating mean, median,

standard deviation, minimum, and maximum for each endpoint. Data analysis will be completed for each monitoring component (community, productivity, and tissue quality).

4.5.1 Community and Productivity

Benthic invertebrate communities will be evaluated using metrics of organism density (organisms per m²; grab samples, and Hess/Surber samples) or abundance[8] (organisms per sample; kick-and-sweep samples), taxonomic richness, Simpson's Index of Diversity, Simpson's Index of Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012a). The Bray-Curtis Index of Dissimilarity will also be used in the evaluation of samples collected for MDMER EEM as per technical guidance (Environment Canada 2012a). These primary indices will be calculated at the LPL of taxonomy for the 250 µm fraction of all samples, with the exception of samples collected for EEM which will be calculated using family-level data for the 500 µm sample fraction (Minnow 2018c). The densities and relative densities of the most abundant taxa will also be calculated (relative densities calculated as the abundance of each respective dominant/indicator taxon relative to the total number of organisms in the sample and expressed as a percentage). Dominant/indicator taxon groups will be defined as those groups representing more than 5% of total organism abundance within each set of areas being compared, or any taxon groups considered to be important indicators of environmental stress. In addition, benthic invertebrate productivity in creeks will also be evaluated using wet and dry total biomass converted to a standard area-based measurement (g/m^2). Summary statistics for all endpoints will be reported by area and year as described above (sample size, mean, median, minimum, maximum, and standard deviation).

Correspondence analysis (CA) or Nonmetric Multidimensional Scaling (NMDS) multivariate ordination methods will be used to further examine benthic invertebrate community structure. These are multivariate ordination methods used to reduce multivariate data into a manageable number of variables and will be applied to assist in the identification of key spatial or temporal differences in benthic invertebrate community (i.e., which stations have distinct benthic communities but also how these benthic communities differ among stations). The results of these multivariate analyses will be incorporated into the comparison of benthic invertebrate indices described below.

Benthic invertebrate community and productivity metrics from exposed areas will be compared to reference results in a control-impact study design, as well as compared temporally to previous monitoring results if data are available. Comparisons will be completed primarily using Analysis

[8] Abundance (as opposed to density) will be calculated only if kick-and-sweep sampling methods are used in creek due to lack of suitable Hess/Surber sampling habitat. See Section 3.1.2 for details.

of Variance (ANOVA) to test for statistically significant differences. For these analyses, the assumptions of normality and homogeneity of variances will be tested on the residuals of the ANOVA model using the Shapiro-Wilk test and Levene's test based on median values, respectively, using a significance level (α) of 0.1. Data will be transformed as necessary to satisfy assumptions of normality and homogeneity of variance. In instances where the residuals of the ANOVA model do not meet the assumptions of normality and homogeneity of variances, a non-parametric Kruskal-Wallis test will be conducted. When the overall results of an ANOVA or Kruskal-Wallis test are significant, differences between specific areas will be evaluated using post-hoc contrasts for ANOVA or Dunn's test for the Kruskal-Wallis test. A Bonferroni correction on the p-values will be used to conserve the overall Type I error rate. Statistical temporal contrasts may also be completed using Two-Way ANOVA (with factors *Area* and *Year*) if data are available for both the exposed and reference areas for all years being evaluated. For the Two-Way ANOVA model, assumptions of normality and homogeneity will be tested on the residuals of the model as described above using the Shapiro-Wilk test and Levene's test based on median values, respectively ($\alpha = 0.05$). Data will be transformed as necessary to satisfy assumptions of normality and homogeneity of variance and if these assumptions are not met, the analysis will be conducted on ranks (equivalent to a non-parametric test). When the interaction between *Area* and *Year* is significant ($\alpha = 0.1$) the following post-hoc contrasts will be conducted, and when the interaction between *Area* and *Year* is not significant, the effect of area and year will be assessed ($\alpha = 0.1$) using the *Area* and *Year* terms in the ANOVA model. Further detailed analyses will be completed as required for data interpretation, and may include graphical comparisons to reference and historical data, and formal spatial statistical contrasts using methods similar to those described above.

If exposed versus reference or temporal differences in benthic invertebrate community and/or productivity results are noted, potential relationships between benthic invertebrate community metrics and physical and chemical conditions of the study areas will be explored using Spearman correlation (often referred to a Spearman Rank-Order correlation). For lake sampling areas, these physical/chemical endpoints may include results of multivariate statistical analyses used to identify key sediment quality parameters (e.g., CA or PCA axis scores; see CEMP Section 6.12). For most areas, correlation analyses will likely only include data from a single year of sampling in order to focus the analysis on differences between rehabilitated and exposed areas relative to reference, rather than on differences among years. Following the derivation of correlation coefficients, a Bonferroni-type correction (i.e., p-value [0.05] divided by the total number of correlations examined for independent variables) will be applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected p-value of 0.05. Any significant correlations found at the

Bonferroni-adjusted p-value or at a p-value of 0.01 will be further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were "leveraged" by outlying points (or groups of points). Although it is recognized that a significant correlation or regression does not indicate causation (e.g., Norton et al. 2015), it is desirable to not only characterize the nature of a response (e.g., differences in benthic invertebrate community), but to also obtain evidence of cause. Correlation / regression analyses are commonly applied tools for identifying potential cause (e.g., Norton et al. 2015). Evidence of causation obtained from correlation or regression analysis will be carefully considered in light of the strength, range, and continuity of the relationships as well as mechanistic knowledge/understanding of potential cause.

4.5.2 Tissue Quality

Data analysis and interpretation of benthic invertebrate tissue quality results will focus on Parameters of Interest (POIs [representing the chemical influence of the TSF embankment breach on sediment quality]: arsenic, copper, iron, and nickel), and on Indicator Parameters (IPs [identified in evaluations of water, soil, or fish tissue quality for Hazeltine Creek]: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium; Golder 2015b, 2016, Minnow 2015a). Benthic invertebrate tissue quality results for these analytes will be compared to available pre-breach data (for selenium only in 2009, 2012 and 2013, and for all analytes in 2010; Minnow 2011, 2013a,b), contrasted between exposed and reference areas, and also compared temporally within exposed areas. In addition, tissue quality results for selenium will be compared to the relevant BCWQG (BCMOE 2014). Detailed analyses and interpretation related to these comparisons will be completed as required, and may include: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations tissue concentrations (control-impact study design using Analysis of Variance [ANOVA]) as described above. Formal statistical temporal and spatial contrasts may also be completed using ANOVA methods similar to those described for benthic invertebrate community data analysis to augment interpretation, where data allows.

Concentrations of the POIs and IPs in benthic invertebrate tissue will also be evaluated relative to concentrations in water. These ratios of concentrations will be calculated as: [tissue sample concentration]/[dissolved water concentration], and are referred to as Bioconcentration Factors (BCFs). BCFs are often used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes other than diet (i.e., Arnot and Gobas 2006), and are applicable to erosional areas where sediment is generally not present. BCFs will be calculated using tissue metal concentrations (dry weight) and mean dissolved metal concentrations in water from each sampling area. Calculated BCFs will then be qualitatively

compared among areas to identify differences in the uptake of metals by benthic invertebrate in areas impacted by effluent discharge and/or the TSF embankment breach.

Additionally, concentrations of POIs and IPs in benthic invertebrates will be evaluated relative to concentrations in periphyton, based on Trophic Transfer Factors (TTFs; the ratio of tissue concentrations in benthic invertebrates relative to concentrations in periphyton (i.e., TTF = [benthic invertebrate sample]/[periphyton sample]). TTFs can be used to generally describe the extent to which the concentration of an analyte increases between lower and higher trophic levels (e.g., Presser and Luoma 2010). TTFs greater than 1 indicate that the analyte is accumulating in benthic invertebrates to a greater extent than would be expected if ingestion of periphyton was the sole source of that analyte to the benthic invertebrates (assuming uptake and excretion of the analyte by the benthic invertebrates are equal). Co-located observations of benthic invertebrate and periphyton tissue chemistry will be used to calculate TTFs for each replicate station. Comparisons of TTFs will then be made between exposed and reference areas as well as with pre-breach results.

An interpretive report based on the benthic invertebrate monitoring data will be prepared for integration into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWQG, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

1 INTRODUCTION

1.1 Background

Periphyton represents an important component of aquatic food webs in creeks, and consists of a complex matrix of organisms. Periphyton generally includes algae, fungi, bacteria, and protozoa attached to submerged substrate (e.g., rocks, bedrock, woody debris). These organisms are representative of the lowest trophic level in running water and take up nutrients such as nitrogen (e.g., nitrate, nitrite) and phosphorus (e.g., ortho-phosphate), as well as other substances dissolved in water (e.g., major ions, metals) to serve physiological functions, which thereby become available via dietary pathways to consumer organisms at higher trophic levels. Periphyton productivity and community characteristics can be influenced by factors such as physical disturbance (i.e., changes to surface water hydrology) and water quality (relating to toxicity or changes in productivity due to nutrient chemistry), and periphyton tissue quality can be influenced by water and/or sediment quality (although the latter is primarily present in suspended form in erosional streams). Therefore, periphyton monitoring is an important tool for both the assessment of creek productivity (through measures of periphyton productivity and community) and the evaluation of the trophic transfer of substances (through measures of periphyton tissue quality), and these monitoring components have been incorporated into the CEMP.

The influence of the Mount Polley Mine on periphyton productivity, community, and tissue quality can occur by several key mechanisms: 1) general mine influence from dustfall and/or uncontained surface or groundwater flows: 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to December 2017, and directly since January 2018]); 3) the TSF embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Reclamation activities in lower Edney Creek and Hazeltine Creek were initiated in 2014 following the TSF embankment breach, and were completed in lower Edney Creek in August 2015 (Golder 2017b). Construction / rehabilitation in areas of upper Hazeltine Creek (Reaches 1 and 2) were completed between July and September of 2016 and 2017, respectively (Golder 2017a,c), with Reach 2 encompassing an upper Hazeltine Creek monitoring area established prior to the TSF embankment breach (W7; Minnow 2009). In lower Hazeltine Creek, initial channel rehabilitation was completed in 2015, and further rehabilitation has yet to be completed.

Periphyton tissue quality in creeks adjacent to the Mount Polley Mine has been monitored since prior to the TSF embankment breach (2010, 2012, and 2013; Minnow 2011, 2013a, 2013b). Periphyton productivity (chlorophyll-a and Ash-Free-Dry-Mass [AFDM]) has been monitored since 2013 (Minnow 2013c, 2018a,b), and periphyton community characteristics have not been

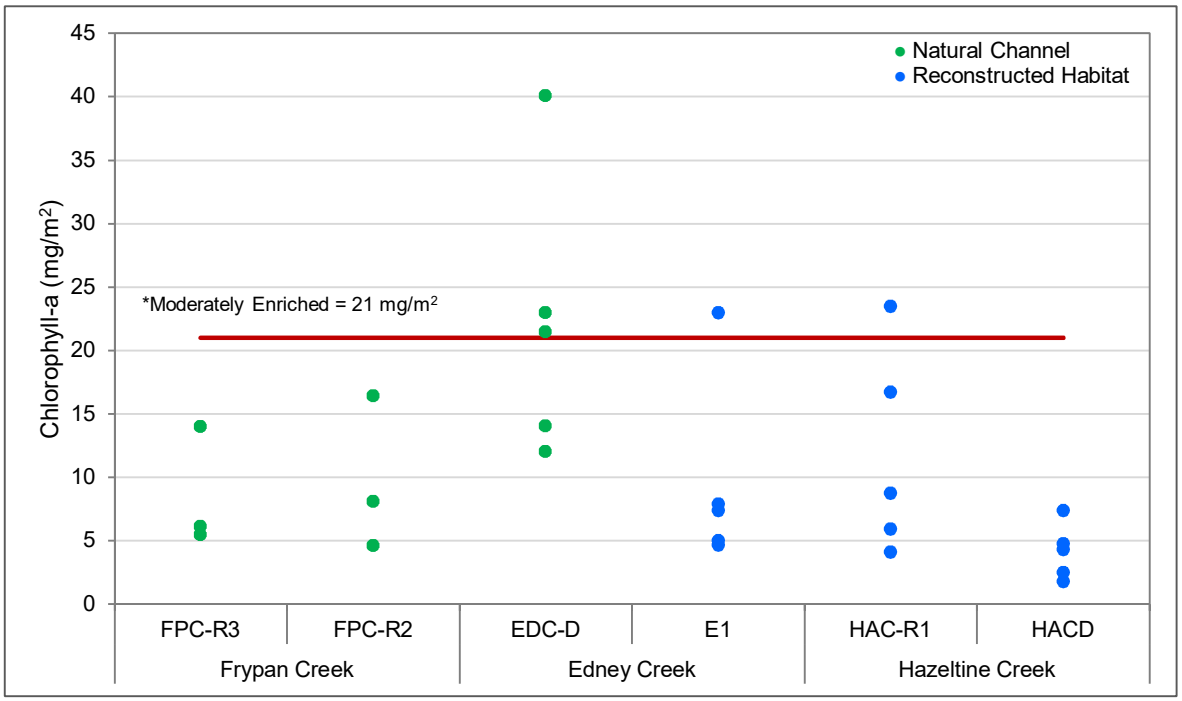
documented in these waterbodies. Results of previous periphyton productivity and tissue quality monitoring are reviewed in Section 2. These results provide context for a periphyton monitoring program that is guided by a combination of available historical findings, representative locations downstream of Mount Polley Mine operations (taking into consideration recent stream rehabilitation activities), representative reference locations, and considerations for a statistically-based design that will facilitate the detection of potential spatial and/or temporal differences in periphyton endpoints (productivity, community, and tissue quality), in addition to providing data to evaluate productivity endpoints (i.e., chlorophyll-a) against provincial water guidelines for the protection of aquatic life (e.g., BCWQG; BCMOE 2018) and literature-based productivity classification values (e.g., Biggs 1996).

The following sections of the CEMP Periphyton Monitoring Plan provide the objectives of periphyton productivity and tissue quality monitoring, a summary of historical periphyton monitoring results, an overview of the CEMP study design and associated rationale (including sampling locations, replication, frequency, and analytes), and detailed methodology for periphyton productivity and tissue quality monitoring (sampling methods, analytical methods, quality control methods, data interpretation, and reporting).

1.1 Monitoring Objectives

The objective of periphyton monitoring in the Mount Polley receiving environment is to evaluate the influence of Mount Polley Mine activities (related to mine operations, the TSF embankment breach, and/or rehabilitation activities) on Hazeltine Creek (the creek receiving environment directly influenced by Mount Polley Mine activity) and lower Edney Creek (a creek environment directly influenced by the TSF embankment breach), and to serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (benthic invertebrates and fish; Sections 6.13 and 6.16). Periphyton monitoring will include assessment of productivity, community composition, and tissue quality, with comparison to previous and/or reference conditions, to applicable guidelines (i.e., chlorophyll-a; BCMOE 2018), and to literature-based criteria (or classification ranges) for productivity. Periphyton monitoring results also provide supporting information for the assessment of benthic invertebrate tissue quality, benthic invertebrate community condition, and fish habitat productivity, as well as supporting the exposure assessment for the ecological risk assessment (ERA) and human health risk assessment (HHRA).

2 SUMMARY OF HISTORICAL FINDINGS



2.1 Productivity

Periphyton productivity monitoring completed during mine operations but before the TSF embankment breach indicated that productivity was low in a creek adjacent to the Mount Polley Mine (Bootjack Creek; 1.42 mg/m^2 of chlorophyll-a; Minnow 2013c) relative to the BCWQG of 100 mg/m^2 (BCMOE 2018). Following the TSF embankment breach, periphyton productivity in rehabilitated areas of upper and lower Hazeltine Creek and lower Edney Creek were also generally low (1.76 to 40.1 mg/m^2 of chlorophyll-a; Minnow 2018a; Figure 1), as evidenced by results well below the BCWQG and generally below chlorophyll-a levels associated with moderately enriched streams (21 mg/m^2; Biggs 1996) despite full sun exposure in these recently rehabilitated areas. Periphyton chlorophyll-a results from these rehabilitated areas following the TSF embankment breach were generally within the range documented in the associated reference areas (4.6 to 40.1 mg/m^2), as was periphyton biomass (AFDM; Figure 1; Minnow 2018a,b).

2.2 Tissue Quality

Periphyton tissue quality has been monitored since 2010 in the vicinity of the Mount Polley Mine (primarily within Hazeltine Creek), with a focus on selenium monitoring relative to reference (Minnow 2011, 2013a,b, 2018c), although additional analytes were included in analyses completed in 2010 (Minnow 2011). Mean periphyton selenium concentrations in upper and lower Hazeltine Creek have shown limited temporal change over the monitoring period, with the most recent results (2017) being similar to, or lower than, concentrations documented prior to the TSF embankment breach (Figure 2).

The inclusion of additional analytes in periphyton tissue quality monitoring continued in 2017 (Minnow 2018d), with tissue quality characterized in three rehabilitated areas of Hazeltine Creek (2 of which were effluent exposed during sample collection), relative to reference (an unimpacted area of lower Edney Creek). Data interpretation of these additional analytes focused on Parameters of Interest (POIs [representing the chemical influence of the TSF embankment breach on sediment quality]: arsenic, copper, iron, and nickel), and on Indicator Parameters (IPs [identified in evaluations of water, soil, or fish tissue quality for Hazeltine Creek]: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium; Golder 2015, 2016, Minnow 2015). Periphyton tissue quality from all rehabilitated Hazeltine Creek areas (both effluent exposed and not exposed) was characterized by copper concentrations that were significantly higher than reference (Figure 3), while concentrations of a number of additional analytes were higher than reference in at least one Hazeltine Creek area (two POIs: arsenic, iron;

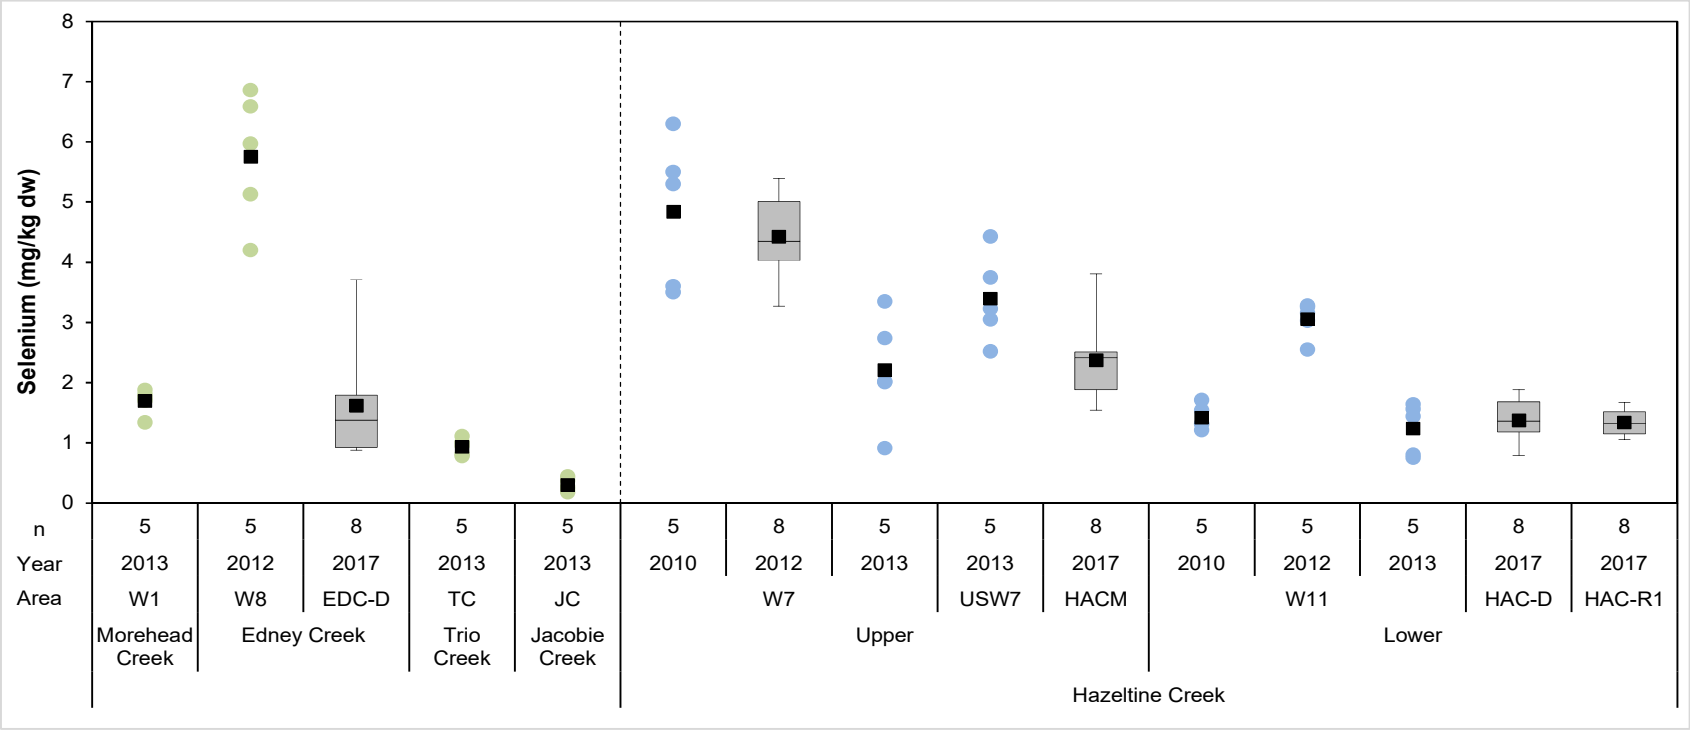
* Value taken from Biggs 1996



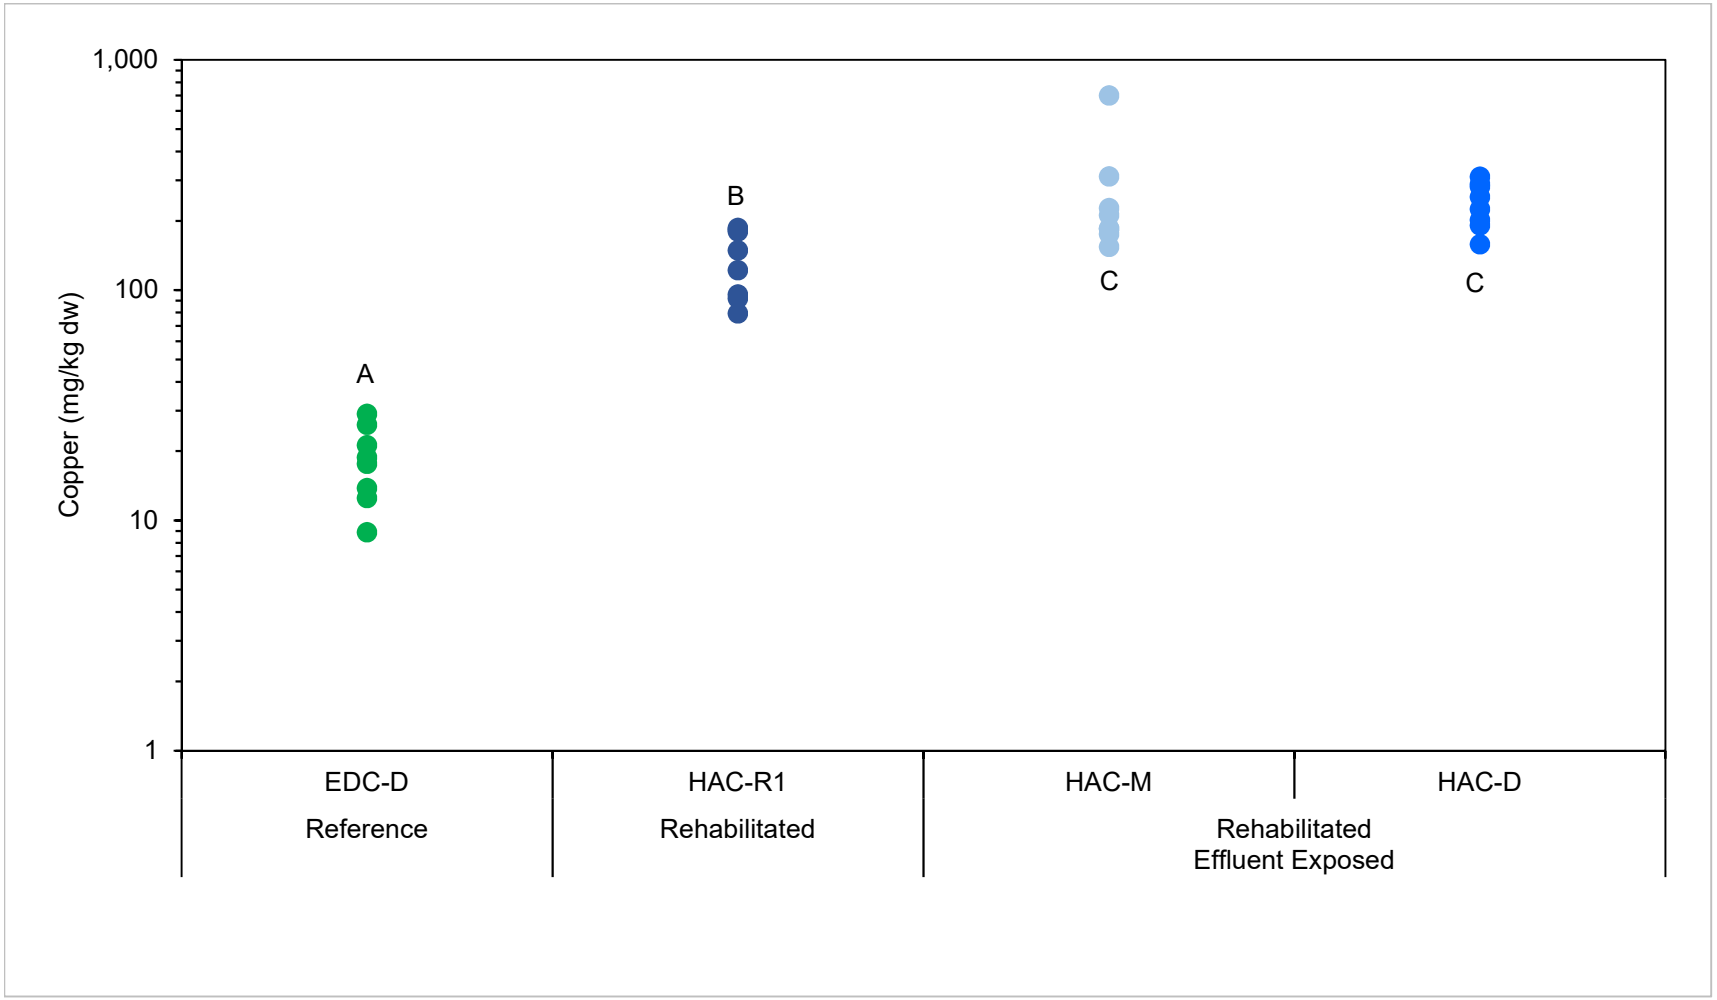


Figure 2: Selenium Concentrations in Periphyton Tissue at Hazeltine Creek with Associated Reference Areas, Mount Polley, 2010 to 2017

Note: Dashed line used to separate reference (left side) and exposed (right side) areas. Black squares represent means and whiskers represent minimum and maximum values. Box plots are presented when there are 8 or more samples.

Note: Groups that share a letter (e.g., AB) are not significantly different from each other.

Figure 3: Periphyton Tissue Copper Concentrations at Rehabilitated and Effluent Exposed (HAC-M, HAC-D), Rehabilitated (HAC-R1), and Reference (EDC-D) Area, Mount Polley Mine, 2017

and six IPs: calcium, cobalt, molybdenum, phosphorus, sodium, and vanadium; Minnow 2018d) These results were consistent with the higher water concentrations of most of these analytes in Hazeltine Creek due to a combination of breach influence and effluent conveyance preceding and during sample collection.

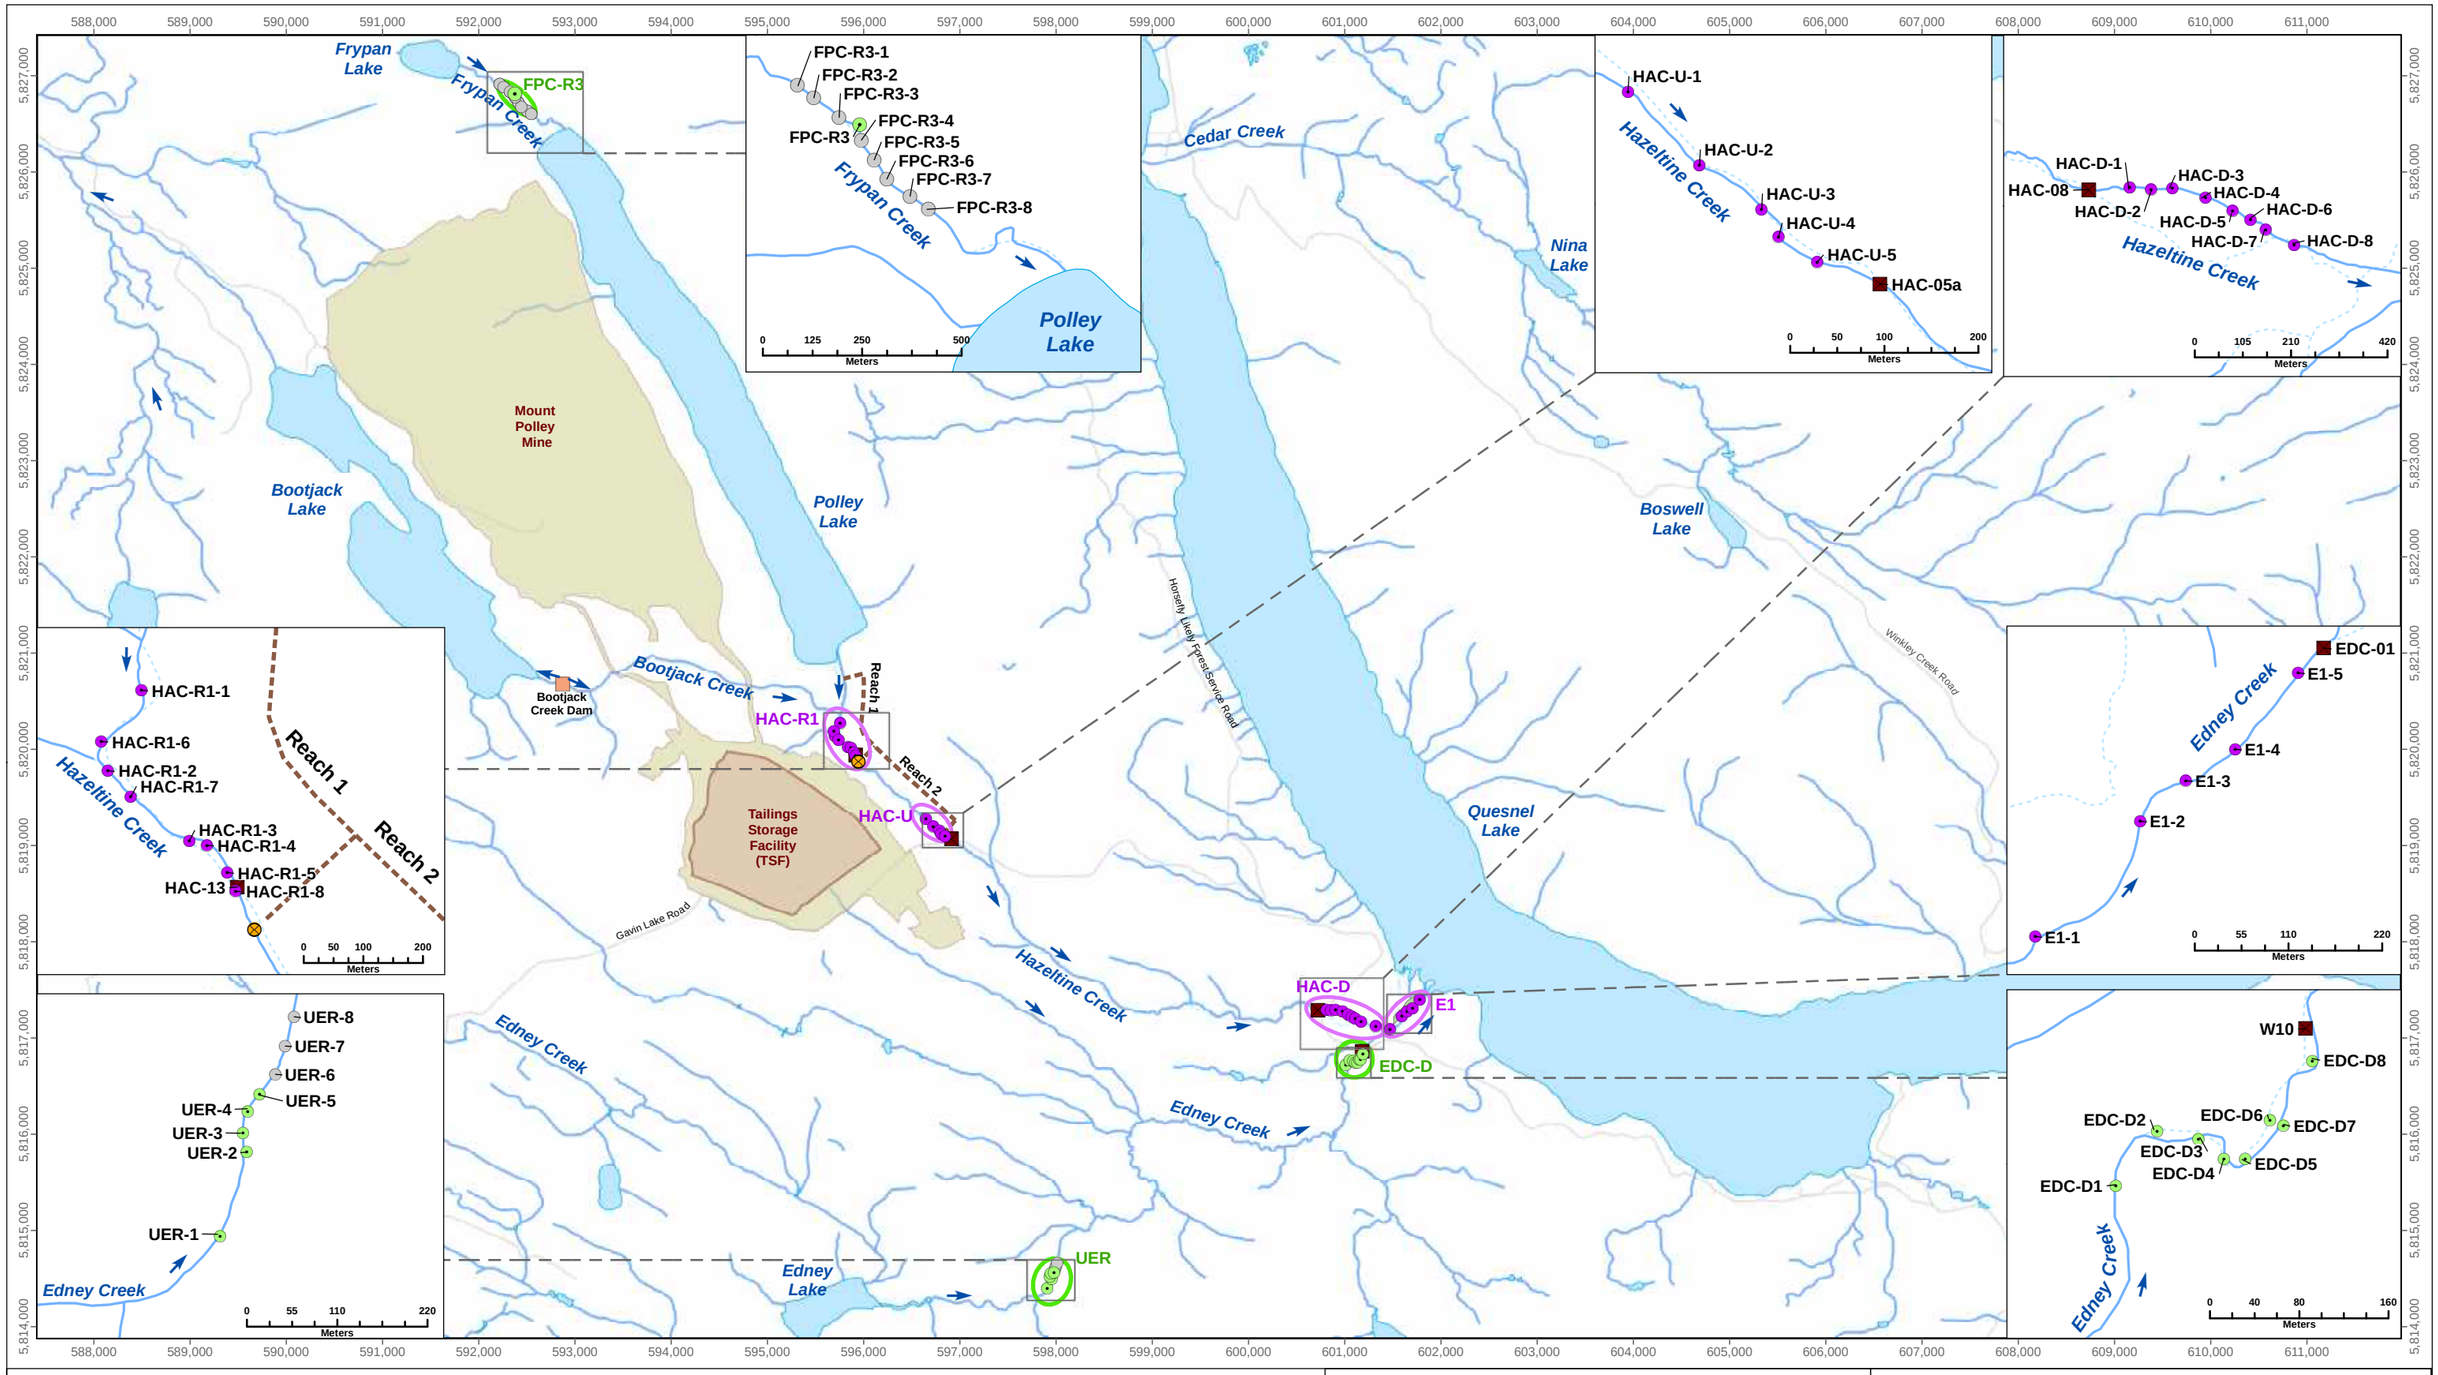
3 STUDY DESIGN OVERVIEW AND RATIONALE

Periphyton monitoring under the CEMP is proposed to meet the combined needs of: 1) operational monitoring (including the previous discharge of treated effluent to Hazeltine Creek); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to reclamation activity following the TSF embankment breach. An overview of the proposed periphyton monitoring program is provided in Table 1 and Figure 4. Periphyton monitoring is focused on Hazeltine Creek and lower Edney Creek with reference areas identified for each mine-influenced sampling area (i.e., upper Edney Creek and Frypan Creek for upper Hazeltine Creek, and an unaffected area of lower Edney Creek for rehabilitated areas of lower Edney Creek and lower Hazeltine Creek; Table 1; Figure 4). As described in Section 1.1, reclamation activities in Hazeltine Creek and lower Edney Creek were initiated in 2014 following the TSF embankment breach, and were completed in lower Edney Creek in August 2015 (Golder 2017b), and in 2016 and 2017 in sections of upper Hazeltine Creek in (Reaches 1 and 2, respectively; Golder 2017a,b). As such, periphyton monitoring in Hazeltine Creek will focus on three areas (Figure 4)[1], including one area in Reach 1 (HAC-R1; where rehabilitation was completed in 2016), one area in Reach 2 (HAC-U; where rehabilitation was completed in 2017), and one area in lower Hazeltine Creek (HAC-D, where initial rehabilitation activities have been completed but additional rehabilitation will be conducted). Monitoring in lower Edney Creek will focus on one rehabilitated area (E1; where rehabilitation was completed in 2015). These sampling areas also align with those proposed for benthic invertebrate community and tissue quality monitoring (see CEMP Section 6.13). It should be noted that sampling areas HAC-U and HAC-D were previously exposed to the discharge of treated mine effluent (December 2015 to December 2017), whereas HAC-R1 is located upstream of the previous discharge point (Figure 4). As of January 2018, treated effluent is no longer discharged into Hazeltine Creek. Concurrent sampling of suitable reference areas will be conducted in lower Edney Creek and Frypan Creek. In Frypan Creek, the reference sampling area was selected to match habitat conditions in upper Hazeltine Creek as closely as possible, based on results of preliminary fish habitat assessment and benthic invertebrate monitoring (area selection was based primarily on substrate type and size; Minnow 2018b).

Periphyton monitoring includes assessment of productivity (chlorophyll-a and AFDM) at all sampling locations. Periphyton community will also be monitored at all locations with the exception of Frypan Creek, which will be sampled in 2018 only for the purposes of comparison of

[1] Note that previous creek sampling station locations are presented in Figure 4. These locations may change slightly depending on substrate, water depth, and water velocity. Similarly, conceptual station locations are displayed for upper Edney Creek and Frypan Creek, and will be established during the field campaign.

Table 1: Mount Polley CEMP Periphyton Monitoring Program Overview



Water Body	Sampling Area	Type	Monitoring Frequency	Components [a]	Replication [b]			Rationale
					T	P	C	
Hazeltine Creek	HAC-R1 (Upper, Reach 1)	Rehabilitated	Annual	T,P,C	5	5	8	adjacent to mine and breach-influenced
	HAC-U (Upper)	Rehabilitated	Annual	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
	HAC-D (Lower)	Rehabilitated	Bi-annual [c]	T,P,C	5	5	8	adjacent to mine, previously effluent-exposed, and breach-influenced
Frypan Creek	FPC-R3 (Reach 3)	Reference	2018 only	P, C	-	5	8	reference for upper Hazeltine Creek
Edney Creek	UER (Upper)	Reference	Annual	T,P,C	5	5	8	reference for upper Hazeltine Creek
	E1 (Lower)	Exposed	Bi-annual [c]	T,P	5	5	-	adjacent to mine and breach-influenced
	EDC-D (Lower, unimpacted)	Reference	Bi-annual [c]	T,P,C	5	5	8	reference for lower Hazeltine Creek [d]

[a] core periphyton monitoring components: T = community taxonomic analysis, P = productivity (chlorophyll-a and Ash-Free-Dry-Mass, see Table 2), C = chemistry (see Table 2 for analytes).

[b] number of replicate stations within the specified sampling area for a given program component.

[c] Bi-annual indicates sampling will occur every other year for all parameters indicated with the exception of tissue chemistry, which will be monitored annually. The next bi-annual sampling event will occur in 2019.

[d] Lower Edney Creek reference area will be located in an unimpacted area upstream of the breach influence (see Figure 4).

fish habitat productivity (Table 1). Periphyton community monitoring provides a means for evaluating re-establishment of the periphyton community in these recently disturbed areas, and is an additional line of evidence for assessing temporal changes in periphyton productivity. Periphyton tissue quality monitoring, which includes evaluation of concentrations of metals[2] and moisture content, will be included at all sampling locations with the exception of the rehabilitated area of lower Edney Creek (E1; Table 1). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; 3) comparison of productivity results relative to BCWQG and literature-based classification values. Accordingly, five stations per area for the assessment of productivity and community, and eight stations per area for the assessment of tissue quality are proposed to provide replication for the statistical contrasts.

Periphyton monitoring will be supported by measures of sampling depth, water velocity, and *in situ* water quality measurements (temperature, dissolved oxygen, pH, and specific conductance) at each sampling station. Additional information to be collected includes GPS coordinates of each station, notes of the presence of aquatic vegetation/bryophytes on sampled substrate and other physical observations, and supporting photographs of the sampling location and samples. Supporting grab water samples will also be collected during the sampling event in areas where water quality is not routinely monitored by the Mount Polley Mine (e.g., in Frypan Creek and upper Edney Creek).

Periphyton sampling will be completed in August or September consistent with previous data collections (Minnow 2011, 2013a,b, 2018a,b,c,d). The initial frequency of periphyton community, productivity, and tissue quality monitoring at upper Hazeltine Creek (and associated reference areas) is annual given the recent disturbance to these rehabilitated areas, and changes to the effluent exposure status (Table 1). This frequency will enable tracking of recovery in these recently disturbed habitats. The frequency of periphyton community and productivity monitoring in rehabilitated areas of lower Hazeltine Creek and lower Edney Creek (and associated reference areas) is every second year because these areas have been undisturbed since 2015, however the frequency of tissue quality monitoring in lower Hazeltine Creek (and the associated reference area) is annual. Monitoring frequencies will be reviewed following interpretation of data collected in 2020, and design modifications (e.g., changes to monitoring frequency or locations) will be made in response to QP recommendations. If results indicate stable periphyton productivity, community, and tissue quality during this period, then a reduction of monitoring frequency to every second year will be considered for upper Hazeltine Creek areas. The Frypan Creek reference area will only be sampled in 2018 (Table 1) to provide comparison for periphyton biomass and

[2] For simplicity, the term metals is used herein to include metalloids.

tissue quality data from upper Hazeltine Creek following the initial reopening of upper Hazeltine Creek as fish habitat (see CEMP Section 6.16).

Periphyton samples will be collected, processed, analyzed, and the associated data interpreted using methodology consistent with previous assessment at Mount Polley (e.g., Minnow 2011, 2013a,b, 2018a,b,c,d), which is also consistent with technical guidance (e.g., BCMOE 2013, 2016). Detailed methodology is provided in Section 4, including: quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality assessment, and data handling and interpretation.

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be led by qualified field staff experienced in the implementation of periphyton monitoring programs, and all sample collection methods, quality assurance and quality control measures, and laboratory analysis methods will be implemented in accordance with technical guidance (BCMOE 2013, 2015, 2016). Specifically, quality assurance and quality control measures will include program review prior implementation, adequate resources for all field teams including field checklists and field data sheets, the availability (and maintenance) of clean sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination.

Quality control (QC) samples will be collected to support the periphyton monitoring program. Replicate samples will be collected from each sampling area in order to capture within-area variability (samples from 5 and 8 separate stations will be collected to represent the sampling area for productivity/community and tissue quality endpoints, respectively). Specific field QC samples will include duplicates (i.e., splits) of periphyton tissue quality samples collected at a frequency of 10% of the total number of samples to assess field precision as part of the Data Quality Review (DQR; Section 4.4). QC samples to assess field precision (field duplicates) will not be collected for periphyton productivity (chlorophyll-a and AFDM) or community monitoring endpoints due to high the inherent natural variability in these parameters. In addition to field QA/QC, the laboratory responsible for the physical or chemical analyses will be accredited by the Canadian Association for Laboratory Accreditation (CALA) for these analyses. Specific QC sampling and associated reporting will for tissue quality and periphyton productivity endpoints be requested of the analytical laboratory, including reagent blank results, laboratory replicate results, and laboratory accuracy results (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). QC reporting will also be requested of the laboratory performing taxonomic analysis of the periphyton community samples, including organism enumeration checks for a minimum of 10% of samples. These results will be assessed as part of the DQR (Section 4.4).

All raw field data will be transcribed from field sheets into an electronic spreadsheet. Data will then checked by a separate individual for data entry errors as part of routine Quality Assurance/Quality Control (QA/QC) procedures.

4.2 Sample Collection Methods

4.2.1 Biomass and Chlorophyll-a

Periphyton samples for chlorophyll-a analysis and biomass (AFDM) will be collected by selecting five representative submerged rocks from each monitoring station. Representative rocks from each station will be selected from locations with similar habitat (depth, velocity, and substrate characteristics), while attempting to match depth and velocity among periphyton collection stations and areas as closely as possible. Selected rocks (excluding those that are too small, highly angular, or uncharacteristic in surface texture) will be taken to shore. For chlorophyll-a sample collection, a thin acetate template with a 2x2 cm opening in the middle will then be placed firmly on each rock, and the periphyton within this area will be scraped off using a stainless-steel razor blade or scalpel. Sample material from each of the five rocks will then be transferred from the razor blade or scalpel to a large (47 mm) 0.45 µm pore diameter Whatman mixed cellulose ester (MCE) filter paper until a single composite sample of approximately 200 mg to 1 g wet weight is obtained per station. If material collected from the five rocks sampled is insufficient, additional rocks will be sampled from the same area with similar habitat characteristics until the required sample volume is obtained. The filter paper will then be folded and placed into a labeled opaque centrifuge tube. The total surface area sampled at each station (0.002 m^2: 5 x 4 cm^2, or any deviations from this surface area), will be recorded to allow calculation of chlorophyll-a on a unit area basis for comparison to the British Columbia Water Quality Guideline (BCWQG; 100 mg/m^2; BCMOE 2018). The same five rocks sampled for chlorophyll-a analysis (and additional rocks if they were required) will be used to collect separate scrapings for analysis of AFDM. For AFDM sampling, sampling methods will follow those outlined above for chlorophyll-a, however material on the razor blade or scalpel from scraping of each rock will be rinsed into a small pre-labelled plastic jar with additional water added to cover the tissue (as necessary). Sampling will be conducted at five replicate stations in each area (see Table 1). Immediately after collection, all chlorophyll-a and AFDM samples will be placed in a cooler on ice for transport to the mine, where they will be frozen.

4.2.2 Community

Periphyton community samples will be collected from the same five rocks used for chlorohyll-a and biomass sampling whenever possible (and additional rocks if they were required), or from rocks of a similar size collected from the same general location and habitat (depth and velocity). Sample collection methods will be similar to those outlined for chlorophyll-a and AFDM. Briefly, a thin acetate template with a 2x2 cm opening in the middle will be placed firmly on each rock and all of the periphyton within this area will then be removed using a scalpel and/or brush and a squirt bottle filled with site water (BCMOE 2013, 2016; Stevenson and Bahls 2006). The collected

periphyton will then be transferred into a labelled sample jar, and this process will be repeated for the five rocks, resulting in a single composite sample from each station. The total surface area sampled at each station (0.002 m^2: 5 x 4 cm^2, or any deviations from this surface area if additional rocks are sampled) will be recorded. Immediately after collection, the sample will be preserved with Lugol's iodine solution until the sample is the colour of weak tea (approximately 1 mL of Lugol's per 250 mL of sample; BCMOE 2013), and will be mixed gently by inverting the sampling jar. All samples will be stored at room temperature. Sampling will be conducted at five replicate stations in each area (see Table 1).

4.2.3 Tissue Quality

Periphyton samples collected for tissue quality analysis will be collected by scraping periphyton from the surface of rocks using a scalpel until sufficient sample weight for analysis is attained (more than 500 mg wet weight). A minimum of five rocks will be sampled to ensure the sample is representative of the sampling station. Rocks sampled for productivity and community will be used preferentially, plus additional rocks (as necessary) to obtain the required sample weight. Periphyton scrapings will be transferred directly from the scalpel onto the wall of a labeled scintillation vial, without rinsing, to minimize the amount of water in each sample. Sampling will be conducted at eight replicate stations in each area (see Table 1). Samples will be placed in a cooler on ice for transport to the mine, where they will be frozen.

4.3 Sample Handling and Laboratory Analysis

Periphyton productivity (chlorophyll-a and AFDM) and tissue quality samples will remain frozen until overnight shipment on ice to the analytical laboratory. Samples will be sent to the laboratory with sufficient time to complete analyses within the recommended sample hold times (28 days for chlorophyll-a, 6 months for AFDM, 1 year for tissue quality [metals analysis]). Analyses will be completed at an analytical laboratory accredited by the Canadian Association for Laboratory Accreditation (CALA) using methods that are consistent with those specified in the British Columbia Environmental Laboratory Manual (BCMOE 2015). Upon sample receipt, the laboratory will provide a sample receipt confirmation which will be reviewed to ensure that all samples are received and that the analytical requests are properly logged. Analysis of chlorophyll-a will follow procedures adapted from USEPA Method 445.0 (USEPA 1997). Briefly, chlorophyll-a will be determined by routine acetone extraction followed by fluorescence detection using a non-acidification procedure (a method that is not subject to interferences from chlorophyll-b). Determination of total AFDM will follow procedures adapted from APHA Method 10300 C (APHA 2010). Total AFDM will be calculated as the difference between the dried sample weight and the ash weight, both of which will be determined gravimetrically. Dry weight will be determined by drying the sample at 105 °C, and the ash weight will be subsequently determined

by ashing the dried sample at 500 °C. Tissue quality samples will be analysed for metals by CRC-ICP-MS (Collision Cell Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/6020A [USEPA 2004]) or HR-ICP-MS (High Resolution Inductively Coupled Plasma-Mass Spectrometry; USEPA Method 200.3 [USEPA 1991]/ 200.8 [USEPA 1994]), mercury by CVAFS (Cold Vapour Atomic Fluorescence Spectrophotometry; USEPA Method 200.3 [USEPA 1991]/Method 245.7 [USEPA 2001]), and moisture content. The method selected for metals analysis will depend on sample weight, with HR-ICP-MS employed for smaller sample sizes. Periphyton productivity and tissue quality parameters are provided in Table 2, with the associated target laboratory reporting limits (LRLs) and detection limit objectives outlined in technical guidance ("consensus detection limits"; BCMOE 2016). Upon completion of the analyses, the laboratory will provide a data report in Microsoft (MS) Excel™ and as an Adobe Acrobat Portable Document Format (PDF). Reporting will include the results of the laboratory QC sample results.

Periphyton community samples will be stored at room temperature until shipment to the taxonomy laboratory for taxonomic identification and enumeration. Samples will be shipped immediately after the completion of the field campaign, however there are no recommended hold times for analysis. Sample analysis will be completed as follows. Briefly, samples will be homogenized, settled in Ütermohl chambers for 24 h, and all cells within randomly selected fields of view will be enumerated until a minimum count of 300 algal units (1 unit = >1 cell for colonial or filamentous taxa) is reached. Identification will be performed using an inverted phase contrast microscope, and algal taxa will be identified to minimum of genus-level according to the most up-to-date taxonomic references. Periphyton density will be determined using the area sampled, proportion subsampled, and the total area of the selected fields of view. Biomass estimates will be generated for each taxon using taxon-specific biovolume formulae (Hillebrand et al. 1999) for cell measurements, and taxon-specific densities.

4.4 Data Quality Review

Upon receipt of all analytical data, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs have been achieved. The DQR will also include an evaluation of differences between duplicate (split) samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the periphyton monitoring data will ensure timely communication with the laboratory should any issues be identified

Specifically, LRLs will be evaluated relative to targets established for the analytes and to "consensus detection limits" (Table 2), and to relevant British Columbia guidelines (i.e., chlorophyll-a for productivity samples; BCMOE 2018). Comparisons between duplicate samples

[a] from Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators (BCMOE 2016).

[b] Method for total mercury analysis will be according to USEPA (1991, 2001).

B) Productivity Parameters

Parameter	Units	Method	LRL
Chlorophyll-a	µg	USEPA 1997	0.02
Ash Free Dry Weight	g	APHA 2010	0.001

will be made by calculating the relative percent difference (RPD) between concentrations between paired duplicates. If the RPD is <25% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Results for laboratory blanks, precision, and accuracy will be evaluated relative to Data Quality Objectives (DQO) established by the analytical laboratory that performed the analyses. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping).

4.5 Data Handling, Interpretation, and Reporting

Upon receipt of data from the analytical laboratories, all laboratory data files will be managed by the Mount Polley Mining Corporation (MPMC) Environment Department. In addition, data provided by the primary analytical laboratories as an Electronic Data Deliverable (EDD) will be imported directly into the MPMC's database following completion of the DQR. Following the DQR, all periphyton data and supporting data will be managed in MS Excel. For all replicated data (typically based on a sample size of five or eight stations per area), data will be provided to the QP and summarized by calculating mean, median, standard deviation, minimum, and maximum for each analyte. Data analysis will be completed for each monitoring component (productivity, community, and tissue quality).

Periphyton productivity (chlorophyll-a and AFDM) results will be converted to a standard area-based measurement (mg/m^2 and g/m^2 for chlorophyll-a and AFDM, respectively), and chlorophyll-a results will be compared to water quality guidelines for the protection of aquatic life (BCWQG = 100 mg/m^2; BCMOE 2018) and to literature-based criteria for moderately enriched streams (21 mg/m^2; Biggs 1996). Periphyton productivity results will also be compared to previous data (where possible), and to reference results. For periphyton community, endpoints including density, taxon richness, diversity indices, and dominant community composition endpoints will be calculated, and compared to reference results. Temporal comparisons of periphyton community results will be made once data are available (2018 represents the first year of periphyton community sample collection). More detailed evaluation of periphyton productivity and community results will include analyses using a control-impact study design. Specifically, Analysis of Variance (ANOVA) will be used to test for differences in periphyton productivity and community endpoints between rehabilitated areas of Hazeltine Creek and lower Edney Creek, and associated reference areas. For these analyses, the assumptions of normality and homogeneity of variances will be tested on the residuals of the ANOVA model using the Shapiro-Wilk test and Levene's test based on median values, respectively, using a significance level (α) of 0.05. Data will be transformed as necessary to satisfy assumptions of normality and

homogeneity of variance as required. In instances where the residuals of the ANOVA model do not meet the assumptions of normality and homogeneity of variances, a non-parametric Kruskal-Wallis test will be conducted. When the overall results of an ANOVA or Kruskal-Wallis test are significant, differences between specific areas will be evaluated using post-hoc contrasts for ANOVA or Dunn's test for the Kruskal-Wallis test. A Bonferroni correction on the p-values will be used to conserve the overall Type I error rate. Further detailed analyses will be completed as required for data interpretation, and may include: graphical comparisons to reference and historical data (if available), graphical plots in relation to guidelines and criteria, and formal statistical temporal and spatial contrasts using methods similar to those described above.

If exposed versus reference or temporal differences in periphyton productivity and community results are noted, relationships between periphyton productivity and community endpoints and supporting water quality will be evaluated using Spearman correlation (often referred to a Spearman Rank-Order correlation). Following the derivation of correlation coefficients, a Bonferroni-type correction (i.e., p-value [0.05] divided by the total number of correlations examined for independent variables) will be applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected p-value of 0.05. Any significant correlations found at the Bonferroni-adjusted p-value or at a p-value of 0.01 will be further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were "leveraged" by outlying points (or groups of points). Although it is recognized that a significant correlation or regression does not indicate causation (e.g., Norton et al. 2015), it is desirable to not only characterize the nature of a response (e.g., changes in periphyton productivity or community), but to also obtain evidence of cause. Correlation / regression analyses are commonly applied tools for identifying potential cause (e.g., Norton et al. 2015). Evidence of causation obtained from correlation or regression analysis will be carefully considered in light of the strength, range, and continuity of the relationships as well as mechanistic knowledge/understanding of potential cause.

Data analysis and interpretation of periphyton tissue quality results will focus on Parameters of Interest (POIs [representing the chemical influence of the TSF embankment breach on sediment quality]: arsenic, copper, iron, and nickel), and on Indicator Parameters (IPs [identified in evaluations of water, soil, or fish tissue quality for Hazeltine Creek]: calcium, cobalt, molybdenum, phosphorus, selenium, silver, sodium, titanium, and vanadium; Golder 2015, 2016, Minnow 2015). Periphyton tissue quality results for these analytes will be compared to available pre-breach data (for selenium only [2010, 2012, and 2013]; Minnow 2011, 2013a, 2013b), contrasted between exposed and reference areas, and also compared temporally within exposed areas. Detailed analyses and interpretation related to these comparisons will be completed as required, and may

include: graphical comparisons to reference and historical data, and formal statistical contrasts of exposed versus reference concentrations tissue concentrations as described above

Concentrations of the POIs and IPs in periphyton tissue will also be evaluated relative to concentrations in water. These ratios of concentrations will be calculated as: [tissue sample concentration]/[dissolved water concentration], and are referred to as Bioconcentration Factors (BCFs). BCFs are often used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes other than diet (i.e., Arnot and Gobas 2006), and are applicable to erosional areas where sediment is generally not present. BCFs will be calculated using tissue metal concentrations (dry weight) and mean dissolved metal concentrations in water from each sampling area. Calculated BCFs will then be qualitatively compared among areas to identify differences in the uptake of metals by periphyton in areas impacted by effluent discharge and/or the TSF embankment breach. Mean BCFs will also be qualitatively compared between or among years to examine any broad temporal changes in metal accumulation in periphyton tissue at exposed sites. In addition, concentrations of POIs and IPs in periphyton tissue will be used in the evaluation of Trophic Transfer Factors (TTFs) to benthic invertebrates; the ratio of tissue concentrations in benthic invertebrates relative to concentrations in periphyton (i.e., TTF = [benthic invertebrate sample]/[periphyton sample]). TTFs can be used generally to describe the extent to which the concentration of an analyte increases between lower and higher trophic levels (e.g., Presser and Luoma 2010; see CEMP Benthic Invertebrate Section 6.13 for details).

An interpretive report based on the periphyton monitoring data will be prepared for integration into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWQG and other guidelines or classification schemes, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

1 INTRODUCTION

1.1 Background

Fish are important and highly valued aquatic ecosystem components. Fish community composition, fish population characteristics (e.g., survival, growth, and reproduction), and fish tissue quality can be effective monitors of potential biological effects associated with water quality, sediment quality, and/or physical disturbance. Fish tissue quality is also an important measure of potential exposure to metals, metalloids, nutrients[1], and other substances to humans and wildlife that consume fish. Lastly, the use of fish habitat by fish is an important monitor of the physical and chemical quality of aquatic habitat.

The influence of the Mount Polley Mine on fish communities, populations, and/or tissue quality can occur by several key mechanisms: 1) general mine influence on creeks and lakes from physical impingement, dustfall, and/or uncontained surface or groundwater flows; 2) direct discharge of mine effluent to Hazeltine Creek (April to August 2014) and Quesnel Lake (December 2015 to present [via Hazeltine Creek from December 2015 to November 2017, and directly since January 2018]); 3) the Tailings Storage Facility (TSF) embankment breach on August 4, 2014; and 4) reclamation activities following the TSF embankment breach. Potential effects associated with effluent discharge are chemical, while those associated with general mine influence, the TSF embankment breach, and subsequent remediation can be both physical and chemical.

Fish in waterbodies adjacent to the Mount Polley Mine have been monitored historically by the provincial government (Burns and Klein 1973; Lirette and Tredger 1991; Bruce and Slaney 1991) and by the Mount Polley Mine starting with baseline investigations in 1989, 1995, and 1996 (Imperial Metals 1990; HKP 1996a,b,c, 1997a). Results of fish monitoring are reviewed in Section 2 and provide context for a CEMP fish monitoring program (community, population, and tissue quality) that is guided by a combination of historical findings, representative locations downstream of Mount Polley Mine operations, representative reference locations, and considerations for a statistically-based design that will facilitate the detection of spatial and temporal differences. Fish tissue quality monitoring data will also be evaluated relative to guidelines for the protection of aquatic life and/or human health (e.g., the British Columbia Water Quality Guideline for selenium [BCMOE 2014] and the Health Canada guideline for mercury [CFIA 2015]). In addition, fish population monitoring is required as part of Environmental Effects Monitoring (EEM) under the Metal and Diamond Mining Effluent Regulations (MDMER) of the

[1] Through the remainder of this section, the term “metals” will be used to include metals, metalloids, and nutrients for ease of communication.

federal *Fisheries Act* (Government of Canada 2018). The focus of the federal EEM fish survey is to determine if there are effects to sentinel fish population characteristics (e.g., survival, growth, and/or reproduction) associated with the discharge of mine effluent (currently to Quesnel Lake). Lastly, fish habitat characterization and fish usage monitoring serves to document and track the effectiveness of fish habitat that has been reconstructed/rehabilitated following the TSF embankment breach.

The following sections of the CEMP Fish Monitoring Plan provide the objectives of fish monitoring, a summary of historical fish community, population, and tissue quality findings, an overview of the CEMP study design and associated rationale (including sampling locations, replication, frequency, and analytes), and detailed methodology for fish monitoring (quality assurance/quality control, sample collection methods, sample handling and laboratory analysis, data quality review, data handling, interpretation, and reporting).

1.2 Monitoring Objective

The objective of fish monitoring is to evaluate the influence of Mount Polley Mine activities on fish communities, populations, and tissue quality in receiving environments (Hazeltine Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions, and to determine potential implications to aquatic ecosystem health and human health (e.g., relative to available fish tissue quality guidelines [BCMOE 2014; CFIA 2015]). Fish monitoring also provides data to support exposure assessment as part of post-breach ecological risk assessment (ERA) and human health risk assessment (HHRA). Lastly, fish monitoring documents fish habitat utilization in creek and lake areas that were physically impacted by the TSF embankment breach (most notably Hazeltine Creek and the lower segment of Edney Creek), thereby documenting the effectiveness of fish habitat rehabilitation efforts. The objective of the MDMER EEM fish monitoring is to evaluate whether there are differences in population endpoints (survival, growth, and reproduction) of sentinel fish species between the area of Quesnel Lake exposed to Mount Polley mine effluent and a reference area (Environment Canada 2012). As prescribed by the MDMER, there is no requirement to monitor fish tissue quality under the MDMER because the concentration of mercury in Mount Polley Mine effluent is less than 0.1 µg/L (0.0001 mg/L; Government of Canada 2018).

2 SUMMARY OF HISTORICAL FINDINGS

Fish monitoring in the vicinity of the Mount Polley Mine has been undertaken since 1989, with most of the monitoring conducted in Polley Lake, Bootjack Lake, Hazeltine Creek, and Edney Creek (Table 1). Fish in Quesnel Lake have also been intensively monitored since the TSF embankment breach in August 2014 and following the initiation of effluent discharge to Quesnel Lake in December 2015. Fish monitoring in the vicinity of the Mount Polley Mine has spanned four distinct time periods:

1. Baseline monitoring (1989, 1991, 1995, 1996);
2. Pre-breach operational monitoring (1997, 1998, 1999, 2007, 2009, 2010, 2012, 2013, 2014);
3. Post-breach operational monitoring (2014, 2015); and
4. Post-breach and post-discharge operational monitoring (2016, 2017).

For Polley Lake and Hazeltine Creek, the second time period can be sub-divided into periods of: 1) prior to; 2) during; and 3) after, an uncontrolled surface runoff event from the north waste rock dump which reported to Polley Lake via North Dump Creek. This runoff started in 2006, was controlled in 2009 with the construction of the Long Ditch, and was characterized by elevated concentrations of sulphate and selenium. In addition to the construction of the Long Ditch, Mount Polley initiated selenium-specific aquatic environmental monitoring in 2009.

Fish community, population, and/or tissue quality data collected prior to the breach were summarized in an Aquatic Environmental Description Report prepared concurrent with an application for water discharge to Polley Lake in 2014 (Minnow 2014a). General findings of the historical monitoring, as well as fish monitoring data collected from 2014 to present, are provided in the following sections, by sampling area, to support the design of the CEMP Fish Monitoring Plan.

2.1 Polley Lake

2.1.1 Fish Community / Population

Baseline monitoring in Polley Lake and reference lakes (Bootjack, Trio, Morehead, and Frypan lakes) was conducted in 1989, 1995, and 1996 and documented the presence of rainbow trout, longnose sucker, and redside shiner. Peamouth chub and largescale sucker have also been reported in Bootjack Lake (in 2014 and 2016, respectively). The fish species composition of Polley and Bootjack lakes has remained the same through operational monitoring and following the perimeter embankment breach. Catchability of rainbow trout and longnose sucker in Polley

[1] C = Community, P = Population, and T = Tissue.

[2] Selenium concentrations only.

[3] Rainbow trout collected from Frypan Creek and pooled with samples from Polley Lake.

Lake and Bootjack Lake by gill netting has remained reasonably consistent from baseline to the most recent gill netting effort in 2016 (Table 2). More recent hoop netting efforts (adopted as a preferred method as captures are non-lethal) document good catchability of both large-bodied species (Table 2).

After the perimeter embankment breach (August 2014), a barrier was installed at the outlet of Polley Lake preventing Polley Lake fish from accessing Hazeltine Creek. There was a noticeable decline in rainbow trout recruitment post-breach as evident in the smaller relative sizes of the age 1 and 2 cohorts in 2016, and the age 1 to 3 cohorts in 2017 (Figures 1 and 2; Minnow 2017a). The barrier preventing fish from entering Hazeltine Creek from Polley Lake was removed in the early spring of 2018 and recruitment is expected to increase accordingly.

2.1.2 Fish Tissue Quality

Tissue quality of Polley Lake (and Bootjack Lake) fish was evaluated in 1989, 1995, 1996, and 1999[2], providing baseline metal concentrations in muscle and liver tissue of rainbow trout and longnose sucker (Imperial Metals 1990; HKP 1996a, 1997a; Beak 2000). Fish tissue quality monitoring was subsequently undertaken in 2009 in response to the uncontrolled surface runoff event from a north waste rock dump which reported to Polley Lake via North Dump Creek (Minnow 2011). Results of the post-runoff but pre-breach monitoring (2009 to 2012) indicated that selenium concentrations in rainbow trout muscle and ovary tissue[3] were stable, that concentrations in muscle tissue were near the British Columbia water quality guideline (BCWQG; BCMOE 2014), and that concentrations in ovary tissue were below the BCWQG (Figure 3). A decrease in selenium concentrations in rainbow trout muscle and ovary concentrations appeared to occur from 2012 to 2014 (pre-breach; Figure 3). Ovary tissue is the best tissue for evaluating the potential adverse effects of selenium to fish (which are considered the most selenium sensitive organisms; Presser and Luoma 2009; Janz et al. 2010; DeForest et al. 2012; Janz 2012). Concentrations in selenium were also well below the effect threshold of 20 mg/kg dw developed by DeForest et al. (2012). Following the TSF embankment breach, an increase in concentrations of selenium in rainbow trout muscle (to above BCWQG) and ovary (below BCWQG) were observed (Figure 3), but the latter remained below the effect threshold.

Following the TSF embankment breach, fish tissue quality investigations were expanded to focus on a suite of analytes that included selenium and also included metals that: 1) were identified as

[2] Although the 1999 collections occurred after mine startup, the results of the collections were verified against previous data and, based on similar results, were used to augment the baseline database to a sample size of ten fish.

[3] Adult rainbow trout were collected either from Polley Lake or from upper Hazeltine Creek. The latter were adult fish from Polley Lake that had moved into Hazeltine Creek to spawn and are considered indistinct from Polley Lake fish for tissue quality monitoring purposes.

Table 2: Catch-Per-Unit-Effort (CPUE) Data for Rainbow Trout and Longnose Sucker in Polley Lake, 1995 - 2017

Year	Data source	Fishing Method	Effort (h)	Rainbow Trout		Longnose Sucker	
				Catch	CPUE	Catch	CPUE
1995	**HKP (1996a)**	Experimental gill net [a] (0.5" - 4" mesh)	15.72	16	0.0006	37	0.0014

[a] CPUE values calculated using reported fishing effort time (15h 43min), and gillnet dimensions (67.5m x 2.35m) (HKP 1996a).
[b] CPUE values calculated as (caught / [ft^2 * h]).
[c] CPUE values calculated as number of fish per trap-day.
[d] CPUE values calculated as number of fish captured per m^2 (Area = 10 m^2).

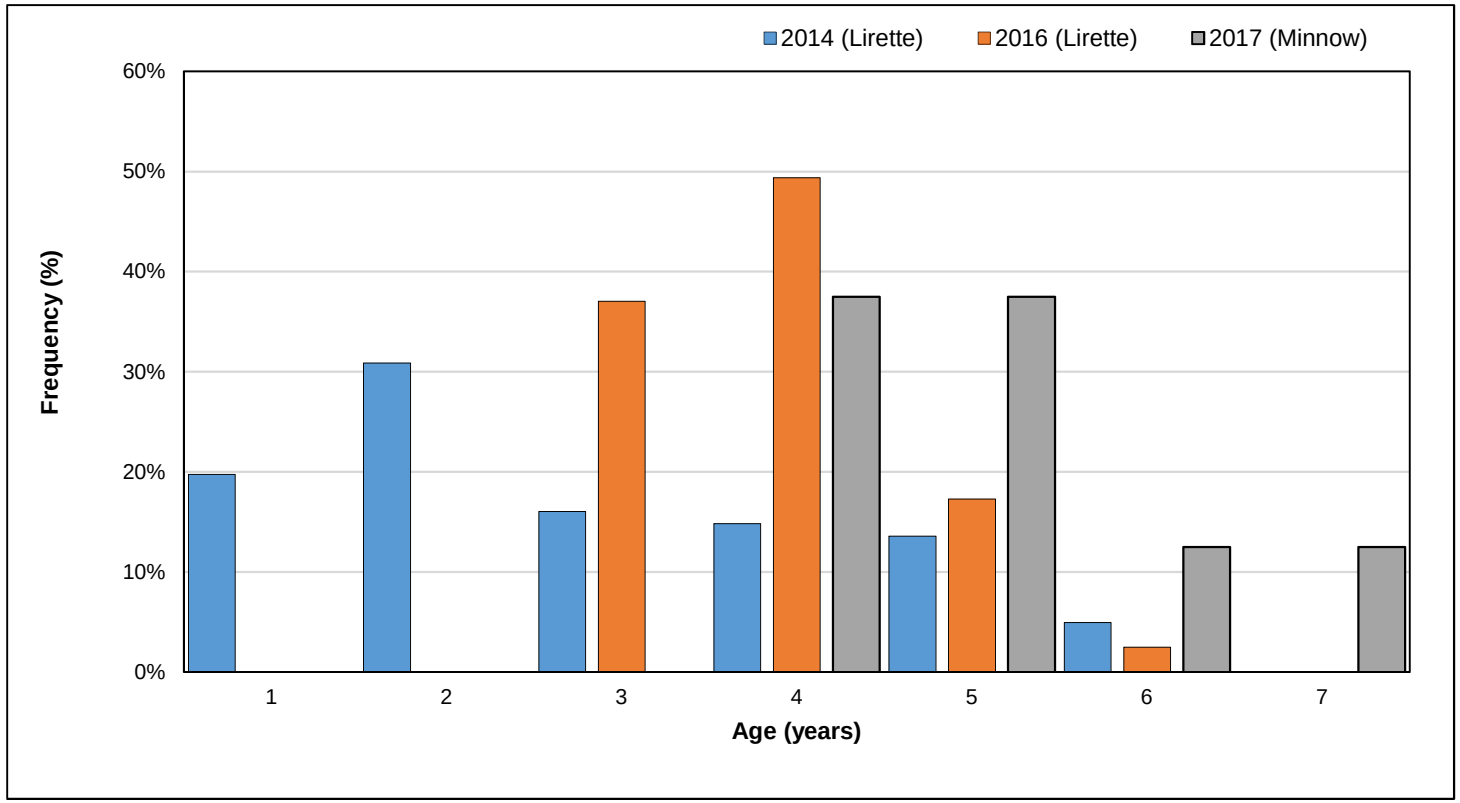

Figure 1: **Rainbow trout age frequency distribution in Polley Lake (data from Lirette 2014 and 2016, and Minnow 2017a)**

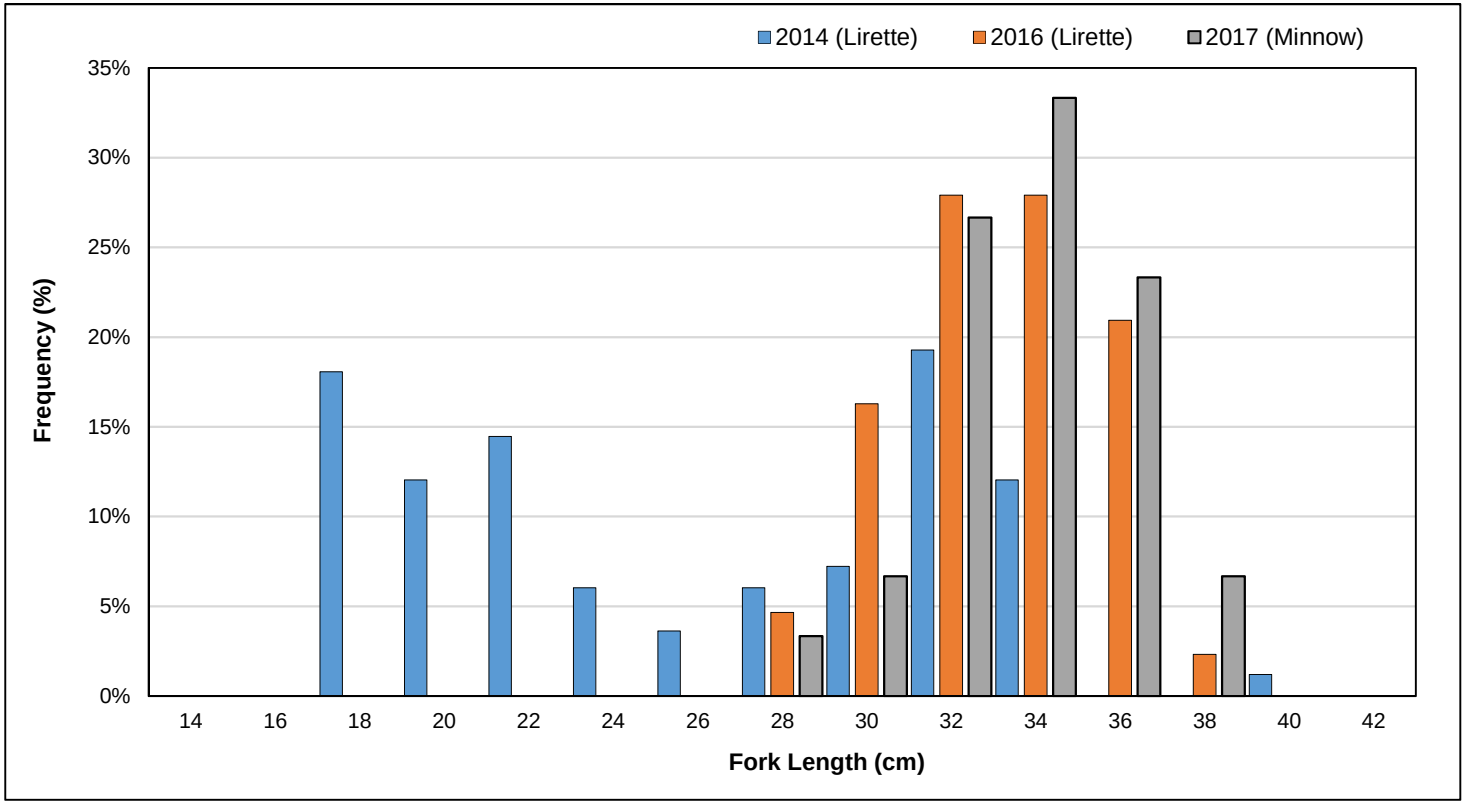

Figure 2: Rainbow trout fork length frequency distribution in Polley Lake (data from Lirette 2014 and 2016, and Minnow 2017a)

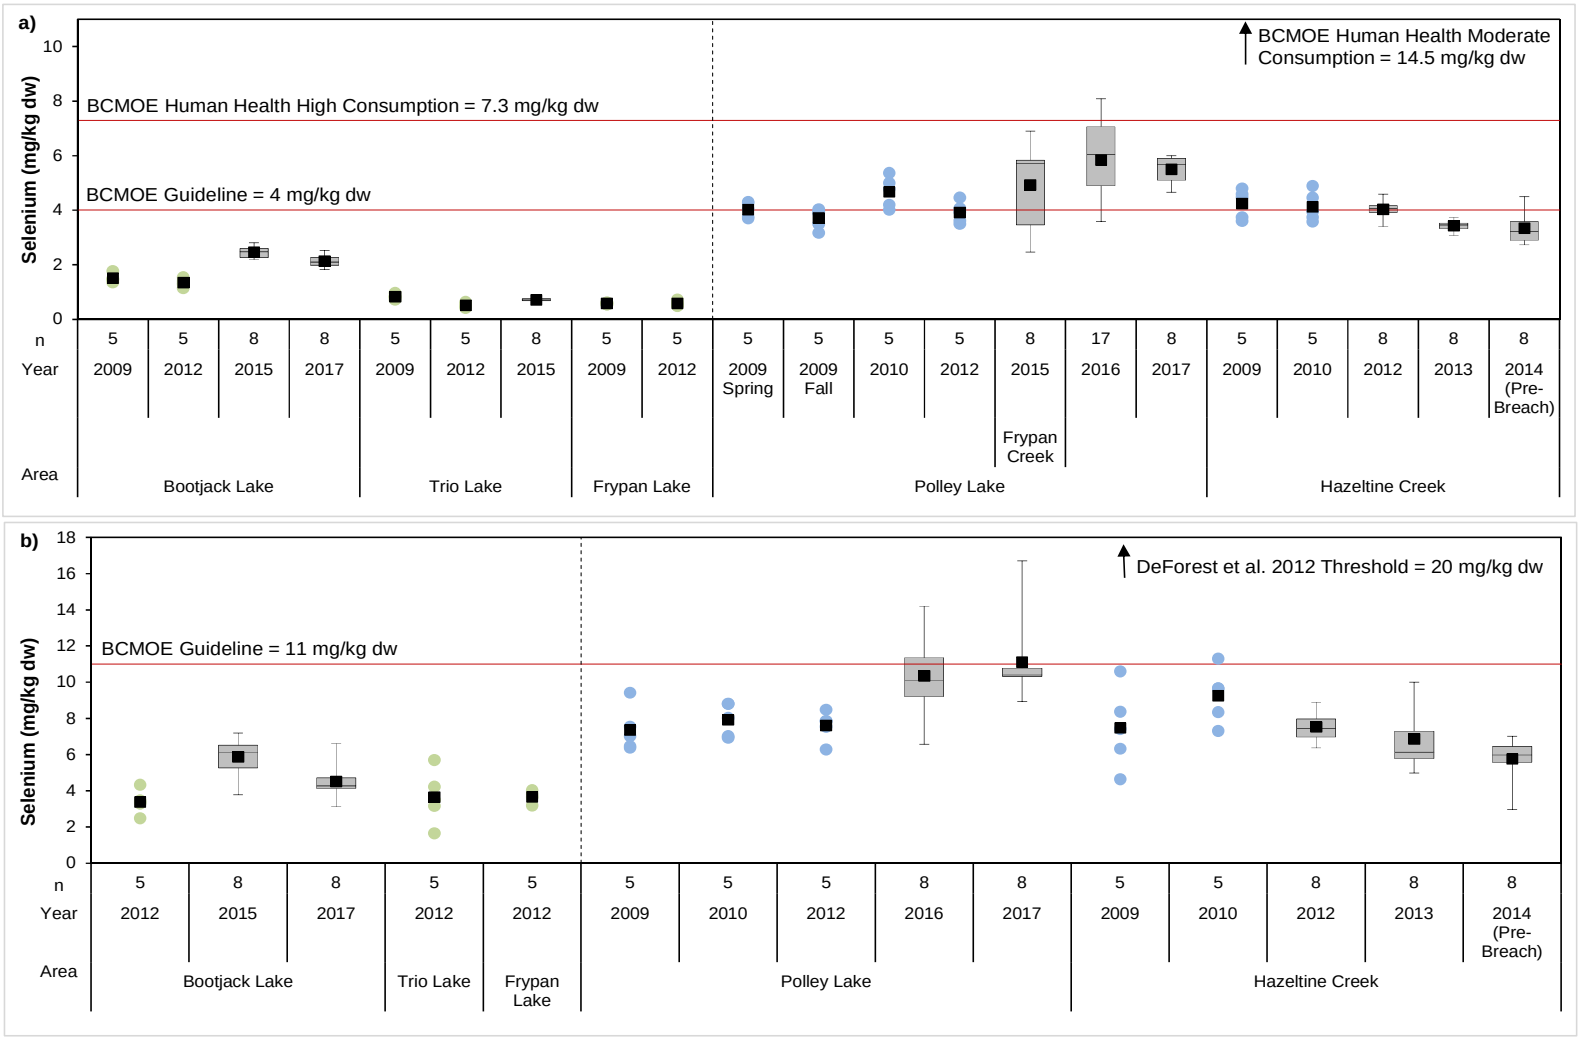

Figure 3: Selenium Concentrations in Rainbow Trout a) Muscle and b) Ovaries from Polley Lake, Hazeltine Creek, and Associated Reference Areas, Mount Polley, 2009 to 2017

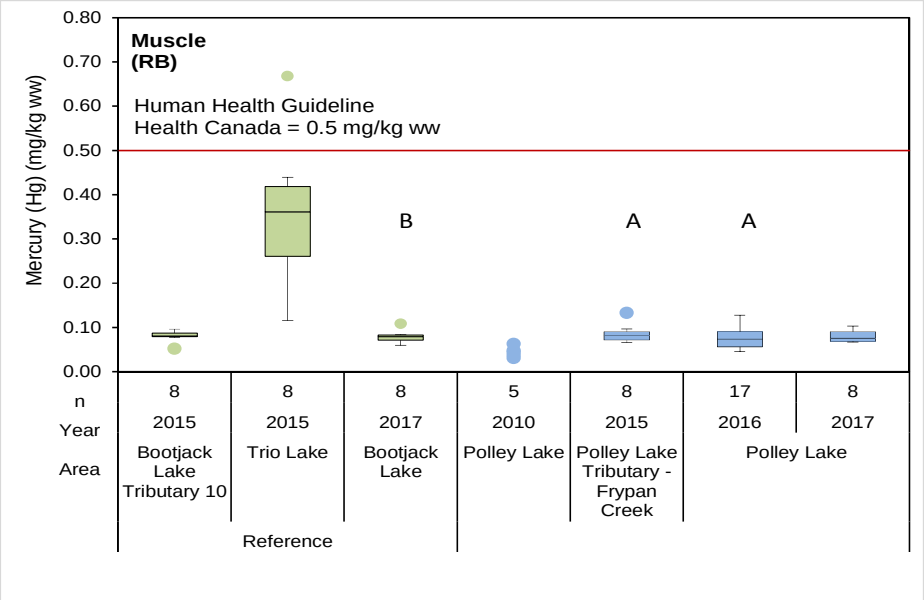
Notes: Dashed line used to separate reference (left side) and exposed (right side) areas. Black squares represent means and whiskers represent minimum and maximum values. Box plots are presented when there are 8 or more samples.



indicative of the influence of the TSF embankment breach on the receiving environment (arsenic, copper, iron [Minnow 2015], molybdenum, phosphorus, selenium [Golder 2015, 2016a]; and/or 2) had tissue quality guidelines (mercury and selenium). Concentrations of mercury and selenium in tissues of rainbow trout and longnose sucker collected in Polley Lake in 2015 to 2017 were lower than guidelines for the protection of human health (Figures 3 and 4), indicating that the fish can be safely consumed at consumption levels typical of the general population (Minnow 2017b, 2018a). Statistical contrasts of concentrations of the expanded suite of analytes in the tissues of Polley Lake fish relative to Bootjack Lake fish showed little agreement in terms of significant differences among species and/or tissues for almost all analytes, nor in the direction of differences when they were observed. This pattern indicates that, if there was any breach-related influence on Polley Lake fish tissue quality, it was minor. In Polley Lake, the only corroborated (reasonably unequivocal) differences were in selenium concentrations in the ovaries of Polley Lake rainbow trout, which were higher than reference and pre-breach in 2016 and 2017, potentially indicative of a breach-related influence (Minnow 2017b, 2018a). The same was not observed in longnose sucker; concentrations in longnose sucker tissues from Polley Lake (2017) were elevated relative to Bootjack Lake (2017), but were significantly lower than selenium concentrations in Polley Lake in 2010. For both species (rainbow trout and longnose sucker), selenium concentrations in ovary tissue were not at levels where adverse effects to fish would be expected (i.e., were not above the effect threshold).

2.2 Hazeltine Creek

2.2.1 Fish Community / Population

The fish community of Upper Hazeltine Creek has been dominated by juvenile rainbow trout during every sampling effort (Table 3). The fish community of Lower Hazeltine Creek (and Lower Edney Creek; both of which flow into Quesnel Lake) included bridgelip sucker, burbot, chinook salmon, coho salmon, kokanee, largescale sucker, longnose dace, longnose sucker, mountain whitefish, northern pikeminnow, peamouth chub, rainbow trout, and redside shiner (Table 3). Most of the fish species documented in Lower Hazeltine Creek or Lower Edney Creek in baseline (1989; Imperial Metals 1990) and in 2007 (Minnow 2009) were also observed in the rehabilitated section of Lower Edney Creek in 2016 and 2017 (Minnow 2018b).

The majority of rainbow trout collected in upper Hazeltine Creek and Edney Creek (79%; SNC-Lavalin 2015) have been young-of-the-year (YOY). In baseline, the density of rearing rainbow trout was 710 fish/100 m^2 and in lower Hazeltine Creek was 325 fish/100 m^2 (Imperial Metals 1990). By comparison, density in Bootjack Creek was 1,500 fish/100 m^2 (Imperial Metals 1990). Sampling in 1991 documented rainbow trout YOY density of 287 to 444 fish/100 m^2 in Hazeltine Creek compared to Bootjack Creek which had a density of 465 fish/100 m^2 (Bruce

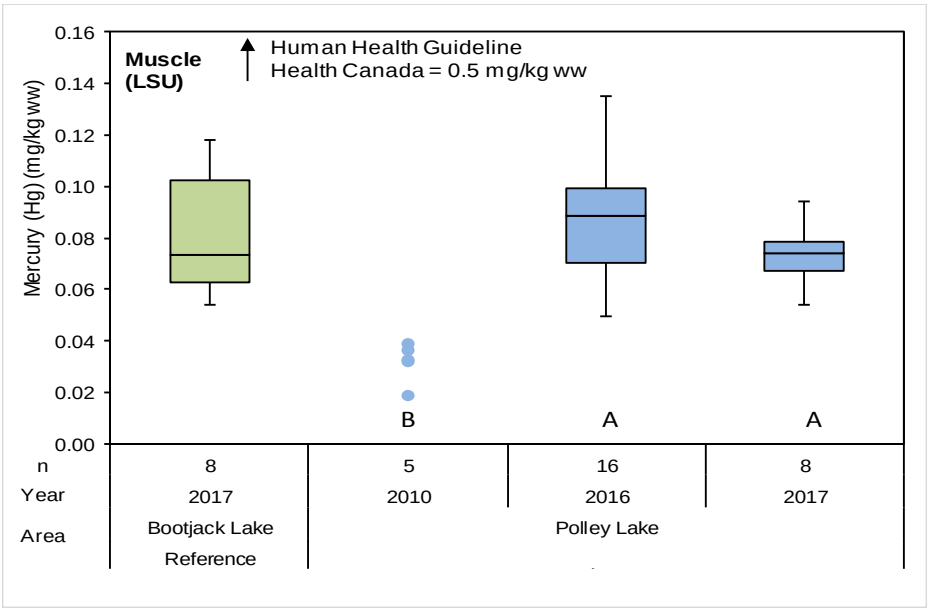


Figure 4: Mercury Concentrations (mg/kg ww) in Muscle Tissue of Fish from Polley Lake (2015 to 2017) Relative to Reference Areas (Bootjack Lake and Trio Lake; 2015 to 2017) and Pre-Breach (Polley Lake; 2010) [a,b,c]

[a] Concentrations in rainbow trout (RB) and longnose sucker (LSU) tissues from Polley Lake (2017) that differed significantly ($p<0.05$) from Bootjack Lake (2017) are denoted by an asterisk (*).

[b] Among-year comparisons were completed for Polley Lake only (2010, 2016 and 2017). The absence of letters (A,B,C) for 2010, 2016, and 2017 indicates no significant difference exists among years. Where significant differences were identified (family-wise $\alpha=0.05$), the years that were not significantly different from each other were assigned a common letter (A,B,C). The year with the greatest mean is assigned "A".

[c] Data summarized as boxplots when sample size was 8 or more; dot plots when sample size was 8 or fewer, or fewer than 8 results were detectable.

[b] Upper Edney Creek includes all stations on Upper Edney as well as two tributaries of Edney Creek
[c] Fry could not be identified to species level but suspected to include Coho, Chinook, and Sockeye

and Slaney 1991). In 2007, Upper Hazeltine Creek had a higher density of rainbow trout (400 to 700 fish/100 m^2) compared to the reference area, upper Edney Creek in 2007 (200 to 640 fish/100 m^2; Minnow 2009). Rainbow trout densities in Edney Creek varied considerably over time, with baseline densities of 169 fish/100 m^2 in 1996 and 17 fish/100 m^2 in 1997 (Minnow 2014b).

2.2.2 Fish Tissue Quality

Fish tissue quality evaluations have focussed on lake fish (see above). Adult rainbow trout have been collected from Hazeltine Creek for tissue quality characterization, and the associated data interpretation is integrated with the data for Polley Lake (above) as adult rainbow trout captured in Hazeltine Creek migrate into the creek to spawn.

2.3 Quesnel Lake

2.3.1 Fish Community / Population

The fish community of Quesnel Lake has been well characterized and includes a total of 20 species (Table 4). Prior to the TSF embankment breach, fish monitoring in Quesnel Lake was limited to collections for tissue quality analysis (2009, 2012, and 2014). These collections resulted in the capture of burbot, lake trout, largescale sucker, longnose sucker, mountain whitefish, peamouth chub, and rainbow trout (Table 5). Fish collections, primarily for tissue quality, have been undertaken annually since the TSF embankment breach in 2014, with community composition similar to that documented previously (Table 5). Additional collections for federal Environmental Effects Monitoring (EEM) were undertaken in 2016 (Minnow 2016).

The Mount Polley Phase 1 EEM included a population study of two sentinel species – northern pikeminnow and largescale sucker (with a supporting evaluation of peamouth chub; Minnow 2016). The objective of this monitoring was to determine if exposure to Mount Polley mine effluent (discharged to Quesnel Lake starting in December 2015) has an effect on the survival, growth, or reproduction of sentinel fish populations as compared to reference populations. Some differences in fish population endpoints (i.e., survival and energy use) were observed for northern pikeminnow, largescale sucker, and peamouth chub captured from effluent-exposed versus reference areas (Minnow 2016). However, there was no concordance between the results of comparisons of effluent-exposed populations to the two reference area populations (i.e., the metrics for effluent-exposed populations were often intermediate between the two references) nor among the three species. Overall, it was concluded that fish communities in the effluent-exposed and reference areas were similar and that effluent discharges from the mine were not affecting fish populations or fish health (Minnow 2016).

Table 4: Fish Species Documented in Quesnel Lake

Common Name	Latin Name
Sockeye Salmon	*Oncorhynchus nerka*
Coho Salmon	*Oncorhynchus kisutch*
Chinook Salmon	*Oncorhynchus tshawytscha*
Kokanee	*Oncorhynchus nerka*
Rainbow Trout	*Oncorhynchus mykiss*
Bull Trout	*Salvelinus confluentus*
Lake Trout	*Salvelinus namaycush*
Pygmy Whitefish	*Prosopium coulteri*
Mountain Whitefish	*Prosopium williamsoni*
Lake Whitefish	*Coregonus clupeaformis*
Burbot	*Lota lota*
Largescale Sucker	*Catostomus macrocheilus*
Longnose Sucker	*Catostomus catostomus*
Slimy Sculpin	*Cottus cognatus*
Northern Pikeminnow	*Ptychocheilus oregonensis*
Peamouth Chub	*Mylocheilus caurinus*
Leopard Dace	*Rhinichthys falcatus*
Longnose Dace	*Rhinichthys cataractae*
Redside Shiner	*Richardsonius balteatus*
Lake Chub	*Couesius plumbeus*

[a] Catch numbers are amount of fish retained for tissue analysis, more fish may have been collected, Golder 2016 Summary Report.
[b] Sample presented as longnose sucker but could possibly be largescale sucker.
[c] Potentially exposed.

2.3.2 Fish Tissue Quality

Tissue quality of Quesnel Lake fish was evaluated following the TSF embankment breach in 2014. This monitoring has included 12 fish species and variously included whole body, muscle tissue, liver tissue, Kidney tissue, and ovary tissue samples (Golder 2016; Minnow 2017b, 2018a). Fish tissue quality investigations were focussed on a suite of analytes that included metals that: 1) were identified as potentially indicative of the influence of the TSF embankment breach on the receiving environment (arsenic, cadmium, copper, iron, mercury, molybdenum, phosphorus, selenium, vanadium, and zinc; and/or or 2) had tissue quality guidelines (mercury and selenium).

Concentrations of mercury and selenium in tissues of fish collected in Quesnel Lake from 2015 to 2017 (burbot, kokanee, lake trout, largescale sucker, northern pikeminnow, peamouth chub, redside shiner) were lower than guidelines for the protection of human health in all cases except for mercury in large burbot and lake trout (Table 6; Minnow 2017b, 2018a). Large burbot and large lake trout (greater than approximately 66 cm in length [fork length and total length, respectively]) had mercury concentrations at levels where consumption limitation should be considered in accordance with provincial and federal guidance (e.g., BCMOE 2014; CFIA 2015). Smaller burbot and lake trout, as well as all other species can be safely consumed at consumption levels typical of the general population. There was no evidence that the Mount Polley Mine had any influence on mercury concentrations in burbot or lake trout. Rather, these species are piscivores (eat other fish) and are expected to have naturally higher concentrations of mercury (which is known to biomagnify). Concentrations of selenium in all fish species and tissues collected in Quesnel Lake were below BCWQGs for the protection of aquatic life.

In Quesnel Lake, uncertainty over fish movement between the exposed and reference areas and the absence of pre-breach datasets (of similar species) made interpretation of fish tissue quality results challenging. In Quesnel Lake, the only corroborated (reasonably unequivocal) differences in tissue metal concentrations of fish collected from exposed versus reference areas were higher concentrations of arsenic, cadmium, mercury, and selenium in tissues or whole bodies of northern pikeminnow and/or peamouth chub collected from exposed areas relative to reference areas. However, results of Environmental Effects Monitoring (EEM) undertaken in 2016 indicated that populations of northern pikeminnow and peamouth chub collected at the exposed area had very slightly (but not biologically meaningful) lower condition than reference fish (3.6% lower; Minnow 2016). Accordingly, the few corroborated differences in tissue metal concentrations were not associated with any adverse effect on the health of peamouth chub or northern pikeminnow. In 2017, no corroborated (reasonably unequivocal) temporal changes were identified for northern pikeminnow (whole bodies) collected from Quesnel Lake (relative to 2016; Minnow 2018a). This

Table 6: Comparison of Muscle and Whole Body Samples Collected in Quesnel Lake to Consumption Guidelines for Protection of Human Health or Guidelines for the Protection of Aquatic Life, MPMC, 2015 to 2017

Sample Collection Timing	Area	Species (Species Code)	Tissue	Sample Size	Mercury (Hg) mg/kg ww		Selenium (Se) mg/kg dw

Fall 2017	near Hazeltine Creek	Northern Pikeminnow (NSC)	Whole Body	8	-	-	-	-	-	2.3	0%

Note: ww = wet weight; dw = dry weight.

Indicates mean mercury concentration greater than Health Canada's Human Health concentration for muscle tissue in fish (0.5 mg/kg ww; CFIA 2015).

Indicates mean selenium concentration greater than the BCMOE Human Health guideline for moderate fish consumption (14.5 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than the BCMOE guideline for muscle tissue or whole body in fish (4 mg/kg dw; BCMOE 2014).

pattern indicates that, if there was any breach-related influence on Quesnel Lake fish tissue quality, it was minor.

2.4 Quesnel River

2.4.1 Fish Community / Population

Fish were sampled in the Quesnel River in 2014, 2015, and 2017, targeting rainbow trout, primarily by angling (Table 7). Other species were captured, including burbot, mountain whitefish, and peamouth chub (Table 7). Rainbow trout that were collected in the Quesnel River in 2017 were of similar age and size to those collected in 2015 (Minnow 2018a).

2.4.2 Fish Tissue Quality

Tissue quality of rainbow trout collected from the Quesnel River in 2015 and 2017 did not exceeded Health Canada's Human Health guideline for mercury (Minnow 2018a). In 2015, selenium concentrations in rainbow trout were below the BCMOE guideline for human health and for the protection of aquatic life, but in 2017, one sample exceeded these guidelines (Minnow 2018a). As observed in Quesnel Lake, no corroborated (reasonably unequivocal) temporal changes were identified for rainbow trout (muscle, liver, and kidney tissue) collected from the Quesnel River in 2017 (relative to 2015; Minnow 2018a).

Table 7: Summary of Fish Collected in Quesnel River, Mount Polley, 2014 to 2017

Area	Year	Report	Fishing Method	Burbot	Mountain Whitefish	Peamouth Chub	Rainbow Trout
Quesnel River	2014	Golder 2016	unknown	-	-	3	12
	2015	Zirnhelt and Dolighan 2015	angling	-	-	-	8
	2017	Minnow 2018a	angling	1	2	-	8

3 STUDY DESIGN OVERVIEW AND RATIONALE

Fish monitoring under the CEMP is designed to meet the combined needs of: 1) operational monitoring (including the discharge of treated effluent to Quesnel Lake); 2) monitoring of the impact of the 2014 TSF embankment breach; and 3) monitoring of the response to remediation following the TSF embankment breach. As previously indicated, fish monitoring includes fish tissue quality monitoring, sentinel fish population monitoring, fish habitat characterization and fish usage monitoring, and fish community monitoring. An overview of the proposed fish monitoring program is provided in Table 8 and Figures 5 and 6.

3.1 Fish Tissue Quality

Fish tissue quality monitoring is focused on Polley Lake and Quesnel Lake, with un-impacted reference areas identified for each mine-influenced sampling area (i.e., Bootjack Lake for Polley Lake, unaffected areas of Quesnel Lake for exposed areas of Quesnel Lake; Table 8; Figures 5 and 6). In Polley Lake, fish tissue quality monitoring is undertaken to monitor the combined influence of general mine proximity, uncontrolled surface runoff from the north dump (2006 to 2009), and influence of the TSF embankment breach. In Quesnel Lake and Quesnel River, fish tissue quality monitoring is undertaken to monitor the combined influence of the TSF embankment breach and the discharge of Mount Polley mine effluent (December 2015 to present). In Polley Lake (and reference), fish tissue quality monitoring will focus on rainbow trout and longnose sucker. Because selenium was elevated in the 2006 to 2009 surface runoff, this monitoring will be focussed on the collection of females in the spring so that ripe ovaries can be collected. The full complement of tissues to be collected will include muscle, liver, kidney, and ovary (Table 8). Scientific consensus is that the best tissues for evaluating the potential adverse effects of selenium to fish (which are considered to be the most selenium sensitive organisms) are ripe ovaries or eggs (Presser and Luoma 2009; Janz et al. 2010; DeForest et al. 2012; Janz 2012). Tissues will be collected for the analytical determination of moisture content, metals, and mercury (Section 4.3). Supporting data will include catch per unit effort, length, weight, and age (see below). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) concentrations relative to fish tissue quality guidelines for the protection of aquatic life and human health (BCMOE 2014; CFIA 2015). A sample size of eight fish per species per area will provide replication for the statistical contrasts. Fish tissue quality monitoring in Polley and Bootjack lakes will be undertaken at an annual monitoring frequency from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

Table 8: Mount Polley CEMP Fish Monitoring Plan Overview

A) Fish Tissue Quality Monitoring [1]

Water Body	Type	Fish Species	Tissues [2,3]	Replication	Frequency [4]	Rationale
Polley Lake	Exposed	RB, LSU	M,L,K,O	8	annual	immediately adjacent to mine and breach-influenced
Bootjack Lake	Reference	RB, LSU	M,L,K,O	8	annual	reference for Polley Lake [5]
Quesnel Lake	Exposed	RB, LT, KO, NSC, PCC	M,L,K,O	8	annual	adjacent to effluent discharge and breach-influenced
	Reference	RB, LT, KO, NSC, PCC	M,L,K,O	8	annual	reference for Quesnel Lake exposed
Quesnel River	Far-Field Exposed	RB	M,L,K,O	8	annual	far-field exposed area near Quesnel Lake outlet

[1] All fish tissues will be evaluated for the following analytes: percent moisture, metals by ICP-MS scan, and total mercury (Table 9).

[2] Fish tissues: M = muscle, L = liver, K = kidney, O = ovary (as available/developed; note that females will only be specifically targeted in Polley and Bootjack lakes).

[3] Except for small bodied fish (PCC and juvenile NSC), which will be submitted whole.

[4] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

[5] Bootjack Lake is retained as the reference for Polley Lake due to the fact that it has not been notably affected by the mine, there is a long-term dataset available for it, and its watershed includes similar geology to Polley lake. The latter is not true for other potential reference areas.

B) Fish Population Monitoring

Water Body	Type	Fish Species	Endpoints	Replication	Frequency [3]	Rationale
Polley Lake	Exposed	RB, LSU	L,W,C [1]	100	annual	immediately adjacent to mine and breach-influenced
Quesnel Lake	Exposed	NSC, RSC	Federal EEM [2]	20 / sex	every 3 years [4]	adjacent to effluent discharge and breach-influenced
	Reference	NSC, RSC	Federal EEM [2]	20 / sex		reference for Quesnel Lake exposed

[1] L = length-frequency distribution (indicative of recruitment and survival), W = weight, C = condition (indicative of overall health / energy storage).

[2] Fish population endpoints prescribed for federal EEM will be applied. These differ for lethal and non-lethal designs as described in Section 4.2.

[3] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

[4] Frequency prescribed for federal EEM.

C) Fish Habitat Characterization and Usage Monitoring

Water Body	Type	Fish Species	Measures	Frequency [5]	Rationale
Upper Hazeltine Creek	Impacted [1]	RB, LSU	Fish habitat characterization [3], fish occupancy and meristics [4]	annual	immediately adjacent to mine and breach-impacted
Lower Hazeltine Creek	Impacted [1]	all / any [2]		every 2 years	breach-impacted
Lower Edney Creek	Impacted [1]	all / any [2]		every 2 years	breach impacted

[1] Impacted by the TSF embankment breach.

[2] A total of 20 fish species have been documented in Quesnel Lake (SNC-Lavalin 2015) and would have access to Lower Hazeltine and Lower Edney creeks.

[3] Fish habitat characterization using methodology applied in 2016 and 2017 (Minnow 2018b), as adapted from Johnston and Slaney 1996.

[4] Fish occupancy as determined by observation (including spawning, and general presence) and by fishing with record of catch/effort and meristic measures (length and weight).

[5] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

D) Fish Community Monitoring

** qualitative fish community data will be collected to support all fish tissue, fish population, and fish habitat usage collections

Water Body	Collection Methods [1,2,3]	Endpoint	Frequency [6]	Rationale
Polley Lake	HN, MT, FT, SN, EF, GN	CPUE [5]	annual	to support fish tissue quality and population monitoring
Bootjack Lake	HN	CPUE [5]	annual	to support fish tissue quality and population monitoring
Quesnel Lake	HN, MT, FT, SN, GN	CPUE [5]	annual	to support fish tissue quality and population monitoring
Upper Hazeltine Creek	MT, FT, SN, EF [4]	CPUE [5]	annual	to support fish population and habitat usage monitoring
Lower Hazeltine Creek	MT, FT, SN, EF [4]	CPUE [5]	every 2 years	to support fish habitat usage monitoring
Lower Edney Creek	MT, FT, SN, EF [4]	CPUE [5]	every 2 years	to support fish habitat usage monitoring
Quesnel River	AG	CPUE [5]		to support fish tissue quality monitoring

[1] In order of preference for non-lethal fish collection methods whenever possible (e.g., hoop netting, minnow trapping, electrofishing).

[2] HN = hoop netting, MT = minnow trapping, FT = fry trapping, SN = seining, EF = electrofishing, GN = gill netting, AG = angling.

[3] Prohibited in waters over twenty degrees Celsius.

[4] Subject to electrofishing prohibition during spawning and incubation periods and in waters below five degrees Celsius.

[5] CPUE = catch per unit effort. For HN, MT, and FT, CPUE will be expressed as catch per unit deployment time; for SN, CPUE will be expressed as catch per unit area; for EF, CPUE will be expressed as catch per unit electroshocking time and per unit area; for GN, CPUE will be expressed as catch per unit net surface area-time; and for AG, CPUE will be expressed as catch per unit of angling effort.

[6] Monitoring frequencies applicable from 2018 to 2010 will be reviewed following data interpretation and modifications may be made in response to QP recommendations.

In Quesnel Lake (exposed and reference), fish tissue quality monitoring will focus on sentinel species. Sentinel species were selected on the basis of their trophic position, their status as sportfish or non-sportfish, their typical home range sizes, and the availability of historical tissue quality data. Rainbow trout (to be collected in the Quesnel River near the lake outlet; see below) and lake trout were selected as the sentinel sportfish species to monitor potential changes in tissue quality over time relative to human consumption of sportfish. In 2018, kokanee will also be monitored for this purpose (as there is a dataset from 2014 to which they can be compared). Northern pikeminnow and peamouth chub were selected as sentinel species with small home ranges to monitor potential changes in fish tissue quality associated with the TSF embankment breach and effluent discharge from the perspective of aquatic ecosystem health. Redside shiner may be used as an alternate sentinel species for this purpose depending upon future capture success. Fish species with small home ranges are better monitors of the potential effects of defined point sources (due to the fact that they are more continuously exposed) than fish with larger home ranges (e.g., Environment Canada 2012). The larger bodied fish will be subject to sampling the full complement of tissues, including muscle, liver, kidney, and ovary (Table 8). Ovary will only be sampled when available (i.e., when fully developed in mature females); additional fish will not be targeted and sacrificed to achieve the target sample size for ovary tissues (i.e., it is expected that ovary sample sizes will be less than eight). The small bodied fish (i.e., small northern pikeminnow, peamouth, and/or redside shiner) will be submitted as headless carcasses (as the heads will be submitted for otolith extraction and age determination). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; 2) statistical comparison to reference conditions; and 3) concentrations relative to fish tissue quality guidelines for the protection of aquatic life and human health (for selenium and mercury; BCMOE 2014; CFIA 2015). It is noted that comparison to reference conditions has previously proven to be challenging due to uncertainty over exposure given the large home ranges of the sportfish species and the apparent absence of a strong mine influence (Golder 2016; Minnow 2017b, 2018a). Thus, the greatest utility of fish tissue monitoring is as a temporal monitor and for comparison to available guidelines. A sample size of eight fish per species per area will provide replication for the statistical contrasts. Fish tissue quality monitoring in Quesnel Lake will be undertaken at an annual monitoring frequency from 2018 to 2020 (although, as previously noted, kokanee will only be collected in 2018), and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

In the Quesnel River, rainbow trout were selected as a sentinel sportfish species to monitor potential changes in tissue quality over time. Rainbow trout will be collected in the late summer and will be subject to sampling the full complement of tissues, including muscle, liver, kidney, and ovary (Table 8). As noted above, ovary will only be sampled when available (i.e., when fully

developed in mature females); additional fish will not be targeted and sacrificed to achieve the target sample size for ovary tissues (i.e., it is expected that ovary sample sizes will be less than eight). Data interpretation will be based on a combination of: 1) statistical comparison to previous conditions; and 2) concentrations relative to fish tissue quality guidelines for the protection of aquatic life and human health (BCMOE 2014; CFIA 2015). A sample size of eight fish per species per area will provide replication for the statistical contrasts. Fish tissue quality monitoring in the Quesnel River will be undertaken at an annual monitoring frequency from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

Fish community and population data will be collected to support all fish tissue quality monitoring (as discussed in greater detail below). All collections will be supported by capture records for all species and documentation of effort that will be used to calculate Catch-Per-Unit-Effort (CPUE). All fish selected for tissue quality will be subject to measurement of length, weight (total and fork), and the collection of structures for age determination. Detailed methodology for fish collection, measurement, tissue sample collection, tissue sample processing, sample handling and laboratory analysis, quality control/quality assurance, data quality review, data handling, interpretation, and reporting is provided in Section 4.

3.2 Sentinel Fish Populations

Fish population monitoring is focused on Polley Lake and Quesnel Lake (Table 8; Figures 5 and 6). In Polley Lake, population monitoring is focused on tracking the population structure of rainbow trout. Specifically, with the inaccessibility of Hazeltine Creek (the major spawning and juvenile rearing location for Polley Lake Fish) between August 2014 and spring 2018, recruitment of Polley Lake rainbow trout was substantially diminished for four years (i.e., juvenile fish in Hazeltine were eliminated with the breach in August 2014 and recruitment from Hazeltine was unavailable in 2015, 2016, and 2017). Following the re-opening of Upper Hazeltine Creek in spring 2018, Polley Lake rainbow trout will again have access to the major spawning and rearing habitat and fish population monitoring will document changes in population structure over time (i.e., recovery of age-class balance). Polley Lake fish population monitoring will be conducted by hoop netting in the spring and fall. This non-lethal technique has previously proven effective for the collection of adult rainbow trout, adult longnose sucker, and larger redside shiner. All captured fish will be identified and counted, and all captured rainbow trout will be measured (total length, fork length, and weight) to provide data that can be used to characterize size-frequency distributions indicative of recruitment and survival. In 2018 only, an additional gill netting effort will be completed in the fall using methodology identical to that applied in 2014 and 2016 (Lirette 2015, 2017). This effort will apply experimental gill nets to achieve a high level of comparability to the previous work. The same measurements as noted above will be collected.

As this technique is destructive (lethal), age structures will also be collected and will allow age-frequency distributions to be determined in addition to the size frequency distributions noted above. Summary rainbow trout population metrics (mean age, mean size, size-at-age, and condition [weight-at-length]) as well as community metrics (CPUE, relative species proportions, as discussed in greater detail below) will be calculated and compared between areas (Polley Lake and Bootjack Lake), and over time. A target sample size of 50 (100 preferred) will provide replication for statistical contrasts. Data collected by the two different techniques in 2018 (hoop netting and gill netting) will be compared to determine if the non-destructive technique adequately addresses key questions, in which case future destructive sampling will be considered unnecessary. Fish population monitoring in Polley Lake will be undertaken at an annual monitoring frequency from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

Additional fishing efforts in Polley Lake shoreline areas will be undertaken to monitor the presence and abundance of juvenile rainbow trout. This will serve to monitor the recovery of rainbow trout in Polley Lake and to specifically augment the monitoring of juvenile trout recruitment determined for Upper Hazeltine Creek (as discussed in more detail in Section 3.3 below). Juvenile rainbow trout will be collected from shoreline areas in Polley Lake by minnow trapping, fry trapping, and backpack electrofishing. All captured fish will be identified, recorded, measured (fork length, total length, and weight) and released. Endpoints of CPUE, mean length, mean weight, size-frequency distributions, and condition will be calculated and monitored for comparison over time. Monitoring of juvenile rainbow trout in Polley Lake will be undertaken annually in the fall from 2018 to 2020, and the annual frequency will re-evaluated prior to 2021 based on QP recommendations.

In Quesnel Lake, populations of sentinel fish species (northern pikeminnow and redside shiner) will be monitored to evaluate potential effects associated with Mount Polley mine effluent discharge in accordance with requirements for EEM under the MDMER of the federal *Fisheries Act* (Environment Canada 2012; Government of Canada 2018). The fish population survey will be undertaken using prescribed methodology (Environment Canada 2012) and as described in detail in the Study Design report for the Phase 2 EEM (Minnow 2018c). Briefly, sentinel fish population monitoring in Quesnel Lake will evaluate population health (survival, growth, reproduction, and condition) of the two sentinel species. The study will be completed as a conventional (lethal) design (Environment Canada 2012) and will target 20 mature males and 20 mature females of each of the two sentinel species at the exposed area (near the Mount Polley effluent discharge) and at a reference area (Table 8; Figure 5). Fish collections will be completed by hoop netting and gill netting, and all fish measurements will be completed as prescribed by Environment Canada (2012) and as described in detail in Section 4.2. Quesnel Lake fish population monitoring will be completed in early spring when the sentinel species are fully

developed prior to spawning (McPhail 2007; Barrett and Munkittrick 2010). Northern pikeminnow typically spawn in the spring at a threshold temperature of 12 °C and redside shiner typically spawn in the spring at a threshold temperature of 10 °C (McPhail 2007). Both species typically spawn in flowing water over clean gravel substrates, but can also spawn in lakes. Sentinel fish species (up to the target sample size) will be subject to sacrifice and collection of the following measures prescribed for EEM: fork length, total length, weight, liver weight, gonad weight, and fecundity (Environment Canada 2012). Sentinel fish population endpoints (survival, growth, and reproduction) will be calculated for each species-area combination and statistically contrasted between effluent-exposed and reference areas as prescribed under EEM (Environment Canada 2012) and described in Section 4. Fish population monitoring in Quesnel Lake will be undertaken at the prescribed frequency of once every three years, with next collection in the spring of 2019. As outlined in EEM technical guidance, future frequency can change is response to findings. Detailed methodology for fish collection, measurement, tissue sample measurement, sample handling and laboratory analysis, quality control/quality assurance, data quality review, data handling, interpretation, and reporting is provided in Section 4.

3.3 Fish Habitat Characterization and Usage

Fish habitat characterization and usage monitoring is focused on Hazeltine Creek and lower Edney Creek, both of which were physically impacted by the TSF embankment breach (Table 8; Figure 6). Fish habitat characterization will monitor key characteristics of rehabilitated Hazeltine and Edney creek habitat in order to document recovery. Fish habitat usage monitoring will document the use of these rehabilitated creek habitats by all fish species and life stages, including the specific documentation of spawning and rearing in spring, summer, and fall months (May to October). Fish habitat characterization methods will be similar to those previously applied (Minnow 2018b) which are adapted from Johnston and Slaney (1996) and described in detail in Section 4.2. Fish habitat will be characterized in spring, summer, and fall in relation to the needs of fish that could potentially use the habitat (i.e., Polley Lake fish in the case of Upper Hazeltine Creek and Quesnel Lake fish in the case of Lower Hazeltine creek and Lower Edney Creek), and will include documentation of in-stream barriers and cover, spawning and overwintering habitat, riparian features, channel hydrology, bank condition, and water quality parameters. Fish habitat usage will be determined by a combination of visual observation and fish collection with measurement. Fish habitat usage monitoring will commence in the spring (May) once fish have begun to aggregate for spawning, and will be conducted again in the summer (August), and in the fall (September / October, including when fish are spawning). Fish collections will be completed using hoop netting, minnow trapping, fry trapping, seining, and backpack electrofishing (the latter only when appropriate based on non-spawning/egg incubation periods and when juvenile salmonids are not present). All captured fish will be identified and enumerated, and

fishing efforts will be documented for CPUE or density calculations (see following section). Up to 100 individuals from each collected species will be temporarily retained for length and weight measurements, which will be used to calculate summary statistics of length, weight, condition, and size-frequency distributions that will be monitored over time to document recovery. Fish habitat characterization and fish usage monitoring in lower Hazeltine Creek and lower Edney Creek will be undertaken at frequency of every two years starting in 2019[4], and the frequency will re-evaluated prior to 2021 based on QP recommendations. Detailed methodology for fish collection, fish measurement, quality control/quality assurance, data quality review, data handling, interpretation, and reporting is provided in Section 4.

For Upper Hazeltine Creek, fish collection will also include closed-station electrofishing that will provide the best possible estimate of the density of rearing rainbow trout (using removal calculators as outlined in Section 4). Fish capture data will be utilized to document the production of rainbow trout and any temporal changes therein including comparison to historical estimates (e.g., Minnow 2009). Fish meristic data will be used to calculate summary statistics of length, weight, condition, and size-frequency distributions that will also be compared to historical results (e.g., Minnow 2009). Fish habitat characterization and fish usage monitoring in upper Hazeltine Creek will be undertaken at an annual frequency from 2018 to 2020, and the frequency will re-evaluated prior to 2021 based on QP recommendations. Detailed methodology is provided in Section 4.

3.4 Fish Community

Fish community monitoring is a supporting measure to be determined in association with all fish collections (i.e., fish tissue quality monitoring, fish population monitoring, and fish habitat usage monitoring). Fish community monitoring effort will only be as required to collect the fish needed for these other purposes. Thus, the locations, timing, and frequency of fish community monitoring will be as outlined above (Sections 3.1 to 3.3, inclusive). In association with each fishing effort, all captured fish will be identified and counted. Details of each fishing effort (GPS coordinates, gear type and dimensions, and actual fishing time) will be recorded to provide the most quantitative record of fish community results possible. Specifically, the effort details will be collected to support the expression of CPUE on the basis of time (catch per time), area (catch per area), or the combination of gear-dimension and time (e.g., catch per 100 m net-hour). Interpretation of CPUE data will be based on a combination of: 1) comparison to previous conditions; 2) comparison to reference conditions; and 3) comparison of species proportions temporally and spatially (e.g., has the relative abundance rainbow trout versus longnose sucker

[4] Note that fish habitat characterization and usage monitoring in lower Hazeltine Creek will only be initiated after lower Hazeltine Creek is opened up as fish habitat (i.e., ponds and/or fish fences are removed).

changed over time and/or relative to the reference lake). Detailed methodology for fish collection, quality control/quality assurance, data quality review, data handling, data interpretation, and reporting is provided in Section 4.

4 METHODOLOGY

4.1 Quality Assurance / Quality Control

All sampling will be performed by qualified field staff experienced in the implementation of fish and fish habitat monitoring programs. Quality Assurance/Quality Control (QA/QC) measures will be consistent with requirements outlined in the BC Field Sampling Manual (BCMOE 2013) and the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016). Specific QA/QC measures will include program review prior implementation, adequate resources for all field teams including field checklists and field data sheets, the availability and maintenance of appropriate sampling equipment and sampling containers, and sampling in a manner that minimizes any risk of sample contamination (i.e., for tissue quality samples).

To capture within-area variability and support the tissue quality component of the fish monitoring program, eight replicate tissue chemistry samples will be collected from each sampling area. Fish tissue samples will include muscle, liver, kidney, and ovary tissues (or whole body analysis for smaller fish). Field duplicates (i.e., split samples collected from the same fish tissue) will be collected at a frequency of 10% of the total number of tissue samples to assess field precision, and will be evenly distributed among species and tissue types, to the extent possible. A Data Quality Objective (DQO) of <25% RPD will be applied to the duplicate (i.e., split) QC samples.

All chemical analyses will be completed by a laboratory that is accredited by the Canadian Association for Laboratory Accreditation (CALA), and will be required to include specific QC samples and report associated results. Specific QC samples will include laboratory blanks, laboratory replicates, and laboratory accuracy samples (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). The QC sample results will be assessed as part of the Data Quality Review (DQR; Section 4.4). Laboratory reporting Limits (LRLs) will also be evaluated in comparison to targets established by the analytical laboratory.

Raw field data recorded on field sheets will be transcribed into an electronic spreadsheet and data collected using digital data collection devices will be exported from a geodatabase to electronic spreadsheets. Electronic spreadsheets will be checked by a separate individual for entry errors as part of routine QA/QC procedures.

4.2 Sample Collection Methods

4.2.1 Fish Collection

All fish monitoring will be undertaken under fish collection permits from the British Columbia Ministry of Forests, Lands and Natural Resource Operations (FNLNRO) and all fish monitoring in

waters frequented by salmon (e.g., Quesnel Lake and Quesnel River) will also be undertaken under fish collection permits from Fisheries and Oceans Canada (DFO). All conditions associated with the fish collection permits will be strictly adhered to (including the general prohibition of fishing in waters with temperatures >20°C).

Fish collections will be completed in accordance with applicable technical guidance outlined in the BC Field Sampling Manual (BCMOE 2013), the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016), and/or the Technical Guidance Document for EEM (Environment Canada 2012). A variety of fish collection techniques will be applied to collecting the fish required for the monitoring of fish tissue quality, fish populations, and habitat usage. To the extent possible, preference will be for non-destructive fish collection methods (e.g., hoop nets, minnow traps, fry traps, backpack electrofishing) in order to minimize the potential impact of fish monitoring on fish populations and/or communities. The following fish collection techniques will be used to support the CEMP fish monitoring plan:

- hoop netting;
- gill netting;
- minnow trapping;
- fry trapping;
- seining; and
- backpack electrofishing.

Hoop netting will be applied to the collection of large-bodied fish in lakes as the preferred collection method due to the fact that it is a non-lethal method. Hoop nets ranging in size from 0.6 m diameter, 2 cm stretched mesh to 0.75 m diameter, 3.8 cm stretched mesh with four to eight hoops and leads of approximately 30.5 m in length will be set as appropriate to target the fish required for tissue quality monitoring and fish population monitoring, and will be checked at a minimum frequency of every other day (although daily checks will be most common). The location of each net set will be recorded using a handheld GPS accompanied by notes on the set configuration (depth, lead to shore, trap to shore, etc.) and the time of deployment. Upon collection, the time of collection will be recorded and fish will be identified and counted as they are removed from the trap. Target species will be identified, counted, and then retained or measured (depending on the objective of the monitoring component). Non-target species will be identified, counted, and released at the location of capture. Individuals of the target fish species will be measured as outlined in Sections 4.2.2 and 4.2.3, per requirements of the particular monitoring component of the CEMP Fish Monitoring Plan.

Gill nets will be used as required to support hoop netting for fish tissue collection in lakes, as required, with application minimized and short deployment duration. Gill netting will also be applied in Polley Lake in late summer 2018 as a repeat of previous efforts (Lirette 2015, 2017). As required, gill nets will be set in lakes to collect large-bodied fish, consistent with historical sampling (e.g., Minnow 2018a) and recommendations from the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016). Net size and deployment configuration will be as required to most effectively capture target fish. For example, lake trout will be targeted in Quesnel Lake using a Profundal Index Netting methodology similar to the Summer Profundal Index Netting (SPIN) method (e.g., Jessup and Millar 2011). Fall 2018 gill netting in Polley Lake will employ experimental gill nets (two multi-panel gill nets of mesh size 38, 64, 38, and 89 mm), which will be set overnight. The nets will be set perpendicular to shore, with the smallest mesh orientated closest to shore. Set locations and configurations will be similar to those used in 2014 and 2016 (Lirette 2015, 2017). The location of each gill net set will be recorded using a handheld GPS accompanied by notes on the set configuration and the time of deployment. Check and retrieval times will be recorded and fish will be identified and counted as they are removed from the net. For experimental nets, fish counts will be recorded for each gill net panel. Non-target species will be identified, counted, and released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Minnow traps (galvanized mesh – 42 cm length, 0.6 cm mesh, 2.5 cm diameter opening) will be set in lakes and creeks to capture small-bodied fish and juveniles. Juvenile rainbow trout (1+ or 2+ rainbow trout) will be targeted in Polley Lake. Minnow traps will be baited and will be tied off on shore or set on the substrate and marked with a float. Minnow traps set in creeks will be set so that the openings will be oriented upstream and downstream. Minnow traps will be checked at a minimum frequency of every other day (although daily checks will be most common). The location of each trap will be recorded using a handheld GPS accompanied by notes on the set configuration and the time of deployment. The retrieval time will be recorded and fish will be identified and counted as they are removed from the trap. Non-target species will be enumerated by species and released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Fry traps will be set in selected lakes and creeks (Polley Lake, Hazeltine Creek, Edney Creek, and Frypan Creek) to augment minnow trap catches. Traps will be placed in habitat deemed suitable for juveniles (e.g., in slow flowing water near undercut banks, behind woody debris) and oriented with the closed end angled upstream. Traps will be weighed down on the streambed using small stones and will be checked daily. The location of each trap will be recorded using a

handheld GPS accompanied by notes on the set configuration and the time of deployment. Fry traps will be checked at a minimum frequency of every other day (although daily checks will be most common). The retrieval time will be recorded and fish will be identified and counted as they are removed from the trap. Non-target species will be enumerated by species and released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Seining may also be completed in lakes and creeks to augment catches by other techniques. A 15 m long seine with a 0.3 mm mesh size will be used. The seine net will be pulled through shallow habitats by wading through the sampling area; in deeper areas, a boat may be used to pull one end of the seine (BCMOE 2013). Care will be taken to ensure that the lead line remains in contact with the substrate and the float-line remains at the surface to prevent fish from escaping. The contents of the seine will be brought to shore, and depending catch numbers, may be emptied into a water-filled tote and the seine will be inspected to confirm that all fish are removed. The location of each effort will be recorded using a handheld GPS accompanied by notes regarding habitat features and the area and maximum depth sampled. The date and time will be recorded and fish will be enumerated by species. Non-target species will be released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Open-station and/or closed-station backpack electrofishing will be completed in Polley Lake (along the shoreline) and in creeks. All electrofishing will be completed by an experienced and certified electrofishing team, consisting of a backpack electrofisher operator and one or more netters using electrofisher settings appropriate for the target species (i.e., frequencies and pulse width) and starting with lowest possible power output (voltage and duty cycle). Open stations will be fished by single electrofishing pass in an upstream direction. During open-station electrofishing, the operator will create a series of smooth, zig-zagging sweeps with the anode. Fish will follow the anode; therefore, the operator will move the anode towards the netter, who will net the stunned fish. Closed stations will be created using 3/8” mesh stop nets and care will be taken to ensure that the enclosed habitat is suitable for the potential presence of target fish. The dimensions (length and wetted and bankfull widths) and water depth (average of three measures) of each open and closed station will be measured at equally-spaced transects using a measuring tape and meter stick, respectively. During each closed station electrofishing effort, the electrofisher operator and netter will employ a multiple pass removal method at each station whereby one upstream pass (or “sweep”) of the enclosed reach is repeated three or more times to yield a fish removal pattern (i.e., diminishing catches) that can be used to determine fish density

using removal method equations. Fish captured during each open electrofishing pass or closed station sweep will be placed in separate buckets of aerated water. The location of each effort will be recorded using a handheld GPS accompanied by the start and end times and active electrofishing seconds. The total sampling area will be documented, along with a habitat descriptions that include observations of stream morphology and substrate characteristics, riparian vegetation and relative stream shading, as well as any potential confounding influences or other observations deemed relevant to interpretation of the fish survey data. The fish in each bucket will be enumerated by species. Non-target species will then be released at the location of capture. Depending on the objective of the monitoring component, individual fish of the target species will be measured immediately or retained for measurement as outlined in Sections 4.2.2 and 4.2.3.

Fish will be captured from the Quesnel River by angling (targeting rainbow trout for fish tissue quality monitoring). Angling will be conducted using barbless, single hook lures, and/or flies. The general location of each effort will be recorded using a handheld GPS accompanied by notes on the hooks/lures/flies used, effort duration, and habitat. Captured fish will be identified and counted. Non-target species will be released at the location of capture and target species will be retained or measured. Retained rainbow trout will be measured as outlined in Sections 4.2.2 and 4.2.3, per requirements of the particular monitoring.

All fishing effort data will be recorded on field sheets or digital data collection devices. *In situ* water quality measurements (i.e., temperature, pH, dissolved oxygen, conductivity, and specific conductance) will also be recorded to support fishing efforts.

4.2.2 Fish meristic data

Meristic measurements on fish that will not be retained for lethal sampling will be recorded prior to releasing the fish at their point of capture. Fish retained for lethal sampling will be anesthetized using a clove oil solution or will be euthanized with a decisive blow to the head and spinal severance. Fish will be subjected to measurement of fork length, total length, and body weight (BCMOE 2013). Fork and total length of large-bodied fish will be measured to the nearest millimeter using a measuring board and fork and total length of small-bodied fish will be measured to the nearest 0.1 mm using digital calipers. Fresh body weight will be measured using an analytical balance or a set of Pesola™ spring scales (depending on fish weight). The Pesola™ scales are demarcated at intervals of 1 to 2% of the total scale range, providing an accuracy of plus or minus (±) 0.3% of the fish mass. The Pesola™ spring scale for individual weight measurement will be selected so that the fish weight is near the top of the scale's range to ensure that measurements achieve a resolution near 1%. Northern pikeminnow and redside shiner that will be lethally sampled as part of MDMER/EEM will also undergo an external health assessment

(Environment Canada 2012). Following external health assessment, each fish will be cut open and sex will be recorded. Gonads and liver will be removed for weighing and sampling as required. Tissues will be weighed to the nearest milligram using a portable analytical balance (capable of measurement to 0.001 g). For EEM, whole ovaries from sexually mature females will be placed in individually labelled sample vials and preserved with a 10% buffered formalin solution for determination of fecundity.

Age structures will be retained for all fish collected for fish tissue quality monitoring using available guidance for the best age structure for each species (e.g., Environment Canada 2012). Otoliths will be removed and used as the primary aging structure for all fish species except for sucker. Pectoral fin rays will be removed and used as the primary aging structure for sucker. Scales will also be collected for use as backup structures for age determination. Aging structures will be wrapped in waxed paper, and placed in labelled coin envelopes, which will then be frozen prior to submission to a qualified fish aging laboratory.

4.2.3 Fish Tissue Quality

For large-bodied fish targeted for tissue quality monitoring, tissue quality samples will be collected after meristic measures are collected and will include muscle, liver, kidney, and ovary (the latter as available). For small-bodied fish targeted for tissue quality monitoring (i.e., juvenile northern pikeminnow and peamouth chub), whole body samples will be analyzed for tissue chemistry. Tissue samples (muscle, liver, kidney, and/or ovary) will be removed, weighed to the nearest 0.001 g (±1% precision) using an analytical balance, placed in labelled Whirl-Pak™ bags, and frozen until analysis. All tissue samples will be collected using clean implements (cutting boards, filet knives, and tweezers; BCMOE 2016). Livers and kidneys will be collected whole, whereas approximately 10 to 50 g of boneless, skinless muscle will be collected, and a similar sized ovary sub-sample will be collected when available (or will be collected whole if smaller than this). Duplicate QC samples (i.e., split samples collected from the same fish tissue) will be collected for 10% of tissue samples to assess field precision, and will be evenly distributed among species and collected tissue types, to the extent possible. A DQO of <25% RPD will be applied to the duplicate (i.e., split) QC samples.

4.2.4 Fish Habitat Characterization and Usage

Habitat characterization methods will include those applied in 2016 and 2017 (Minnow 2018b; adapted from Johnston and Slaney 1996). Data will be recorded on field data sheets or using digital data collection devices. The following characteristics will be documented:

- stream dimensions (i.e., wetted and bankfull width, length, and depth) within each habitat unit;

- channel gradient;
- substrate type;
- in-stream barriers and cover;
- the presence/absence of spawning and overwintering habitat;
- riparian features (e.g., vegetation types and canopy cover);
- channel hydrology;
- bank condition; and
- *in situ* water quality.

Habitat characterization methods will be a composite of two standard methods: 1) Reconnaissance Fish Habitat Inventory (RIC 2001); and 2) Level 1 Field Fish Habitat Assessment ("Habitat Unit Assessment"; Johnston and Slaney 1996). Habitat characterization using methods adapted from RIC (2001) will be completed at replicate stations (three per area) and will include include measures of channel dimensions, water velocity, and in situ water quality at each station. Channel dimensions (bankfull width, wetted width, and a minimum of 5 incremental wetted depth measures), will be measured using a tape measure and metre stick. Water velocity will be measured using a portable velocity meter. At each velocity transect, water velocity, wetted depth, and bankfull-wetted depth will be measured at a minimum of five incremental distances (points) along one wetted channel cross-sectional width. Water velocity measurements will be obtained at 60 percent of depth as an estimate of the mean vertical velocity at each measurement point. In situ water quality measures will include temperature, specific conductance, dissolved oxygen, and pH using a calibrated handheld portable field meter. Additional habitat characteristics to be assessed at each station will include description of channel bed features (substrate type, relative proportion of each substrate type, etc.), channel and bank gradient, substrate size, bank stability, riparian vegetation (vegetation types, overhead shading), and in-stream cover (as the relative proportion that each contributed to total creek surface area at each station). Substrate size will be assessed (100 randomly selected rocks per station) for the purpose of monitoring temporal changes in substrate size distribution. Photographs of representative habitat will be taken at each station in each season to further support the habitat descriptions. During each seasonal survey, any unique or significant physical or biological features (e.g., tributaries, groundwater seeps, partial or seasonal fish barriers to fish migration) will be documented, including a brief description of the feature, together with its GPS coordinates. In addition, the GPS coordinates of pools present in the rehabilitated and reference reaches, and physical dimensions of the pools (length, width, and maximum depth) will be recorded.

Habitat assessment using Level 1 Field Fish Habitat Assessment methods ("Habitat Unit Assessment"; Johnston and Slaney 1996) will also be undertaken. At least seven consecutive habitat units (i.e., pool, glide, or riffle) will be identified towards the center of each reach and the dimensions of each habitat unit will be recorded. Specifically, the length, mean width (wetted and bankfull; mean of at least 3 measures), and mean depth (wetted and bankfull; mean of at least 5 measures) will be determined for each habitat unit using a tape measure and meter stick. For pools, the maximum and residual (maximum minus crest depth) wetted depth will also be measured, as well as pool type. A minimum residual depth of 0.2 m is required for classification of a habitat unit as a pool (Johnston and Slaney 1996). Additional habitat characteristics assessed at each habitat unit will include included channel gradient, substrate type, riparian vegetation (vegetation types, growth stage, and canopy cover), in-stream cover, access to off-channel habitat, the number of pieces of large woody debris (LWD) present, and indicators of disturbance.

Fish habitat usage monitoring will document the use of these rehabilitated creek habitats by all fish species and life stages, including the specific documentation of spawning and rearing in spring, summer, and fall months (May to October). Fish habitat usage will be determined by a combination of visual observation and fish collection using techniques described above (hoop netting, minnow trapping, fry trapping, seining, and backpack electrofishing; the latter only when appropriate based on non-spawning/egg incubation periods and when juvenile salmonids are not present). All captured fish will be identified and enumerated, and fishing efforts will be documented for CPUE or density calculations (as described above). Any observations of specific behaviours (e.g., spawning) will be noted.

4.3 Sample Handling and Laboratory analysis

To the extent possible, sample handling and laboratory analyses will be completed in accordance with technical guidance outlined in the BC Field Sampling Manual (BCMOE 2013), the Water and Air Baseline Guidance Document for Mine Proponents and Operators (BCMOE 2016), the Technical Guidance Document for EEM (Environment Canada 2012), and the BC Environmental Laboratory Manual (BCMOE 2015).

At the termination of each field program or at intervals of no more than seven days, fish tissue samples will be shipped in coolers with ice packs and chain-of-custody forms (COCs) to the analytical laboratory. Shipment transit time will be less than one day. Chemical analyses will be completed by a CALA-accredited analytical laboratory and will include moisture content and total metal concentrations (Table 9). Concentrations of mercury and other metals will be analyzed using Cold Vapour Atomic Fluorescence Spectrophotometry (CVAFS; USEPA [United States Environmental Protection Agency] Method 200.3/245.7) and Collision Cell Inductively Coupled

Table 9: Analytes and Laboratory Reporting Limits for Mount Polley CEMP Fish Tissue Quality Monitoring

[3] Health Canada guideline for mercury (CFIA 2015).

[4] British Columbia Water Quality Guideline for aquatic life for selenium in fish ovary tissue (BCMOE 2014). Additional guidelines for the protection of aquatic life of 4 mg/dw in fish muscle or whole fish and for the protection of human health at moderate consumption levels (14.5 mg/kg dw for the general population) will also be applied.

Plasma-Mass Spectrometry (CRC-ICP-MS; USEPA Method 200.3/6020A) or High Resolution Inductively Coupled Plasma-Mass Spectrometry (HR-ICP-MS; USEPA Method 200.3/200.8), respectively (USEPA 1991, 1994, 2001, 2004). All samples will be submitted to the laboratory with a chain-of-custody (COC) record, a list of expected Laboratory Reporting Limits (LRLs), and laboratory QA/QC requirements.

Aging structures will be shipped to a qualified fish ageing laboratory, along with a chain-of-custody form (COC), for determination of fish ages. At the fish aging laboratory, samples will be thawed, otoliths extracted from heads if required, and the otoliths and fin rays will be sectioned, mounted on a glass slide using a mounting medium, and then read under a compound microscope using transmitted light. For each structure, age and edge condition will be recorded along with a confidence rating for the age determination. Scales collected as backup structures will only be used as required. Similarly, preserved egg samples will be shipped to a qualified laboratory, along with a chain-of-custody form (COC), for determination of fecundity. Methods for determining fish age and fecundity will be fully consistent with the technical guidance (Environment Canada 2012).

4.4 Data Quality Review

Upon receipt of fish tissue quality data from the analytical laboratory, a Data Quality Review (DQR) will be performed. The DQR will confirm that all requested analyses are complete, and that acceptable LRLs are achieved. The DQR will also include an evaluation of differences between duplicate (i.e., split) samples, as well as the QA/QC data reported by the laboratory. Completion of the DQR promptly following receipt of the tissue quality data will ensure timely communication with the laboratory should any issues be identified.

Comparisons between duplicate samples will be made by calculating the RPD for concentrations measured in paired samples. If the RPD is <25% for concentrations that are >5 times the LRL, then the duplicate sample results will be considered acceptable. Analyte concentrations in laboratory blank samples will be evaluated in relation to their respective LRLs, and the results will be used to identify potential contamination associated with equipment (e.g., cleanliness) and sample collection and handling procedures (e.g., collection, shipping).

4.5 Data Handling, Interpretation, and Reporting

Catch-per-unit-effort (CPUE) and summary statistics for meristic measurements taken in the field will be calculated. CPUE will be calculated for each fish species by fishing method and sampling area. For hoop netting, minnow trapping, and fry trapping efforts, CPUE will be expressed as number of fish per day. For seining, CPUE will be calculated as the number of fish per square metre. CPUE will be calculated as the number of fish per 100 electrofishing seconds for open-

station electrofishing efforts. For closed station electrofishing, density will be determined using removal calculators (i.e., number of fish per unit area determined using Moran-Zippin estimators; Ricker 1971). CPUE for gill netting and angling will be calculated as the number of fish captured per square metre-hour and the number of fish per angler day, respectively.

Although community and population data is collected during every phase or component of the fish monitoring program, the sample size will be defined by the study objectives and may be insufficient to address corollary questions. For example, the sample size required for tissue quality analyses (n = 8) is not large enough to support formal contrasts of population endpoints. To this end, evaluation of fish community data will rely on qualitative comparisons, and conclusions regarding fish populations will be supported by non-lethal measurements and sampling under the MDMER/EEM (with larger sample size), as described in Section 4.2.2 and below. Analysis methods for the MDMER/EEM fish population data will be consistent with EEM technical guidance (Environment Canada 2012). Summary statistics, including mean, median, minimum, maximum, standard deviation, standard error, and sample size, will be calculated for fish age, fork length, total length, body weight, condition, liver weight, gonad weight, and fecundity; calculations will be completed according to species and area. In a lethal design EEM fish survey, detailed statistical analyses will focus on indicators of survival, energy use, and energy storage and will be completed based on guidance from Environment Canada (2012). These indicators include fish age, size-at-age, gonad size relative to body weight, condition, liver size relative to body weight, and fecundity, and egg size relative to body weight (Table 10). In a non-lethal design, histograms will be used to examine length-frequency distributions by species and area, and indicators include fish size and condition. All data sets will be assessed for normality and equality of variance in order to determine the suitability of parametric statistical procedures. An effect on the fish population will be evaluated for each of these measures and is defined as a statistically significant difference between the effluent-exposed area and the reference area (Environment Canada 2012). For each endpoint, statistically significant differences between effluent-exposed and reference areas (by species and sex) will be assessed using ANOVA, Analysis of Covariance (ANCOVA), or non-parametric equivalents, as appropriate, following technical guidance (Environment Canada 2012).

For the fish tissue data sets, statistical comparisons of age, length, weight, and concentrations of metals in fish tissues (n = 8) will be completed among years and locations. Following completion of the DQR, fish tissue quality data will be provided to the QP and summarized according to species, tissue type, and area. The LRL for each analyte and the number of samples below the LRL will be determined. Censored data will be managed using methods described in Helsel (2012), and those used in the R package NADA: Non-detects and Data Analysis for Environmental Data (Lee 2017). Any value below a LRL (i.e., a <LRL result) that exceeds the

Table 10: Survival, Energy Storage, and Energy Use Endpoints for Mount Polley EEM Fish Population Evaluation

Response		Measurement Endpoints [a]	Statistical Procedure
Effects on Fish [a]	Survival	Age	ANOVA[c]
	Energy Use	Size-at-age (body weight against age)	ANCOVA[c,d]

		Relative liver size (liver weight against body weight)	ANCOVA[c,d]
Supporting Response Variables [b]	Energy Use	Relative fecundity (# of eggs/female against body weight)	ANCOVA[c,d]
		Relative egg size (mean egg weight against body weight)	ANCOVA[c,d]

Notes: ANOVA = Analysis of Variance; ANCOVA = Analysis of Covariance; # = number.

[a] Endpoints to be used for determining "effects" as designated by statistically significant differences between effluent-exposed and reference areas.

[b] These analyses are for informational purposes and significant differences between exposure and reference areas are not necessarily used to designate an effect (Environment Canada 2012).

[c] Or appropriate non-parametric equivalent, as required.

[d] For the ANCOVA analyses, the first term in parentheses is the endpoint (dependent variable Y) that is analyzed for an effluent effect. The second term in parentheses is the covariate, X (age, weight, or length).

maximum detected value for that parameter at the given station will be removed. The removal of the poor LRLs does not influence the estimation of the mean or standard deviation, but does influence the overall sample size. The sample size, mean, median, standard deviation, standard error, minimum, maximum, 5th percentile, and 95th percentile will be calculated for each analyte. Means will be calculated using the Kaplan-Meier (K-M) method. The standard deviation and the median for each analyte will also be calculated using the K-M method. When a standard deviation cannot be estimated (i.e., when an analyte has a high proportion of censored values), it will be reported as "not calculated".

Statistical comparisons of age, length, weight, and concentrations of metals in fish tissues will be completed among years and locations. Statistical comparisons among groups will completed using an analysis of variance (ANOVA) if assumptions of normality and homogeneity of variances are met. These assumptions will tested using the Shapiro Wilk's test and Levene's test (α=0.05), respectively. Data will be transformed, as required, to meet these assumptions. If the assumptions cannot be met, the Kruskal-Wallis test will be used. Response variables with censored observations will be compared among groups using the Wilcoxon score test. Specific contrasts will be conducted after an overall significant difference among groups. Bonferroni adjustments to the p-values will be made to maintain the family-wise Type I error rate at α=0.05. A magnitude of difference (MOD) will be calculated for each contrast. For metals for which information is available on accumulation in specific organs (e.g., copper accumulation in fish liver; Grosell 2012), interpretation will focus on the results associated with that organ.

Statistical comparisons of concentrations of mercury in fish tissue will be compared using analysis of covariance (ANCOVA) with fork length as a covariate (as mercury is known to bioaccumulate in fish tissue; e.g., Kidd and Batchelar 2012). The response variable and covariate will be $\log_{10}$-transformed, as required, for analysis. The significance of the interaction term of the ANOVA model will be assessed to compare regression slopes between groups. If the interaction term is not significant (α=0.05) it will be removed and the parallel slope ANCOVA model will be fit. If the fork length is not a significant predictor of mercury concentration in the parallel slope ANCOVA model, it will be removed from the model and comparisons of mercury concentrations between groups will be conducted using a t-test. If the fork length is a significant predictor of mercury concentration in the parallel slope ANCOVA model, comparisons of mercury concentrations between groups will be assessed using the group term of the model. Adjusted means will be reported for the average (geometric mean) fork length from the parallel slope ANCOVA model. A MOD will be calculated for each contrast.

Fish tissue quality data will also be evaluated in comparison to tissue quality guidelines for human health and/or for aquatic ecosystem health (available for mercury and selenium). Tissue quality

guidelines will include the Canadian Food Inspection Agency/Health Canada mercury guideline for the protection of human health (0.5 milligrams per kilogram wet weight [mg/kg ww]; CFIA 2015) and the BC selenium guidelines (BCMOE 2014). Selenium guidelines for BC include guidelines for the protection of human health, which are based on fish consumption levels (7.3 milligrams per kilogram dry weight [mg/kg dw] for subsistence consumers, 14.5 mg/kg dw for the general population, and 75 mg/kg dw for the recommended two servings of fish per week). Selenium guidelines for BC also include guidelines for the protection of aquatic life, which are 4 mg/kg dw in muscle tissue and whole body samples, and 11 mg/kg dw in egg/ovary tissues. Selenium concentrations in fish ovaries will also be compared to the threshold for reproductive effects in eggs and ovaries (20 mg/kg dw; DeForest et al. 2012).

Results of the fish habitat characterizations for Upper Hazeltine, Lower Hazeltine, and Lower Edney creeks will be summarized, along with fish usage results, according to season (spring, summer, and fall) and year. Fish habitat characterization measures will be summarized by season, reach, and area (rehabilitated and reference), with summary statistics (mean and standard deviation) calculated for all numerical parameters. These summarized variables will then be compared to general habitat preferences for relevant fish species. Additionally, recorded habitat measures will also be compared to "optimal" ranges of habitat parameters indicated in Habitat Suitability Index (HSI) models (i.e., suitability index value = 1) or in the literature (where available) for those fish species identified in rehabilitation design criteria and objectives. Specifically, mean results for habitat measures collected in each season at each reach will be compared to the tabulated optimal "habitat suitability criteria" ranges and identified as either meeting or not meeting these criteria. The proportions of habitat measures meeting the habitat suitability criteria in the rehabilitated and reference areas, respectively, will also be compared.

Habitat unit assessment measures will be summarized by habitat unit type within each reach, with mean values calculated for all numerical parameters. Measures will be used to calculate endpoints such as bankfull width to depth ratio, channel complexity, % pool, pool frequency, and LWD pieces per bankfull channel width. These endpoints and other observational measures (presence of off-channel habitat) will then be evaluated relative to diagnostics of salmonid habitat condition modified from Johnston and Slaney (1996), rated as poor, fair, or good. Lastly, quantitative (closed station) data will be used to determine fish density (number of fish per unit area determined using Moran-Zippin estimations; Ricker 1971). The presence and abundance of juvenile rainbow trout in these creeks will be compared to densities previously observed in Edney and Bootjack creeks (Minnow 2014a).

An interpretive report based on the fish monitoring data will be prepared to be integrated into the Annual Environmental and Reclamation Report for the Mount Polley Mine that is prepared

annually by MPMC and submitted to the regulators and other stakeholders by March 31 of the following year. The interpretive report will provide all data in an appendix and will include the DQR, the results of the screening against BCWQGs, and the results of temporal and spatial comparisons. All data interpretation will be summarized in clear text form supported by tables and data plots.

STUDY DESIGN CONCEPT: TERRESTRIAL COMPONENT FOR THE MOUNT POLLEY MINE COMPREHENSIVE ENVIRONMENTAL MONITORING PLAN – MOUNT POLLEY MINE

1.0 INTRODUCTION

1.1 Purpose of the Study Design Concept

Mount Polley Mining Corporation (MPMC) is preparing a Comprehensive Environmental Monitoring Plan (CEMP) to integrate the environmental monitoring components from a variety of regulatory processes applicable to the Mount Polley Mine into a single document. An Ecological Risk Assessment (the ERA; Golder 2017) was prepared that integrated the available chemical and biological information to provide an overall conclusion about the magnitude and extent of ecological risks associated with the deposit of tailings. The ERA was accepted by the Ministry of Environment & Climate Change Strategy (ENV) on 31 January 2018, contingent on the implementation of additional monitoring in relation to specific areas of uncertainty identified in the ERA. There were several points of uncertainty in the terrestrial ERA with respect to plants, soil invertebrates and wildlife and these are outlined in Table 53 of the ERA. The purpose of this memorandum is to outline the monitoring concept proposed to MPMC to address those terrestrial ERA uncertainties in the CEMP. Contingent on acceptance by ENV, a detailed study design document and specific work instructions will be prepared by Golder as the basis for executing of the CEMP process.

1.2 Scope and Approach of the Risk Assessment

The ERA evaluated the site conditions as they existed in the first few years after the failure of the glacial lacustrine layer beneath the Perimeter Embankment of the Tailings Storage Facility. The terrestrial ERA included the “floodplain” area where the forest and native soils were removed by the debris flow, and the “halo” area where the forest floor was relatively undisturbed but buried to varying depths by scoured material and tailings. Tailings can limit the successful re-establishment of ecological communities because of a variety of chemical and/or physical limitations in the soil (Hossner and Hons 1992). The ERA used a “triad” style approach to evaluate the relative influence of physical issues versus chemical issues for a given receptor group using three different types of information:

- What is the magnitude of the exposure associated with tailings?
- What is the magnitude of effects associated with tailings under controlled experimental conditions?
- What is the magnitude of effects associated with tailings under field conditions?

Golder and the G logo are trademarks of Golder Associates Corporation **golder.com**

Copper was identified as the primary contaminant of concern. The ERA also found that the bioavailability of copper in tailings at the site was low. A low bioavailability does not mean that bioaccumulation was zero as copper has bioaccumulated in different parts of the ecosystem at concentrations that are greater than reference areas. However, the overall conclusion, based on a weight-of-evidence integration of the available information collected over several years, was that risks associated with copper were low, and that the effects associated with nutrient deficiencies and soil structural limitations were likely to be a larger influence on the long-term management goal of reintroducing a biologically diverse, functional and self-sustaining ecosystem. As with any complex risk assessment, there was uncertainty associated with the risk conclusions which were described in the risk assessment.

1.3 Summary of Main Areas of Uncertainty

The study design concept focuses on reducing the main sources of uncertainty described in Table 53 of the ERA. In brief, the main sources of uncertainty in the terrestrial ERA were:

1) Field-based monitoring of the diversity or abundance of plants, soil invertebrates or other parts of the soil ecosystem is valuable in an ecological risk assessment but was not practical in the current application because of the expected variability related to natural successional changes.

2) The ability to quantify the relative influence of copper versus the physical limitations of the soil is important from a theoretical perspective. This would typically be evaluated using controlled experiments. However, further experiment-based studies are not warranted unless there is evidence (from field monitoring) that natural succession is not progressing. It is reasonable to continue refining the site-specific understanding of copper bioaccumulation in plants and soil invertebrates in lieu of further experimental studies while the long-term field monitoring is executed.

3) Risks to wildlife are assessed with a single technique (a food chain model). Conservative assumptions were used in the model. Hazard quotients were less than 1 for eleven of the 15 receptor species evaluated in the model. Further refinement of the wildlife food chain model was requested with respect to the four receptor species that had a hazard quotient greater than 1.

Each of these main sources of uncertainty are addressed in further detail in Section 3.

2.0 BASIS OF DESIGN

Golder understands that MPMC is structuring the CEMP to be a stand-alone document that does not require reviewers to have a detailed understanding of the ERA. A summary of the available data and how those data were evaluated in the ERA (Golder 2017) is provided in this section as context for the specific recommendations in Section 4.

2.1 Plants

Information relevant to plants that was evaluated in the ERA included:

- Concentrations of metals in tailings were lower than numerical standards for the protection of soil invertebrates and plants, except for copper (and marginally, vanadium).
  - For copper, the numerical standard is 150 mg/kg. The 95% upper confidence limit of the mean (UCLM) concentration in untreated tailings was 737 mg/kg. Treatment (scarification, intermixing or transplanting soils) resulted in 95% UCLMs ranging from 197 to 538 mg/kg.
  - For vanadium, the numerical standard is 200 mg/kg. The 95% UCLM vanadium concentration in untreated tailings and the three treatment types were less than the numerical standard. Vanadium was retained as a contaminant of potential concern because the 90th percentile concentration in untreated tailings was marginally greater than the standard (213 mg/kg versus 200 mg/kg).
- A 42-d lodgepole pine (*Pinus contorta*) and bluebunch wheatgrass (*Pseudorogneria spicata*) germination and growth toxicity test was conducted on two representative samples of tailings (Section 3.3.3 of the ERA). Seedling emergence or survival was not impacted, but greater than 20% reductions in growth were observed for both species compared to the performance of a negative control consisting of clean silica sand of a similar grain size. All plants demonstrated some degree of growth over the 42-day exposure, despite copper concentrations ranging from approximately 800 to 1100 mg/kg.
- Multiple lines of evidence in the ERA demonstrated that copper had low bioavailability. The lines of evidence included geochemical modeling and three different chemical surrogate measurements in tailings samples (water soluble fraction; humidity cell and leach tests; physiological-based extraction tests – see Section 3.2.2 of the ERA). The toxicity testing (see above) also included a side-by-side trial where an equivalent concentration of copper was added to clean silica sand (in the form of copper sulphate). The bioavailability of copper from tailings was much lower than copper added to the tailings.
- There were physical effects of tailings on plant growth. The toxicity testing (see above) found that tailings tended to form hard crusts and germination was highest in the surface cracks. The measured bulk densities of tailings, till and lacustrine deposits at the site were greater than values from the literature that correspond to reductions in plant growth. Nutrient levels in the tailings were also limited and in a range that could limit plant growth (see Section 3.2.3.2 of the ERA).
- Plants appeared to bioaccumulate copper, but bioaccumulation factors were less than 1 and the bioaccumulation was concentration-dependent. There were no obvious differences in copper bioaccumulation during the 42-d toxicity testing (see above) between tailings and copper added to soils. There was no consistent pattern where copper concentrations in field-collected plant samples were greater in the impacted areas than in background and/or baseline samples (see Section 3.3.2.2 of the ERA). Copper concentrations were within the range of concentration considered to be adequate for plant growth (see Section 3.3.2.4 of the ERA) despite being collected over a wide range of soil concentrations. Overall, these lines of evidence demonstrate that many plants can control the uptake of copper.

2.2 Soil Invertebrates

The ERA involved fewer lines of evidence for soil invertebrates because: a) the findings of low copper bioavailability from plants would be expected to be consistent for soil invertebrates, and b) the physical alterations to the soil and habitat would be expected to have a more significant effect on soil invertebrates. Further discussion about the overall ecological succession expected at the site is provided below in Section 3.1. Additional information specific to soil invertebrates that was considered in the ERA included:

- There were relatively few soil invertebrates collected in 2015 and 2016. Composite samples were collected for beetles/ants (n = 15), spiders (n = 4), and worms/slugs (n = 8). Between two and four tissue samples of each soil invertebrate type were collected from background areas and the data used in a control chart (i.e., the average ± 2 standard deviations [SD]). There was a high degree of variability between individual samples in a given tissue composite type, but the average concentration of copper in beetle/ant composite samples was higher than the average (+ 2SD) upper limit of the control chart.
- The limited number of worm/slug samples had an average copper concentration that was within the range of copper tissue concentrations from laboratory studies that had the potential for reduced survival, growth or reproduction of soil invertebrates. There was not sufficient data to determine the relationship between soil concentrations and the tissue concentration of specific types of soil invertebrates, and many of the papers that evaluated the critical body residue of copper in soil invertebrates acknowledge that there are many factors that can limit site-specific bioavailability. The available data were thus not definitive that a risk to soil invertebrates is present but did provide a qualitative indicator that monitoring was appropriate.

2.3 Wildlife

Risks to wildlife were evaluated using a food chain model. In brief:

- A total of 15 surrogate species were selected from different feeding guilds (e.g., herbivores, carnivores; Table 1). Species-specific variables such as body weight, ingestion rates, and dietary preferences were adopted from federal risk assessment guidance or other reputable sources.
- Realistic worst-case exposure concentrations were determined for soil, water and the various dietary items, typically based on the 95% upper confidence limit of the mean. Site-specific bioaccumulation models were developed and used to predict tissue concentrations from soil concentrations. Bioaccumulation factors for small mammal tissue concentrations (needed to evaluate risk to carnivores) were taken from the literature.
- Relative bioavailability was used to calculate the dose for the wildlife receptors. Relative bioavailability of copper in water was assumed to be 100%. Relative bioavailability of copper in soil was based on site-specific physiologically-based extraction test (PBET) data. Relative bioavailability of copper in dietary items was assumed to be 40% based on information from the literature.
- The total amount of copper ingested per day was compared to conservative toxicity reference values. The food chain model was run separately for different areas and different soil rehabilitation approaches (i.e., transplanted, scarified or intermixed). A risk estimate for each surrogate species was calculated for the entire study area using area weighting. Risks were also calculated for background areas for context.

- Hazard quotients (HQ) were less than 1 for all receptors exposed to vanadium, and most receptors exposed to copper. HQs were greater than 1 for robin, common nighthawk, olive-sided flycatcher and masked shrew. The aggregate HQs (i.e., the area-weighted HQ for the site as a whole) for those four receptors ranged from 1.7 to 2.8. The maximum observed HQ for an individual subarea was 5.1 for masked shrew in the Polley Flats area.
- A hazard quotient greater than 1 does not mean that there are risks to wildlife. The food chain model used many conservative assumptions which were identified in the terrestrial ERA. HQs were also greater than 1 for olive-sided flycatcher and masked shrew exposed to background copper concentrations.

Table 1: Wildlife receptors evaluated with the food chain model

Receptor Group	Feeding Guild	Surrogate Species
Birds	Herbivore	Dark-eyed junco
	Insectivore	Robin; olive-sided flycatcher; common nighthawk
	Omnivore	Raven
	Carnivore	Northern pygmy owl
	Piscivore	Osprey, great blue heron
Mammals	Herbivore	Meadow vole; mule deer
	Insectivore	Masked shrew
	Omnivore	Deer mouse
	Carnivore	Ermine, fisher
	Piscivore	River otter

3.0 FURTHER CONSIDERATION OF UNCERTAINTY

3.1 Uncertainty Related to Ecological Succession

A “triad” style approach (exposure, experimental effects, field effects) is common in weight-of-evidence because the three different types of information are complementary. A well-designed field study provides a meaningful evaluation of risks because it provides direct information about what is being protected under realistic conditions. However, field studies are not always able to determine the cause of effects (if any are observed) and can be confounded by many different variables. Many of those variables (e.g., weather) are unrelated to the management question being evaluated.

A “triad” approach was used in the terrestrial ERA but it was not possible to assess every terrestrial receptor with a field study. In areas of the site that were subjected to extensive scouring, there was a near-complete loss of natural soils and their related ecological communities (i.e., soil microbes, fungi, invertebrates and plants). Quantitative assessment to establish the magnitude of that physical impact was unnecessary. Field measurement of the structure of the plant or soil invertebrate community was not possible because recolonization and ecological succession had only just started. Nevertheless, field studies are expected to be an important aspect of long-term monitoring because they will help to determine if the soil ecosystem is recovering as expected over time.

3.1.1 Summary of Expected Ecological Succession

An example of ecological succession in a hypothetical plant community is provided in Figure 1. Succession progresses through several distinct phases:

- Early succession is dominated by opportunistic species that have high growth or reproductive output, or some specialized ability to occupy a niche that other species cannot. An example would be an invasive, weedy species with a high output of wind-carried seeds. Species that can grow in nutrient-poor soil because they can convert nitrogen to a useable form (“nitrogen fixation”) would also have an advantage. Mites are an example of a primary colonizer from the soil invertebrate community because they have a high dispersal capacity, can tolerate low nutrient levels, and reproduce quickly (Hagvar et al. 2009).
- Middle succession involves increasing competition for resources (i.e., the limited nutrients that are introduced by the decay of leaf litter from the early stages). An example of the middle stages of succession would be the proliferation of alder which have a similar capacity for nitrogen fixation as grasses, but also the ability to outcompete grasses for moisture and light through root and shoot growth. Examples of invertebrates at this stage include ground-dwelling beetles or ants.
- Late succession continues competition in an increasingly diverse number of niches. At a late succession stage, the humic layer has regenerated through the decay and processing of organic material, and there is an ongoing cycle of nutrients in soils from the activity of microbes, fungi and soil invertebrates. Earthworms and other invertebrates that process organic material would be common. The overall ecological function (e.g., production of biomass, respiration, diversity) in the ecosystem has reached its maximum capacity, and the ecosystem has settled into a dynamic equilibrium.

Golder has identified several examples of natural ecological succession from the literature in Table 2, including recolonization of a landscape after a landslide or retreat of a glacier, or reclamation from non-metal mining such as quarrying.

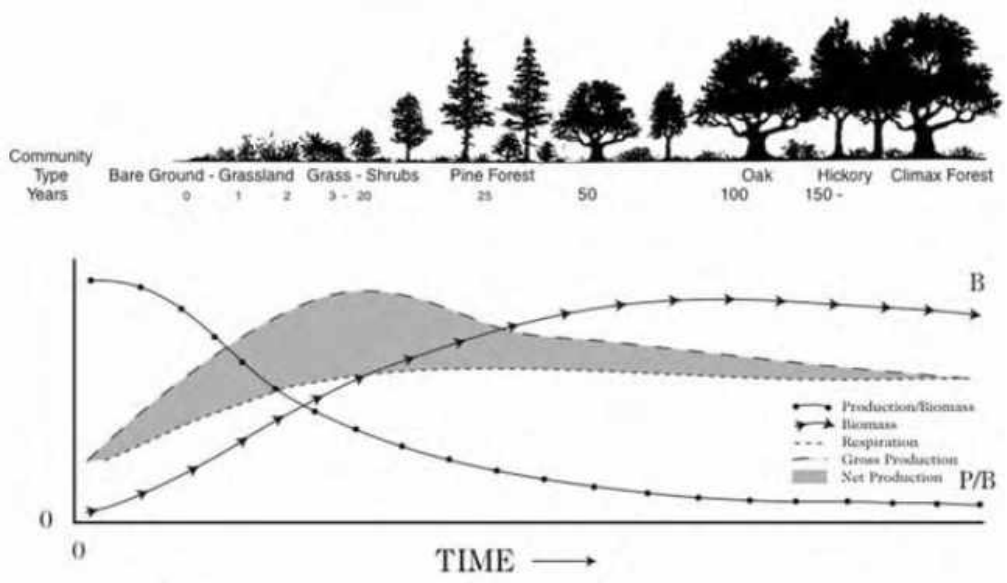

Figure 1: General schematic of vegetative succession over time (from Schneider 2008)

Table 2: Examples of Ecological Succession

Authors	Site Context	Observations
Russell and La Roi (1986)	34-hectare spoil heap of overburden generated from coal mining activities in Rocky Mountain foothills, Alberta.	Vegetative cover limited by coarseness of material and low nutrient levels. Total plant cover is less than 10% despite relatively long length of time since formation of the spoil heap (34 years). Perennial grass and forbs are the dominant species.
Frouz et al. (2008)	Chronosequence of 27 sites on four different coal mine spoil heaps (100+ km^2) in Europe. Total length of time since disturbance was 40 years.	Plant and soil invertebrate communities were assessed. Statistical analysis found that succession was driven by the formation of the humic layer. Sites tended to switch from “no humus” to “humus forming” at roughly 15 years, and from “humus forming” to “humus present” at roughly 25 years.
Miles and Swanson (1986)	Chronosequence of 25 landslides in Oregon. Total length of time since disturbance was 30 years.	Total vegetation cover ranged from 51% (in the primary scar) to 78% (in the primary deposition area). Cover consisted of trees (approximately 50% of the total), shrubs (25% of total) and herbs (25% of total), suggesting that succession had progressed to a mature state.

Authors	Site Context	Observations
Smith et al (1986)	Chronosequence of 49 landslides in Haida Gwaii. Total length of time since disturbance was 150 years. Logged and non-logged areas included for comparison.	Humic layer reformed relatively quickly but had decreased nutrient levels until Year 30. There was a relatively thick cover of red alder (an early colonizing tree species) within 20 years, but the total vegetative cover in the slide areas did not reach the undisturbed areas for 50 years. (For context, a logged area returned to a total cover like the undisturbed area within 20 years).
Gobbi et al. (2006).	Chronosequence of soil invertebrates colonizing a receding terminal glacier moraine. Total length of time was 150 years.	Species richness increased from 2 to 26 genera. Spiders and beetles were the primary colonizers, while ants and centipedes are only present in the older sites. The pattern of succession was consistent with the available information about the habitat preference and life history strategies of each species.

Note: A chronosequence is an ecological study that investigates a set of similar sites that share similar attributes and a similar disturbance but have different ages in order to understand the time-dependent aspects of succession.

3.1.2 Influence of Natural Succession on the Design of the CEMP

Although MPMC has conducted a variety of actions over the last two years to facilitate natural ecological succession, the plant and soil invertebrate community in the area impacted by tailing deposition is likely still in the early, opportunistic stages of recolonization. Further information about the following activities conducted to date can be found in the Conceptual Remediation Plan (Golder 2018):

- Soil manipulation (e.g., scarification to create a “rough and loose” soil material with better physical structure)
- Blending and placement of native topsoils to improve moisture retention and nutrient levels, and to reintroduce native microbes, fungi, seeds and soil invertebrates
- Mounding and placement of coarse woody debris to create preferential microsites where plant recolonization can be accelerated
- Placement of wood chip mulch to increase organic carbon and nutrient levels as the mulch decays
- Riparian planting of native shrubs and conifers
- Seeding of upland areas with a mix of native grasses

The net effect of the original impact and the subsequent rehabilitation effort is that a high degree of variability between areas is still expected because the treated and untreated areas are still in the first few years of succession. The total length of time to reach a mature, dynamic equilibrium is unknown, but likely on the order of 20 to 30 years based on the examples from Table 2. The rehabilitation activities described above would be expected to accelerate and enhance that process. A field study to measure the difference between "control" and "impact" that could separate the relative influence of copper versus physical limitations would be challenging in this early phase. Specifically:

- Comparison to reference is not expected to be practical in the near-term (i.e., one can reasonably conclude that there will be substantive changes between the impacted areas and areas that have not covered with tailings). No suitable reference areas (i.e., an area that has been logged and all vegetation and humic material removed) are currently known.
- Comparison between individual years may not add significant value because differences in weather (e.g., rainfall, snowpack, temperature) would also introduce significant year-to-year variability.

Instead, monitoring of the plant and soil invertebrate community should focus on establishing a long-term trend analysis rather than to support a multitude of pair-wise comparisons that would have limited value for making site management decisions. This would involve:

- **Selecting representative, permanent monitoring plots.** The number of plots will depend on the number of different habitat units to be monitored. These units could be based on copper concentrations, remedial areas, the types of rehabilitation already applied, or other attributes that will influence succession (e.g., slope, moisture content, distance from undisturbed edge).
- **Monitoring each plot in a consistent manner to support analysis of trends over time.** No consensus exists at this time about which specific metrics are needed to monitor progress towards a biologically diverse, functional and self-sustaining ecosystem. Input from other subject matter experts (e.g., mine reclamation specialists) is likely required given that the timelines for monitoring will extend into the mine closure process.
- **Sufficient sampling effort to make informed management decisions.** A defensible trend analysis needs to consider statistical power. Statistical power is influenced by the minimum measurable change and the variability amongst replicates of a given habitat unit. Even if a formal power analysis is not needed, the study design needs a common understanding about how the trend analysis would be used to make future decisions. For example, trend analysis may benefit more from measuring 5 metrics at 50 plots for three years followed by a 5-year hiatus than measuring 10 metrics at 20 plots every year. The 750 measurements in the first option may be more meaningful than the 1,600 measurements in the second option because option 1 provides more spatial coverage and measures inter-year variability.

3.2 Uncertainty about the Relative Influence of Copper on Soil Invertebrates and Plants

The ERA concluded that risks from copper were low, and therefore, further focused investigations to determine the relative influence of copper on soil invertebrates and plants versus physical variables (such as through toxicity testing or greenhouse experiments) were not warranted until there was information from the field monitoring that succession was not progressing towards the long-term management goal of reintroducing a biologically diverse, functional and self-sustaining ecosystem (Table 53 of the ERA). A trend analysis will not provide a definitive check on progress towards this management goal for several years. In the meantime, continued refinement of the site-specific relationships between copper concentrations in soil and copper concentrations in various soil invertebrate and plant tissues is recommended because:

- The presence of sufficient plants or invertebrates for sampling across the range of copper concentrations in soil provides important qualitative evidence (pending confirmation from the trend analysis) that copper is not exerting a significant effect on the survival of soil invertebrates or plants. If areas with the upper range of copper concentrations in soil lack soil invertebrates, or show visual evidence of copper toxicity to plants, it would be a trigger for the more focused investigation (or, could lead directly to supplemental remediation as part of the overall adaptive management strategy).
- Refining the soil-to-tissue relationships provides direct evidence about copper bioavailability and bioaccumulation. This helps to clarify potential differences in copper bioaccumulation between different species or taxonomic groups, and the site-specific relationships can be compared to similar relationships from the scientific literature or other copper-contaminated sites to provide further support to the ERA conclusion that copper bioavailability is relatively low.
- The site-specific bioaccumulation relationships are also used as part of the wildlife food chain model. Some of the existing relationships are based on limited data sets, which have added uncertainty to the results of the food chain model. A more robust relationship between soil and tissue concentrations increases the overall sophistication and future application of the food chain model as part of the CEMP.

3.2.1 Uncertainty in Risk Estimates for Wildlife Species

The food chain model used appropriately conservative assumptions and model parameters consistent with common practices for a screening-level risk assessment.

In terms of risk management decisions, some qualified professionals default to a prescriptive interpretation that any HQ than 1 represents a potential risk that requires further assessment or remediation. Realistically, marginal HQs (e.g., less than 2 or 3) are unlikely to present an unacceptable risk but there is no consensus on a specific threshold between acceptable or unacceptable risk beyond the prescriptive guidance about HQ = 1. The existing HQs are not considered to represent an unacceptable risk but are sufficiently higher than 1 to warrant further refinement of the model to reduce uncertainty. The uncertainty in the HQs generated from the food chain model is the product of the uncertainty in each of the variables used. Not all variables need to be refined. The variables that would benefit most from refinement are:

- Improving the quality of data with respect to tissue concentrations in invertebrates. This can be accomplished by expanding on the bioaccumulation sampling as described in Section 3.2. The food chain model has also conservatively assumed that flying insects have the same tissue concentrations as soil-dwelling insects, which is a data gap that should be addressed by further sampling.

- Refining the toxicity reference values (i.e., the denominator in the HQ). The current toxicity reference value was taken from the ECO-SSL guidance (USEPA 2018) and is based on a conservative “no-observed adverse effect level” from the available literature. This toxicity reference value may be substantially lower than a true “acceptable” concentration that corresponds to low (i.e., not statistically significant) effects on growth or reproduction. A common area for refinement in a wildlife risk assessment is to update the toxicity reference value to reflect an effects-based threshold in lieu of a highly conservative screening threshold.
- Reviewers of the ERA identified the use of relative bioavailability as an uncertainty in the food chain model but did not reach a consensus about whether this issue was significant in terms of the final risk conclusion. There are unresolved differences in professional opinion on this topic which would ideally be addressed as part of the food chain model refinement. Golder notes that ENV has previously accepted the approach used in the current ERA at other sites and believes that further dialogue on this point prior to initiating additional investigation is warranted.

Refinement (or resolution) on these three topics is expected to reduce the overall uncertainty in the food chain model. Golder understands that the refined model would be run for the same subareas and HQs presented for both individual subareas and for the aggregate of the entire study area. Golder also understand that ENV desires that bats (*Myotis* sp.) be added as an additional receptor.

4.0 CONCEPTUAL STUDY DESIGN

4.1 General Approach

A proposed approach to address the remaining areas of uncertainty in the terrestrial ERA is provided in Figure 2. In brief, the following activities are proposed for the remainder of 2018 and the first quarter of 2019:

- Conduct a reconnaissance-level assessment and conduct limited pilot-scale investigation for candidate metrics for inclusion in the long-term trend analysis monitoring of ecological succession.
- Engage stakeholders and subject matter experts in a workshop to review the findings from the reconnaissance-level assessment and to obtain consensus about how a “biologically diverse, functional and self-sustaining ecosystem” will be measured.
- Conduct a one-time supplemental sampling program to refine the current information regarding copper bioaccumulation and relative bioavailability. Refine the toxicity reference values and use all three outputs from the one-time supplemental sampling program to update the food chain model.
- Develop the preliminary design for the trend monitoring in terms of specific metrics, sampling effort, frequency and interpretative approaches and submit for regulatory approval.

At the completion of these four activities, the CEMP will be updated to incorporate the specific design for long-term monitoring of the ecological succession expected to occur over time. The long-term monitoring will need triggers for when ecological succession will be deemed to be insufficient (even if such triggers are narrative). Additional rehabilitation or additional investigation regarding the cause of the insufficient progress would occur if those triggers are exceeded.

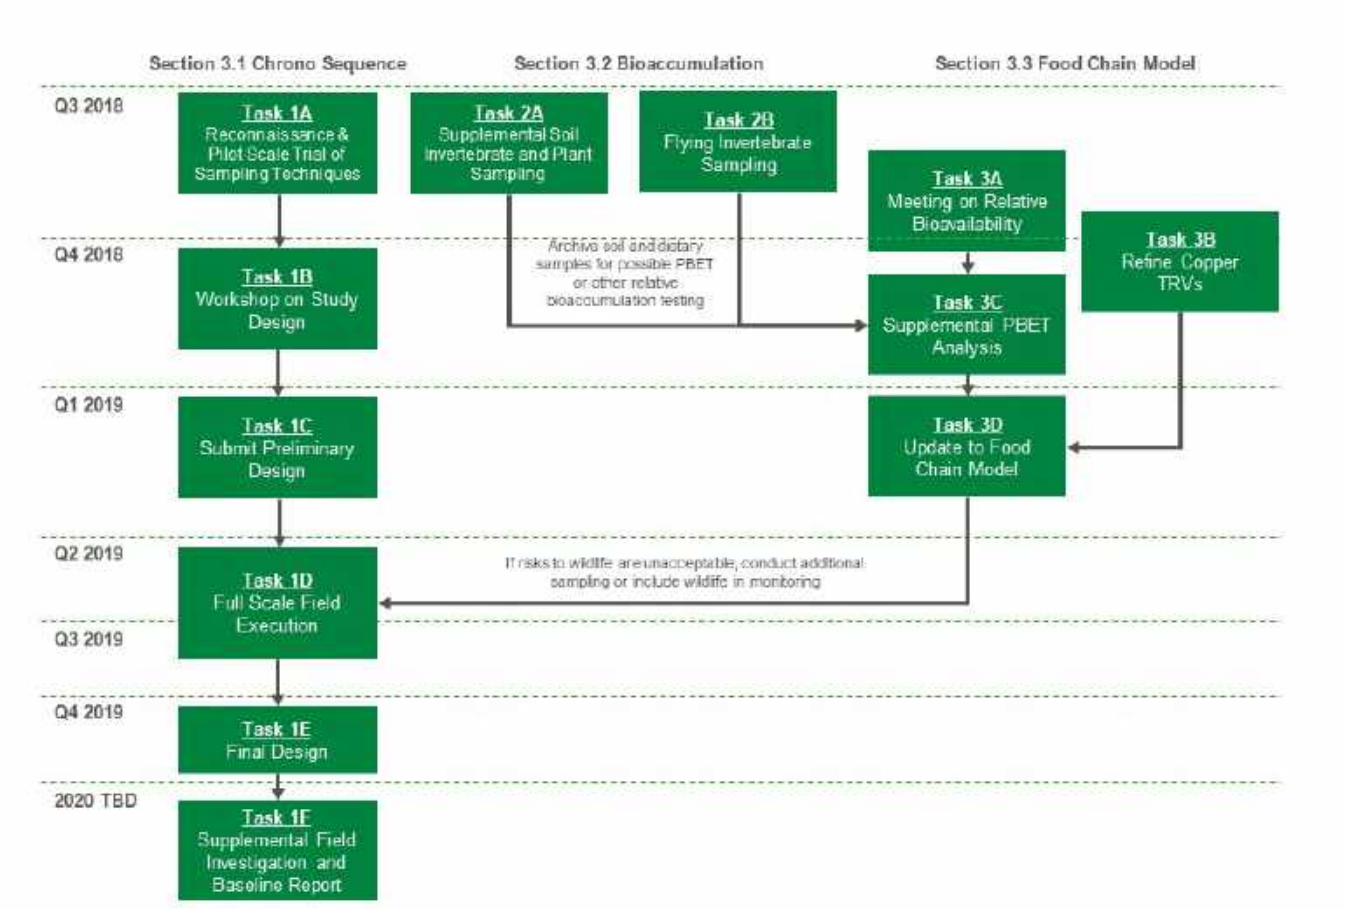

Figure 2: Proposed Approach for the Terrestrial CEMP Component

4.2 Additional Information

4.2.1 Task 1A – Reconnaissance and Pilot-Scale Sampling

There is value in conducting a reconnaissance-level sampling program in the summer of 2018 to provide at least a narrative description (supported by field measurement) of the current state of ecological succession. The reconnaissance-level sampling will focus on:

- Determining the diversity and percent cover of plants in three plots in each of the seven major terrestrial units (Halo; Untreated – Polley Flats; Untreated – Upper Hazeltine; Untreated – Lower Hazeltine; Transplanted; Intermixed; Scarified) for a total of 21 plots.
- Making detailed observations about plant succession in selected locations where additional rehabilitation was conducted (e.g., placement of large woody debris, mounding, placement of mulch).
- Conduct an overall site inspection to identify if there are areas that were subject to additional rehabilitation where no ecological succession appears to be occurring.

- Conducting a standardized bird survey at five locations (for spatial coverage) to document which species are using the available habitat. (Birds are selected for the survey because of the potential that listed species would use the habitat). Habitat monitoring for other wildlife species is not included in the scope of this reconnaissance-level sampling.

Data from the reconnaissance sampling will help to inform the design of the long-term trend analysis. Golder will also use the opportunity to conduct a pilot-scale trial of sampling techniques that could be used to measure other aspects of ecological succession. For example, the future trend analysis (see tasks below) may involve a metric related to soil invertebrate diversity, density or function. The literature describes a wide array of possible sampling techniques (e.g., a soil core to measure the diversity and abundance of mites; a bait-trap to measure the biomass of ants; a pit-fall trap to measure the diversity of ground-dwelling beetles). Golder is using malaise traps, pit-fall traps and Berlese funnels as part of the tissue sampling, any one of which could add value to the design of the long-term monitoring.

4.2.2 Task 1B – Workshop on Design of Trend Analysis

Golder expects that reviewers and stakeholders would comment extensively on the design of the trend analysis, and a variety of technical opinions are expected. There is a wide diversity of possible technical approaches, compounded by an absence of risk assessment guidance on how ecological succession should be monitored.

Golder expects that it will be necessary to draw on regulatory guidance from other relevant Ministries (e.g., Mines, Forestry) where landscape level changes in plant communities are more commonly assessed. For example, BCMOFR/BCMOE (2010) provides guidance on how to assess terrestrial ecosystems, but guidance on measuring successional state is limited to a semi-quantitative assessment that tracks the proportion of early colonizers (‘seral’ species) to later colonizers (‘climax’ species). No specific thresholds for the different states are described and therefore, the site could conceivably remain in a “pioneer” state for 60 or more years. This type of narrative assessment, although described in regulatory guidance, would not add value for site management decisions. Conversely, there are examples of how plant succession is being monitored for mine closure purposes in a quantitative manner (e.g., Highland Valley Copper focuses on plant diversity and functional contribution as a surrogate for the broader ecological succession; Smyth et al. 2016) but no specific thresholds are described beyond “continued progress”.

Golder proposes a one-day workshop where a focused overview of the findings from the reconnaissance-level sampling and tissue sampling can be presented, followed by discussion of relevant examples of risk-based mine closure and monitoring elsewhere in British Columbia. Potential examples where publicly-available information is likely available include the Britannia Mine, the Sullivan Mine, and Highland Valley Copper. It is important to establish at least a preliminary consensus with the regulators about the intended application of this part of the CEMP before effort is expended on the design and costing of specific methods. This workshop is intended to be similar to the Problem Formulation Workshop that helped to build consensus on how the ERA was ultimately executed.

4.2.3 Task 1C – Preliminary Design of Trend Analysis

Golder will develop a preliminary design for the long-term trend analysis based on the reconnaissance sampling, further consideration of relevant examples at other BC mine sites, and input from the reviewers.

4.2.4 Task 1D – Full Scale Field Execution

Golder proposes that the preliminary sampling design would be implemented in the spring and summer of 2019. The scope of this program is currently unknown, pending the outcome of the preliminary design.

4.2.5 Task 1E – Refinement to Design

Conceptually, Golder envisions that the preliminary design might specify a larger number of potential metrics which would be reduced to a final subset based on the data collected in 2019. The intent of the refinement step is to provide a formal check that the preliminary design has been fully optimized in terms of effectiveness and efficiency. A key aspect of optimization is that it is not necessary to continually monitor all aspects of the ecosystem as a conservative, precautionary approach. Instead, the goal is that the CEMP component provides a science-based framework for adaptive management. Adaptive management focuses on monitoring a smaller number of metrics (but monitoring them well) so that there is a clear baseline with pre-defined triggers for when one-time supplemental investigations might become necessary.

4.2.6 Task 1F – Baseline Report

Conceptually, the terrestrial monitoring component will focus on monitoring succession at pre-defined intervals rather than annually. The ERA and its supporting appendices contain information about conditions up to approximately D+3 (disturbance + 3 years). The reconnaissance sampling is effectively an interim snapshot about D+4, and the full field execution would provide the formal baseline that reflects conditions at D+6 (and possibly D+7, if year-to-year variability is included in the study design). Subsequent cycles of the terrestrial monitoring program would then document the ongoing ecological succession at defined intervals post-baseline (e.g., baseline + 2 years, B+5, B+10, B+20).

4.2.7 Task 2A – Soil Invertebrate and Plant Sampling

This task is a standalone activity intended to reduce the uncertainty in the existing site-specific bioaccumulation models (Figure 3) for soil invertebrates and plants. Both models could be improved by obtaining additional co-located soil and tissue samples so that the relationships are not based on composite samples (e.g., separate ‘surface insects’ into ‘ants’, ‘spiders’ and ‘beetles’; separate ‘grass’ into the main species that have been seeded on the site). Conceptually, Golder would target different specific taxa or species emphasizing areas that have not yet been sampled (i.e., the three reclamation treatments). These areas tended to have copper concentrations in the middle of the range bounded by the background and untreated areas. All data (i.e., data from Golder 2017 and data collected in August 2018) will be used to refine the existing bioaccumulation relationships (see Figure 3, below). Note that the total number of tissue samples submitted for analysis will be dependent on the trap effectiveness. A decision on whether the supplemental data are sufficient will be made in light of the uncertainty in the regression equation.

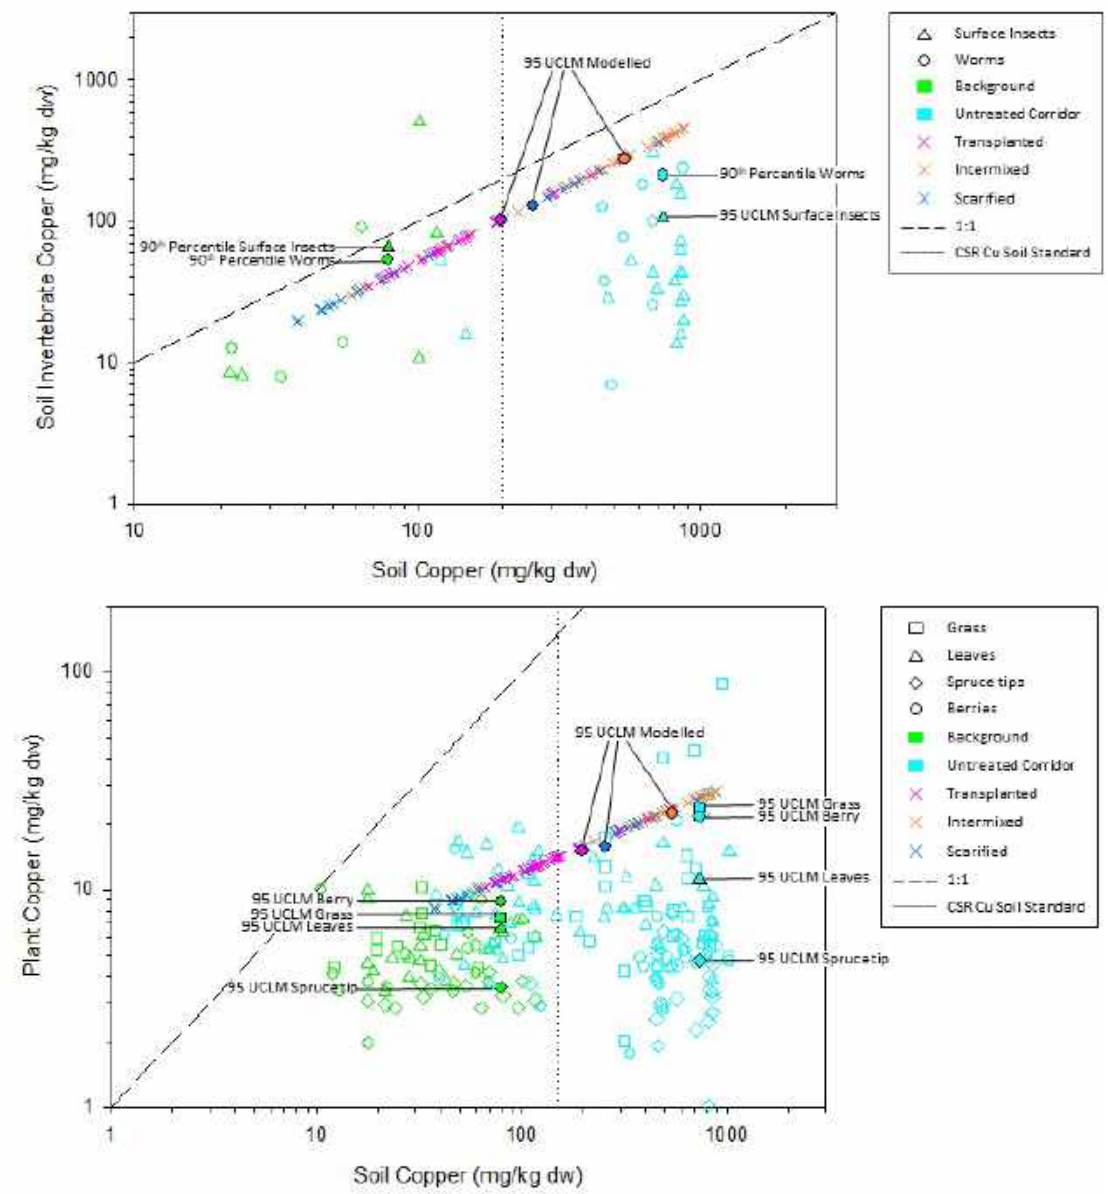

Figure 3: Existing bioaccumulation models for soil invertebrates and plants (from Golder 2017, Appendix F)

4.2.8 Task 2B – Flying Insect Sampling

This task is a standalone activity to address a data gap in the food chain model. Golder will collect flying insects (e.g., moths, flies, flying ants, grasshoppers) using malaise traps with lights. These taxonomic groups reflect the likely dietary items for insectivorous birds and bats. Hand collection with butterfly nets will also be employed. Ideally, sufficient biomass will be collected from a single location to allow for submission of taxa-specific composites (not a composite of all flying insects). Tissue concentrations are not expected to be directly related to local soil concentrations because flying insects are mobile, and therefore, the goal would be to focus on sampling from five broad zones (e.g., Polley Flats, Upper Hazeltine, Lower Hazeltine, Halo, and Background. The goal is to obtain at least seven tissue samples per taxonomic group per area (to allow for the calculation of a 95% upper confidence limit of the mean). The total number of tissue samples submitted for analysis will be dependent on the trap effectiveness.

4.2.9 Task 3A – Meeting on Relative Bioavailability

There was conflicting feedback from technical reviewers about how the food chain model incorporated the relative bioavailability of copper in water, food and dietary items once ingested by different ecological receptors. Golder assumed that copper in water would have a 100% bioavailability relative to the form of copper added to the food used in the original mammalian or avian toxicity test. Site-specific PBET data was used as a surrogate for the relative bioavailability of soil, and information from the literature was used to provide a conservative estimate of the relative bioavailability of copper once incorporated into biological tissues. Similar approaches have been approved by ENV at other sites, including the risk-based management of elevated copper in soils at the Britannia Mine. Relative bioavailability for soil and dietary items has also been evaluated in the risk assessment literature with specific consideration of the potential for differences in gastrointestinal bioavailability between mammals and birds (e.g., Sample et al., 2014; Kaufman et al., 2007).

Golder recommends holding a focused meeting on this specific technical topic with the subject matter experts and ENV. Eliminating relative bioavailability from the food chain model would be demonstrably over-conservative and inconsistent with the scientific principles that influence how an ingested dose is ultimately absorbed by birds and mammals. If the consensus from that meeting is that further quantitative assessment is needed to support the existing approach, it would be completed this fall in Task 3C. Golder proposes to collect archive tissue and soil samples in the summer sampling program (Task 2A) as a precaution (subject to the availability of sufficient tissue mass).

4.2.10 Task 3B – Refinement of Copper TRV

Golder will update the existing toxicity reference values for copper to use a multi-study concentration profile in lieu of the existing point-estimate based TRVs adopted from ECO-SSL. A similar approach has been proposed in the amphibian monitoring component of the CEMP. The development and application of ECx-based toxicity reference values in wildlife food chain model is well-established in the scientific literature (e.g., Allard et al. 2010) and has been adopted by provincial and federal risk assessment guidance manuals (e.g., Environment Canada 2010) as an accepted practice to refine screening-level ERAs.

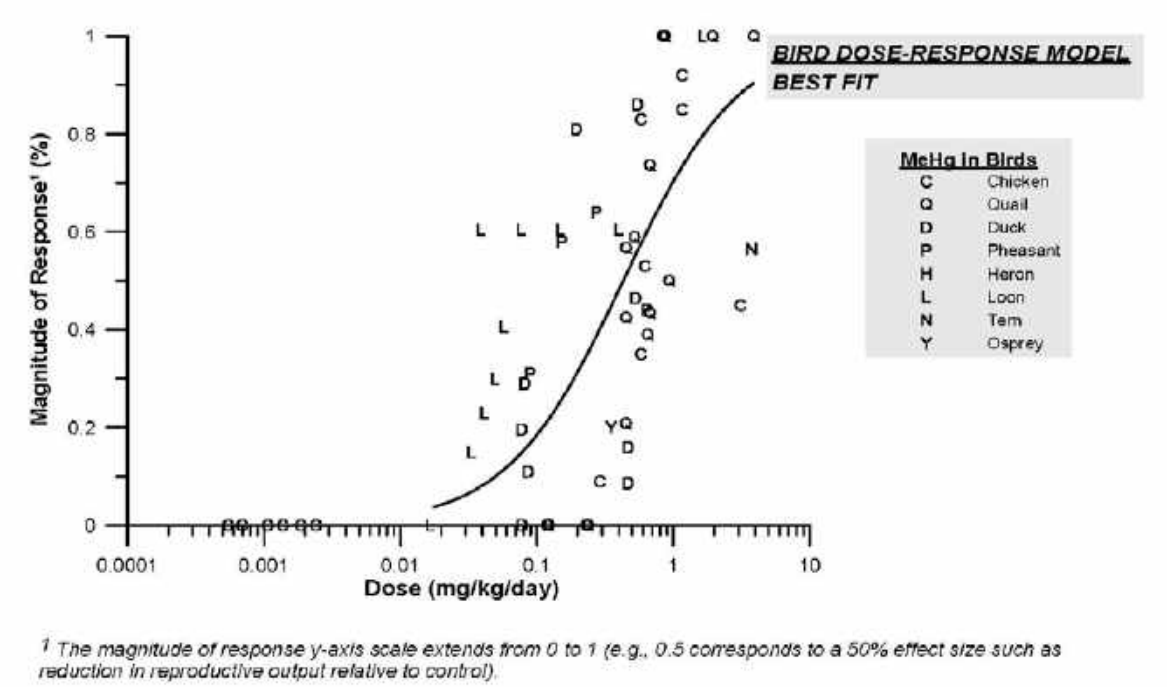

Figure 4: Example of a multi-study concentration response profile (from Environment Canada 2010, courtesy of Azimuth Consulting Group)

4.2.11 Task 3C – Supplemental Bioavailability Analysis

Golder believes that there is sufficient technical support and past precedents for the current use of relative bioavailability in the wildlife food chain model. However, if necessary based on Task 3A, Golder would conduct additional analysis on archived soil, plant and invertebrate tissue samples to provide further information about how bioavailability can be incorporated into the food chain model. Conceptually, relative bioavailability is about establishing a common modifying factor to interpret the total copper concentrations that are established by the chemical analytical laboratory. A focused assessment that involves the same bioavailability analysis on water, soil, food and representative “spiked-food” samples made to duplicate the original approach used in the key toxicology studies from the literature would create a common basis for relative bioavailability in the food chain model.

4.2.12 Task 3D – Update to Food Chain Model

This task is a standalone activity to update the food chain model with the information obtained in Tasks 2A, 2B, 3B, and 3C. Depending on the quantity of information from 2A and 2B, it may be possible to add additional refinement in terms of dietary preferences to more closely reflect how different receptors would be expected to use the site. A bat will also be added as an additional surrogate receptor per ENV’s request. The deliverable for this task would be an update to the existing food chain model report (Appendix F of the ERA).

5.0 SUMMARY

This memorandum describes a proposed approach for the terrestrial component of the CEMP. Not all tiers are recommended for immediate implementation, and there are significant technical and regulatory issues that would need to be resolved as part of the design and execution. Golder recommends that the current CEMP focus on executing the proposed tasks up to the end of Q1 2019. This includes progressing the proposed chrono sequence approach for the long-term CEMP up to the point of submitting a preliminary design for formal ENV approval. The proposed tasks also include activities to reduce the uncertainty in risk estimates to soil invertebrates and wildlife that addresses the content of Table 53 of the ERA.

6.0 CLOSURE

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this technical memorandum.

STUDY DESIGN CONCEPT: AMPHIBIAN COMPONENT FOR THE MOUNT POLLEY MINE COMPREHENSIVE ENVIRONMENTAL MONITORING PLAN

Introduction

Golder Associates Ltd. (Golder) understands that Mount Polley Mine is preparing a Comprehensive Environmental Monitoring Plan (CEMP) to integrate the monitoring components from a variety of regulatory processes applicable to the mine into a single document. One element of the regulatory process involved the submission of an Ecological Risk Assessment (the ERA; Golder 2017) which integrated the available chemical and biological information to provide an overall conclusion about the magnitude and extent of ecological risks associated with the deposit of tailings. The ERA was accepted by Ministry of Environment & Climate Change Strategy (ENV) on 31 January 2018, contingent on the implementation of additional monitoring in relation to specific areas of uncertainty identified in the ERA. One of the identified areas of uncertainty at the conclusion of the ecological risk assessment (Table 53 of the ERA) was that amphibians were not formally assessed. The ERA identified amphibians and reptiles as a relevant receptor group (Section 2.3.3.4 of Golder 2017) with western toad and common gartersnake identified as possible receptors. Western toad was selected as the receptor of potential concern for the broader amphibian and reptile community because it is also a listed species.

This purpose of this memorandum is to outline the monitoring concept proposed to address the uncertainty associated with the amphibian component for the Mount Polley CEMP. If this concept meets ENV expectations, a detailed study design document and specific work instructions will be prepared by Golder as the basis for executing this component as part of the Mount Polley-led CEMP process.

Golder and the G logo are trademarks of Golder Associates Corporation

Basis of Design

The basis of design consists of a summary of the available data and how those data were evaluated in the ERA, provided for the convenience of the reviewers. Copper and vanadium were retained as the contaminants of potential concern in the terrestrial ERA, and copper was retained as the contaminant of potential concern in the aquatic risk assessment. Although no amphibian-specific toxicity reference values were available, these contaminants of potential concern were selected by comparing the maximum observed concentrations conservative, regulatory-approved standards and guidelines. The maximum observed vanadium concentration was only marginally greater than the generic soil standard, and therefore, copper is expected to be the primary contaminant of potential concern for amphibians. Other data relevant to amphibians were described in Section 3.4 of Golder (2017) and consisted of:

- Substantial numbers of tadpoles were observed in 2015 in pooled water that formed throughout the Hazeltine Creek corridor. These tadpoles were confirmed to be western toad (*Anaxyrus boreas*) which is listed on Schedule 1 of the federal *Species at Risk Act*. More than 75,000 individual western toads (approximately 66,000 tadpoles, 9,000 juveniles, 300 sub-adults and 50 non-breeding adults) were subsequently salvaged from 40 different standing water depressions over a two-month period in 2016 prior to the start of rehabilitation. Long-toed salamanders (*Ambystoma macrodactyllium*) and Columbia spotted frogs (*Rana luteiventris*) were also salvaged (at lower numbers). Golder (2017) concluded that the salvage provided qualitative information that amphibians were able to successfully survive, grow and reproduce despite direct contact with tailings and surface water.
- Tissue samples were collected from three amphibians (species not identified) were collected by ENV in August 2016. Golder was not able to confirm the methods used for sampling, processing or analysis and did not review the certificate of analysis with respect to quality assurance/quality control measures. Tissue concentrations in two samples collected from impacted areas ranged from 56.4 to 871 mg/kg Cu dry weight. A tissue sample collected from Gavin Lake (considered by ENV to be a background area) was 12.4 mg/kg Cu dry weight. Data were compared to literature that indicated that copper tissue concentrations corresponding to a lowest-observed effect concentration (LOEC) or no-observed effect concentration (NOEC) ranged from 60 to 325 mg/kg dw (Attachment F, Appendix J of Golder 2017). The average concentration of the two impacted samples was also considered in the uncertainty analysis for the wildlife food chain model (i.e., would the risk conclusion be different if piscivorous birds and mammals had a diet consisting entirely of amphibians). Beyond these qualitative observations, data were not formally evaluated because methods and quality assurance/quality control practices could not be verified.
- Multiple lines of evidence in the ERA demonstrated that copper had low bioavailability. The lines of evidence included geochemical modeling and three different chemical surrogate measurements in tailings samples (water soluble fraction; humidity cell and leach tests; physiological-based extraction tests – see Section 3.2.2 of Golder 2017). Speciation modelling of copper in water showed most of the dissolved copper in Quesnel Lake water would be bound to carbonates which have lower bioavailability than copper ions (see Section 4.2.1.3 of Golder 2017). Golder concluded that the bioavailability of copper would be unlikely to be high for amphibians if there were multiple lines of evidence showing that copper bioavailability to other receptors was low.

Further Consideration of Uncertainty

The purpose of this section is to expand on the specific uncertainties identified in the ERA to be evaluated by focussed monitoring as outlined in this conceptual design document. Golder (2017; Table 53) provided an overview of the uncertainties to assist with future risk management decisions, but a one or two sentence summary does not necessarily convey sufficient detail to show how the design of the amphibian monitoring is linked to the findings of the ERA.

For amphibians, uncertainty is because of the absence of quantitative risk assessment for amphibians. Notwithstanding the value of the inferences and qualitative observations described above, there was only a limited amount of direct measurement of exposure or effects relevant to amphibians at the time the ERA was undertaken. From a practical perspective, rehabilitation of the riparian areas, and restoration of Hazeltine Creek was ongoing throughout the risk assessment process and therefore the habitat suitability for amphibians was considered low. Moreover, completion of the ERA for other major groups of receptors (e.g., mammals, plants) was needed to determine if further remediation activities, which would further disrupt habitat suitability, was needed to address the residual concentrations of copper in the deposited material. Therefore, Golder (2017) determined that it would be inappropriate to arrive at a risk conclusion at that time without further evaluation.

The ERA found that risks for the major groups of receptors were generally low to moderate (reflecting the low bioavailability of copper in tailings) and therefore, extensive additional intrusive works are less likely. Thus, it is appropriate to now consider a monitoring plan that will contribute to confirming that the risk conclusions for other major groups of receptors are also applicable to amphibians.

Conceptual Approach

The amphibian component is essentially a continuation from the problem formulation already completed (Golder 2017) (which identified amphibians as a relevant receptor). In brief, the proposed approach is to continue the risk assessment process by proceeding through the following tiers to the point needed to support an informed risk management decision. The tiering is described in Figure 1, and consists of the following main tasks:

1) Conduct a hazard evaluation – Screen existing soil, sediment and surface water chemistry data for different habitat units against a conservative amphibian-specific screening value. Eliminate habitat units from consideration if copper concentrations are sufficiently low (i.e., the 90th percentile and 95% upper confidence limit of the mean) that risks are not expected.

2) Conduct an exposure assessment – For those areas that are not screened out in Step 1, compare the distribution of soil (or sediment, or water) concentrations for that area to a multi-study concentration response profile for copper. Areas where the average concentrations (e.g., 95% UCLM) are less than the toxicity reference value (TRV) (e.g., geometric mean of chronic, relevant no-observed effect levels) will be excluded from evaluation. Areas that cannot be excluded will be prioritized according to their potential risks (e.g., based on the degree of overlap between the distribution of concentration data and the response profile).

3) Conduct a laboratory-based effects assessment – The exposure assessment above assumes that copper in tailings is equally bioavailable as the original toxicity test. This is unlikely to be true because the ERA had multiple lines of evidence that showed bioavailability of tailings were low. If Step 2 demonstrates the potential for unacceptable risks, then laboratory-based toxicity testing will be used to establish a site-specific copper TRV and the representative soil, sediment and surface water data will be re-screened. Laboratory testing will likely need to include the physical nature tailings as a variable.

4) Refine the application of the toxicity reference values – The evaluation in Steps 2 and 3 assume that all soils, sediment and surface water are representative of a potential amphibian exposure. There may be portions of the terrestrial zone that are unlikely to be suitable amphibian habitat because of their distance from water, substrates or other factors. Refinement of the screening process from Step 3 to focus on the potential areas of habitat may be considered.

5) Conduct a field-based effects assessment – A field-based effects assessment is not contemplated unless concentrations in relevant amphibian habitats exceed both the literature-based and site-specific TRVs. Field-based measurements focus on comparison of population-level or organism-level endpoints between impacted and reference amphibian habitats. A mesocosm study could also be considered (e.g., transplant amphibian larvae between enclosures established in reference and impacted habitats and measure survival and growth at end of chronic exposure)

6) Integrate toxicity and habitat data in a population model – If a copper concentration response relationship has been established, it could be used in a population model to determine the relative influence of copper and physical stressors in the context of natural stressors (e.g., low precipitation) and habitat quality. This assumes that there is adequate information about the population dynamics of the western toad.

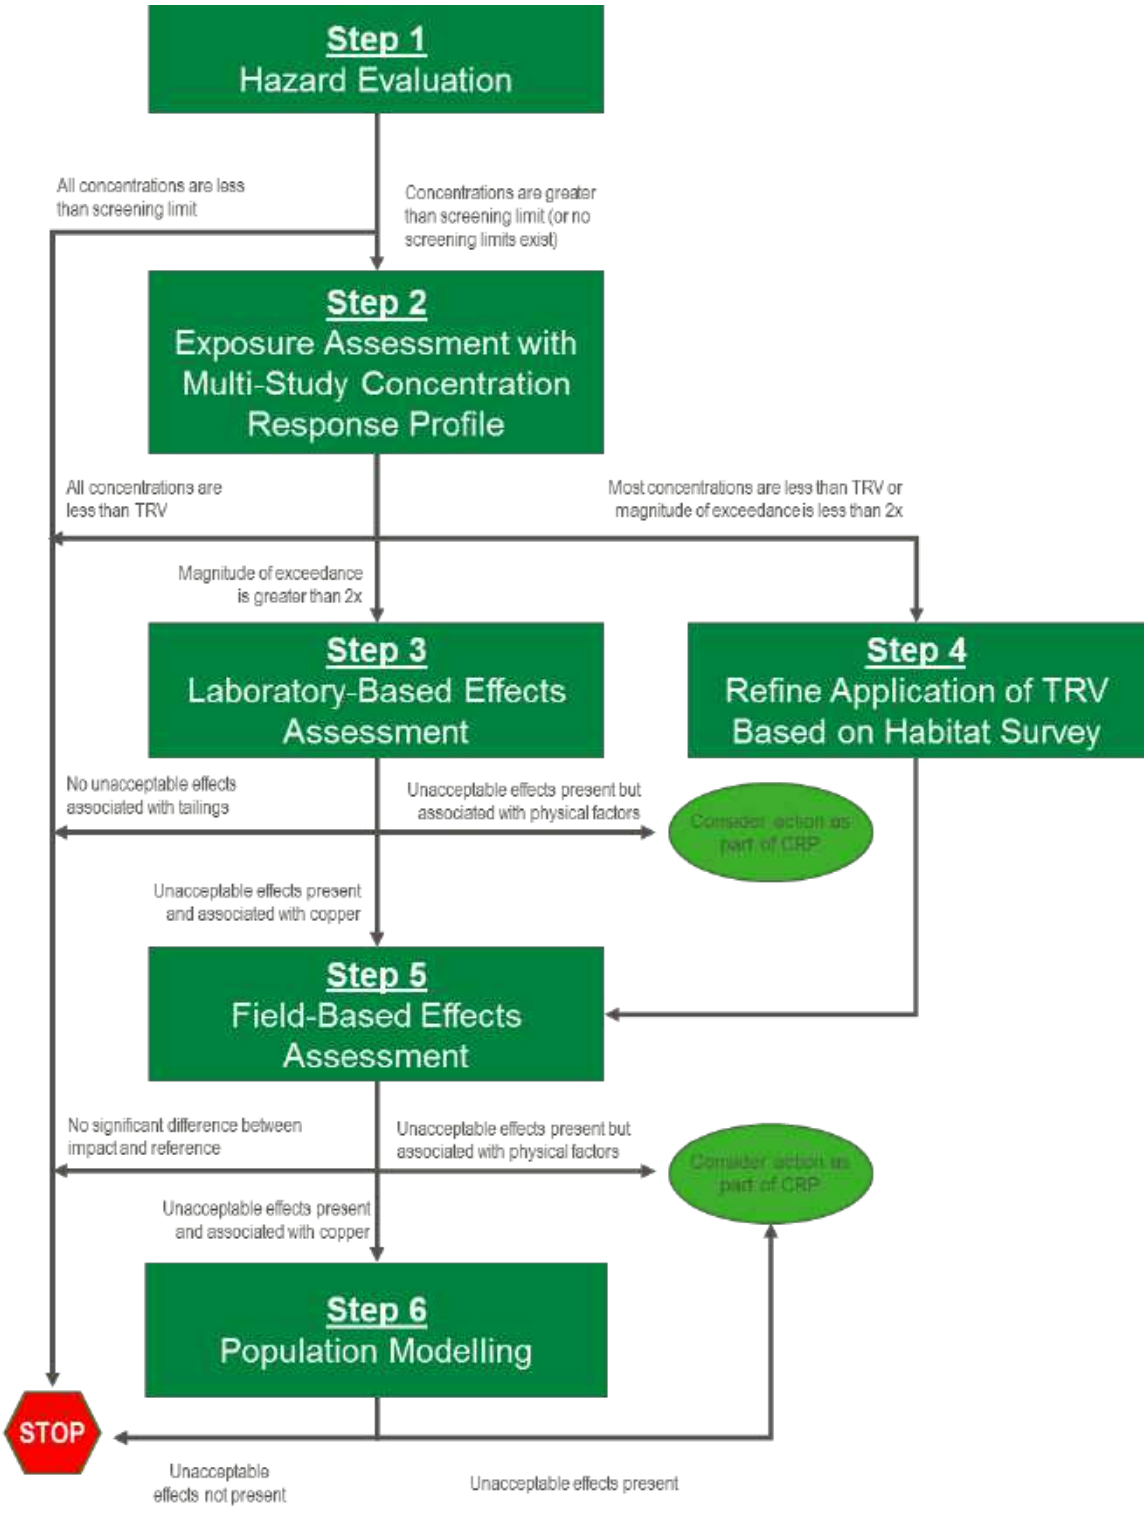

Figure 1: Proposed Tiering for Amphibian CEMP Component

Additional Information

This section expands on each tier in terms of potential sampling activities, levels of effort, and decision criteria. Further expansion of the rationale in the detailed study design is expected based on ENV feedback regarding the approach. The following guidance documents were reviewed as part of the development of this conceptual approach:

- FSCAP. 2016. Module 6: Ecological Risk Assessment for Amphibians on Federal Contaminated Sites. Draft (Not Approved as Guidance).
- Navfac (US Navy, Naval Facilities Engineering Command). 2004. Development of a standardized approach for assessing potential risks to amphibians exposed to sediment and hydric soils. TR-2245-ENV.

These documents provide amphibian-specific risk assessment information that was considered in the context of provincial guidance on conducted detailed ecological risk assessments at contaminated sites.

Step 1: Hazard Evaluation

FSCAP (2016) comment that there are relatively few summaries of amphibian toxicity data that provide generic screening limits. Golder will conduct a brief literature search to seek out amphibian-specific screening limits and review the available environmental quality guidelines to determine the degree to which they are protective of amphibians. The screening limits (if available) will be used to provide an initial evaluation of the soil, sediment and surface water data that is representative of the current-day exposure scenario for amphibians. The purpose of this initial hazard evaluation is to determine if portions of the site can be excluded from the amphibian assessment. An area will be excluded if: a) there is sufficient data to characterize the defined unit; and b) if the 90th percentile and 95% upper confidence limit of the mean concentrations in the unit are less than screening limit. If multiple screening limits are identified, an area will be excluded only if it has concentrations that are less than all limits. If no defensible screening limits are identified, we will proceed directly to Step 2.

Step 2: Multi-study Concentration Response Profile

FSCAP (2016) describe a process for integrating all available literature toxicity data into an overall concentration response profile for each media This “response profile” is then used to derive point-estimate screening limit (i.e., a single “safe” concentration) or effects-based TRVs (e.g., the range of values that correspond to a ECx effect). An example for zinc from FSCAP (2016) is provided in Figure 1.

Golder will develop multi-study concentration response profiles for copper in water and sediment/hydric soils consistent with FSCAP (2016). The overall process involves a literature review (with quality assurance procedures to eliminate unreliable data) consistent with ECO-SSL procedures. The general approach to integrating the literature data into a concentration-effect relationship is like that described by Allard et al. (2010) for wildlife TRVs. The ECO-SSL process is endorsed as a preferred approach in BC risk assessment by Technical Guidance 6 (guidance under the Contaminated Sites Regulation) and wildlife TRVs that consider the entirety of the available literature (instead of a single point estimate) are increasingly common in contaminated sites risk assessments.

Not all data have the same value in the derivation process:

1) Data that fail to meet basic test acceptability criteria (e.g., negative control are not present) will be rejected.

2) More weight will be given to North American species. Many toxicity studies use the African clawed toad (*Xenopus*) as a surrogate, but this species is not native to North America. Removing species that cannot be present at the site is consistent with provincial guidance about establishing site-specific water quality objectives (BCMOE 2013) and is also discussed by FSCAP (2016).

3) More weight will be given to studies that involved measured (instead of nominal) concentrations and/or involved field-collected samples instead of laboratory-spiked samples.

The specific derivation of a screening limit or a TRV is ultimately dependent on the quality and quantity of toxicity data available. It is likely that there will be a wide range of effects associated with a given concentration (e.g., Figure 2, which is for lead), and therefore, a specific derivation rule cannot be proposed at this time. FSCAP (2016) recommends that the data set should be explored to determine if there are significant differences in toxicity profiles for different species, exposure duration, endpoints and life stage. A specific decision about what constitutes an acceptable effect was not proposed by FSCAP (2016), but realistically, screening limits or toxicity reference values that are meant to be protective of western toads would need to reflect a low risk (e.g., EC10 or EC20). Moderate-to-high risk limits (e.g., an EC50-based TRV) may also be derived to help provide further context. Golder will need to consider the totality of the available data and provide a rationale for the TRV proposed. The available soil data will be compared to the TRVs using the same approach as described in Step 1.

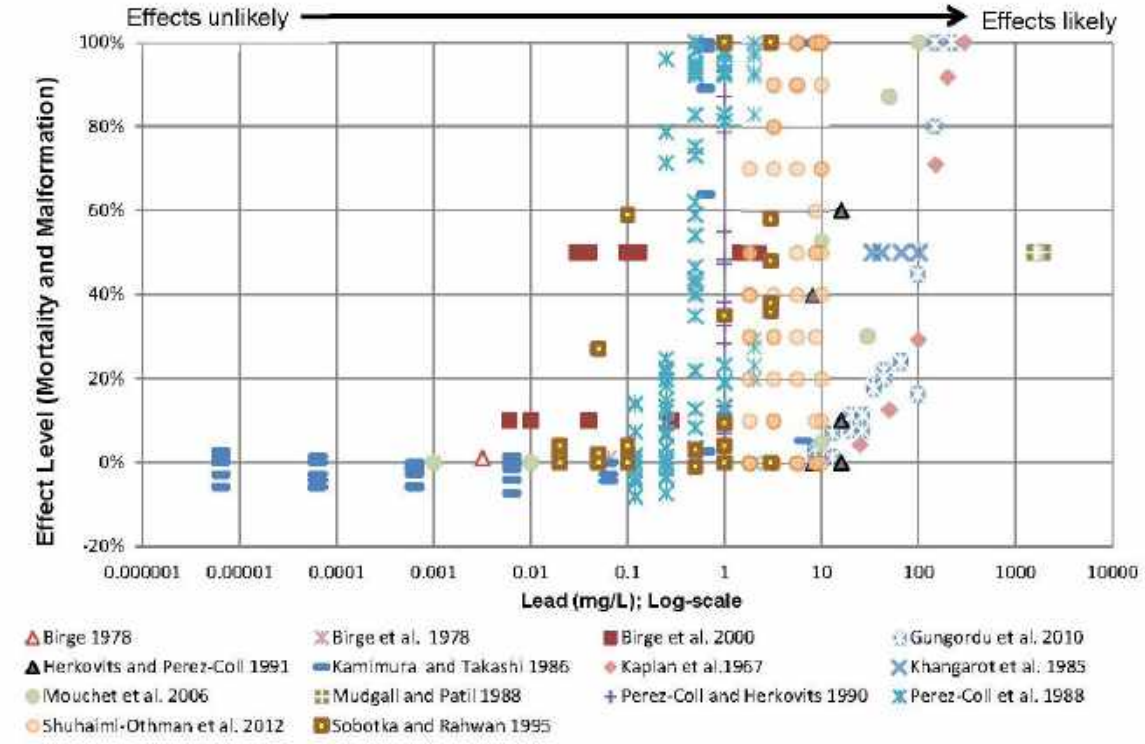

Figure 2: Example of a concentration-response profile (from FSCAP 2016)

Detailed reviewer comments were provided by ENV on May 29, 2018 and a teleconference was held on 9 July 2018 to discuss the conceptual approach and the reviewer comments. Golder understood from the teleconference that a topic of concern relates to how the results from the comparison of soil, sediment and surface water data to the amphibian-specific TRVs would account for amphibian habitat requirements.

Golder notes that there have been many soil samples collected from the site which were considered in the terrestrial risk assessment, and that additional soil sampling is being conducted in August 2018 as part of the supplemental terrestrial monitoring described under separate cover. Nevertheless, it would be a potential gap in the assessment if there were no data available regarding concentrations of copper in soil in areas that are important rearing or feeding habitat for amphibian species. Golder intends to present the data screening from Steps 1 and 2 in a manner that provides context for how the available data helps to inform hazards to amphibians. Specifically, a qualified biologist will provide a summary of habitat requirements for each of the individual amphibian species found in the area and will determine the extent of “high-quality” and “low-quality” habitat using existing information. This desktop-level review will help to place the hazard evaluation from Steps 1 and 2 in context. Further refinement of the hazard assessment based on a detailed habitat survey (Step 4) or a field-based assessment of effects (Step 5) will be considered based on the outcome of Steps 2 and 3.

Step 3: Site-specific Concentration-Response Relationship

A site-specific concentration response could be developed using amphibian toxicity testing in a manner similar to the approaches used for benthic organisms and plants in the ERA. Conceptually, the testing would include:

- Between 5 and 10 field-collected samples with varying copper concentrations that capture the range at which copper would be expected to exert a negative effect (based on Step 2).
- Additional negative controls to evaluate the physical nature of the tailings (e.g., low organic carbon; grain size and shape).
- Inclusion of spiked-copper samples (e.g., silica sand and natural soils spiked with a range of copper concentrations) to evaluate the difference in bioavailability between tailings and the typical literature values.

A detailed design for a laboratory-based toxicity test has not yet been developed, and there would need to be clarification from ENV about how the amphibian toxicity data would be used to make site management decisions before a suitable detailed design could be prepared. Amphibian toxicity testing is not a common approach and there are multiple laboratory-, organism- or sample-related factors that could lead to an unacceptable level of uncertainty in the results. For example:

- Nearly all available standardized protocols (ASTM, USEPA) use *Xenopus* which is not native to North America and it is not clear that this species is appropriate for the current application. Environment and Climate Change Canada (ECCC) is in the process of developing a standardized protocol with a relevant, Canadian species, but Golder understands that there are methodological challenges and organism supply issues yet to be resolved. The status of the draft method is unknown.

- Most standardized protocols are designed for spiked-water applications which would not necessarily provide value to the current application. One exception is NavFac (2004) which describes a method for exposing North American frog and toad tadpoles to field-collected sediment samples for a 10 to 14-day exposure. An ASTM test method is also available for sediment (but it uses *Xenopus*).
- It may be necessary to field-collect test organisms which would not be possible without applicable provincial scientific collection permits and/or federal permits under the Species at Risk Act.

Step 3 could provide value for site management decisions, but there are technical and regulatory issues to be resolved. Further development of a detailed study design for amphibian toxicity testing is not recommended until Step 2 has been completed, and only if there is consensus about how risk management decisions would factor in the possibility of high uncertainty associated with the use of a non-standard toxicity testing method. Ideally, an approved ECCC test method would be available at the time this step would be undertaken.

Step 4: Refinement of the TRV Application

A specific design for this step has not yet been developed. As a default, all soil, surface water and near-shore sediment data will be evaluated in Steps 2 and 3. The general concept for Step 4 is to refine how those TRVs are applied to different areas of the site based on whether the area provides (or will in the future) meaningful habitat for amphibians. The nearshore of the various waterbodies and their immediate riparian zones are likely amphibian habitat and would be included. Conversely, although western toads forage over relatively large areas and can use a range of different habitats (ECCC 2016), portions of the study area that are not suitable habitat for amphibians would then be excluded from the exposure estimates. Step 4 would involve a survey of the impacted area by biologists with specialized amphibian expertise. Areas of the site would be classified according to their suitability as amphibian breeding, hibernation, and foraging habitat (both at present, and in the future). This information would be used to refine how the TRVs are applied (e.g., exclude areas with minimal value to amphibians, and focus on understanding the risks in areas that are key to sustaining the amphibian population).

Step 5: Field-based Effects Assessment

From a risk assessment perspective, field programs provide valuable information because they provide a direct measurement of effects under field conditions. However, in the current application, direct measurement of effects does not necessarily help to differentiate the effects of the residual concentrations of metals associated with tailings from the physical effect of the tailings themselves. The physical alteration of habitat in the impacted areas was substantial, and as a result, a control-impact study design needs to account for the fact that risk management decisions will be different depending on whether the main stressor is physical or chemical.

FSCAP (2016) comments that amphibian risk assessment can incorporate field-based assessments and lists a number of standard methods for conducting field surveys for amphibians. Field assessment would involve a control-impact comparison (similar to the approach used for the benthic taxonomy studies in Quesnel and Polley Lake) and each type of area would preferably involve multiple locations to minimize the effect of natural variability of the risk management outcome. A variety of endpoints could be measured in a control-impact study design (e.g., number of egg masses per unit area; frequency of lesions or malformations per adult; abundance of amphibian larvae per unit catch effort).

Further development of a detailed study design for an amphibian field assessment is not recommended until Step 2 has been completed, and only if there is consensus about how risk management decisions would factor in the possibility of high uncertainty in its outcome. A key question is to determine the number of amphibian breeding sites within the impacted area, and to conduct a baseline survey to confirm that there is an adequate number of potential control sites available in the area. This baseline survey could be conducted as part of Step 4.

Step 6: Population Model

An additional line of evidence in an amphibian risk assessment is to combine the available toxicity and habitat data into a population model. A population model, in this context, simulates the stability of a given local population under a range of future conditions. The model is used to determine if reductions in survival, growth or reproduction from the physical or chemical stressors associated with tailings will impact the population as a whole. An example of a contaminant-habitat population model is provided for context.

Willson et al. (2012) used a population model (at a site unrelated to Mount Polley) to evaluate the impact of mercury on individual toads on the overall viability of population of American toads (*Bufo americanus*). The model simulated the population dynamics of toads to establish a baseline discrete-time model (e.g., how many toads will survive to each successive life-stage based on habitat quality; how big are the toads at reproductive age as a function of food availability; how many eggs will be produced as a function of adult toad size). The effect of mercury on the population was then added to the model as a reduction in the survival, growth and reproduction baseline as a function of mercury concentration. The net effect was a model that simulated how different concentrations of mercury would contribute to the stability of the toad population over time, and to determine which type (and how much) habitat enhancement was needed to off-set the influence of mercury.

In the current application, a model similar to Willson et al. (2012) would provide value by integrating the information from Steps 3, 4 and 5. However, a model like this would only be appropriate if there was evidence that copper was exerting an unacceptable effect which could not be readily remediated. Golder recognizes that habitat compensation to address residual contamination is a policy question that would need to be resolved, particularly for a listed species where the intent is to protect the individuals of the population, not just the population itself. There are also technical limitations to this type of model in terms of the quality and quantity of data available for parameterization. Golder assumes that there would be sufficient species-specific information for western toads because the species is listed and would be a priority for researchers (at least relative to other Canadian amphibians). It may also be reasonable to assume the population variables for western toads are similar to American toads.

Further development of a detailed study design for an amphibian population model is not recommended until Step 2 has been completed, and only if there is compelling evidence that there is a chemical-related impact that would be likely to cause an unacceptable outcome to amphibian populations. In the absence of a chemical-related impact, a model would not necessarily add any value (i.e., a decision to conduct habitat improvement to mitigate a physical stressor does not need to be based on a model).

Summary

This memorandum describes a proposed tiered approach for the amphibian component of the CEMP. Not all tiers are recommended for implementation, and there are significant technical and regulatory issues that would need to be resolved as part of the design and execution of Steps 3 onwards. However, Steps 1 and 2 provide a framework that is similar to a screening-level risk assessment for amphibians, and the process for accomplishing those steps has already been described by draft regulatory guidance (i.e., there is a basis for developing a clear process for those steps).

Golder recommends that Steps 1 and 2 should be completed as part of the current CEMP. No further action would be necessary if risks to amphibians can be shown to be low based on comparison of the relevant soil, surface water and chemistry data to toxicity reference values derived from the available literature. A preliminary review indicates that there will be sufficient data in the literature of suitable quality to support Step 2. If risks are found to be unacceptable at the conclusion of Step 2, further investigation following the tiered approach described in this memorandum may be necessary.

Closure

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this memorandum.

Please do not hesitate to contact the undersigned if there are questions regarding this memorandum.

STUDY DESIGN FOR DEVELOPING REFERENCE CONDITIONS FOR POLLEY LAKE – MOUNT POLLEY MINE

Dear Mr. Parsons,

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with this study design for characterizing reference conditions for Polley Lake. This study design was prepared in response to a condition set by the Ministry of Environment and Climate Change Strategy (ENV) for approval of the Comprehensive Environmental Monitoring Plan (CEMP), specifically:

> *An updated study design must be provided, which includes the monitoring location, frequency, and methods for assessing reference conditions for Polley Lake, and which includes a description of the process for characterizing the relative differences between Bootjack Lake, Polley Lake, and the newly identified reference location.*[1]

1.0 OBJECTIVES

Polley Lake is adjacent to the Mount Polley Mine, and environmental monitoring is undertaken to assess the potential for mining activities to affect biological communities in the lake. At the present time, the reference lake for Polley Lake is Bootjack Lake, on the opposite side of the mine site from Polley Lake. Because there is potential for mine-contact water to enter Bootjack Lake in the future, ENV requested that MPMC identify one or more alternate lakes to function as references and to begin data collection early on to provide temporal and spatial continuity to the program. The purpose of this letter is to provide a decision framework and methods for selecting candidate alternate reference lakes for Polley Lake.

[1] 9 November 2018 letter from D. Hill, ENV, to D. Reimer, MPMC, "Approval of the August 15, 2018 Comprehensive Environmental Management Plan (CEMP) – Mount Polley Mine Permit PE-11678".

2.0 IDENTIFICATION OF CANDIDATE LAKES

The decision framework for identifying potential candidate reference lakes is illustrated in Figure 1. The primary variables expected to have an influence on hydrodynamics and biological communities in a given lake, and which can be characterized at a desktop level, are: biogeoclimatic zone, size, depth, surrounding land use, and underlying geology. Ideally, reference areas will have as similar characteristics to the exposed area as is reasonably practicable. Once a subset of lakes is identified, collection of sediment and water samples will be needed to select the final candidate reference lake(s).

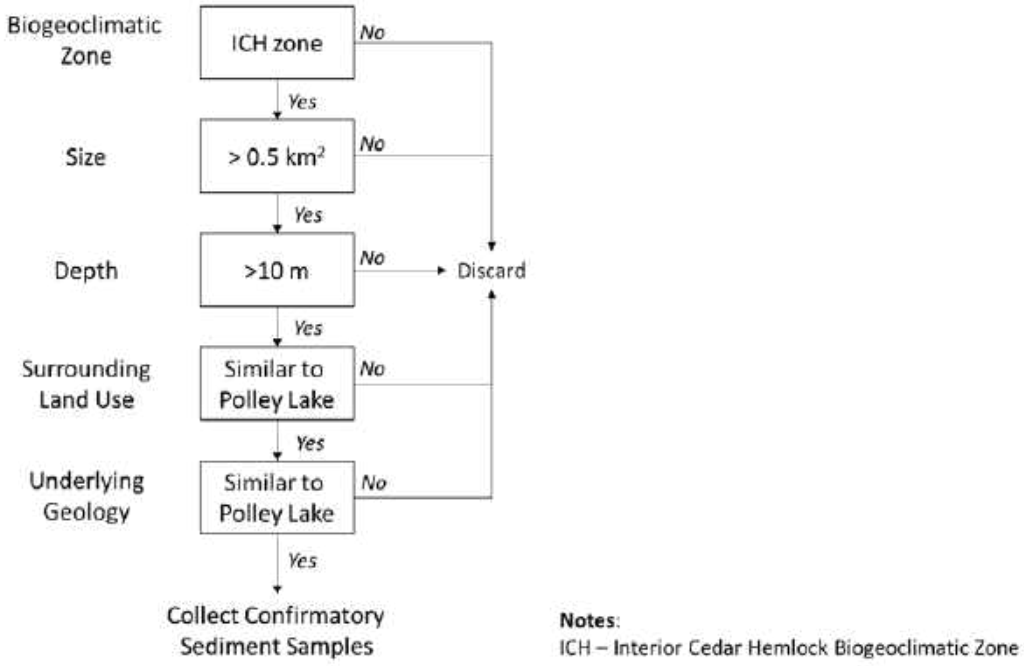

Figure 1: Decision Framework for Selection of Candidate Reference Lakes

Following this approach, Table 1 provides a summary of an initial subset of candidate reference lakes. Jacobie Lake was sampled in 2018 and the results confirm that the underlying geology is likely too dissimilar to Polley Lake to provide a suitable reference. It is also expected that Spanish Lake is unsuitable because it is in a wet subzone (wk2) of the Interior Cedar Hemlock (ICH) zone, has notably different underlying geology (arsenic and selenium is enriched in rocks on the opposite shore of Quesnel Lake), and is subject to mineral exploration and planned mine development (and therefore potential future mine-related activities).

Morehead and Gavin Lakes are both in the moist cool subzone (mk3) of the ICH zone, and Morehead coincides with at least one geological unit (LT_{Nvl}) that is similar to Polley Lake. Geological mapping will be further reviewed to evaluate similarity in the composition of the underlying geology vis-à-vis similarity to be a source of primary metals/metalloids of concern (e.g., copper, selenium, arsenic). However, Morehead Lake receives drainage from Bootjack Lake.

Table 1: Characteristics of Polley Lake and Candidate Reference Lakes

Lake	Elevation (m) [(a)]	Area (km^2) [(a)]	Depth: max (mean) (m) [(a)]	Underlying Geology [(b)]	Biogeoclimatic Zone [(c)]	Activities
Polley Lake	920	3.9	35 (18)	LT_{Nvl}, LT_{MPic}, LT_{Nav}	■ ICHmk3	■ Adjacent to Mount Polley Mine ■ Recreation (camping, fishing)
Bootjack Lake	983	2.6	15	LT_{Nvl}, LT_{Npt}	■ ICHmk3	■ Adjacent to Mount Polley Mine ■ Recreation (camping, fishing)
Jacobie Lake	1,122	0.86	20 (7)	LT_{Npv}, LT_{Nvb}	■ ICHmk3	■ Recreation (camping, fishing)
Morehead Lake	916	2	17	$LT_{Nvl,}$ Qal	■ ICHmk3	■ Recreation (camping, fishing)
Gavin Lake	963	0.94	24	MJ_{Qm}, LT_{Ns}	■ ICHmk3	■ Recreation (camping, fishing)
Spanish Lake	919	4.6	72.5 (29.6)	MLT_{Ns}	■ ICHwk2	■ Mineral exploration ■ Recreation (camping, fishing)

LT_{Npt}: Plagioclase phyric, pyroxene lapilli tuff, breccia and minor flows.

LT_{Npv}: Green and maroon pyroxene porphyry breccias, pyroxene-olivine basalt flows, and crystal-rich sediments.

LTNs: Grey siltstone, normal graded sandstone and cherty shale with pyroxene and plagioclase-rich crystal sandstones.

LTNvb: Massive, coarse polymictic volcanic breccias, graded sandstones, siltstone and rare limestone breccia horizons.

LTNvl: Red-brown, massive, polymictic breccia, feldspar, and hornblende crystal tuff.

MLTNs: Graphitic and quartzose phyllite, shale, siltstone and sandstone.

MJQm: Hornblende-biotite quartz monzonite.

mk3: moist cool zone.

wk2: wet cool zone.

3.0 VERIFICATION OF SUITABLE REFERENCE LAKE

Prior to the 2021 benthic invertebrate sampling program for Polley Lake, five sediment samples will be collected from lakes with similar geology to Polley Lake and analyzed for metals and grainsize distribution. Water samples will be collected from two locations and two depths (surface and depth) and analyzed for metals, hardness, total and dissolved organic carbon, and nutrients. At each of the two sampling locations, field measurements of pH, temperature, dissolved oxygen and conductivity will be recorded at 1 m intervals. Sampling methods (including quality assurance/quality control procedures) as outlined in the CEMP will be followed.

The resulting physico-chemical data will be compared to data from Polley Lake and Bootjack Lake. The comparisons may be made visually using graphs; through screening against sediment quality guidelines; and/or using statistical tests such as principle components analysis (PCA) or non-metric multidimensional scaling NMDS). The specific tests will be determined at the time of analysis, as factors such as variance and distribution (normal/non-normal) of the data and proportion of detectable versus non-detectable concentrations will need to be taken into account.

Sampling of the benthic invertebrate community of the selected lake will be conducted in 2021, along with sampling in Polley Lake.

4.0 CLOSURE

We trust that this letter provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at 604-296-4200.

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

Yours very truly,

Golder Associates Ltd.

STUDY LIMITATIONS

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by Golder for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents Golder's professional judgement based on the knowledge and information available at the time of completion. Golder is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document

pertain to the specific project, site conditions, design objective, development and purpose described to Golder by MPMC, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by Golder are considered its professional work product and shall remain the copyright property of Golder. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

Appendix C

Combined Monitoring Schedule 2019

Mount Polley Mining Corporation

Monitoring Schedule

Task	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
	31	**1**	**2**	**3**	**4**	**5**	**6**
					No staff on weekend		
Lakes							
Surface Water		Discharge: E19, HAD-3 Surface water sampling: W1, WA (W1 dup), W4a, W5, W8, W8z, W20, W21, Gavin's Ditch, WL (W12 dup), East 12204 (East MTD dup), West MTD, LD, SERD, E1a, ED (E4 dup), **2 ppl; 8**	Surface water sampling: E13, E14, E15, E17, E18, E19a, E20, E21, E22, E23, STD, TB + FB ; JCP, Boundary Seep 2, MDC, SERD Seep 13 **2 ppl; 8 hours**	SERD Seep Survey **2 ppl; 5 hours**			
Reclamation		Seeding/Monitoring as necessary					
Groundwater				GW15-1A/B & GW15-2A/B SWLs			
Hydrology							
Weather		Snowpack/Manual Rain Gauge		Manual Rain Gauge			
Inspections		Mill Potable Water Meter **2 per; 5 hours (winter)**	HAC Fish Spawning Survey **1 per; 6 hours** **2 ppl; 4 hours**	EDC Fish Spawning Survey; Waste Inspection			
Soil/Sediment		ABA (if dumping NAG waste)					
	7	**8**	**9**	**10**	**11**	**12**	**13**
Lakes	P1 (S+P)[1] + PA-B + P2 (S+P)[1] B1 IS+P) + B2 (S+P) + BB-S **2 ppl; 8 hours**						
Surface Water		**DO all locations:** HAC-01c, HAC-13 + HAC-08, HAC-05a, HAC-10 + HAC-J + HAC-10-FB, POF-1, POF-5, CSD Bridge photos Discharge:E19, HAD-3 + HAD-C BAC-01 (Ladies Dry) **2 ppl; 8**	PAG Seep Survey **2 ppl; 5 hours**	East RDS Seep Survey **2 ppl; 5 hours**			
Dustfalls				Dustfalls **2 ppl; 7 hours in winter** **1 per: 4 hours in summer**			
Reclamation	Seeding/Monitoring as necessary						
Groundwater	GW15-1A/B & GW15-2A/B SWLs						
Hydrology	W1b, W5, W12, SERD, H6 **if safe and not frozen**						
Weather	Manual Rain Gauge	snowpack if melting event forecast		Manual Rain Gauge			
Inspections	Waste inspection	Spring/Fall Ditch Inspections	HAC Fish Spawning Survey	EDC Fish Spawning Survey			
Soil/Sediment	ABA (if dumping NAG waste)						
	14	**15**	**16**	**17**	**18**	**19**	**20**
Lakes	QUL-ZOO-8 (S+C)[3] + QUL-ZOO-8-FB QUL-ZOO-7 (S+C)[3] QUL-ZOO-1 (S+C)[3]	QUL-58 (S+C)[1] + T.Hg + Ra-226 QUL-57 (C) + QUL-59 (C) QUL-2a (S+C)[1] + T.Hg + Ra-226	QUL-18 (S+C)[1] + QUL-R-50m QUL-120a (S+C)[f] + QUL-ATa-190m				
Surface Water		Discharge: E19, HAD-3 + T.Hg + Ra-226+ toxicity[a, g, h] (100L) BAC-02 (Pit shop sink)		NEZ Seep Survey + DO at all locations: NEZ Samples + 2119 NEZ Seep LD (US NEZ Seep LD dup)+ Martel Sump + NEZ Seep -TB			
Reclamation	Seeding/Monitoring as necessary						
Groundwater	GW15-1A/B & GW15-2A/B SWLs						
Hydrology	H1, H2, H3, H4 **if safe and not frozen**						
Weather	Manual Rain Gauge	snowpack if melting event forecast		Manual Rain Gauge			
Inspections	Waste inspection	Trailer Inventory	HAC Fish Inspection (if ice free)/Fish Spawning	EDC Fish Spawning Survey

Inspections	Waste inspection	Spring/Fall Ditch Inspections	HAC Fish Spawning Survey	EDC Fish Spawning Survey			
Soil/Sediment	ABA (if dumping NAG waste)						

C = cast + secchi
P = profile + secchi
S = sample

Special Sampling:
1) Chlorophyll a, phytoplankton, [zooplankton - POL only] (Jun/Aug)
3) Zooplankton, chlorophyll *a* , phytoplankton, surface sample

QA/QC Sampling:
Field Blank - 2x monthly minimum
Trip Blank - 2x monthly minimum
Equipment Blank KEM2 - monthly; GW - quarterly
Duplicates - 2x monthly minimum

Quarterly Wells (SWL): Complete Q1

~~GW96-1a~~	GW96-2a
GW96-4a	GW16-2a,3a,4a,5a
GW00-1a	GW96-3a
GW00-2a	GW00-3a

Flows:
Purple:Bucket Black: Tracker

Ongoing/When Time:
Crew Training
Battery recycling
Trailer Clean Up/Safety -test PFDs
Wash trucks (in and out)

Seep Sampling:

SERD	WHR
PAG	TSF
BOUNDARY	NBD
EAST RDS	NEZ

Reclamation Activities:
Grass Seeding

QUL Sample Depths (m):

QUL-18	0, 20, 50, 100
QUL-2a	0, 20, 40, 60
QUL-58	If detect plume: Middle of plume (MP) + 5m above (AP) + 5m below (BP) (all sites) If can't detect plume: S, 1m above thermo , 1m below thermo [or MID if no thermo], bottom * write sample depths in field book **4x per year: T.Hg taken at QUL-58 (depth at which plume expected), QUL-2a (close to same depth as QUL-58), & HAD-3 *** write field parameters for each sample taken and indicate if discharging in field book
QUL-55	0, 15, 30
QUL- 42:	0, 10, 20
QUL-120a:	0, 40, 80, 120, 140 well-mixed: 0, 80, 190

BJ + POL Sample Depths (m):
S, 1m above thermo , 1m below thermo [or MID if no thermo], bottom
* write sample depths in field book
** monthly profiles between spring and fall overturns

Toxicity:
a) 96h LC50 RBT, 48h LC50 *D. magna*
b) 7 day ELS RBT
c) 7d C. dubia S&R
d) 7d RBT S&G
e) 30d ELS RBT
f) 30d ELS top-up (100L)
g) 72h algal (MMER)
h) 7 day duckweed (MMER)

Chorophyll *a* :
250ml polyethylene bottle wrapped in aluminum foil

Phytoplanton:
polyethylene bottle, preserved with Lugol solution

Zooplankton taxonomy (1 haul):
Quesnel Lake --> 150µm mesh net to 30m depth (1 tow), preserved with buffered sucrose
Polley Lake --> 50µm mesh net to 28m depth (1 tow), preserved with 85% ethanol

Zooplankton metals:
minimum amount of water, kept frozen, multiple hauls (depending on biomass)
QUL --> 50 µm mesh net minimum amount of water, kept frozen, multiple hauls (depending on biomass)
POL --> 50 µm mesh net minimum amount of water, kept frozen, multiple hauls (depending on biomass)

Special Analyses:
T.Hg - 40ml glass vial with 1x HCl
Ra-226 - 1L plastic with 6x HNO3

Appendix D

Site Matrix

Mount Polley Mining Corporation

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
W1 Morehead Creek	E 587262 N 5826275	1990	Meandering creek with lots of willows and grass, no distinct trail. Large marsh to the North.	Drive to km 4.5 on Bootjack Road to a small opening in the trees, and walk down the bank on the south side for 50 m. Trail and site marked with orange flagging tape.	Radio communication must be used on the Bootjack Road (Channel RR-25). Ensure that vehicle is parked to the side of the road out of the way of traffic. Watch for wildlife. Watch for rotten logs while approaching site. Follow working in/near water procedures.	Downstream of mine impacted area. Provides opportunity to monitor potential changes in POI's in Bootjack Lake.
W1b Morehead Creek	E 588920 N 5825173	2003	Meandering creek that flows under a bridge.	Drive to approx. km 7 on Bootjack Road and turn south onto side road for approx. 90 m until you reach a bridge. Walk down an embankment on the upstream side of the bridge to the creek.	Radio communication must be used on Bootjack Rd (Channel RR-25). Watch for wildlife. Watch your footing when walking down embankment. Follow working in/near water procedures.	Monitoring flow out of Bootjack Lake.
W4a North Dump Creek	E 593152 N 5824689	2014	Small stream that flows under the Wight Pit road through a culvert.	Drive towards the Wight Pit, before entering pit there will be one last runaway lane on the left hand side, park vehicle on right side of the road. The sample site is located over the berm and down an embankment; there is a large log on the hillside to indicate the sample location.	Watch for wildlife. Watch your step while descending the embankment to monitoring location; there are loose rocks. Follow working in/near water procedures.	Downstream of mine impacted areas. Provides opportunity to monitor for non-contained seeps or run-off collection ditches.
W5 Bootjack Creek	E 594481 N 5820782	1990	Small stream runs through culvert	Drive down the TSF haul road towards Polley lake weir, turn left at the central collection sump. Turn left onto deactivated logging road across from SERD outlet pipe. At top of hill, turn right and at the valley in the road park truck. Trail down to the creek is on the upstream side of creek. Site trail is indicated by fallen tree across path.	Contact Pit Shifter prior to entering haul roads. Drive with caution on haul roads and give heavy equipment the right-of-way. Use 2-way radio communication (Channel 5 – Pit Ops 1). Watch for wildlife. Slippery slopes with quite a few willows and one fallen tree. Old logging road can be very rough and muddy, recommend 4X4 or walk in during snowy conditions. Follow working in/near water procedures.	Downstream of mine impacted areas. Provides an opportunity to monitor for seepage from the SERD.
W8 Edney Creek Tributary	E 597005 N 5817606	1995	Small stream with easy access from the road.	Turn S at the old ABR onto a narrow road. Drive for roughly 2 km, until you come to a small stream flowing under road through a culvert. Monitoring site is located on the downstream side of the road.	This road can be very muddy, recommend 4X4 or walk in during snowy conditions. Look for old orange ribbon. Watch for wildlife. Follow working in/near water procedures.	Downstream of mine impacted area. Provides opportunity to monitor for potential seepage from TSF.
W8z Edney Creek Tributary (control)	E 593290 N 5817920	1997	Small creek flows under road through a culvert. Many trees down over stream and many willows.	Drive to Gavin Lake Rd and turn right. Drive a few kms to about km 15 board, just before a junction with a deactivated logging road. The monitoring location is on the right hand side of the road (upstream side of the road) just before the second landing.	Look for pink ribbon. Park to the side of the road. Short steep incline to access the monitoring site. Watch your step; there is not much room near the creek. Watch for wildlife. Follow working in/near water procedures.	Upstream of mine. Allows for monitoring of seasonal variability of surface water.
W10 Edney Creek	E 601183 N 5816862	1995	Lower Edney Creek underneath a bridge.	Turn left onto Gavin Lake Rd. Continue on and turn right on Ditch Rd towards Horsefly. Travel to the second bridge crossing. On the right hand side of the road past the bridge (upstream side of the creek), there is a path down to the creek.	Watch for public traffic on the road and ensure vehicle is parked out of the way. Flows may be high during freshet. Ice can build up on edges of creek in winter conditions. Watch for wildlife. Follow working in/near water procedures.	Outside of mine impacted area. Allows the opportunity to monitor for changes in newly constructed creek downstream and to monitor for seasonal variability.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
W12 6K Creek (Tributary to Morehead Creek)	E 588360 N 5825961	1990	Small stream that enters a marsh at the end of an old overgrown road. Small fish present in the stream.	Drive to km 5.5 on Bootjack Rd., to the chain-up pullout. Walk down old road on the NE side of Bootjack for roughly 150 m.	Radio communication must be used on the Bootjack Rd (Channel RR-25). Ensure that vehicle is parked to the side of the road out of the way of traffic. Watch for wildlife. Follow working in/near water procedures.	Upstream of mine. Allows for monitoring of seasonal variability of surface water.
W20 Un-named Tributary to Bootjack Lake	E 592161 N 5821586	2013	Small creek on the NE side of Bootjack Lake, lots of grass, willow, alder and fallen trees. Creek flows roughly parallel to the West Ditch.	Walk in or boat access only. Drive midway on the West Ditch Rd. between the Booster Station and Mine Drainage Creek Sump. Park and walk W to the creek. Follow creek to the lakeshore. Monitoring location is in the creek channel approx. 15 m from the lakeshore. Look for orange ribbon at monitoring location.	If accessing by boat, follow safe boating SOP. If walking, watch for wildlife. Watch for Devil's Club. Walk with caution, as there are lots of blowdown. Ensure vehicles are parked out of the way. Follow working in/near water procedures.	Downstream of mine impacted area. Provides the opportunity to monitor for any seepage from the west ditch.
E1a Tailings Storage Facility	E 594495 N5819187	1997	TSF Supernatant	Drive along the TAR to the TSF. Enter the TSF near corner 5 and follow road to the barge.	Use radio communication when travelling on haul roads and contact Pit Shifter prior to entering haul roads and TSF area (switch from Channel 5 to Channel 1 (Tailings) when entering TSF area). Give right-of-way to heavy equipment. Follow working in/near water procedures. Watch for slippery surfaces in freezing conditions.	Monitoring supernatant WQ in the TSF.
E11 Springer Pit	E 591701 N 5823327	2011	At bottom of the Springer Pit.	Travel down into the bottom of the Springer pit ramp and the monitoring location is near the pipes coming out of the springer pit.	Contact the Pit Shifter prior to entering and leaving the Springer Pit. Use caution when walking under highwalls.	When not storing water from other sources on site: source terms. When storing water from other sources on site: monitoring for potential discharge.
E19	E 595760 N 5819760	2015	Water Treatment Plant Influent	Travel down the TSF haul road towards corner 2 of the TSF. Approx. half way to corner 2 there is a road on the left that goes to the WTP. Monitoring site is located inside facility at the influent pipe at the main entrance to plant.	Use caution when driving on haul roads; contact the Pit Shifter prior to traveling to and from WTP. Watch for haul trucks on haul roads. Give the right-of-way to heavy equipment and used 2-way radio communication.	Provides ability to monitor efficacy of treatment.
HAD-3	E 595772 N 5823583	2015	Water Treatment Plant Effluent	Travel down the TSF haul road towards corner 2 of the TSF. Approx. half way to corner 2 there is a road on the left that goes to the WTP. Monitoring site is located inside facility at the effluent pipe located by the door that leads to the WTP office.	Use caution when driving on haul roads; contact the Pit Shifter prior to traveling to and from WTP. Watch for haul trucks on haul roads. Give the right-of-way to heavy equipment and used 2-way radio communication.	Compliance point for discharge to environment.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
H1 Hazeltine Creek	E 597030 N 5818978	2015	Mid Hazeltine Creek hydrology station approximately 100 m downstream of Gavin Lake Bridge.	Travel to Gavin Lake Rd and turn left. Cross the Gavin lake bridge and park off to the side. Walk approx. 100 m downstream of the bridge to hydrological monitoring station and is marked with staff gage and metal pipes.	Used caution when driving on TSF haul road. Contact the Pit Shifter prior to traveling on haul roads. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch your footing on loose rocks. Watch for wildlife. Use caution in high flow times. Follow working in/near water procedures. May need hip waders.	To monitor hydrology of mid Hazeltine Creek.
H2 Hazeltine Creek	E 601024 N 5817253	2015	Lower Hazeltine Creek hydrology station.	Travel to the Gavin Lake Rd and turn left. Continue on road until you reach the Ditch Rd, and turn right towards Horsefly. Before the Ditch Road bridge, turn left through the gate. The station is approx. 200m from the gate. Hydrology station is marked with staff gage and metal pipes.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Watch for wildlife. Use caution in high flow times. Follow working in/near water procedures. May need hip waders.	To monitor hydrology of lower Hazeltine Creek.
H3 Edney Creek	E 601538 N 5817123	2015	Edney Creek Hydrology station.	Travel to the Gavin lake Rd and turn left. Continue on road until you reach the Ditch Rd, and turn right towards Horsefly. Drive past the Ditch Road bridge and turn left through the gate. Drive approx. 300 m and the hydrology station is marked with staff gage and metal pipes on the right hand side of the road.	Park vehicle to the side of road. Watch footing when walking to hydrology station – some loose rocks. Use caution in high flow times – do not complete task if flow is too strong. Follow working in/near water procedures. Watch for wildlife. May need hip waders.	To monitor hydrology of Edney Creek.
H4 Hazeltine Creek	E 595892 N 5819997	2015	Upper Hazeltine Creek hydrology station at Polley lake weir..	Drive down the TSF haul road to Polley lake weir. Hydrology station is marked by staff gauge approx. 50 m downstream, of the weir.	Use caution when driving on haul roads, radio contact the Pit Shifter prior to entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times. Follow working in/near water procedures. Watch footing on loose rocks down to the creek. May need hip waders.	To monitor hydrology in upper Hazeltine Creek and out of Polley Lake.
HAC-05a Hazeltine Creek	E 596916 N 5819074	2015	Upper Hazeltine Creek just upstream of Gavin Lake bridge.	Travel as described above to H1. Monitoring location is the upstream side of Gavin Lake bridge.	Used caution when driving on TSF haul road. Radio contact the Pit Shifter prior to entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch your footing on loose rocks. Watch for wildlife. Use caution in high flow times and winter conditions. Follow working in/near water procedures.	Monitor WQ downstream of the effluent discharge - when discharging. To monitor WQ post creek reconstruction - when not discharging.
HAC-08 Hazeltine Creek	E 600723 N5817290	2015	Lower Hazeltine Creek just upstream of Ditch road bridge.	Travel as described above to H2, but instead of turning left before the bridge, drive to the bridge and park to the side. Monitoring location is just upstream of the Ditch road Bridge.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Use caution in high flow times. Use caution in freezing conditions as ice can build up – may need swing sampler in these conditions. Follow working in/near water procedures.	This site was established to monitor WQ below the canyon. As Hazeltine Creek remediation continues there are opportunities to monitor the effect of remediation on the creek.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
HAC-10 Hazeltine Creek	E 595793 N 5820738	2015	Upper Hazeltine Creek monitoring site just downstream of Polley Lake weir.	Travel as described above to H4. Sample location is just downstream of Polley lake weir, from a large rock on the west side bank.	Use caution when driving on haul roads, radio contact the Pit Shifter before entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times and winter conditions. Follow working in/near water procedures.	Monitor the surface WQ of Polley Lake as the water flows out of the lake and into Hazeltine Creek. The data from this site provides quick feedback on important parameters for fish habitat in the creek (pH, DO, and temperature).
HAC-12 Hazeltine Creek upper settling pond	E 601577 N 5817292	2015	Lower Hazeltine Creek monitoring site at diffuser pipes in upper settling pond.	Travel as described above to H2, but drive approx. 500 m past it towards Quesnel Lake. Site is marked with two curved pipes sticking out of the ground.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Use caution in high flow times and icy conditions as ice can build up on edges. Follow working in/near water procedures.	This site currently monitors the quality of the mixture of effluent discharge and Hazeltine Creek water prior to the outflow to Quesnel Lake – when discharging. Site will be removed from the sampling program once discharge pipeline is complete.
HAC-01c Hazeltine Creek outflow	E 601661 N 5817598	2015	Hazeltine Creek outflow to Quesnel Lake.	Travel as described to HAC-12, and then drive towards Quesnel Lake. Monitoring Site is located at the outflow of Hazeltine Creek into Quesnel Lake.	Park vehicle to the side of road. Watch for wildlife. Call km boards on the radio while traveling in both directions. Use caution in high flow times and icy conditions as ice can build up on edges. Follow working in/near water procedures.	Monitor WQ at the mouth Hazeltine creek at Quesnel lake once the discharge pipeline is complete. It will replace HAC-12 as the outflow site when it is removed from the sampling program.
HAC-14 Hazeltine Creek	E 598742 N 5817299	2017	Mid Hazeltine Creek monitoring site above the canyon.	Drive as described to H1, but continue down Gavin Lake road to approx. km 5.5 and turn right on the creek access road. Continue on road for approx. 2 km and turn right at the second road on the right hand side. Monitoring site is located at the bottom of the ramp marked by a red and white stripped flagging tape.	Use caution when driving on haul roads, radio contact the Pit Shifter before entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times and winter conditions as ice can build up on edges of creek. May need snowshoes in winter. Follow working in/near water procedures.	Monitor WQ of Hazeltine creek above the canyon.
POF-5 Polley Flats	E 595682 N 5820174	2017	Drainage from Polley Flats into Hazeltine Creek	Drive as described to HAC-10. Just before the weir, turn right and follow road to the end. Site is on the left hand side towards Hazeltine Creek and is marked with an orange stake at the outflow to Hazeltine Creek.	Use caution when driving on haul roads, radio contact the Pit Shifter before entering area. Give the right-of-way to heavy equipment and used 2-way radio communication. Watch for wildlife. Use caution in high flow times and winter conditions. Follow working in/near water procedures.	Monitor WQ of the drainage from the Polley Flats.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
EDC-01 Edney Creek	E 601811 N 5817445	2015	Lower Edney Creek Sample site approx. 20 m upstream of the flood channel.	Follow travel instructions as described above to H3. Follow Edney Creek downstream towards Quesnel Lake and the monitoring location is approx. 20 m upstream from the flood channel.	Park vehicle to the side of road. Watch footing over loose rocks to the creek. Use caution in high flow times and freezing conditions as ice can build up on edges of creek. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ of Edney Creek post reclamation of the lower section and its input to Quesnel Lake.
B1 Bootjack Lake	E 590049 N 5823528	2001/2007	Bootjack lake north WQ monitoring site	Drive on the Bootjack Forest service road to the Bootjack lake campsite at km 8 on the access road.	Follow Safe Boating SOP. Contact Pit Shifter and Front Gate person when leaving mine site. Call kms on Channel RR-25 on the Bootjack FSR. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ for potential mine influence in Bootjack Lake.
B2 Bootjack Lake	E 591263 N 5821647	2001/2007	Bootjack Lake south WQ monitoring site	Drive on the Bootjack Forest service road to the Bootjack lake campsite at km 8 on the access road.	Follow Safe Boating SOP. Contact Pit Shifter and Front Gate person when leaving mine site. Call kms on Channel RR-25 on the Bootjack FSR. Watch for wildlife. Follow working in/near water procedures.	Monitor water WQ for potential mine influence in Bootjack Lake
P1 Polley Lake	E 593708 N 5824693	2001/2007	Polley Lake north WQ monitoring site	Drive down the TSF haul road to Central collection sump near corner 1. Turn left as if going to the central collection sump but then drive approx. 500 m and then turn right onto Polley lake boat launch.	Follow Safe Boating SOP. Contact the Pit Shifter prior to traveling on Haul roads. Use caution on Haul roads, give the right-of-way to heavy equipment and use 2-way radio communication. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ water quality for potential mine influence in Polley Lake
P2 Polley Lake	E 595348 N 5821863	2001/2007	Polley Lake south WQ monitoring site	Drive down the TSF haul road to Central collection sump near corner 1. Turn left as if going to the central collection sump but then drive approx. 500 m and then turn right onto Polley lake boat launch.	Follow Safe Boating SOP. Contact the Pit Shifter prior to traveling on Haul roads. Use caution on Haul roads, give the right-of-way to heavy equipment and use 2-way radio communication. Watch for wildlife. Follow working in/near water procedures.	Monitor WQ for potential mine influence in Polley Lake
QUR-11 Quesnel River	E 596625 N 5830438	2016	Quesnel River WQ monitoring site at Likely Bridge	Drive on the Likely Highway towards the town of Likely, approx. 30 km from the Bootjack Forest service road. Park in the pullout just before the bridge. Collect water from the bridge using the Kemmerer sampler. Monitoring site is indicated by darker brown coloured post in the middle of the bridge.	Wear reflective PPE, watch for traffic. Use caution in the winter as bridge can get slippery.	This site was established to mirror the Federal Provincial Monitoring site for the outlet of Quesnel Lake that is funded by MPMC. Monitor WQ in Quesnel River.
QUL-2a Quesnel Lake	E 607988 N 5817214	2014	Quesnel Lake post-breach and effluent discharge monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ upstream of diffuser ports in Quesnel Lake.
QUL-120a Quesnel Lake	E 618271 N 5818030	2014	Quesnel Lake background WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor Quesnel Lake WQ at background site.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
QUL-18 Quesnel Lake	E 600795 N 5819749	2014	Quesnel Lake post-breach and effluent discharge monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ downstream of diffuser ports in Quesnel Lake
QUL-58 Quesnel Lake	E 601791 N 5818025	2015	Quesnel Lake effluent discharge monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor the initial dilution zone of the effluent plume in Quesnel Lake. Default WQ monitoring site when not discharging.
QUL-ZOO-1 Quesnel Lake	E 601058 N 5819925	2015	Quesnel Lake zooplankton and WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ and zooplankton community and tissue in the West Basin of Quesnel Lake.
QUL-ZOO-7 Quesnel Lake	E 612469 N 5816656	2015	Quesnel Lake zooplankton and WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ and zooplankton community and tissue near Horsefly River in Quesnel Lake.
QUL-ZOO-8 Quesnel Lake	E 630691 N 5821991	2014	Quesnel Lake zooplankton and WQ monitoring site.	Quesnel Lake is accessed via the boat launch near the effluent discharge (see access description for HAC-12), at Mitchell Bay, or at Cedar Creek (Likely).	Follow Safe Boating SOP. Call the Pit Shifter and Front Gate person when leaving mine site. Use caution when hauling the boat. Watch for wildlife.	Monitor WQ and zooplankton community and tissue background in Quesnel Lake.
Weather Station #1	E 592792 N 5823182	2012	HOBO weather monitoring station.	Drive along the Wight Pit Haul road and turn left onto the road to the Leach Pad. Park beside the leach pad and walk up the grassy hill between the sulphur pile and the research tree plots. Weather station is located at the top of the hill.	Call the Pit Shifter prior to traveling on Haul roads. Give right-of-way to heavy equipment. Watch for wildlife. Use caution near sulphur pile and watch footing walking up hill. Snowshoes may be required in winter.	Monitor wind speed/gust/direction, rain, solar radiation, and min/mean/max temperature continuously for water balance monitoring on site.
Weather Station #2	E 591092 N 5819976	2012	HOBO weather monitoring station.	Drive along light duty road towards the Orica site. Drive up the Orica site road (approx. 30 m) and park slightly off the road as to not block access. The Weather Station is located on top of a small hill on the right hand side of the road.	Call the Pit Shifter prior to traveling on Haul roads. Give right-of-way to heavy equipment. Watch for wildlife. Watch footing walking up hill.	Monitor wind speed/gust/direction, rain, solar radiation, and min/mean/max temperature continuously for water balance monitoring on site.
Snow Course Site: Weather Stn #1	E 592792 N 5823182	1997	Snow course monitoring site.	Follow instructions as described above for Weather Station #1.	Call the Pit Shifter prior to traveling on Haul roads. Give right-of-way to heavy equipment. Use caution when driving in winter conditions. Watch for wildlife. Use caution near sulphur pile and watch footing walking up hill. Snowshoes may be required.	Monitor snowpack-water equivalent for water balance monitoring on site.
Snow Course Site: JCP	E 593632 N 5823895	2012	Snow course monitoring site.	Drive along Wight Pit haul road towards the Wight Pit. Turn right at the third road on the right hand side. Drive up to stream crossing. May need to walk in snowy conditions approx. 100 m to clearing on the left hand side. Snowpack course site is in that clearing.	Call Pit Shifter prior to traveling on haul roads and give right-of-way to heavy equipment. Used Caution when driving in winter conditions. Watch for wildlife. Snowshoes may be required.	Monitor snowpack-water equivalent for water balance monitoring on site.
Snow Course Site: TSF	E 594092	1997	Snow course monitoring site.	Drive as described above to Weather Station #2, but instead of turning at the Orica site, drive past it	Call Pit Shifter prior to traveling on haul roads and give right-of-way to heavy equipment. Used	Monitor snowpack-water equivalent for water balance monitoring on site.

Sampling Site	UTM	Monitored Since	Site Description	Site Location	Access or Safety Concerns	Rationale for Monitoring
	N 5819976			approx. 100 m. Pull over to side of road when a small clearing in the trees is reached on the right hand side. A ditch indicates the site.	Caution when driving in winter conditions. Watch for wildlife. Snowshoes may be required.	
Snow Course Site: PAG	E 590835 N 5823537	2015	Snow course monitoring site.	Drive along haul road towards the PAG dump. Take the small ramp on the left hand side towards the 9k sump. Drive to the NW sump. Site is located up ramp beside the sump.	Call Pit Shifter prior to traveling on haul roads and give right-of-way to heavy equipment. Used Caution when driving in winter conditions. Watch for wildlife. Snowshoes may be required.	Monitor snowpack-water equivalent for water balance monitoring on site.

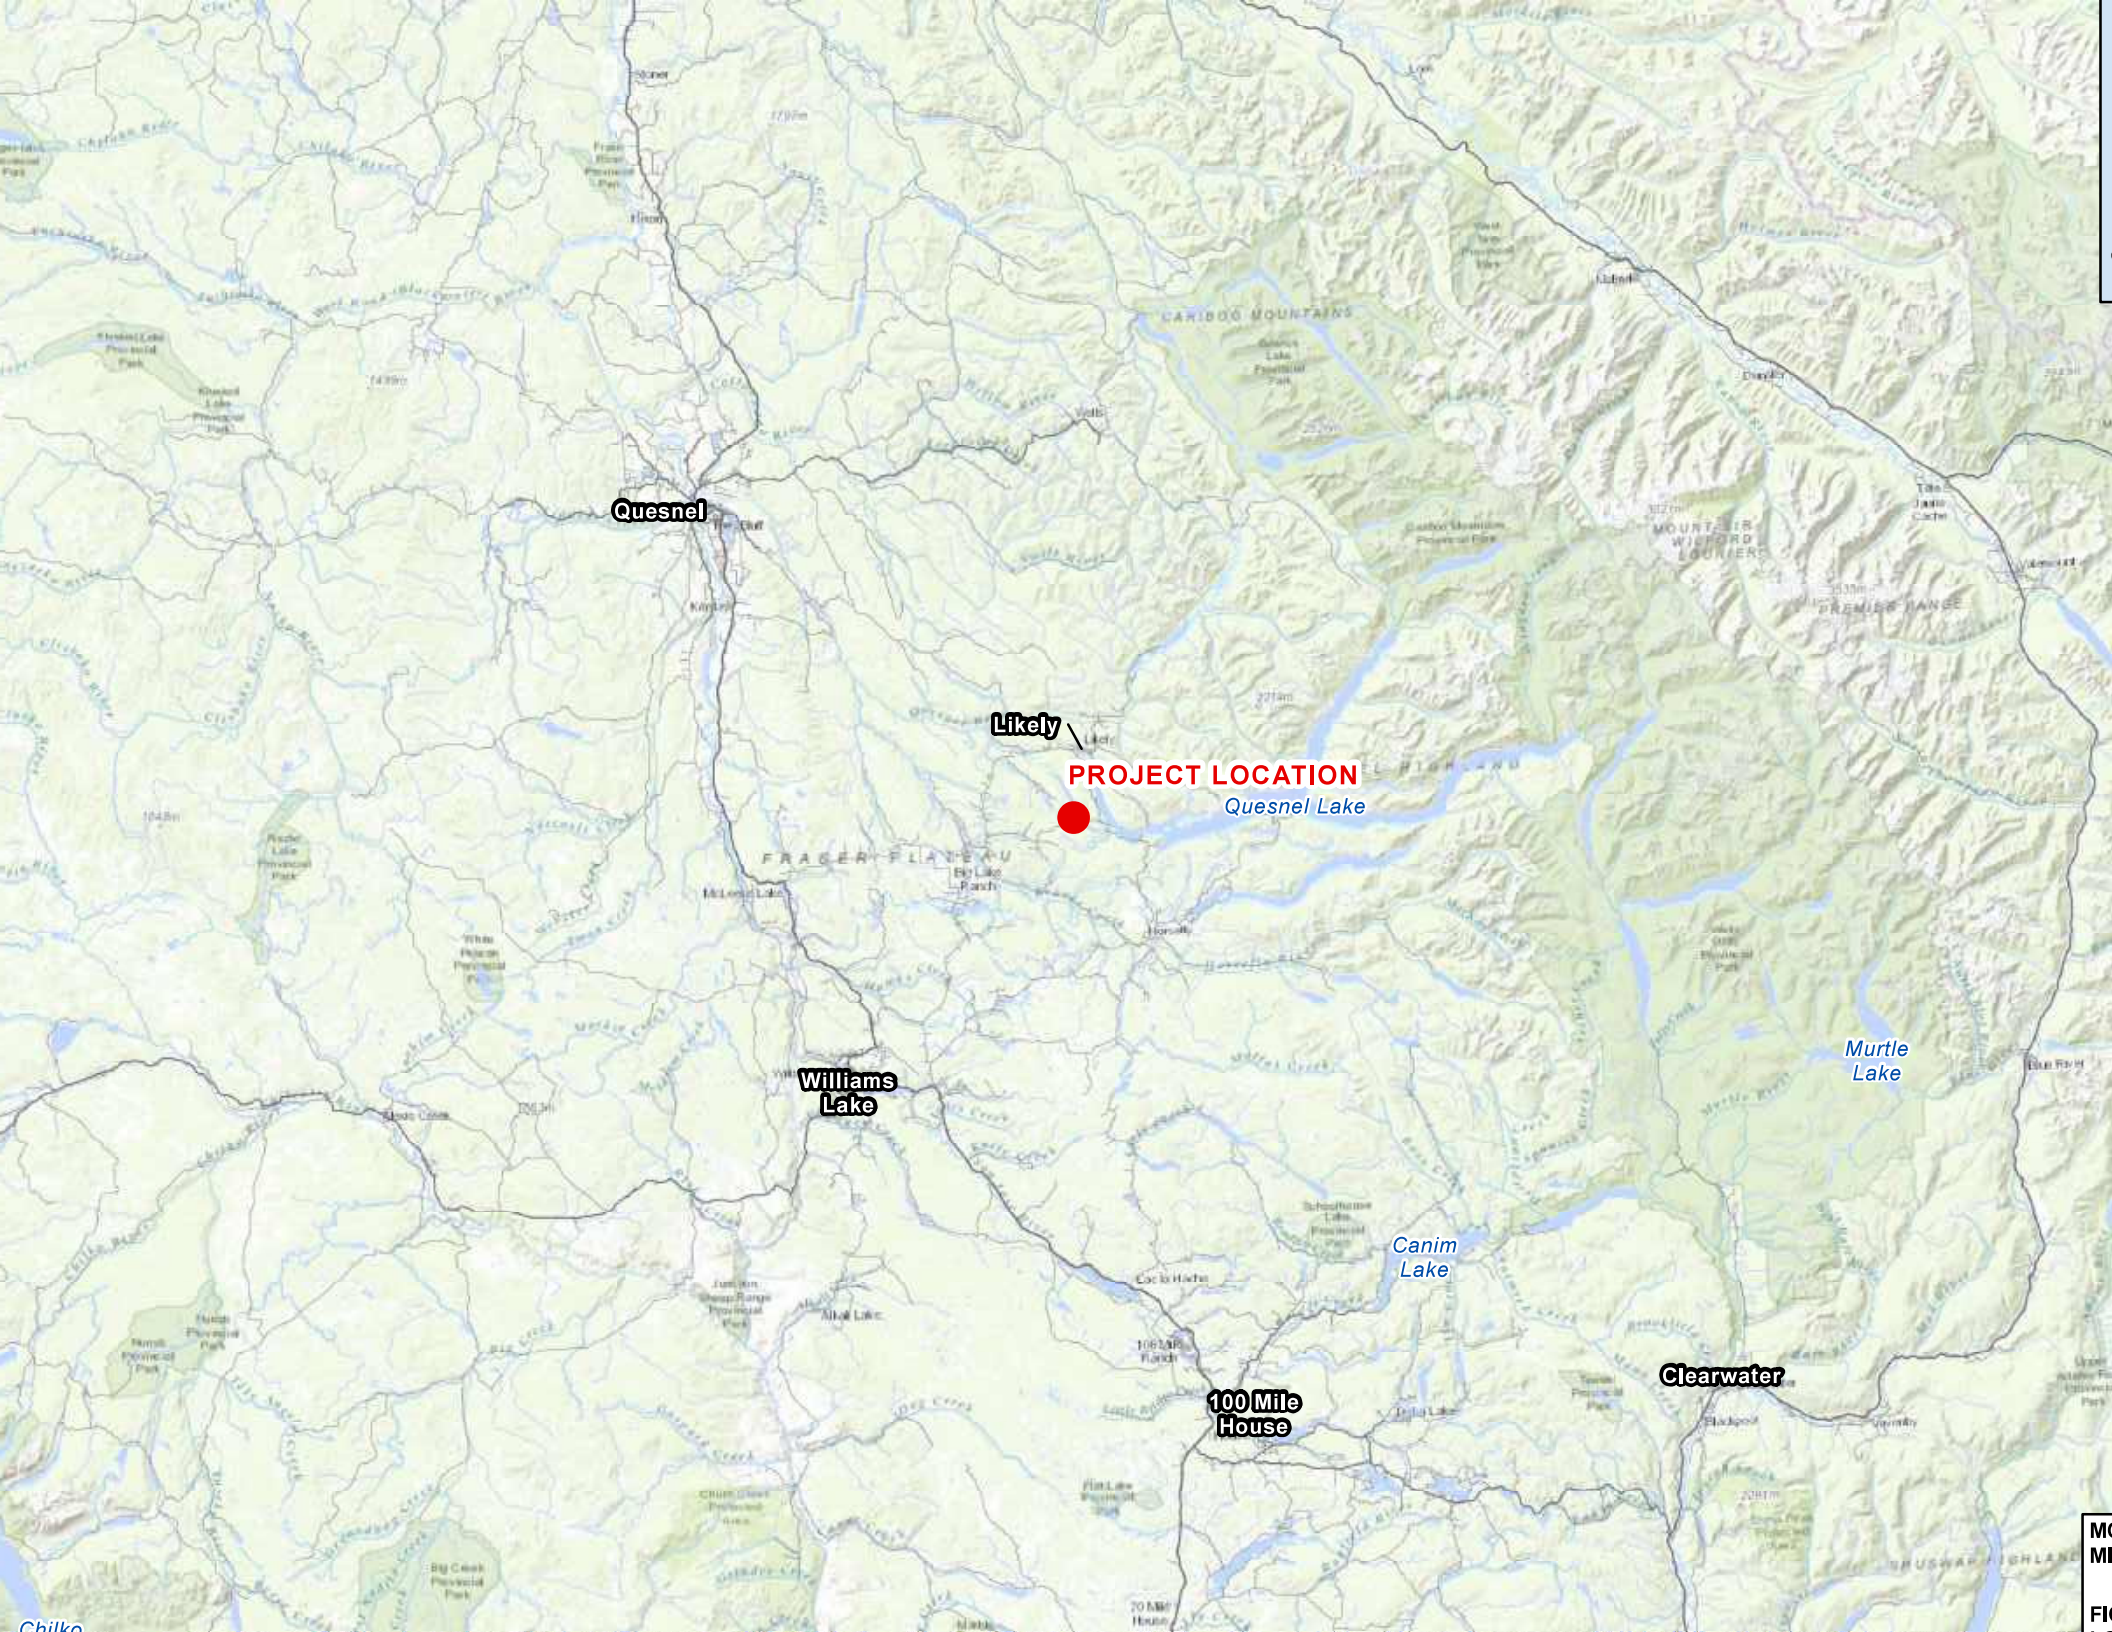
1 INTRODUCTION



This “Sediment and Erosion Control Management Plan” (the Plan) provides direction for the management of surface erosion at Mount Polley Mine (the Mine). The Plan addresses existing and potential surface erosion impacts associated with mine expansion (construction activities), operation, and decommissioning phases, and applies to all Mount Polley personnel and contractors. The main objective of this Plan is to minimize erosion of surficial sediments and intercept and manage sediment laden water as close to the source as possible. Erosion and sediment control measures and best management practices (BMPs) are incorporated in the Plan as approaches to prevent erosion and the introduction of sediment into natural water bodies and watercourses. Guidelines for monitoring the efficacy of measures in this Plan are also presented.

2 DESCRIPTION OF THE PROJECT

2.1 Project Location

The Mine, operated by Mount Polley Mining Corporation (MPMC, a wholly owned subsidiary of Imperial Metals Corporation), is an open pit copper/gold mine with an underground component located in south-central British Columbia. It is located 8 kilometres (km) southwest of Likely and 56 km northeast of Williams Lake, British Columbia (BC) (refer to Figure 1). The Mount Polley Mine has the capacity to process 20,000 to 22,000 tonnes per day (tpd) of ore when in normal operations. The mine property covers 24,077 hectares (ha), consisting of 7 mining leases totalling 2,007 ha, and 51 mineral claims encompassing 22,070 ha. Mine concentrates are trucked to facilities at the Port of Vancouver, then shipped to overseas smelters or transported by rail to smelters in North America.

The Mine property is located on the eastern edge of the Fraser Plateau physiographic sub-division, characterized by rolling topography and moderate relief. Elevations range from 920 metres above sea level (masl) at Polley Lake to 1266 masl at the summit of Mount Polley.

2.2 Project History

Clearing of the site and construction of the entire facility began in 1995, with the mill commissioned in June 1997. In May 1997, the Mine received a BC Ministry of Environment and Climate Change Strategy (BC ENV) (previously the Ministry of Water, Land and Air) Effluent Permit, *Environmental Management Act* (EMA) Permit 11678 (PE11678)', issued under the provisions of the provincial EMA. This permit authorized the discharge of concentrator tailings, mill site runoff, mine rock runoff, open pit water, and septic tank effluent to a tailings storage facility (TSF). Approval of the original Mount Polley Mine Reclamation and Closure Plan by the BC Ministry of Energy, Mines and Low Carbon Innovation (BC EMLI) (previously Ministry of Energy, Mines and Petroleum Resources) resulted in the issuance of *Mines Act* Permit M–200 in July 1997.

The first full year of mining and milling at the Mine took place in 1998. The mine suspended operations in October 2001 due to low metal prices, then reopened in December 2004, with mill production commencing in March 2005.

The Mine is currently coming out of care and maintenance and entering full operations, having been in care and maintenance since 31 May 2019. The operational period of the mine is planned to extend beyond 30 June 2025, which is the last day of approved discharge under the current version of EMA Permit 11678 (amended 1 December 2022).

2.3 Plan Objectives

The intent of this plan is to provide site-specific sediment and erosion control measures for the activities at the Mount Polley Mine site, including protective measures and guidance to be implemented during all phases of the mine activities, concentrating on construction activities. The sediment and erosion mitigation strategies will follow applicable Best Management Practices (BMPs) along with site-specific measures for water management, and sediment and erosion control during construction. The mitigation measures and strategies outlined in the Plan will assist MPMC in meeting or exceeding the Projects regulatory conditions during mining and construction activities. More specifically, the Plan is intended to prevent or minimize the transport, and deposition of sediments and soil particulates from the mine site into environmentally sensitive areas such as nearby watercourses and affect downstream water quality.

The general approach applied in this document is to reduce sediment sources and minimize contact between sediment sources and water. Where avoidance is not possible, mitigation measures are adopted to reduce erosion. The BC Ministry of Transportation and Infrastructure (MOTI) describes erosion and sediment controls as: (i) erosion control – prevent or minimize the dislodgement of soil particles, and (ii) sediment control – to capture water-borne particles in a controlled manner before undesirable damage is caused (MOTI 2022). Sediment and erosion control measures are, and will continue to be, used during construction, operation, and decommissioning activities at the Mine. Activities that may result in erosion include clearing vegetation and stripping topsoil, stockpiling topsoil, and constructing roads, infrastructure, and tailings and water management structures. Potential hazards from these activities, in the absence of planned mitigation measures, include increased surface erosion from disturbed areas, increased sediment load to downstream receiving environments, and siltation or erosion of downstream watercourses or water bodies.

The main objectives of the Sediment Control and Erosion management plan are:

- Minimize the quantity of contact water by intercepting and/or diverting surface water before it enters a disturbed area with exposed soils or co-mingles with contact water.
- Collect and manage all contact water for treatment before discharge to the environment.
- Allow discharge to the environment if regulatory discharge criteria are met (PE11678).

The following are guidelines applicable to surface erosion prevention and sediment control. These documents may be used as a resource when developing project specific environmental management plans (EMPs) for the Mine.

- "Erosion and Sediment Control Manual", (MOTI 2022).
- "Developing a Mining Erosion and Sediment Control Plan Version 1.0" (BC Ministry of Environment [MoE] 2015).
- "Environmental Best Management Practices for Urban and Rural Land Development in British Columbia" (Draft) (MWLAP 2004).
- "Standards and Best Practices for Instream Works" (MWLAP 2004).
- "Best Management Practices Guide for Storm water: Appendix H Construction Site Erosion and Sediment Control Guide" (Dayton and Knight 1999).
- "Land Development Guidelines for the Protection of Aquatic Habitat" (DFO 1993).

2.4 Roles and Responsibilities

Mine Manager: The Mine Manager will be aware of the Plan and how the proposed or ongoing mining activities could affect soil erosion potential and sediment delivery to adjacent watercourses and water bodies. The Mine Manager is accountable for allocating resources for implementing the measures outlined in the Plan to comply with relevant water quality guidelines and applicable water quality objectives.

Environmental Superintendent: The Environmental Superintendent will be accountable for implementing the requirements of the Plan, including monitoring and reporting activities. The Environmental Superintendent will be aware of and familiar with the relevant legislation and permit requirements listed in Section 2.2 to ensure compliance with the regulatory requirements. Responsibilities of the Environmental Manager include:

- Implementation of the Plan.
- Tracking compliance with provincial and federal legislation and applicable permit conditions.
- Communicating environmental requirements and performance to the Mine Manager.
- Investigating and reporting environmental incidents.
- Developing and implementing strategies to address environmental risks, incidents, and non-compliance situations.

The Environmental Superintendent will use external Qualified Professionals (QP) who have specific expertise in erosion protection and sediment control, as necessary, for implementation or improvement of the Plan.

Employees and Contractors: All employees and contractors involved in the planning, design, and carrying out of site preparation and earthworks at the Mine site will be required to undergo basic training and orientation to become familiar with the contents of the Plan.

3 LEGISLATION AND REGULATIONS

3.1 Legislation

The following lists the federal and provincial regulatory requirements with regards to surface erosion prevention and sediment control. The guidance in the subsequent sections is designed to help works proceed in accordance with these regulations:

- BC *Water Sustainability Act*
- BC *Environmental Management Act*
- BC *Mines Act*
    - Health, Safety and Reclamation Code for Mines in British Columbia (EMLI 2021)
- Canada Fisheries Act
    - Metal and Diamond Mine Effluent Regulation
- Canada *Environmental Protection Act*

3.2 Existing Permits

MPMC has received and is currently operating under the following two permits:

- BC Mines Act Permit M200 (5 May 2023)
- BC Environmental Management Act (EMA) PE11678 (1 December 2022)

Permit M200 contains sections that address sediment and erosion control management for the site and are included in Appendix A.

4 EXISTING SITE CONDITIONS

4.1 Topography

Terrain and geomorphology of the region comprise flat and gently rolling topography with hummock bedrock exposures, dissected by a network of streams and lakes. Surface drainage patterns are influenced by bedrock topography. In the Tailings Storage Facility (TSF) area, the gentle topography and surface expression of the lowland area at the head of the west arm of Quesnel Lake is the result of glacial advance followed by glacial retreat and inundation by meltwater, creating a glacial lake (glaciolacustrine) environment. The regional surficial geology is predominantly the result of erosion and deposition associated with the most recent glaciation.

4.2 Geologic Setting

Volcanic rocks generally underlay this part of the plateau with inclusions of intrusive rocks. Most of the area is covered by a deposit of unconsolidated till which contains fluvial, lacustrine, and colluvial deposits. Some patches of organic soils are present in poorly drained areas (i.e., wetlands). The property is in an alkali porphyry copper-gold deposit hosted in the Central Quesnel Belt along the Intermountain Belt of BC.

4.3 Vegetation

The site is located within the Interior Cedar Hemlock bio geoclimatic zone. Local forests consist of western red cedar, douglas-fir, hybrid spruce, and subalpine fir, with a lesser presence of trembling aspen, black cottonwood, and paper birch. Much of the area was historically harvested in commercial logging operations and was also used for cattle grazing.

4.4 Soils

The regional surficial geology is predominantly the result of erosion and deposition associated with the late Pleistocene (Wisconsinan) glacial episode referred to as the Fraser Glaciation. The stratigraphic sequence identified in the area of the TSF can be generalized in order of increasing depth as follows:

- Fill and anthropogenic materials.
- Till, interpreted as till derived from sediment entrained within the glacial ice and deposited by melting water and ice (ablation till).
- Glaciolacustrine sediments.
- Glaciofluvial sediments.
- Basal till.
- Bedrock.

4.5 Watercourses

The Mine is drained by three main watersheds: Hazeltine Creek (30.2 km^2) at Quesnel Lake, Edney Creek (87.4 km^2) at Quesnel Lake, and Morehead Lake (62.7 km^2) (Figure 2). The Hazeltine Creek watershed includes Polley Lake and conveys all water from Polley Lake, the east side of Mount Polley, and the area surrounding the TSF. The Morehead Creek watershed includes the Bootjack Lake catchment area (11.2 km^2). The regional topography, water bodies, and watersheds are shown in Figure 2.

4.6 Climate

The average annual precipitation in the area is 612 millimetres (mm). Precipitation typically occurs as snowfall from November through March, with an average maximum of snowpack of 185 mm snow water equivalent occurring at the end of March. Average monthly temperatures at the Mine range from -13.1 degrees Celsius (°C) in December to 18.9 °C in July. Prevailing winds are from the northwest near the TSF, and from the southwest (and to a lesser extent from the northwest) near the mill.

4.7 Climate Baseline

The climate baseline for the Mine was updated in 2022 (Golder 2022). A summary of the baseline climate parameters is provided in Table 1 and is described in Golder 2022.

Table 1: Summary of Key Climate Parameters

Parameter	Value
Mean annual total precipitation (mm)	612
1:2-year 24-hour rainfall (mm)	33
1:200-year 24-hour rainfall (mm)	69
Projected annual total precipitation anomaly from baseline for 2050's (%)	+5
Projected annual total precipitation anomaly from baseline for 2080's (%)	+8
Mean annual temperature (°C)	3.9
Average winter season (sub-zero mean monthly temperatures)	November to March
Projected annual air temperature anomaly from baseline for 2050's (°C)	+1.8
Projected annual air temperature anomaly from baseline for 2080's (°C)	+2.7
Mean annual relative humidity (%)	68.1
Mean annual solar radiation (W/m^2)	135
Mean annual shallow lake evaporation (mm)	673
Mean annual potential evapotranspiration (mm)	863
Mean snow water equivalent for the month of March (mm)	185

Note: Statistics are based on reviewed historical records from multiple climate stations and measured and derived data (where applicable).

mm = millimetre; °C = degrees Celsius; W/m^2 = watts per square metre.

4.8 Land Use

Infrastructure at the Mount Polley Mine site includes open pits, an underground mine, a crusher, a mill, and office spaces, a TSF, a water treatment plant (WTP), waste rock disposal areas, collection and settling ponds, a surface water collection system, haul roads, access roads, and storage facilities. The total lease area associated with the Mine is 18,892 hectares (ha).

5 RISK ASSESSMENT

The sediment and erosion controls required are based on associated risk to the environment. Table 2 relates potential sediment sources to the sensitive areas on and surrounding the Mine site and assigns a level of risk based on sensitivity of the receiving environment (receiver size, fish bearing status, etc.) and erosion potential.

Table 2: Mount Polley Sediment and Erosion Control Risk Matrix

Receiving Environment Area	Area Sensitivity	Primary Potential Source(s)	Secondary Potential Source(s)[a]	Erosion Potential Considerations[b]	Risk[c]
6 km Creek	- Not fish bearing in upper reaches. - Variable forest buffer.	- Access road. - Junction Zone Ditch or 9 km Sump.	- NW PAG Stockpile soil stockpiles - NW PAG Stockpile/Junction Zone Ditch access roads. - NW Sump.	- Established gravel ditch bottom. - Upstream area mostly covered with waste rock. - Soil stockpiles revegetation. - Two high traffic road crossings.	Medium.
Mine Drainage Creek	- Not fish bearing. - Connected to Bootjack Lake.	- Mine Drainage Creek Sump. - West Ditch.	- Waste Haul Road. - Helipad reclamation parcel. - Crusher Access Road. - Ore Switchback Road. - Cariboo .Stockpile and soil stockpiles. - Pipeline from Springer Pit to water treatment plant.	- Some unarmoured ditch sections. - Some till placed on outer slope of Waste Haul Road. - Active haul traffic on roads (can develop sediment-laden puddles). - Caribou Stockpile soil stockpiles new. - Helipad reclamation parcel revegetating. - Majority of runoff into ditch (including from reclamation and soil stockpile areas) filters through rock haul road. - Water in pipeline to treatment plant contains low total suspended solids.	Medium.
W20 Creek	- Fish bearing (very low productivity). - Variable forest buffer.	- West Ditch. - West Ditch Access Road.	- Light Vehicle Tailings Road. - Waste Haul Road. - Above Waste Haul Road reclamation parcel. - Pipeline from Springer Pit to water treatment plant.	- Ditch armoured - Reclamation parcel revegetating; upstream of Waste Haul Road. - Active haul traffic on roads (can develop sediment-laden puddles). - Water in pipeline to treatment plant contains low suspended solids. - Majority of runoff into ditch filters though rock haul road.	Medium.

Table 2: Mount Polley Sediment and Erosion Control Risk Matrix

Receiving Environment Area	Area Sensitivity	Primary Potential Source(s)	Secondary Potential Source(s)[a]	Erosion Potential Considerations[b]	Risk[c]
Bootjack Lake	- Fish bearing. - Medium sized receiver. - Variable forest buffer.	- NW Sump. - NW Ditch. - Mine Drainage Creek Sump. - West Ditch. - West Ditch Access Road. - Mine Drainage Creek. - W20 Creek.	- Waste Haul Road. - Helipad reclamation parcel. - Crusher Access Road. - Ore Switchback Road. - Caribou Stockpile and soil stockpiles. - Light Vehicle Tailings Road. - Waste Haul Road. - Above Waste Haul Road reclamation parcel. - Pipeline from Springer Pit to water treatment plant.	- Some unarmoured ditch sections. - Some till placed on outer slope of Waste Haul Road. - Active haul traffic on roads (can develop sediment-laden puddles). - Caribou Stockpile soil stockpiles new. - Reclamation parcels revegetating. - Water in pipeline to treatment plant contains low total suspended solids. - Majority of runoff into ditch filters through rock dumps and rock haul roads.	Medium.
North Dump Creek	- Not fish bearing in upper reaches. - Variable forest buffer.	- Joe's Creek Coffer Dam. - Joe's Creek Pipeline. - Gavin's Ditch (clean water diversion). - Wight Pit Ditch (clean water diversion). - Wight Pit Haul Road.	- North Bell Dump reclamation areas and soil stockpiles. - Access Road. - East Dump reclamation areas and soil stockpiles.	- Joe's Creek Coffer Dam/Pipeline water very low turbidity/suspended solids. - Ditches armoured or have established of have low-erodibility substrates except some potentially erodible sections in Wight Pit Ditch. - East Dump reclamation area in early stages of revegetation. - Varying levels of soil stockpile revegetation (some new). - Two moderate use road crossings.	Medium.
Bootjack Creek	Not fish bearing Connected to Polley Lake.	- Bootjack Creek Sump. - Tailings Access Road Ditch. - SERDS Ditch.	- Tailings Access Road. - Tailings Access Road soil stockpiles. - SERDS access roads. - Southeast Zone soil stockpiles.	- Some erodible ditch sections. - Portion of runoff into ditches filters through waste rock roads/dumps. - Three high use road crossings.	Medium.

Table 2: Mount Polley Sediment and Erosion Control Risk Matrix

Receiving Environment Area	Area Sensitivity	Primary Potential Source(s)	Secondary Potential Source(s)[a]	Erosion Potential Considerations[b]	Risk[c]
Polley Lake	- Fish bearing. - Undergoing rehabilitation. - Sedimentation ponds constructed at outflow.	- Wight Pit Ditch (clean water diversion). - Long Ditch. - North Dump Creek.	- North Bell Dump reclamation areas and soil stockpiles. - Access Road. - NEZ Dump reclamation area and soil stockpile. - East Dump reclamation areas and soil stockpiles. - Tailings Access Road. - Tailings Access Road soil stockpiles. - SERDS access roads. - Southeast Zone/SERDS soils stockpiles.	- Varying levels of revegetation of upstream reclamation areas and soil stockpiles. - Ditches armoured or have established low-erodibility substrates except some potentially erodible sections of Wight Pit Ditch.	Low.
Hazeltine Creek[d]	- Fish bearing. - Undergoing rehabilitation. - Sedimentation ponds constructed at outflow.	- Polley Lake. - Long/SERDS Ditch (combined). - Central Collection Sump. - Perimeter Till Borrow Pit and ditch from Central Collection Sump. - Pipeline from Springer Pit to water treatment plant. - Edney Creek.	- TSF and associated infrastructure. - TSF Perimeter Embankment and PAR soil stockpiles. - TSF Ditch (clean water diversion). - TSF South Toe Drain Ditch. - TSF Main Seepage Pond. - ABR/Main Seepage Pond Ditch.	- High volume water transfers. - Water has time to settle in the TSF and Perimeter Embankment Till Borrow Pit. - Water in pipeline to treatment plant contains low total suspended solids. - Soil stockpiles varying levels of revegetation. - South Till Borrow area revegetation is advanced. - Active TSF construction upstream.	Medium (Risk will increase when the creek returns to fish-bearing status).

Table 2: Mount Polley Sediment and Erosion Control Risk Matrix

Receiving Environment Area	Area Sensitivity	Primary Potential Source(s)	Secondary Potential Source(s)[(a)]	Erosion Potential Considerations[(b)]	Risk[(c)]
Edney Creek	- Fish bearing. - Forest/wetland buffer.	- TSF Ditch (clean water diversion). - TSF South Seepage Pond. - TSF South Toe Drain Ditch. - TSF Main Seepage Pond. - ABR/Main Seepage Pond Ditch. - South Till Borrow reclamation area.	- TSF and associated infrastructure. - South and Main Embankment soil stockpiles.	- Few erodible ditch sections. - Low water volumes managed. - Water seepage ponds contain low turbidity/suspended solids. - New soil stockpiles (early stages of revegetation). - Active TSF construction upstream. - South Till Borrow area revegetation is progressing.	Low.

(a) Secondary sources are potential sources of sediment that are upstream of (i.e., potentially contribute to) primary erosion.

(b) Historic turbidity and total suspended data in relevant water collection infrastructure were considered when assessing erosion potential; water management contingency measures in place across water management system.

(c) Based on combination of area sensitivity and erosion potential.

(d) Sediment and erosion control in Hazeltine Creek beyond the mine footprint related to the Tailings Storage Facility embankment breach is managed under a separate program.

Based on the risk matrix and site conditions, water management works appear to be the largest risk to receiving environment systems, because:

- Reclamation areas and soil stockpiles on site (with the exception of localized active stripping and stockpile locations) have been seeded or inspected to confirm natural revegetation is underway (Appendix B). Site-specific observations from routine reclamation inspections and annual soil stockpile surveys indicate that minimal erosion occurs at these sites.
- Mine site hydrology is snowmelt dominated, and periods of high flow are experienced annually during freshet, meaning that:
    - There is higher potential for in-ditch erosion.
    - There is higher potential for erosion by surface runoff that reports to collection ditches.
    - Risk of an emergency release of water is elevated.
- Collection ditches are located downstream of disturbed areas on site and collect and convey any turbid water that is generated from disturbed areas on site.

6 BEST MANAGEMENT PRACTICES (BMPS)

Best management practices for water and sediment management will be implemented within and around the various construction areas (e.g., roads, tailings embankments, process plant platform, ponds) with the main objective of controlling runoff and seepage from the construction areas at the source, to the extent practicable. BMPs will include:

- Engagement of Qualified Professionals to support the development of specific management plans and update the Plan every 5 years.
- Strive to divert non-contact water around work areas, wherever possible, and convey contact water to the existing contact water system for treatment prior to release.
- Limiting work activities as much as possible to dry weather conditions and covering/ revegetating disturbed areas as quickly as possible after completing work in an area.
- Ensuring that no construction activities take place in, or construction equipment passes through existing watercourses.
- Stockpiling any materials on site as far as possible from watercourses.
- Ensuring that all stockpiles on site with the potential for erosion to a watercourse be covered and/or revegetated to reduce sediment generation.
- Inspecting and maintaining covers and diversion/conveyance ditches on a regular basis.
- Grading the site such that the potential for ponding is minimized.
- Ensuring that extra covers and clean granular materials are available onsite for channel and stockpile maintenance.

The following sections provides general sediment and erosion control guidelines to be followed for future construction projects and/or new surface development on the mine site through the different project phases.

6.1 Pre-project Planning

The BMP guidance documents referenced in Section 3.3 and, when necessary, QPs, are to be consulted to support planning of a specific project. Prior to starting any new construction work, the following should be considered:

- Design of projects to minimize the amount of ground cleared and disturbed.
- Design of projects to minimize disturbance adjacent to receiving environment watercourses and water bodies.
- Planning of works such that areas adjacent to waterways and drainage lines remain undisturbed or protected from erosion for as long as practicable.
- Planning of work to minimize the use of heavy equipment and have equipment conduct work as efficiently as possible.
- Planning of interim water and runoff management strategies to reduce erosion and identify available mitigation techniques if sediment is mobilized.
- Planning of long-term erosion control measures to be implemented after project completion.

- Identification of monitoring and inspection requirements for, during and after the project.
- Design of project criteria, construction plans, and mitigation for stream and other watercourse crossings to meet or exceed all standards and codes established by relevant authorities for the project.

Permitting, notification, and reporting requirements for projects will vary based on their location and proximity to natural water bodies and water. If the project has potential to impact natural watercourses or water bodies (i.e., if the work is outside site contact water collection systems and/or is adjacent to natural waterways), a site-specific environmental management plan (EMP) for project work should be developed. The EMP should include, at minimum:

- A summary of how information requirements, as detailed above, are being implemented.
- Details of drainage patterns over the area, both clean water and potential construction runoff.
- Locations of adjacent environmentally sensitive areas that could be impacted.
- A general outline of the planned work.
- Details of existing or planned erosion and sedimentation control methods to manage construction runoff.
- The location of any existing or planned drainage diversions.
- An inspection and monitoring schedule.
- A revision number and date.

For projects requiring an EMP, appropriate training and awareness to supervisors, workers (employees and contractors) regarding their responsibilities to comply with environmental laws and applicable codes. Workers are to be made aware of the required mitigation measures for a task, in addition to any requirements contained in any public or private approvals and agreement documents.

The following subsections outline additional sediment and erosion control techniques that may be incorporated into planning.

6.1.1 Stabilization and Treatment Methods

Erosion control measures are to be planned and, if required, installed prior to any clearing or earthwork activities. Stabilization measures are put in place to prevent or reduce the mobilization of sediment by stabilizing the source (e.g., exposed soils). Typical erosion control measures that may be used to stabilize areas that have the potential to be sources of sediment to water bodies or watercourses include:

- Seeding or mulching.
- Non-vegetative cover (e.g., gravel or straw).
- Riprap placement.
- Slope modification to reduce erosive energy (e.g., flattening or benching).
- Surface ripping and roughening to promote infiltration.
- Slope drains/chute construction.
- Erosion blankets.

While pro-active stabilization measures are used to minimize the presence of sediment laden water, treatment measures may be necessary when it is not possible to completely prevent the mobilization of sediment. Typical sediment control measures that may be used to manage sediment in contact water include the following:

- Check dams or weir structures.
- Outlet protection.
- Sediment retention ponds, sediment traps and sediment basins.
- Silt fence or similar barrier, such as straw bales.
- Swales.
- Vegetated buffer zones.

6.1.2 Runoff Collection Ditches

Runoff collection ditches may be either temporary or permanent structures. Permanent surface runoff control works should be sized to convey runoff from a 1 in 10 year 24-hour flood flow and to withstand a 1:200-year, 24-hour event without significant damage as per BC ENV Permit 11678.

The design of sections of ditch may depend on topography, excavation material (till or bedrock) and design discharge. Different material gradations or design approaches may be used for armouring depending on site-specific conditions and material availability. Any convergences with other ditches or streams should be armoured.

It is expected, in observance of Permit 11678, that new runoff collection ditches will direct flow to the contact water system and result in treatment at the water treatment plant.

6.2 Construction

Construction should comply with the plans developed in the pre-construction phase (Section 7.1) so that work is conducted in a manner that avoids or minimizes erosion and the discharge of silt, sediment, or other deleterious substances into any watercourse. Changes to the construction plan are to be reviewed by the appropriate Environmental Department and Engineering Department staff prior to implementation to allow sediment and erosion control management plans to be revised accordingly. Monitoring is to be carried out as per Section 7 of this document.

Additional measures recommended for all stages of construction include:

- Monitor weather forecasts for upcoming rainfall or other climatic conditions that may affect the construction works and surrounding environment.
- Suspend work in areas adjacent to natural water bodies or watercourses during heavy precipitation or runoff conditions.
- Follow the project EMP (especially for pumping, diversion, or relocation of water undertaken) and revise it if the project work plan changes.
- Refer to the site Emergency Response Plan in the event of a major incident.

6.2.1 Soil Salvage

Under MPMC's Mines Act Permit M-200, surficial soils are required to be stripped from the areas to be disturbed in advance of construction of works including waste rock dumps, waste or ore stockpiles, and roads. Stockpiles are often required to store salvaged soils for later use in reclamation, and further erosion control considerations apply, in addition to the earthworks project considerations discussed above. Stockpiles should be promptly seeded with an appropriate native seed mixture. If stockpiles have the potential to impact natural watercourses or water bodies, temporary erosion and sediment control measures should be installed and maintained until a vegetative cover is established.

6.3 Post-Construction

When a project is completed, long-term sediment retention and erosion control measures may need to be considered. These measures may include elements of the stabilization and treatment options in Section 6.1.1, as well as:

- Restricting access to areas being rehabilitated.
- Establishing a vegetative cover.
- Armouring areas receiving surface runoff.
- Slope modification to reduce erosive energy, such as flattening or benching.
- Surface ripping and roughening to promote infiltration.
- Diversion berms and drains (to intercept upstream runoff).

Any interim measures should remain in place until long-term controls are established. When monitoring and inspections (as described in Section 7) find long-term measures are sufficient, interim, or temporary erosion and sediment control features may be reclaimed.

6.4 Decommissioning and Reclamation

At closure, MPMC is responsible for leaving the mine site in compliance with all regulations, including site runoff water quality and revegetation to meet end land use and land capability objectives.

Detailed soil application and revegetation plans that include methods for reducing erosion are included in the site Reclamation and Closure Plan.

6.5 Mine Operations

Sediment and erosion control practices for new disturbances at the mine site are to follow the procedures outlined in the previous sections, but measures are also to be implemented and maintained on a site-wide scale.

6.5.1 Collection of Mine Contact Water

Collection of runoff from disturbed areas on site that may impact water quality in the receiving environment is to be carried out across the mine site. Water from these collection systems is conveyed to the PETBP and sent to a treatment plant prior to discharge from the site and is not permitted to be discharged to the environment unless specific regulatory requirements are met. These requirements include maximum allowable total suspended solids and turbidity levels.

The overall operating premise at the Mine is that contact water is captured and conveyed via channels, ditches, and pipelines to a centralized location and treated through the water treatment plant (WTP) prior to discharge to Quesnel Lake via submerged diffuser. The WTP outlet is the primary monitoring point for compliance with PE11678 (location HAD-3). There is a secondary PE11678 monitoring point near the diffuser discharge within Quesnel Lake (Location QUL-58).

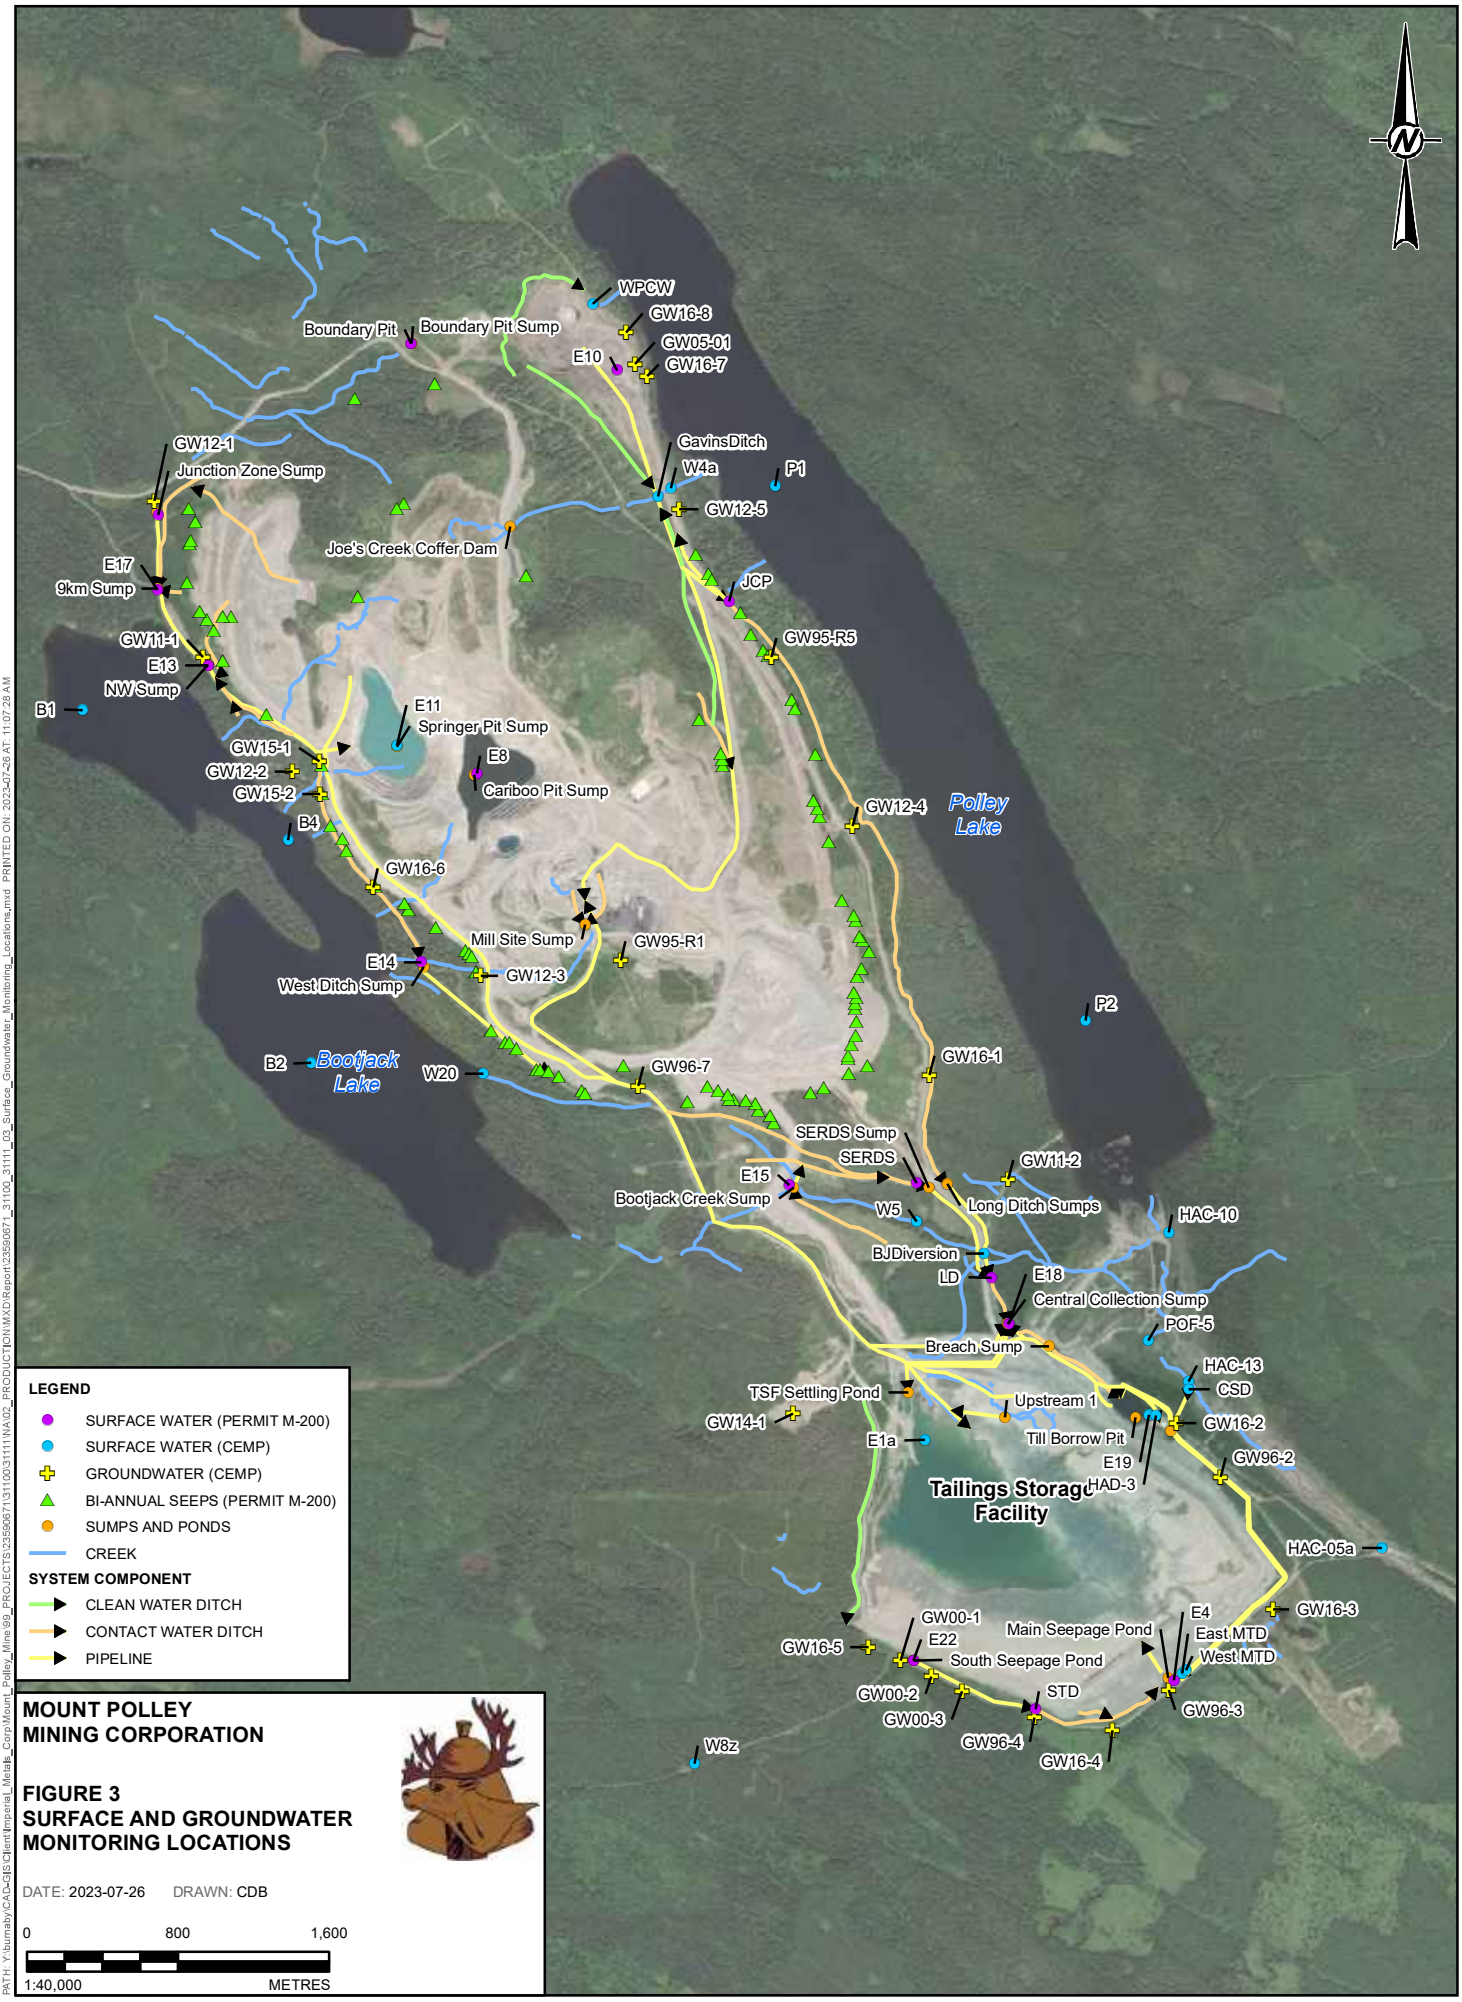
6.5.2 Emergency Release of Water

If emergency release of water from the site water collection system should occur, sediment and erosion control materials are to be installed, as required, to avoid the displacement of sediment as water moves over land. These materials are stored in the Environmental C-Can located beside the Leach Pad, and the Environmental Department staff is available to guide proper installation. The Mount Polley Emergency Response Plan and Water Management Inspection Manual outline in more detail response protocol for such events, and Section 7.2 outlines event-based monitoring procedures.

7 ENVIRONMENTAL MONITORING AND REPORTING

Water quality is monitored on-site per the Comprehensive Environmental Monitoring Plan (CEMP) (MPMC 2019) to ensure that the water quality conforms to the EMA permit requirements. Monitoring frequency and location of various water quality parameters are outlined in the CEMP. If water quality exceeds trigger levels for any parameter as listed in Section 7.2 of the EMA permit, MPMC will immediately complete Trigger Response Plan actions as outlined in their Annual Discharge Plan (MPMC 2018).

7.1 Routine Inspections



Daily inspections of site water containment infrastructure are completed (refer to the Water Management Inspection Manual, MPMC, 2019 to verify the collection system is working as designed). As per this document, inspections are completed at least once on day shift and night shift during high-risk periods (i.e., freshet). The inspection form template is included as Appendix C. Completed forms are provided to the Environmental Department for review and filing at the end of each seven (7) day set. Note that protocol and triggers are in place for immediate notifications to occur if deficiencies are observed. Daily inspections are the responsibility of Mill Maintenance, and the Environmental and Engineering Departments are responsible for updating the Water Management Inspection Manual, which is a component of the site Operation Maintenance and Surveillance (OMS) Manual.

Inspections of all site water management infrastructure (sumps, ditches, culverts, pipelines, etc.) are completed in spring after freshet and in fall prior to freeze up, as per EMA Permit 11678. This is the responsibility of the Environmental Department. Results are documented in the inspection form (refer to the template provided as Appendix D) and filed internally. Inspection results are used to inform upgrades of water management structures. Noted deficiencies, including areas of erosion or sedimentation, are compiled, and prioritized in a project list which is provided to the Engineering Department to address, based on the identified levels of urgency.

7.1.1 Contact Water Monitoring

Routine monitoring of mine site contact water conveyed through various infrastructure components is conducted as per Mines Act Permit M-200. This sampling program, including sample locations, frequencies, and QA/QC procedures, is detailed in the CEMP, which is regularly updated to account for operational changes at the mine site. All routine samples collected on site are analysed for physical parameters (including total suspended solids and turbidity), anions, nutrients, and total and dissolved metals. Monitoring locations and frequencies (at the time of this update) are shown in Figure 3.

These sample results are included in the annual reporting to BC ENV and BC EMLI. Results from these samples are used, along with inspection results, to identify potential upgrade opportunities for site water conveyance.

7.1.2 Receiving Environment Monitoring

The Environmental Department conducts water quality monitoring in receiving environment water bodies and watercourses as per MPMC's CEMP, which is required under EMA Permit 11678. Note that chemistry and flow monitoring at a few contact water sites is included under this program, including monitoring related to the permitted effluent discharge. In addition to regular sampling (e.g., monthly, quarterly), a five (5)-week intensive turbidity and total suspended solids monitoring program is conducted in spring and fall in receiving environment streams that could potentially be impacted by erosion from the mine. This includes the following creeks downstream of inflows from runoff diversion ditches:

- North Dump Creek
- Bootjack Creek
- Edney Creek

7.2 Event/Incident Based Monitoring

Results from routine or freshet/fall rainy period monitoring of receiving environment or general observations from carrying out other work at the mine site may indicate increased sedimentation from mine-related sources. Table 3 outlines the triggers for additional monitoring and required follow up actions if elevated suspended sediment levels are observed or measured.

Table 3: Event-based Monitoring Protocol for Receiving Environment Waterways

Trigger	Actions and Responsibilities
Receiving environment waterway or waterbody is observed to have a “cloudy” appearance.	- Observer to report observation to the Environmental Coordinator (or member of the Environmental Department if Environmental Coordinator cannot be reached). - Environmental Coordinator, or their delegate from the Environmental Department, is to carry out in situ monitoring at this site, following the turbidity triggers and associated protocol below.
80-100% of BC Water Quality Guideline for Protection of Aquatic Life for turbidity observed.	- Environmental Technician to notify Environmental Coordinator. - Environmental Technician to organize investigation into the sediment source, with support from the Environmental Coordinator and other relevant workers, depending on the specific scenario. If the investigation indicates this sedimentation is not related to mine activities: - Document the findings. - If any illegal activity is noted, report it accordingly. - Closely monitor this site until conditions have returned to normal or, it is established that the sedimentation will continue. If the investigation indicates that sedimentation is related to mine activities: - Take actions to control the source. - Increase frequency of receiving environment turbidity monitoring. - Closely monitor the site until the sediment source is being appropriately managed and turbidity readings return to below the BC Water Quality Guideline.
100% of BC Water Quality Guideline for Protection of Aquatic Life for turbidity observed.	- Environmental Technician to notify Environmental Coordinator. - Environmental Technician to organize investigation into the sediment source, with support from the Environmental Coordinator and other relevant workers, depending on the specific scenario. If the investigation indicates this sedimentation is not related to mine activities: - Document the findings. - If any illegal activity is noted, report it accordingly. - Closely monitor this site until conditions have returned to normal or, it is established that the sedimentation will continue. If the investigation indicates that sedimentation is related to a mine activity: - Stop any construction or mine activities that may contribute to or exacerbate erosion and sedimentation. - Take actions to control the source. - Increase frequency of receiving environment turbidity monitoring. - Closely monitor the site until the sediment source is being appropriately managed and turbidity readings return to below the BC Water Quality Guideline.

A detailed event-based monitoring program for the receiving environment should be included in project EMPs. Table 4 provides recommended protocol to incorporate.

Table 4: Recommended Event-based Monitoring Protocol for a Construction Project

Trigger	Actions and Responsibilities
80-100% of BC Water Quality Guideline for Protection of Aquatic Life* for turbidity observed in scheduled construction monitoring.	- Environmental Monitor to notify Environmental Coordinator and construction supervisor. With support from the Environmental Coordinator and construction supervisor (and any workers they designate), the Environmental Monitor is to: - Inspect all erosion and sediment control works and construction areas to identify the source. - Take actions to control the source. - Increase frequency of receiving environment turbidity monitoring.
100% of BC Water Quality Guideline for Protection of Aquatic Life* for turbidity observed in scheduled construction monitoring.	- Environmental Monitor to notify Environmental Coordinator and construction supervisor. - Construction supervisor to stop all local construction work. With support from the Environmental Coordinator and construction supervisor (and any workers they designate), the Environmental Monitor is to: - Inspect all sediment and erosion control works and construction areas to identify the source. - Take actions to control the source. - Increase frequency of receiving environment turbidity monitoring. Work is not to recommence until the sediment source is being appropriately managed and turbidity readings return to below the BC Water Quality Guideline.
Rainfall (or snowmelt) ≤ 10 mm/h or 25 mm/d.	During minor rainfall or snowmelt runoff events, the Environmental Monitor is to: - Increase the frequency of receiving environment turbidity monitoring and follow the turbidity triggers and associated protocol above. - Increase the frequency of visual inspections of potential sediment sources (soil stockpiles, sediment ponds, etc.).
Rainfall (or snowmelt) /10 mm/h or 25 mm/d.	During major rainfall or snowmelt runoff events, the Environmental Monitor is to: - Notify the Environmental Coordinator and construction supervisor. - Increase the frequency of receiving environment turbidity monitoring and follow the turbidity triggers and associated protocol above. - Increase the frequency of visual inspections of high-risk areas (soil stockpiles, sediment ponds, etc.). Environmental Coordinator and/or construction supervisor are to consider full work stop in the area based on conditions.

Note: Upstream monitoring site may be used as “background” reference.

7.3 Reporting and Performance

Water management at the Mount Polley site involves the collection of all mine contact water (see Environmental Management Act Permit PE11678 for this requirement). Contact water is conveyed through a series of ditches and collection sumps to the Perimeter Embankment Till Borrow Pond (PETBP) which is an influent source to the Water Treatment Plant (WTP). This WTP is designed for the removal of suspended solids from contact water and treated effluent is discharged to a pipe that conveys treated water to Quesnel Lake for discharge through submerged diffuser. This discharge is regulated by PE11678 and has a primary compliance monitoring location at the WTP outlet (HAD-3) and has a secondary compliance monitoring location in Quesnel Lake near the diffuser discharge (QUL-58).

Given the water management in place and the single, monitored discharge point, and given that this point is regulated by permit, this location and the permit limits provide the best point at which measurement of the ESCP performance, in aggregate, be evaluated.

The effluent permit provides a site- and discharge-specific regulatory discharge standard with which MPMC must comply.

8 REPORTING AND RECORD KEEPING

8.1 Annual Reporting

Site inspections and monitoring activities associated with surface erosion prevention and sediment control during construction, operations, and closure activities will be documented and reported in accordance with the requirements of MPMC's EMA Permit 11678 and Mines Act Permit M-200.

8.2 Incident Reporting

Significant releases of sediment-laden water from onsite disturbed areas will be appropriately characterized concerning extent and loading and reported to Emergency Management BC, with follow up reporting to provincial regulatory agencies as required by regulations and permits. The Environmental Superintendent will review the reports internally to identify necessary improvements in water management procedures.

8.3 Emergency Reporting

In the event that an emergency release of water from the site collection system occurs, the protocol in the Water Management Inspection Manual (MPMC, 2019) outlining responsibilities, notification requirements, documentation (refer to the form in Appendix E), and actions to carry out would apply. One key action is the installation of sediment and erosion control materials and/or structures.

Monitoring associated with an emergency release of water is the responsibility of the Environmental Department, and should include the following:

- Assessment of the spatial extent of the release and if the release reached receiving environment waterways or water bodies.
- Monitoring of water released (visual observations, flow measurements/estimates, field parameters including turbidity, and/or sampling, based on the observed location, conditions and size of the release).
- Monitoring (visual observations, field parameters including turbidity, and sampling) of downstream waterways or waterbodies into which water was released.

Reporting to Emergency Management BC and follow up reporting to provincial regulatory agencies will likely require this information, in addition to the information required to be collected as per the Water Management Inspection Manual (refer to the form in Appendix E).

8.4 Record Keeping

Monitoring data will be entered into an electronic database and have quality control checks completed upon receipt of results. Data will be entered into a standard format that allows for data reporting and analyses. Data and data comparisons will be stored in a single file format for each type or monitoring activity.

9 EVALUATION AND ADAPTIVE MANAGEMENT

9.1 Sampling and Monitoring Data

The CEMP is, at minimum, updated every three years, based on the results of detailed three-year monitoring program interpretive reports. More frequent changes are, however, anticipated to reflect changing site conditions and, as per the mechanisms described in the CEMP, written notice of proposed changes will be provided to the BC ENV. First Nations and stakeholders will also be updated, as per MPMC's Communication Plan. The CEMP is also referenced in the site OMS Manual, which is regularly updated to account for operational changes at the mine site.

Results from monitoring completed as per the CEMP are submitted to the BC ENV quarterly and are also included in the Annual Environmental and Reclamation Report, which is submitted to the BC ENV and BC EMLI annually. The Environmental Superintendent or their designate (the Environmental Coordinator) is responsible for ensuring this reporting is carried out.

9.2 Maintenance and Inspection Reports

As per the Water Management Inspection Manual, supplemental inspections are to be completed by Mill Maintenance, Mine Operations, and the Environmental Department during high-risk periods (i.e., during precipitation and/or snowmelt runoff events), with support from the Engineering Department. Inspection reports from high flow periods provide feedback on the functioning of site water collection systems under conditions when erosion potential is high. Noted deficiencies are incorporated into project planning for continuous improvements along with findings from routine inspections as described above.

An annual inspection was completed in June 2023 to review the existing sediment and erosion control measures that are in place at the mine site. A summary of the 2023 inspection is included in Appendix F.

9.2.1 Collection of Mine Contact Water

Collection of runoff from disturbed areas on site that may impact water quality in the receiving environment is to be carried out across the mine site. Thus, runoff from disturbed areas that potentially contains sediments is not directly released to the environment. Water from these collection systems is stored on site and is not permitted to be discharged to the environment unless specific regulatory requirements are met. These requirements include maximum allowable total suspended solids and turbidity levels, necessitating removal of suspended sediments through active or passive treatment prior to discharge.

To minimize the volume of contact water collected and stored at the site, upstream ditches to divert non-site contact water may be constructed. As water from these works enters the receiving environment, for construction of new diversion ditches, an EMP should be developed and followed for construction, and the guidelines in Sections 6.1 to 6.3 followed.

Inspection and monitoring requirements for site water collection systems and diversion ditches are outlined in Section 7.

9.3 Onsite Plan Review

Construction should comply with the plans developed in the pre-construction phase (Section 6.1) so that work is conducted in a manner that avoids or minimizes erosion and the discharge of silt, sediment, or other deleterious substances into any watercourse. Changes to the construction plan are to be reviewed by the appropriate Environmental Department and Engineering Department staff prior to implementation to allow sediment and erosion control management plans to be revised accordingly. Monitoring is to be carried out as per Section 6 of this document. Actions and maintenance that may be required based on monitoring observations include:

- Correcting deficiencies of the erosion and sediment control measures as soon as they are observed.
- Removal of any sediment and debris accumulation that compromises the effectiveness of the erosion and sediment control measures.
- Implementation of additional stabilization and treatment measures listed in Section 6.1.

Additional measures recommended for all stages of construction include:

- Monitor weather forecasts for upcoming rainfall or other climatic conditions that may affect the construction works and surrounding environment.
- Suspend work in areas adjacent to natural water bodies or watercourses during heavy precipitation or runoff conditions.
- Follow the project EMP (especially for pumping, diversion, or relocation of water undertaken) and revise it if the project work plan changes.
- Refer to the site Emergency Response Plan in the event of a major incident.

9.3.1 Adaptive Management

This Plan is designed to be updated as sediment and erosion control science and BMPs develop over time. It is also designed to be adapted for operational changes and water management needs at the mine site. Continuous improvements that may be carried out include:

- Changes to the design of works to eliminate deficiencies that are noted during inspections and require regular maintenance.
- Implementation of mitigation measures in response to water quality trends noted in the receiving environment.
- Implementation of measures that reduce treatment needs prior to discharging water.
- Implementation of measures to reduce maintenance costs.
- Implementation of measures to reduce environmental risk.

10 QUALIFIED PROFESSIONALS

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this report.

Permit Approving Mine Plan and Reclamation Program
Mount Polley Mining Corporation, Mount Polley Mine
Date: 10 December 2020

8. Sediment and Erosion Control

(a) The Permittee shall implement the Erosion and Sediment Control Plan (Document 42.1).
(b) The Permittee shall ensure that the Erosion and Sediment Control Plan is reviewed annually, and updates reported in the Annual Reclamation Report. Substantive changes shall be provided to the Chief Inspector prior to implementation.
(c) The Permittee shall appropriately characterize any significant releases of sediment-laden water, defined as an unauthorized discharge to the receiving environment, with respect to extent and loading, and report it to the Chief Inspector.
(d) The Permittee shall ensure that the characterization of unauthorized discharges of sediment-laden run-off include, at a minimum, flow, total suspended solids, turbidity, pH, conductivity, temperature, dissolved oxygen, and total and dissolved metals, of both the effluent and the receiving water.

Sediment and Erosion Site Inspection – June 2023

Sediment and Erosion Site Inspection – June 2023

WSP was retained by MPMC to undertake a visual inspection of the Long Ditch and West Ditch drainage systems at the Mount Polley mine on 7 June and 8 June 2023. Don Kidd, Senior Engineer, Q.P. P.Eng. undertook the visual inspection of both drainage systems. The visual inspection confirmed that both drainage systems were in good condition, with no ditch erosion evident in the mostly vegetated riprap lined ditches.

Based on the visual inspection the following action items are recommended.

- Undertake bathymetry surveys of SFRD and Central Collection Sumps to confirm that adequate storage is available for the design storm events, and if not undertake dredging works to provide the storage required.
- Provide written documentation of pump capacity required at each sump, based on previous hydraulic modelling work undertaken by WSP (formerly Golder) and confirm that the correct pump and backup capacity is available.
- Where the system has sections of ditch replaced by culverts/pipes, confirm the pipe is sized correctly to convey the design storm event.

Monitoring should be carried out in accordance with project specific EMPs developed as per Section 2.2.3 and regulatory permits and legislation requirements. If the project has the potential to impact natural water courses, and requires an EMP, a designated environmental monitor should oversee the project. The environmental monitor's daily tasks are to be defined in the EMP, and should include:

- Visual inspections of erosion and sedimentation controls.
- Visual inspections of equipment for leaks.
- Visual inspections of spill kits to confirm appropriate supplies are available.
- Visual inspections of potential sedimentation sources, such as soil stockpiles, new disturbances, and active construction areas.
- Monitoring of the weather forecast and current conditions.
- Documentation of the above.

If a project does not have the potential to impact natural water courses, and EMP is not developed, monitoring is still expected and BMPs for sediment and erosion control should still be applied. Inspections should be conducted by a designated qualified member of the Mount Polley Environmental or Engineering Department for the tasks outlined above.

In active construction areas where activities could impact receiving environment water quality, additional monitoring may be required beyond routine sampling described in Section 5.1. Monitoring may include in situ turbidity testing and/or partial or full suite water quality sampling (full suite = parameters listed for routine samples in Section 5.1). Results should be compared against pre-construction data and the BC Water Quality Guidelines for Freshwater Aquatic Life. Downstream monitoring site(s) should be located at a sufficient distance to ensure mixing of construction runoff and ambient stream water. An upstream control site of sufficient distance to be isolated from any construction-related impacts may be monitored simultaneously and compared to downstream monitoring results. Monitoring requirements and sampling frequency depend on the specific project and a monitoring plan should be included in the project EMP.

APPENDIX 9-2: Soil Management Plan

1	Update to reflect site changes	2012	KM
2	Update to reflect site changes and results of site soil stockpile assessment; addressed *Mines Act P*ermit M-200 conditions	March 2014	KM
3	Update of site specific components; added document tracking and formatting to be consistent with other MPMC EMPs	January 2017	KM

1 Introduction

All surficial soil at the Mount Polley Mine (the Mine) identified through soil surveys as being appropriate for plant growth are salvaged and either used immediately in the reclamation program or stored in a suitable manner for future use. This is a requirement of the British Columbia (BC) *Mines Act* and associated BC Health Safety Reclamation Code. In addition, Mount Polley Mining Corporation's (MPMC's) *Mines Act* Permit M-200 contains specific conditions related to soil management that are addressed in this Soil Management Plan (the Plan).

The purpose of this Plan is to outline the procedures to characterize, salvage, store, and apply all suitable growth material in accordance with regulatory requirements and to support reclamation of the Mine site to the desired land capability and end land uses.

2 Soil Handling and Management

The following subsections outline procedures for soil handling and management through the different stages of the mine life at the Mount Polley Mine.

2.1 Soil Characterization

Site-specific soil surveys must be completed for areas scheduled for disturbance by a qualified individual and submitted to the BC Ministry of Energy and Mine (MEM) Chief Inspector for approval. The following survey procedure is recommended and is consistent with soil surveys previously conducted at Mount Polley Mine; however, this methodology may be modified by a qualified individual based on site conditions, existing information, and their experience.

1. Pre-stratify the area according to terrain using aerial photographs. Confirm the stratification is appropriate with a site inspection.

2. Select soil pit locations at representative sites or using a predetermined systematic grid or transect. Soil pit density may range from one pit per half hectare to one pit per two hectares, depending on site variability.

3. Expose the soil profile by machine excavation or hand-dug holes. Existing road cuts and excavations can also be cleaned for use.

4. Describe the soil and site characteristics at each soil profile location as per the BC Ministry of Environment standards and guidance in the "Field Manual for Describing Terrestrial Ecosystems" (MoE, 2010).

5. Sample soils at select, representative sites to provide local soil quality data. Sampling intensity may be adapted based on the level of preexisting soil quality data for the area.

6. Present and interpret the soil survey data in a report and recommend salvage depths for (1) soil appropriate for reclamation, and (2) subsoil which could be used in reclamation with soil amendments or as a subsoil.

For reference, soil and landform inventories completed to date for the Mount Polley Mine include:

- Southeast Dump, Boundary Pit and West PAG Projects (2010)
- Wight Pit Rock Waste Dump Extension Project (2006)

- Southeast Pit Project, Wight Pit to Tailings Pond Road, and Southeast Pit to Tailings Pond Road (2005)
- Northeast Extension Project (2004)
- Springer Pit (2001)
- Baseline Soil Survey and Agricultural Assessment of proposed Tailings Storage Facility, Open Pit, and Waste Rock Dumps (1995).

2.2 Soil Salvage

2.2.1 Salvage Materials and Depths

Material to be salvaged is grouped into four types as described below, which should be stripped and stockpiled separately. Delineation of these materials in the field is to be supported by a qualified individual, as described in Section 2.2, however, some general field guidance is as follows.

1. Non-merchantable woody debris is to be salvaged prior to removing soil and stockpiled for use in reclamation (or immediately used in reclamation, if possible). Small woody debris may be stripped with soil and incorporated into soil stockpiles.

2. Soil appropriate for reclamation should be salvaged to the depth pre-determined in the site-specific survey described in Section 2.1; however, as a general guide, soils are to be salvaged to the effective rooting depth.

3. Underlying subsoil is classified as the material between the soil horizons appropriate for reclamation and the soil parent material.

4. Organic soils from wetlands are recognizable by their black colour and “mucky” texture.

2.2.2 Procedure

A qualified individual representing the Environmental Department should train and oversee equipment operators to ensure salvage operations are completed to the specifications described in this Plan.

Non-merchantable coarse woody debris is to be salvaged first and stockpiled (small woody debris can be mixed in with topsoil piles). Organic matter (grass, plants, chipped woody material, etc.) is to be incorporated into the topsoil piles by salvaging plant materials on the surface with the topsoil. To minimize compaction caused by equipment, use single lift operations rather than repeatedly driving over the surface scraping off thin layers. With a single pass, a bulldozer or backhoe can push the soil into a pile or windrow for storage or for loading into a truck by an excavator or backhoe for transport. If suitable soil is still visible after the initial scraping (this can generally be identified by the presence of roots), another pass will be required to salvage all soil materials appropriate for use in reclamation. Soil inventory and strata delineation information collected prior to salvaging will guide the stripping depths and are to be verified in the field by the Environmental Department representative overseeing salvage operations. Desired volumes of subsoil material are to be stripped in a second lift and stored in separate stockpiles from the topsoil.

Soil should ideally be handled when it is in a loose friable state; operations are to be ceased if the soil is too wet or dry to prevent degradation of its physical structure. If wet soil is sticking to the equipment, wait until the soil has dried. Conversely, if the soil is dry and hard to handle resembling flour, wait until the soil is wetted through precipitation (or active methods, such as sprinkling). In addition, stripping should be ceased in high wind events, if the wind is mobilizing soil as it is being handled. Scheduling stripping work to avoid wet and dry months (e.g., freshet and late summer, respectively) can reduce the risk of having to temporarily stop operations. It is possible to strip in winter months and freezing conditions decrease

compaction of the soil being handled, however, snow should be removed prior to stripping and should not be incorporated into soil stockpiles.

2.3 Soil Stockpiling

When possible, it is preferable for soil to be directly applied for reclamation, allowing microbes and viable seeds to remain in the soil. If this is not possible:

1. Carefully select the storage location because once stockpiled, the soil should not be disturbed again until it is used in final reclamation. Minimize exposure to wind, southwest sun, and water/flooding. To minimize risk of sedimentation of natural water courses, stockpiles should, where possible, be located upstream of site water collection ditches.

2. Stockpile the soil in a manner that maximizes surface area and minimizes soil depth. When possible, the maximum depth should be the height of a pile dumped from a haul truck (~2.5m).

3. Promptly seed stockpiles with the custom MPMC native grasses and forbes blend or, in areas where invasive plant establishment is a concern (i.e., seed sources are present nearby), the custom MPMC aggressive seed mix. Both seed mixes are certified weed free. Revegetation will help to mitigate wind and water erosion, reduce risk of weedy species ingress, and maintain microbial activity.

4. Take a representative sample of the stockpile to assess soil quality, as per the procedure in Appendix A.

5. Place signage on the stockpiles to avoid accidental disturbance.

6. Enter stockpile construction date, soil type, location, and soil volume into the Soil Stockpile Inventory spreadsheet and associated GIS map file. Document seeding in the Environmental Department Reclamation Field Book.

7. Add stockpile locations to site maps and plans for Mine Operations to avoid disturbance or loss of stockpiles.

2.4 Soil Stockpile Inspections

Inspection of soil stockpiles is to be completed annually. For each soil stockpile, the following information should be documented: date; photo number (if a photo is taken); percent vegetation coverage; percent invasive plant coverage; species present; signs of erosion and/or sedimentation; any erosion prevention works; and any additional comments or observations. Where possible, inspections should be completed in the summer months when vegetation is actively growing and easiest to identify.

Results are to be reviewed and any stockpiles exhibiting erosion and/or poor vegetation coverage are to be added to MPMC's bi-annual seeding list for re-seeding in spring or fall when weather conditions are most appropriate for seeding. Alternative options for more significant erosion may be implemented, as per the MPMC Sediment and Erosion Control Plan, such as berms or silt fences. Occurrences of invasive species are to be managed as per MPMC's Invasive Plant Management Plan. If a stockpile has been seeded twice, and still exhibits low vegetation cover, alternative vegetation options can be investigated, including:

- Amending the soil with compost tea or compost;

- Hydroseeding with a mulch/tackifier mixture designed for poor soil and/or steep slopes;

- Installation of horizontally placed logs to act as catch berms and retain moisture;
- Development of a seed mixture specifically designed for poor quality soils;
- Planting with primary successional shrubs. Willow and cottonwood can be planted using bioengineering techniques, such as live stakes and wattles, for additional erosion control.

2.5 Soil Amendment

Recommendations for amendment of soils to be used in reclamation are based on results from a site soil stockpile quality assessment conducted in September 2013, as well as results from ongoing reclamation research and progressive reclamation. Soil amendments may include biosolids and fertilizer, and recommendations for use are detailed in the site Reclamation and Closure Plan. Results from the September 2013 assessment are presented in Appendix B.

If biosolids are used as a soil amendment, they can be mixed with the soil prior to application to ensure thorough mixing and to reduce compaction caused by the dual application of soil followed by biosolids.

2.6 Soil Application

Soil should be replaced to the depths specified for that Mine site unit in the site Reclamation and Closure Plan or research trial design.

To reduce compaction, soil placement should only occur under appropriate moisture conditions. Work should be stopped under wet conditions (i.e., if the soil is sticking to the equipment) and very dry conditions (i.e., if the soil resembles flour). In addition, equipment traffic on the reclamation area should be minimized. This can be done by working systematically and planning access routes so equipment do not have to pass over completed areas, and, if applicable, equipment can do multiple tasks at a time (e.g., site preparation and placing of coarse woody debris).

Site preparation of placed soil should be conducted to create increased microtopography, which reduces erosion and provides more diverse plant microsites, including microsites with improved moisture retention. Site preparation methods are described in detail in Appendix C.

If woody debris is not already incorporated into the soil being placed, it should be applied onto the soil surface concurrently with or following site preparation. Even if woody debris is already in the soil, it may be desirable to place additional coarse woody debris as habitat features or for erosion control. Woody debris can help create more diverse microsites and habitats, retain moisture, contribute to long-term soil organic matter, and improve catch of native seeds. Recommendations for coarse woody debris application are:

- Create occasional pyramids or stacks of multiple pieces of woody debris to create more complex habitat structures and vertical structure.
- Lay logs horizontally across the slope, so they’re more likely to stop the flow of water and erosion. This is especially helpful if logs are placed downslope of depressions to help them retain soil and organic matter.
- Mix tree species of the debris, where possible, as different species decompose at different rates, staggering the release of nutrients for vegetation.

If coarse woody debris is not available or only in small amounts, boulders or rock fragments can be placed in piles and individually. Although rocks are not a source of nutrients over time, similar to woody debris they can increase moisture retention, promote plant microsite diversity, provide habitat, and reduce soil erosion.

Following soil application, the site should be inspected and test pits dug to verify that the target soil depth was achieved across the site (accounting for the variability associated with site preparation).

3 Reporting

The following information will be submitted to the MEM, as well as the BC Ministry of Environment, each year in the MPMC Annual Environmental and Reclamation Report:

- An update of soil management and handling activities, including erosion and sediment control measures, and soil replacement depths on reclamation sites;
- An updated soil stockpile inventory, including stockpile volumes and locations;

MPMC also is required to submit an updated Reclamation and Closure Plan to MEM every five years (at minimum), as well as with all major permit amendment applications for changes to the mine plan. The Reclamation and Closure Plan is to include an updated material balance to verify that sufficient quantities of suitable soil are present to reclaim existing and planned disturbed areas to the recommended prescriptions (i.e., soil depths) for meeting land capability objectives. Contingency options are to be assessed if sufficient volumes of suitable soil may not be available.

4 Responsibilities

Responsible individuals for implementing this Plan are described below.

Environmental Superintendent or designate (e.g., Environmental Coordinator):

- Be knowledgeable of and adhere to all aspects of this Plan.
- Ensure all other responsible individuals have reviewed the most up to date version of this Plan.
- Be aware of high level mine planning, to ensure that soil characterization and stripping supervision are incorporated into plans.
- Schedule and assign staff or external contractors to carry out all requirements of this Plan, including soil baseline characterizations, overseeing stripping operations, annual inspections, seeding, and reporting.
- Ensure that individuals conducting soil characterization surveys, overseeing soil stripping, and inspecting soil stockpiles have appropriate training.
- Ensure that this Plan is routinely updated to reflect changes in site conditions and procedures, and that the revised plan is submitted to MEM in the Annual Environmental and Reclamation Report and/or a Reclamation and Closure Plan update.

Qualified individual overseeing salvage operations (likely an Environmental Technician/Technologist):

- Be knowledgeable of and adhere to all aspects of this Plan.
- Coordinate with and supervise Mine Operations to ensure soil handling and management procedures are followed during stripping operations.

- Maintain an up to date soil stockpile inventory and provide a soil management update in the Annual Environmental and Reclamation Report, as directed by the Environmental Superintendent.

Mine Planning Engineer and General Foreman:

- Notify the Environmental Superintendent or designate of planned disturbances that will require soil salvaging. Work with that individual to ensure that the soil is characterized prior to stripping and a qualified individual is present to oversee salvage operations.
- Assign appropriate equipment for handling soil.
- Work with the Environmental Superintendent or designate to assign areas for soil to be stockpiled or directly placed.
- Ensure that all material suitable for reclamation is stripped prior to expansion of mine works.

Mine Operations Supervisors:

- Coordinate with the qualified individual overseeing a salvage operation (likely an Environmental Technician or Technologist).
- Only allow operations to proceed when weather and soil moisture conditions are appropriate.
- Notify the General Foreman and qualified individual overseeing the salvage operation of any concerns that arise and address these concerns prior to proceeding with the work.

Mine Operations Operators:

- Follow instructions from the qualified individual overseeing a salvage operation (likely an Environmental Technician or Technologist) and Mine Operations Supervisors.
- Clarify uncertainties or address any concerns that arise with the Mine Operations Supervisor and/or qualified individual overseeing the salvage operation prior to proceeding with work.

Appendix A: Soil Stockpile Sampling Procedure

When taking soil chemistry samples from stockpiles, the following procedure is recommended:

1. Take a photo of the stockpile to document characteristics, including size and vegetative cover.

2. For each sample, use a new (clean), plastic sample bag.

3. Collect a composite sample from a minimum of three locations that are representative of the different sections of the stockpile. Record the GPS coordinates for each location.

4. If the stockpile has recently been created (within one year), samples can be collected from the surface. If stockpiles are older, at each sample location dig a profile using a shovel or mini back-hoe to greater than 1m (from all surfaces of the stockpile). Take a sample from 0.1 to 0.2m and 1.0m depths (this encompasses the more biologically active surface soils, as well as less active soils at depth). Ensure that equal volumes are sampled at every location and depth so that the composite is representative. The minimum total sample volume is approximately 500ml.Label each sample with a unique sample ID and the date.

5. Document sample collection in the MPMC Environmental Department Reclamation Field Book, including date, sample ID and description, collector, and any additional relevant observations or details.

6. Store samples in the refrigerator until ready for shipment to the lab (typically ALS Environmental in Burnaby, BC). Ship in coolers with ice packs within the time frame required to meet lab hold times.

7. Request lab analysis for parameters including, but not limited to:

    - Moisture content
    - Texture
    - pH
    - Electrical conductivity
    - Total nitrogen
    - Available phosphorus
    - Organic matter
    - Micronutrients including sulphur and potassium

Appendix B Soil Stockpile Sample Results

Methods

Soil samples were collected on September 3, 2013 from 23 soil stockpiles across the Mount Polley Mine site. At each stockpile three profiles representing variability across the stockpile were dug to greater than 1m with a mini backhoe. Equal volume samples were collected from 0.3m and 1m depths at each of the three locations and all samples from each stockpile were composited in a clean, labeled plastic sampling bag. Samples were stored in a cooler with ice upon collection, and then transferred to a refrigerator for storage until shipping. Samples were shipped in coolers on ice to ALS Environmental in Burnaby, BC, then were subsequently transported to the ALS Environmental Saskatoon laboratory for analysis. Fertilizer recommendations were generated by ALS, using wheat growing at 36 bushels per acre as a proxy.

Results

Results are presented in Tables B. 1 – B.3. General findings based on analytical results are:

- pH has increased from a baseline average of approximately 5.5 to between 6 and 8.
- Soil is deficient in nitrogen.
- Soil has marginal to deficient phosphorus and organic matter levels.
- Soil is marginal to deficient for potassium levels; however, concentrations are similar to levels in baseline soil samples.
- Micronutrients levels are sufficient for copper, iron, manganese, and zinc.
- Micronutrient levels are marginal to deficient for boron and chloride.
- Nutrient loss increases with stockpile storage time.

Soil Amendments

Direct application of stripped soil helps maintain soil microbial communities, native seed viability, and nutrient levels. When using stockpiled soil, incorporation of woody debris and other organic matter and including nitrogen fixing species in revegetation prescriptions are methods for rebuilding deficient nutrient pools. Soil amendments can also be used for improving levels of nutrients in which soil is deficient. Based on laboratory agricultural recommendations for grass cover:

- Average nutrient requirements to meet target nutrient levels of stockpiled soil are: 52 mg/kg of nitrogen, 13 mg/kg of phosphorus, and 19 mg/kg of potassium, which corresponds to a need for 61.9-15.7-22.5 (nitrogen-phosphorus-potassium) fertilizer at 187 kg/ha.
- Average micronutrient requirements to meet target nutrient levels are 0.2 mg/kg of boron and 7 mg/kg of chloride.

MPMC has historically accepted biosolids from Metro Vancouver for use in reclamation. Typical biosolids (Attachment 1) contain sufficient levels of potassium and phosphorus to ameliorate deficiencies identified in the 2013 soil sampling results. Routine biosolids assessment does not test for boron or chloride; however, these results show that in general, metal and anion levels are elevated. Biosolids also contain

an average of 11 mg/kg of Nitrate-N, which provides more than a six-fold increase over the average soil stockpile concentration of 1.7 mg/kg.

These results are to be incorporated into reclamation prescriptions in the MPMC Reclamation and Closure Plan, which include recommendations for use of soil amendments. Recommendations should be supported by site research and mine reclamation best practices, which will provide guidance on when soil amendments are necessary, and what types and quantities to use. This should include long-term considerations, as soil amendments may only provide a short-term nutrient source.

Appendix C: Site Preparation Methods

Surface roughening is a key element for reducing erosion, retaining moisture, and reducing compaction.

Some approaches that can be used are:

1. Ripping (Figure C.1) is used as a soil roughening technique in areas too large to economically roughen with a backhoe or excavator, and is typically best for dry soils. Ripping breaks up compacted layers of soil. Rip soils when they are dry to permit shattering beneath the surface. Ripping guidelines:
    a. Rip to a depth of ~0.5 to 1m (or as deep as possible given the soil texture and coarse fragments).
    b. Make rips contour to the slope.
    c. The distance between rippers should be equal to the depth ripped.
    d. Lift the ripper from the soil every 3 to 6m to allow for some downslope water drainage. Offset drainage breaks in the ripping rows.

2. Trenching can be used for medium moisture level soils. The easiest method is to use a bull dozer and angle the blade to make “horizontal windrows”. Lift the blade every 3 to 6m to allow for some downslope water drainage. Offset the drainage breaks in the trenches.

3. Mounding (Figure C.1) is typically best for wetter sites and can be carried out on slopes or on flat terrain. Mounding can be done with a backhoe or excavator with a digging bucket to create microbasins for extreme surface roughening as follows:
    a. Start at top/bottom of the slope and work up/down in lines parallel to the contours, depending on site access.
    b. Dig, poke, or push a basin that is ~0.5m deep and has the width of the equipment bucket. This allows the basin to be up to ~1 to 1.5m wide.
    c. Drop the excavated soil on the soil surface adjacent to the basin (on the upslope side if working on a slope).
    d. Create one mound every ~2 to 3m in a random pattern that reduces the ability of water to flow straight downslope. The frequency can be increased or decreased depending on erosion risk associated with the terrain.

4. Mechanical Screefing (Figure C.2) can be applied on level ground or on slopes and can be utilized in snowy conditions, as this technique reduces the likelihood of incorporating snow into the soil. The results are similar to mounding, but shallower. Mechanical screefing can an be done with an excavator with a digging bucket as follows:
    a. Start at top/bottom of the slope and work up/down in lines parallel to the contours, depending on site access.
    b. Push bucket into snow and up to ~0.5m into the underlying soil.
    c. Rake bucket downslope ~1m creating a shallow depression with a shallow downslope berm.
    d. Create one screef every ~2 to 3m in a random pattern that reduces the ability of water to flow straight downslope.

ML/ARD MANAGEMENT PROCEDURE MANUAL

OBJECTIVE

The objective of this Metal Leaching/Acid Rock Drainage (ML/ARD) Management Procedure Manual is to provide detail on how ML/ARD potential is considered in material management at the Mount Polley Mine (MPM). This document summarizes all the various procedures and considerations related to ML/ARD potential through mine life processes.

DOCUMENT REVISION HISTORY

This document replaces earlier versions of similar documents that directed ML/ARD Management at MPM in response to *Mines Act* Permit M-200 issued on August 3, 1995. This update reflects requirements outlined in the current M-200 Permit, amended May 3, 2023.

Document Update Summary

Revision Date	Author	Comment
June 30, 2016	Chad Cameron Ben Harding Katie McMahen Luke Moger Ryan Brown Stephen Day (SRK)	Original Document
August 04, 2022	Mathieu O'Leary Gabriel Holmes Aaron Zwiebel (DWB) Shauna Litke (SRK)	Added contacts, water treatment plant waste ML/ARD characterization, QA/QC sampling, and PAG misplacement action plan.
October 23, 2023	Mathieu O'Leary Gabriel Holmes	Updated NPR criterion for Springer Deep and WX Zones, and annual blast fractionation confirmatory sampling.

	Alicia Lalonde (DWB) Shauna Litke (SRK)	

KEY CONTACTS AND QUALIFIED PROFESSIONALS

Numerous personnel at Mount Polley are responsible for carrying out the procedures written in this plan. Key mine personnel and their contact information are as follows.

Name	Role	Phone	Email
Kelly Parker	General Manager	236-800-4771	kelly.parker@mountpolley.com
Don Parsons	Chief Compliance Officer	604-488-2652	don.parsons@imperialmetals.com

BACKGROUND

Metal leaching and acid generation are naturally occurring chemical processes which may have negative impacts on the receiving environment. The potential environmental impact of ML/ARD will depend on their magnitude, the sensitivity of the receiving environment, dilution and/or attenuation, as well as any mitigation measures that are in place.

Metal leaching occurs as a result of weathering of metal-containing minerals (i.e., exposure to water and oxygen), drainage conditions that increase solubility, and flow of water through source materials. Acid generation occurs when minerals containing reduced sulfur (e.g., sulfide and elemental sulfur) are exposed

to the weathering effects of oxygen and water. In iron sulphide minerals (e.g., pyrite) acidity is also generated when ferric iron precipitates. Other minerals in the source rock, primarily calcium and magnesium carbonates can neutralize the acid. ARD occurs when the amount of acid-generation exceeds the ability of the source rock to neutralize this acid. Any surplus acid is entrained in water and can create acidic and metal-containing run-off.

Pre-mining and operational geochemical characterization has shown that ARD potential at MPM is restricted due to the abundance of acid-consuming carbonate minerals compared to acid generating sulphide minerals. In addition, the presence of natural carbonate and oxide copper minerals in the pre-mining weathering zone reinforce the expectation that weathering conditions are dominantly basic. However, due to the potential consequences of acid generation for long term management of the site, Mount Polley Mining Corporation (MPMC) actively manages waste rock based on its ARD potential as described in the following sections.

MPMC has focused on managing potential for ARD due to the link between acid generation and enhanced solubility of copper which is expected to be the primary concern for ML. Selenium leaching has also been identified as occurring at MPM. Selenium is released by oxidation of sulphide minerals, but leaching is not necessarily associated with pH depression. Selenium leaching occurs regardless of whether waste rock is classified as potentially ARD generating (PAG) or non-PAG (referred to as NAG at MPM).

UNDERSTANDING OF THE DISTRIBUTION OF ARD POTENTIAL

Like other alkalic porphyry deposits (e.g., Copper Mountain, Brenda), MPM lacks the strong hydrothermal alteration zoning that is commonly observed in calc-alkalic porphyry deposits (e.g., Highland Valley Copper, Island Copper, Gibraltar). In particular, phyllic alteration is absent at MPM. A common feature of calc-alkalic porphyry deposits is often a pronounced pyritic halo that surrounds the copper mineralization and is associated with phyllic and propylitic alteration. At MPM, discontinuous pyritic zones are present but do not appear to be mineralization halos. MPMC geological staff identified a pyritic zone in the south wall of the Springer Pit which extends into the adjacent Cariboo Pit.

This ML/ARD Management Procedure Manual applies to waste rock and ore stockpiles. Tailings are consistently NAG due to removal of copper sulphides by ore processing.

MANAGEMENT OF PAG ROCK

Best practice for management of PAG rock is subaqueous disposal in a configuration that provides permanent and low maintenance containment. At MPM, this has been implemented by disposing of waste rock in completed open pits that will subsequently fill with water. Mine planning is carried out at MPM such that the open pits have sufficient capacity that PAG material can be re-handled into the open pits and stored subaqueously at closure. The following pits are available for subaqueous disposal (in sequence):

- Cariboo Pit
- Bell Pit
- Pond Zone Pit

- Southeast Zone Pit
- Wight Pit
- Cariboo-Springer Pit.

For the Springer Pit, backfill locations are not currently available. The PAG rock is therefore stockpiled adjacent to the open pit in the Temporary Northwest PAG Stockpile for backhauling to the Cariboo-Springer Pit upon completion of mining.

For the small Pond Zone Pit, low sulfur PAG waste rock is layered with NAG waste rock.

Onset of acidic conditions in waste rock at MPM takes at least decades as shown by humidity cells, and the lack of acidification in the natural exposure of the deposit indicates that flooding of PAG waste rock does not need to be immediate. The current approaches of backfilling into dry pits and stockpiling following by backfilling allows PAG rock to be submerged before it acidifies.

DETERMINATION OF ML/ARD POTENTIAL

Waste rock on site is separated into two categories, NAG and PAG, using Neutralizing Potential Ratio (NPR) defined as:

$$NPR = NP/AP.$$

Acid Potential (AP) (in kg $CaCO_3$/t) is measured from:

- Total sulfur (%) x 31.25

Neutralizing Potential (NP) (in kg $CaCO_3$/t) is measured from total carbonate NP determined from:

- Total carbon (%C) x 83.33.

Due to the dominantly intrusive rock host at MPM, total carbon is an appropriate proxy for carbonate (SRK 2023a).

NPR CRITERION

A site-specific criterion (NPR) of 1.6 was developed by SRK for Springer Deep and WX Zones (SRK 2023b). To derive the NPR*, the stable rate of sulphate release was compared to the relative rate of acid neutralization by calcium and magnesium carbonate minerals, as well as potassium and sodium to account for cation exchange. The data showed a tendency toward consumption of approximately 1.6 moles of calcium, magnesium, sodium, and potassium per mole of sulphate released.

Rock sourced from other zones is defined as PAG when NPR $\leq$ 2.

BLAST FRACTIONATION

SRK was retained by MPMC to refine ABA procedures and understand the specific factors controlling ARD potential at MPM to support mining of the Springer Deep and WX zones. This work has led to the

development of site-specific ABA procedures for these particular geological zones. An excerpt from the summary report provided by SRK (2023b) is included below.

"Mineral partitioning during blasting can have an effect on the classification of waste rock ARD potential since fines tend to be more reactive. If carbonate minerals preferentially partition into the blast fines, the use of a bulk TIC-NP/AP classification factor can lead to misclassification of rock that will probably not generate acid as PAG. The reverse can also occur if sulphide minerals preferentially partition to the fines."

Review of SRK's results of blast fractionation for the Springer Deep and WX Zones showed:

- No difference in levels of total sulfur in the fine and bulk fraction.
- NP (calculated from TIC) was enriched in the fine fraction compared to the bulk fraction.

SRK (2023b) derived a regression for the NP/AP relationship between the fines and the bulk fraction.

An NPR* of 0.7 in the blast hole cuttings is used to determine dig limits for PAG rock because this is equivalent to an NPR* of 1.6 in the blast fines, which is the reactive component in the rock. For all other rock types, an NPR of 2 in the blast hole cuttings will be used to determine dig limits until a relationship is confirmed.

MATERIAL CHARACTERIZATION OVERVIEW

This section provides an overview of characterization procedures.

The MPM program characterizes all material types that will be handled during the mine life. Analysis is completed on site by Mount Polley's LECO™ instrument , allowing MPMC to best manage mine waste by directing it to suitable storage sites, or to construction usage when required (and if deemed suitable).

On each bench, a sample of cuttings is collected from each blast hole and analyzed for total copper, non-sulphide copper, iron, and gold. Areas of ore and waste are identified by interpolation of these assay results and the economic analysis of the resulting metal grades. Ore/waste boundaries are then established based on the calculated mill head values.

In areas which have proven to be consistently NAG on previous adjacent benches in blasthole samples, the waste tonnage in each blast is divided by 40,000 in order to determine the number of ABA samples to be submitted (i.e., one per 40,000 tonnes (t) of waste). However, in areas where PAG has been modelled through either exploration sampling, or results of previous blasthole sampling on other benches, (or where NAG and PAG may coincide), the sample density is doubled to one per 20,000 t. This approach results in greater sampling density in areas of suspected NAG/PAG boundaries, and increases the certainty of defining PAG. Typically structures at MPM are vertically oriented, and relatively continuous. This provides some assurance that blasthole samples from previously mined benches have relevance for determining where additional samples should be taken on new benches.

Any ore that will be stockpiled rather than processed immediately is sampled at a frequency of one (1) per 20,000 t to determine if it is classified as PAG or NAG. Millfeed ore areas are excluded from ABA analysis, as this material is processed through the Mill.

Composite tailings samples are collected and analyzed every month when processing of ore occurs to represent the tonnage of tailings deposited.

Water treatment wastes are quantified monthly and sampled quarterly, with material characterization performed to assess ML/ARD potential and contribute to a material inventory.

As a confirmatory sampling measure, the Environmental Department takes random weekly grab samples from the NAG waste dump when NAG is being dumped and/or used for construction, to verify that material is being appropriately characterized and handled.

In the event that a confirmatory sample or other activities result in the discovery of PAG material in a NAG-designated area, a QP is to be informed without delay, who will dictate the response actions in coordination with site contacts. Mount Polley is permitted to blend pockets of less than 1,000 t of PAG materials with non-PAG materials at a ratio of 20:1, as described in *Mines Act* Permit M-200 Section D.3.(c)(i)(d). If these conditions cannot be met, it may be necessary to remove PAG material from NAG areas.

Water chemistry monitoring of seepage from rock dumps, water treatment plant wastes, and contact water from the site water collection systems is also conducted by the Environmental Department to inform development of geochemical source terms and long-term water quality predictions. Similarly, tailings composites and monthly random drill pulp samples are sent to a third-party laboratory for metals analysis as an additional source of data for site geochemical models.

IN-PIT SEGREGATION

Blasthole Samples:

1. After the production drill has completed and moved away from the hole, the sample may be taken.
2. Using a tube sampler, the Driller will take a representative sample of the cuttings pile.
3. Samples are to be collected in a clean plastic sample bag.
4. The Driller is to complete a Blasthole Sample Tag, tearing off the tag once completed and inserting it into sample bag.
5. The sample bag is to be tied off using ribbon.
6. In the case where multiple composite samples are to be taken from a single hole, the remaining cuttings after the sample are to be removed by the Driller so a clean new pile of cuttings can be formed.
7. Completed samples are to be left on the drill by the Driller. At the end of shift, the Mine Operations Pit Supervisor (or designate) will collect all samples and deliver them to the Bucking Room.

Bucking Room:

1. Each sample is to be transferred from the sample bag to a clean metal tray. The Blasthole Sample Tag is to be kept with the sample.
2. The sample is to be dried at 105°C.
3. The sample is then to be crushed in the Primary Crusher.
4. The sample is then to be crushed in the Fine Crusher.
5. The sample is to be split until the sample size is approximately 200 g.

a. Reject from the sample is to be wasted.

6. The sample is then to be pulverized for 75 seconds.
7. The sample is to be placed in a pouch with the Blasthole Sample Tag stapled to the pouch.
8. If the pouch is a pit sample, it is to be sent to Assay Lab 1. If the sample is an ABA sample, it is to be sent to Assay Lab 2.

Assay Lab 1:

1. The Assay Lab is to run the sample through the atomic absorption analyzer which automatically transfers the copper (CU), non-sulphide copper (CUNS) and iron (FE) values into the LIMS database.
2. The samples for gold analysis are to be fire assayed and analyzed by atomic absorption which automatically transfers the gold (AU) value into the LIMS database.
3. The sample is then to be placed into storage. Pit samples are to be stored for 21 days.

Ore Control Technician 1:

1. Once assays have been entered into the LIMS database, the Ore Control Technician will review the data and roughly determine where in the blast any Mill Feed Ore will be located.
2. Once the Ore Control Technician drafts the Mill Feed Ore locations, the Ore Control Technician will evenly select holes in the non-Mill Feed Ore areas (including materials designated for ore stockpiles) at a ratio of one (1) sample per 20,000 t of rock. This equates to about one for every nine blast holes. Additional samples can be requested whenever additional data is desired for improving understanding of the geological conditions. An example of a sample layout is included as Figure 1.

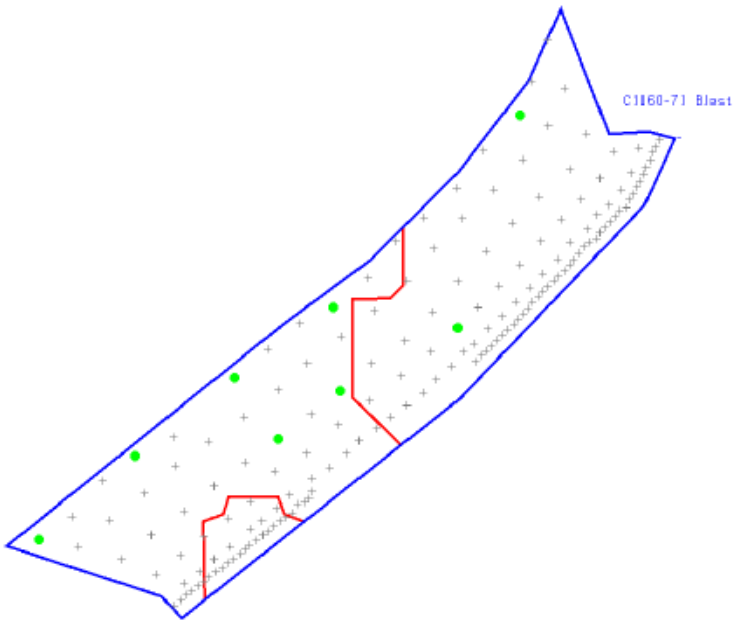

Figure 1: Location of ABA samples (green dots) within a blast. Red polygons denote mill feed ore, remainder is waste. The Ore Control Technician focuses sampling on areas which are designated waste and/or stockpile ore by the blasthole model. Reference blast = 149,173 t.

3. The Ore Control Technician is to then make an Analysis Request with the holes selected to the Assay Lab.

Assay Lab 2:

1. If the Assay Lab receives an Analysis Request, they will retrieve the sample pouch from storage, otherwise the sample will be delivered to the Bucking Room.
2. The Assay Lab will run the sample through the LECO CS230 Carbon Sulfur Analyzer.
3. Once analyzed, the machine transfers the carbon percentage (C%) and the sulfur percentage (S%) to a spreadsheet where NPR, NP and AP are calculated.
4. The NPR, NP, AP, C% and S% are transferred automatically to the LIMS database.
5. The sample is then to be placed into storage. ABA samples are to be stored for 14 days.

Ore Control Technician 2:

1. Once all the assays and ABAs have been entered into the LIMS database, the Ore Control Technician is to review the data and model the blast.
2. Modeling the blast
    a. The software used is MineSight.
    b. The model is based on a 5 metre (m) x 5 m x 12 m block system.
    c. The block closest to the ABA sample will closely match the sample.
    d. The blocks between the samples receive a weighted average of the sample carbon and sulfur grades.
    e. Once each block gets the weighted C% and S%, then the AP, NP and NPR is calculated for each block.
    f. Using the calculated NPR value, the model is to be coded as Ore/NAG/PAG by the Ore Control Technician and the resulting markup design is to be provided to the Surveyor.
3. The Ore Control Technician is responsible for the release of the final ore markup to the Surveyor. An example of a sample layout is included as Figure 2.

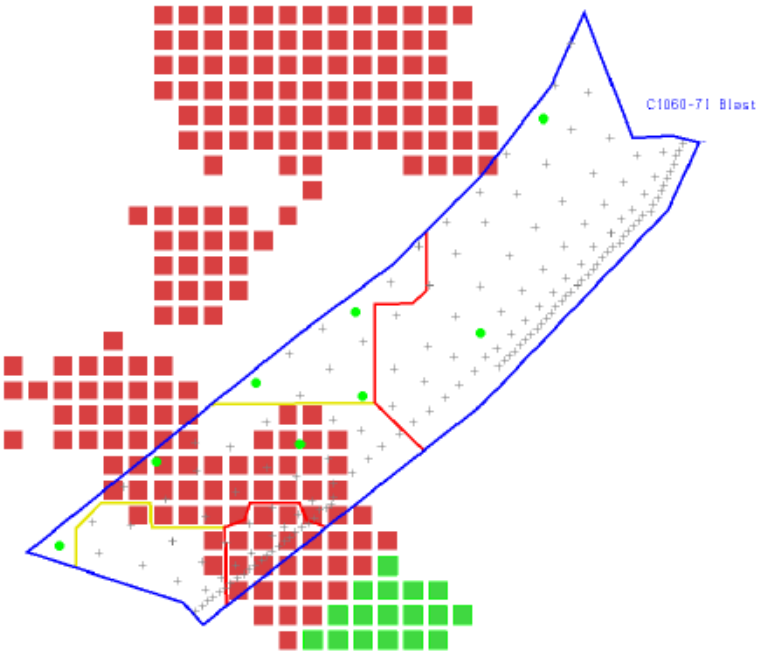

Figure 2. ABA results from samples shown in Figure 1 are used to update the blasthole PAG model item which identifies blocks which meet PAG criteria (red). The Ore Control Technician then marks up the PAG waste (yellow polygon) and the complete ore/waste markup is released to the Surveyor.

Surveyor:

1. The Surveyor will be responsible for the layout all Ore/NAG/PAG, as determined by the Ore Control Technician, in the field.

2. Using four (4) foot stakes spaced approximately 5 m apart, the Surveyor will mark out the contacts using marked placards.

    a. Red Placard = High Grade Ore
    b. White Placard = Super High Grade Ore
    c. Green Placard = Low Grade Ore
    d. Yellow Placard = PAG
    e. Blue Placard = NAG
    f. Pink Ribbon = High Grade Mill Feed Ore

3. Once complete, the Surveyor will print out maps of the area delineating material types for the shovel operator(s), and, if required, provide field verification of material types.

MATERIAL HANDLING

Shovel/Haul Truck Operators:

1. The Shovel Operator will mine the rock, following the contacts laid out by the Surveyor.

2. The Shovel Operator will ensure that all material contained within the contact stakes is routed as described by the markup and that any uncertainty in material classification is resolved by seeking the assistance of either the Pit Supervisor or the Engineering Department.
3. Upon loading a haul truck, the Shovel Operator shall direct the Haul Truck Driver as to the material type being hauled, and destination, using a horn sequence. The Haul Truck Driver will then take the material to the designated area.

IN-PIT MONITORING

Shovel Operator:

The Shovel Operator follows the staking of the Surveyor. Any material marked out as PAG is only to be hauled to approved locations. If a discrepancy is found, the Surveyor is to be called out to verify the material markup.

Pit Supervisor:

Throughout the shift, the Pit Supervisor will check in with the Shovel Operator and confirm the material type being loaded and that the destination is correct.

Haul Truck Driver:

If the Haul Truck Driver is uncertain of the material loaded, the Haul Truck Driver will confirm with the Shovel Operator or the Pit Supervisor.

Ore Control Technician:

The Ore Control Technician is to check Shovel Operator dig faces and confirm that the markup is appropriate and material is being routed appropriately.

Surveyor:

The Surveyor is to verify that material staking is visible and correct.

Environmental Department:

Once a month, the Environmental Department is to send a randomly selected drill hole pulp sample that MPMC analyzed for total sulfur and total carbon at the Assay Lab to a third-party laboratory (typically ALS Environmental in Burnaby, BC) for element analysis by ICP-MS following aqua regia digestion as an additional source of data to support site geochemical models.

Additionally, the Environmental Department takes water samples from all pit sumps to inform long-term geochemical predictions. Samples are collected as per MPMC-SOP-002: Surface Water Quality Monitoring. Monitoring locations and frequencies are regularly updated to reflect site developments and are summarized in the Comprehensive Environmental Management Plan.

TAILINGS MONITORING

Mill Metallurgy

1. The Mill Metallurgy Department is to take a monthly composite sample of the tailings generated through the month.
    - Slurry is to be sampled every two (2) hours and made into a composite for the shift.
    - The shift composite is then to be added to a monthly composite.
    - At the end of the month, the monthly composite is to be given to the Bucking Room and prepared for ABA total sulfur and carbon analysis.
2. The Environmental Department is to send the monthly tailings composite sample to a third-party laboratory (typically ALS Environmental in Burnaby, BC) for element analysis by ICP-MS following aqua regia digestion to provide data for site geochemical modelling.

WATER TREATMENT PLANT WASTE

Environmental Department:

1. Record the value on the waste line totalizer monthly when Water Treatment Plant (WTP) data are downloaded.
2. Collect samples of waste which has exited the WTP quarterly to characterize WTP wastes. Samples shall be taken of material that has exited the sludge line, to the West of the WTP and down-flow from where microsand is cycloned for re-use.
3. Sampling Method for liquid wastes (adapted from MPMC-WORK-002):
    - Record in-situ measures: pH, temperature, conductivity, and turbidity.
    - Take a water sample from the pipe outflow and send for lab analysis corresponding with other contact water samples as described in the Comprehensive Environmental Monitoring Plan, including but not limited to: physical parameters, pH, total and dissolved metals.
4. Sampling method for solid wastes (adapted from MPMC-WORK-016):
    - Take a composite sample of solids from the sludge pile adjacent to the WTP, with samples from at least 5 locations on the pile.
    - Send to an external laboratory for total sulfur, total inorganic carbon, elemental analysis by ICP-MS following aqua regia digestion and shake flask extraction testing to assess the ML/ARD potential of solids.
5. Review and archive lab data in a timely manner for use by personnel responsible for the Annual Reclamation Report.
6. The TSS concentration in wastewater will be used along with the waste line totalizer values to quantify the solids delivered to the TSF. The relationship between total and dissolved metals in the WTP waste line sample will be used to quantify the suspended (filterable) metals in this sample.
7. This information will be included in the MLARD materials inventory, and reported to EMLI in the Annual Reclamation Report as per Code Section 10.5.7 on water treatment wastes and by-products.

NAG Material Monitoring

Environment Department

1. As a confirmatory sampling measure, the Environmental Department is to take ABA grab samples from the NAG Dump and any area where NAG rock is used for construction on a weekly basis, while NAG dumping and/or NAG rock construction is occurring. Sampling will conform with MPMC-SOP-016: ABA and Soil Sampling. Two size fractions (+2 mm and -2 mm) will be analyzed for each sample collected. Sieving to be completed by lab once samples have been collected.
2. To assure data quality, as recommended in the BC Field Sampling Manual, a minimum of one in ten samples will be a duplicate sample, as written in MPMC-SOP-016.
3. Seeps and contact water collected on site are sampled to provide data for site geochemical modelling. Samples are collected as per MPMC-SOP-002: Surface Water Quality Monitoring. The frequency and locations of these monitoring sites are updated regularly to reflect changes to the mine site are summarized in the Comprehensive Environmental Management Plan.

Ore Control

1. As a blast fractionation confirmatory sampling measure, ten samples of blast muck will be collected each year. Blasts to sample will be selected based on mining activities and by targeting a range of sulfur contents.

Response to Finding PAG in NAG Areas

Environmental Department

1. Upon reviewing data indicating PAG material has been found in a NAG area, without delay contact one or more Qualified Professionals listed in this document, and the Pit Supervisor or designate to pass along the relevant data and sampling location.
2. Return to the location where PAG material was discovered and stake the sampling location. Note that material may have been dozed, buried or pushed down the dump face, in which case personnel are to mark as close as possible.
3. At the discretion of Qualified Professionals, undertake additional ABA sampling to assess the prevalence of PAG material.

Pit Supervisor:

1. Discuss NAG/PAG separation with shovel and haul truck operators and investigate the possibility of a loading or dumping mix-up. This is not a punitive activity but meant to identify potential causes and estimate material volume.
2. At the discretion of Qualified Professionals, organize the removal of PAG material from the non-PAG area.

ML/ARD Qualified Professional

1. Work with site contacts to develop an appropriate plan of action to address the situation.
2. If it is not possible to demonstrate that PAG material meets conditions outlined in M-200 Section D.3.(c)(i)(d), it may be necessary to remove recoverable PAG material.

REVIEW OF RESULTS AND PROGRAM EFFICACY

Data collected and corresponding interpretation regarding the ML/ARD program are included in the Annual Environmental and Reclamation Reports (AER and ARR, respectively), due annually to the British Columbia Ministry of Environment and Ministry of Energy and Mines on March 31 of each year, reflective of the previous calendar year. Personnel responsible for the AER/ARR may recommend updates to the ML/ARD program based on operational changes or findings of annual reporting. The AER/ARR include sections on: waste rock characterization and disposal; drainage water quality monitoring; and, updates to long-term predictions (kinetic testing).

Executive Summary

Background

The Mount Polley Mine (The Mine, or Site) is a copper-gold mine owned and operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. The Mine is located 56 km northeast of Williams Lake, British Columbia. As a result of a foundation failure of the Tailings Storage Facility (TSF) in 2014, mining and milling operations were suspended and MPMC did not have a permitted water discharge. An interim restricted operations M-200 permit application was submitted to regulators on March 20, 2015, and approval to resume operations was received on July 9, 2015. Milling operations resumed on August 4, 2015. Tailings and mine contact water were conveyed to and temporarily stored in the Springer Pit until 2016 when the Tailings Storage Facility was repaired and authorized for use under Mines Act Permit M-200 and *Environmental Management Act* (EMA) Permit 11678.

Also in 2016, MPMC submitted a Technical Assessment Report (TAR) to the British Columbia Ministry of Environment and Climate Change Strategy. The TAR provided details of the proposed Long-term Water Management Plan for the Mine, including the discharge quantity and quality for the operations, closure, and post-closure phases of mine life. It included a technical assessment of the effluent discharge during operations to identify whether or not receiving water uses would be impaired and recommended a preferred discharge approach using an active treatment system and a pipeline discharging treated mine water at depth in Quesnel Lake.

Under Section 1.2.3 of Permit 11678, the “authorized discharge period” for discharge of effluent to Quesnel Lake expires on June 30, 2025. This discharge period is anticipated to support the permitted Phase 4 Cariboo-Springer Pit. However, MPMC is pursuing an extension to the life of the Mount Polley Mine with the development of the Springer Expansion Project, which will add approximately 8 years of operational mining life. If market conditions remain favourable and operations occur continuously, the mine would operate beyond June 30, 2025. Approval of this project will be sought through a Joint Application through the Ministry of Energy, Mines, and Low Carbon Innovation (EMLI) and the Ministry of Environment and Climate Change Strategy (BC ENV), with the request to BC ENV being an extension of the discharge period beyond 2025.

This Water Management Plan (WMP) addresses permit requirements for assumed future operations of the site, which at the time of writing are expected to run through March 31, 2031. This WMP also summarizes and discusses predicted water quantity, quality, and treatment during closure (April 1, 2031, through March 31, 2041) and post-closure (April 1, 2041, through March 31, 2131) phases. It should be noted that these dates are expected dates for mining operations; however, as with all mines, such schedules are subject to changes that result from commodity pricing and other factors.

Approach

The timeline for operations and closure has been assumed based on mine planning information available at the time of writing and is subject to change over time. The current Reclamation and Closure Plan (MPMC 2022a) describes the plan for closing the site.

This WMP describes the water management approach for the Site during both operations and closure. The regulatory framework for the Site is described in detail, including a table of concordance outlining how the WMP addresses the Joint Application information requirements. The proposed mine plan is described, including the assumed dates for operation, closure, and post-closure phases for modelling purposes.

Baseline information is summarized for the Site, including geology, climate, hydrology, and the receiving environment water quality (Quesnel Lake discharge via submerged diffuser). A major component of this WMP is a summary of the water balance and water quality models developed for the Mine, including a summary of inputs into these models and a summary of the results. These two models are described in detail in the appended reports (Appendix A and Appendix B). The results of the water balance and quality models provides critical information to define the design basis for water treatment for the site (summarized in this WMP), during operations and during closure/post-closure. An update of treatment technology development for closure/post-closure is also provided.

This WMP also provides discussion regarding remediation of landforms on mine sites during closure and post-closure activities.

Final Design and Technology Development

For the purposes of this revised WMP, the “final design” of the site is defined as the water management infrastructure design in place at closure of the site. During operations, the water management infrastructure (i.e., collection ditches, pipes, sumps, pumps, etc.) will remain in its current configuration. During the remainder of operations, plans will be put in place to develop the final design for water management and treatment into closure and post-closure.

A key component of developing the final design during operations is developing alternative treatment technologies that could be considered for closure of the site. This WMP provides an update on progress on a number of possible treatment technologies included in the water treatment technology inventory.

Study Limitations

WSP Canada Inc. (WSP) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by WSP for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents WSP's professional judgement based on the knowledge and information available at the time of completion. WSP is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to WSP by MPMC and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by WSP are considered its professional work product and shall remain the copyright property of WSP. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. 1.0 INTRODUCTION

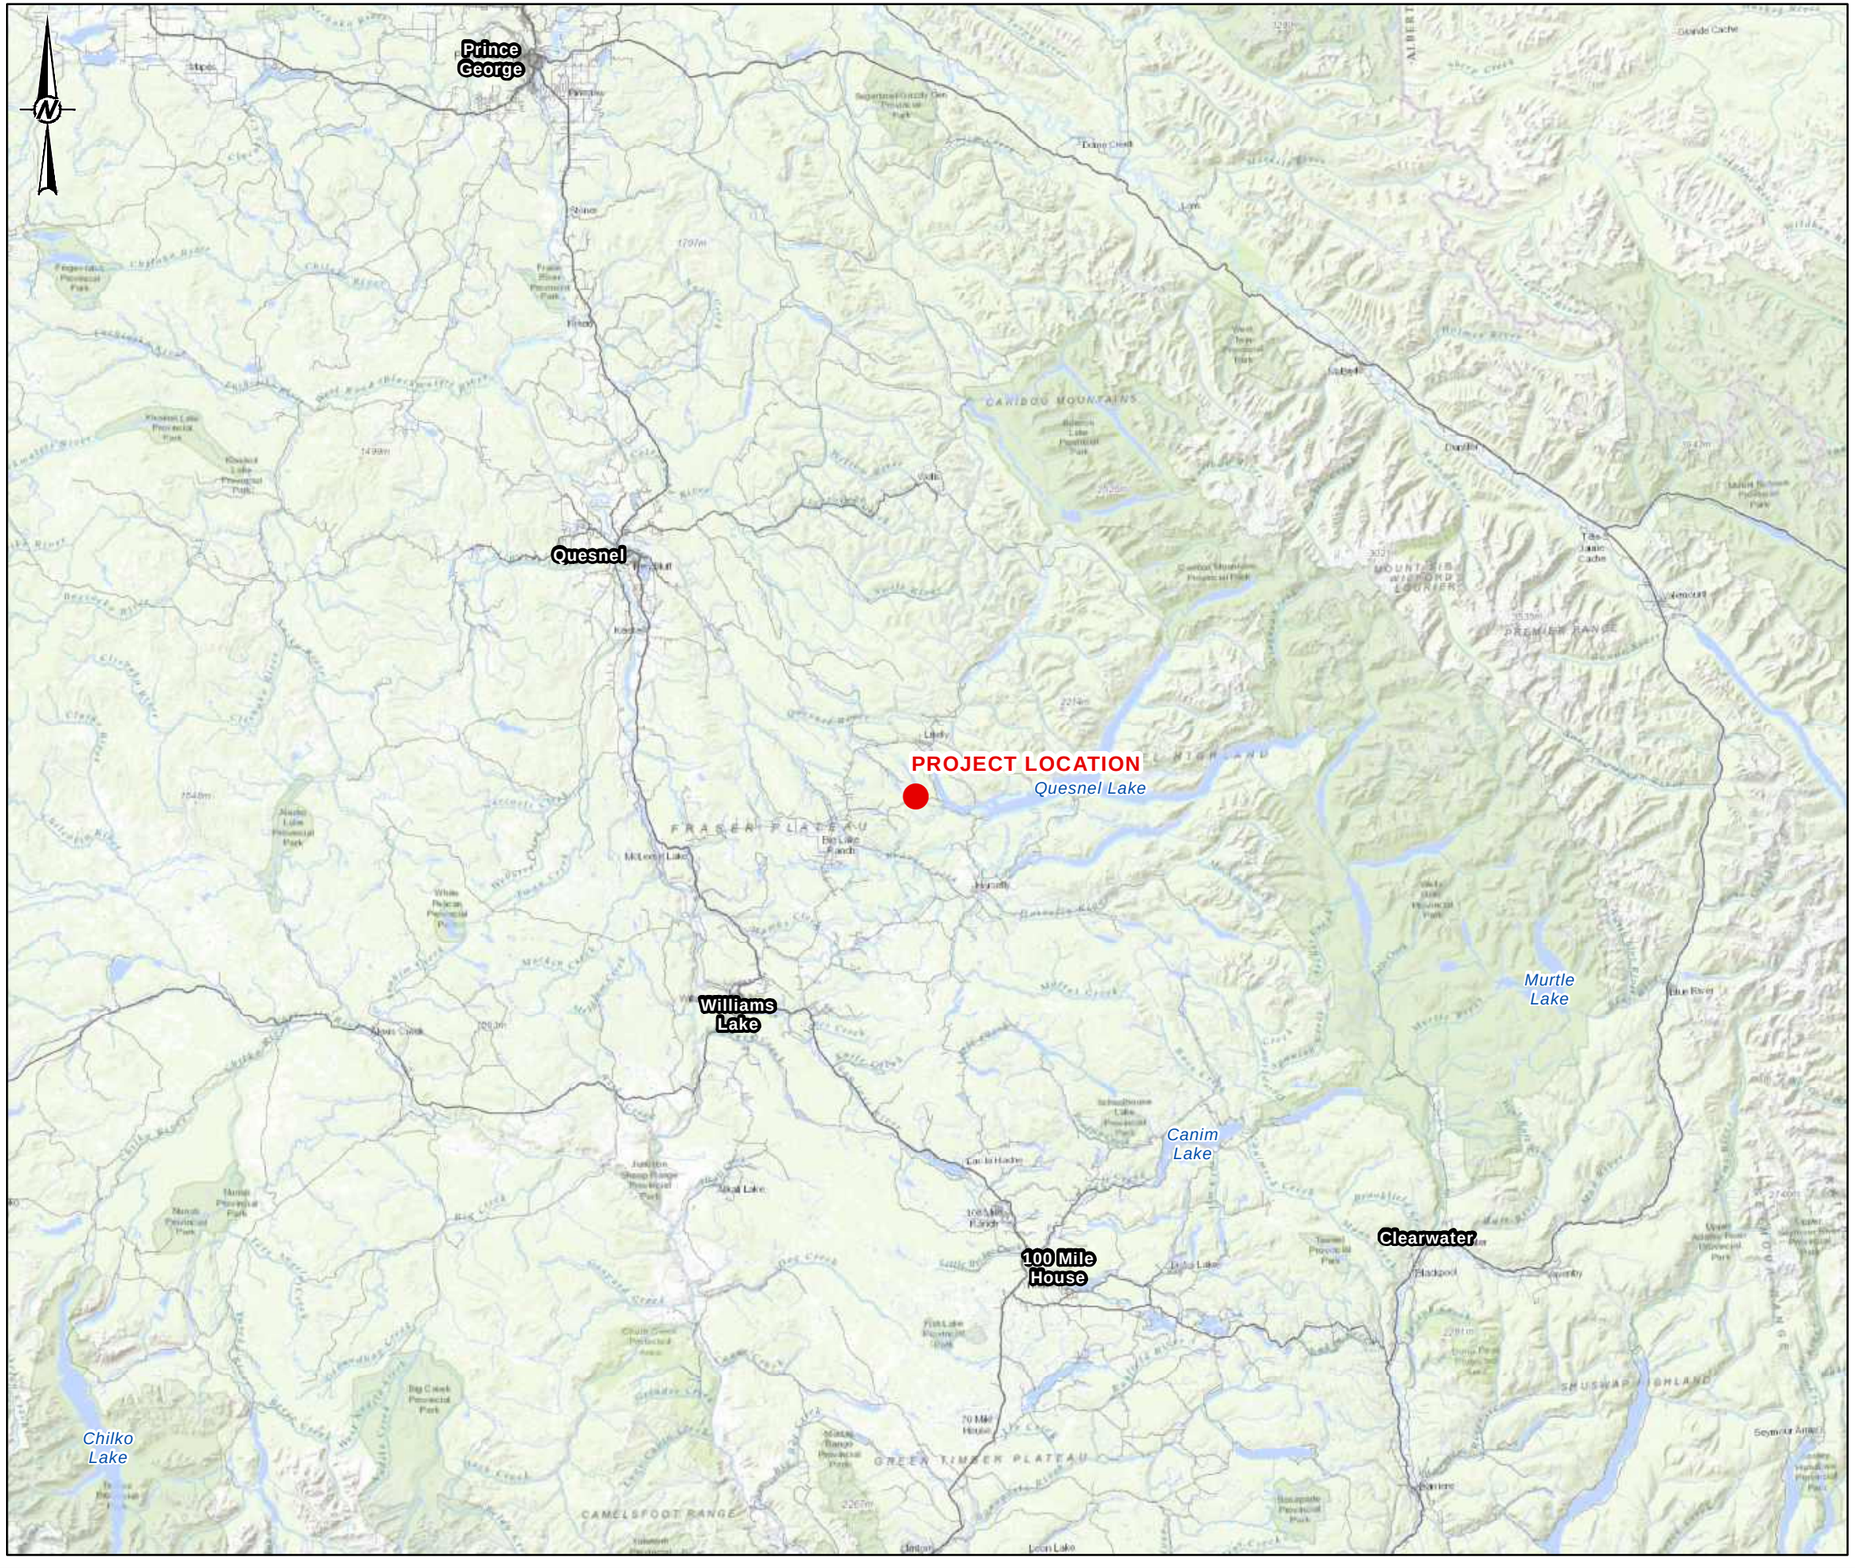
1.1 Background

The Mount Polley Mine (the Mine, or Site) is a copper and gold mine operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. The Mine is located 56 km northeast of Williams Lake, British Columbia (BC), and is located between Polley Lake and Bootjack Lake. The Mine location is shown in Figure 1 and the Mine site layout is shown in Figure 5.

MPMC began production at the mine in 1997 and operated until October 2001 when operations were suspended temporarily for economic reasons. In March 2005, the Mine restarted production and it was in continuous operation until August 4, 2014, when a subsurface failure of the Tailings Storage Facility (TSF) foundation resulted in mining and milling operations being suspended. MPMC was subsequently issued with a Pollution Abatement Order (Order #107461) by the BC Ministry of Environment and Climate Change Strategy (BC ENV). Containment infrastructure for collection of drainage from the breached section of the TSF was constructed by September 4, 2014, and all contact water was subsequently directed to and contained within the Springer Pit. This measure was implemented as part of the emergency response and was considered a temporary Water Management Plan to deal with changed conditions arising from the breach.

On July 9, 2015, MPMC was provided approval by the Ministry of Energy, Mines and Petroleum Resources (MEMPR) to return to restricted operations for a one-year period using the Springer Pit for tailings deposition and subject to the conditions stated in the M-200 Permit (Mine No. 1101163). On June 23, 2015, MPMC was provided approval by MEMPR to return to normal operations using the TSF for tailings deposition under an approved four-year mine plan as stated in the M-200 Permit.



MPMC had been in care and maintenance since May 31, 2019, which resulted in an extension to the operational period needed to develop the permitted Phase 4 Cariboo-Springer Pit. In addition to this, the results of exploration and strong resource prices have provided the basis for an extended life of mine plan that will result in mining activity beyond Phase 4 Cariboo-Springer Pit, to include additional phases that will expand Springer Pit to consolidate Springer and Cariboo pits adding approximately 8 years to the life of the mine.

For the purposes of this WMP, WSP Canada Inc. (WSP) has assumed that the mine will be in operation until March 31, 2031, followed by a closure phase from April 1, 2031, to March 31, 2041, and a post-closure phase from April 1, 2041, to March 31, 2131. It should be recognized that this mine life may change as a result of metal prices, new exploration, care and maintenance periods, revisions to the mine plan, and other factors that are common to mining operations. These are only assumed mine phase dates to allow completion of modelling and should not be considered by regulators as static dates.

MPMC has a permit to discharge treated effluent from the Mine under the *Environmental Management Act* (EMA; SBC 2003) as Permit 11678. The permit was issued on May 30, 1997, and most recently amended through a Consent Order on September 18, 2020. An interim extension to Section 1.2.3 of PE-11678 was granted by BC ENV in 2022, allowing the existing discharge to Quesnel Lake to continue until June 30, 2025. The (2022) TAR provided an update on, among other things, receiving environment data and, in aggregate, provided scientific rationale to support the view that the discharge is not causing pollution. Under Section 1.2.3 of Permit 11678, the “authorized discharge period” for discharge of effluent to Quesnel Lake expires on June 30, 2025. This discharge period is anticipated to support the permitted Phase 4 Cariboo-Springer Pit. However, MPMC is pursuing an extension to the life of the Mount Polley mine with the development of the Springer Expansion Project, which will add approximately 8 years of operational mining life.

Approval of this project will be sought through a Joint Application through the Ministry of Energy, Mines, and Low Carbon Innovation and the Ministry of Environment and Climate Change Strategy, with the request to BC ENV being an extension of the discharge period beyond 2025.

Section 2.10 of EMA Permit 11678 requires the development of a WMP that addresses future Water Management Plans beyond the end of 2022 and during mining operations. This WMP seeks to provide a practical plan for managing mine water for the proposed life of mine and to do so in a manner that reflects the requirements of Section 2.10 of the permit, based on information available at the time of writing. It also proposes an implementation schedule and revision process for the WMP.

1.2 Water Management Approach and Framework

1.2.1 Introduction

This document presents a WMP that addresses water management throughout the future operational, closure, and post-closure phases. This WMP mainly serves to provide support for the joint permit application associated with the proposed Springer Expansion Life of Mine (LOM) Plan.

A Table of Concordance outlining the Joint Application Information Requirements (JAIR) and how this WMP addresses those requirements can be found in Table 1. Sections 1.2 and 1.3 (this report) describe the water management framework, project development process, and the regulatory framework for this document.

A site-wide water balance model (SWWBM) and site-wide water quality model (SWWQM) were developed as part of this WMP (Appendix A and Appendix B) which describe proposed water management quantities and qualities for operations, closure, and post-closure phases of the Mine. A discussion of water treatment during operations and closure/post-closure is also provided, including treatment design bases for these LOM phases.

An additional objective of this WMP is to provide updates on treatment technology development and alternative water treatment strategies that are being explored by MPMC for implementation both in operations and upon closure of the site.

1.2.2 Water Management Approach

The primary approach to water management on site is to separate contact (mine affected) and non-contact (non-mine affected) sources of runoff and seepage. The distinction between the two water sources can be characterized as follows:

- **Contact water:** water that may have come into direct contact with mining or milling activities. This water generally requires management or treatment before release to the environment and is captured by the requirements of PE-11678.
- **Non-contact water:** non-contact water is understood as runoff originating from areas unaltered by mining activity that does not contact mining areas. Such water is not captured under the effluent permit (PE-11678). It is typically diverted to the extent practicable and allowed to discharge directly to the receiving environment.

In 2016, MPMC submitted a TAR (Golder 2016g) describing the water management strategy and configuration for the resumption of normal operations. The main objective of the TAR was to define the water management practices that will help prevent the year-over-year accumulation of contact water at the mine, and to mitigate the potential for unplanned and/or non-compliant releases to the environment. Managing water to prevent a year-over-year accumulation of stored water is also consistent with the advice from the TSF Engineer of Record and from the Independent Engineering Review Panel, both of whom act in roles created under the *Mines Act*. The following strategies were proposed to meet this objective:

- To the extent practicable, reduce the volume of non-contact water collected on site by diverting non-contact water away from mine-impacted areas and from site contact water collection systems.
- Treat and discharge surplus water so that minimal water accumulates from year to year, and infrastructure is in place to store and treat all flows up to a 1-in-10-year 24-hour storm event and withstand all flows up to the 1-in-200-year 24-hour storm event without significant damage.

- Maintain a minimum water volume of 1 million cubic metres (M-m^3) in the TSF for operation of reclaim pumps and a maximum water volume of 1.7 M-m^3, consistent with the Quantitative Performance Objectives for the TSF (Golder 2020b).
- Maintain a minimum of 100 m long tailings beaches at the TSF, consistent with the Quantitative Performance Objectives for the TSF (Golder 2020b).

These strategies assume that there will be minimal storage of contact water on site; however, during freshet (April through June) and storm events, the volume of mine water runoff will exceed the discharge and treatment capacity. Therefore, temporary detention of freshet and storm runoff volume will be necessary to equalize flows prior to discharge.

This WMP, to a large extent, builds on the strategies listed above by validating existing water management practices against applicable regulatory decisions and permit requirements that have come into effect since the TAR was submitted. This has been achieved through a review of the following information:

- Approved and assumed mine plans.
- Water management infrastructure works (e.g., pumps, sumps, channels, ditches).
- Current surface and groundwater monitoring practices.
- Water treatment configuration during operations and closure/post-closure.
- The review of the above information has been facilitated by revisions to the calibrated SWWBM and SWWQM, with appropriate sensitivity to a range of applicable water quality parameters. The water balance and water quality data outputs from the calibrated models have been used to address water management planning for mining operations through closure and post-closure.

1.2.3 Water Management Framework

Figure 2 provides a visual representation of the water management framework used in this WMP, and the subsections that follow the figure describe these concepts in more detail.

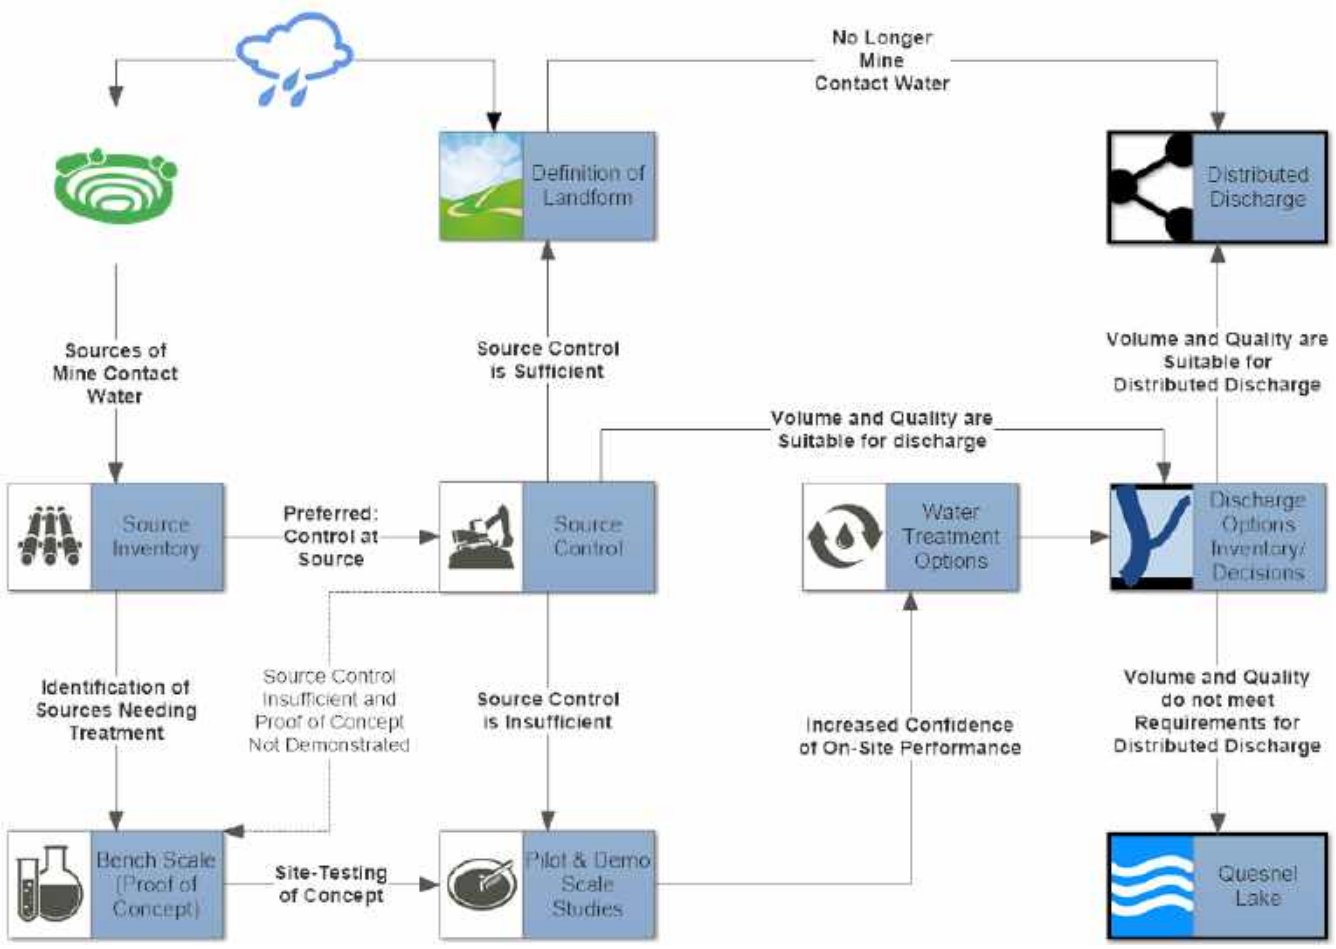

Figure 2: Water Management Plan Framework

Source Inventory

A source inventory has been developed to identify areas of the site that generate contact water. The source inventory includes information on location, modelled or measured flow, modelled or measured water quality, and current on-site collection or discharge locations. This inventory provides a list of sources where water management (i.e., diversion, source control, to other means) or water treatment is required. This has been developed to be a “living database” that will be updated as the Mine layout changes over time, or as the Mine transitions into closure and post-closure.

Source Control

Source control is the preferred approach to managing water quantity and quality. Source control is a preferred option in most waste management hierarchies because it controls risks at their source. Where source control measures are effective in reducing the volumes of mine contact water (i.e., runoff from a reclaimed landform without containing mining materials), then it would be suitable and prioritized for distributed discharge, subject to receiving waterbody or watercourse’s volume and flow capacity. Typically, this latter form of source control would be implemented as part of closure.

Water Treatment

Contact water would require management in accordance with the MPMC's effluent permit and may include treatment using active, passive, or semi-passive technologies. It may also include direct bypass where the water, treated through settling in situ and not through an active treatment system, is found to meet the permit limits.

This is a multi-phase process starting with identifying sources, modelling quantity and quality of water needing treatment, followed by bench-scale, pilot-scale, and demonstration-scale studies to systematically test and demonstrate the viability and feasibility of developed technologies for the Site. The length of time it takes for a specific technology or treatment process to advance from pre-conceptual to the execution stage is typically on the order of years.

Since the TAR was issued, one focus of the water treatment work has been to identify opportunities to treat waters at source through passive or semi-passive treatment options. Passive treatment is being pursued with the desire of it providing a low energy, low-reagent use and therefore low greenhouse gas footprint post-closure treatment method. To that end, several technologies and treatment options have been subject to conceptual level studies and testing trials and updates to this technology development process has been provided in this WMP.

Discharge Inventory

Discharge options for contact water would be decided based on the Best Achievable Technology (BAT; BC ENV 2015) selected, the modelled quantity and quality of treated water expected to be discharged, and the assimilative capacity of the receiving waterbodies. A decision gate would use this information to determine the best choice of discharge options, whether that is a local watercourse or waterbody.

Non-contact water and treated water suitable for distributed discharge would be discharged to site watercourses, subject to volume and quality decision gates and applicable regulatory requirements. The only current permitted treated water discharge under PE-11678 is discharge to Quesnel Lake via submerged diffuser and must show that the concentrations of the water quality parameters in Table 1 of the permit are met at the "Edge of Quesnel Lake Initial Dilution Zone (IDZ)" in Quesnel Lake. This WMP only provides update regarding the Quesnel Lake receiving environment (the assumed discharge location for the remainder of operations); details regarding alternative discharge locations distributed around the Site are discussed in Golder 2020e.

1.3 Regulatory Framework

1.3.1 Overview

This section provides an overview of the applicable regulatory documents and bodies that are relevant to the development of this WMP. The applicable legislation for effluent discharges to aquatic receiving environments in BC includes the provincial EMA, which contains a general prohibition against causing pollution, and the federal *Fisheries Act* (RSC 1985, c. F-14), which contains a general prohibition against the deposit of a deleterious substance into waters frequented by fish (Section 36). What constitutes a deleterious substance is a matter of expert opinion; however, for the purposes of discharges involving a metal mine, which applies to the current effluent discharge permit amendment application, what constitutes a deleterious substance is specifically defined in the Metal and Diamond Mining Effluent Regulations (MDMER; SOR/2002-222).

While this WMP has been prepared in support of MPMC's water management planning and a provincial permit requirement, federal requirements have also been addressed in the evaluations carried out, either through this plan, the 2020 WMP (Golder 2020e), or through the TAR submitted in 2016 (Golder 2016g), because MPMC must comply with both provincial and federal laws.

1.3.2 Environmental Management Act

The EMA is BC's principal pollution control statute with regulations made pursuant to that Act for more specific regulatory purposes. The EMA prohibits causing pollution, and (per subordinate regulation) requires specified dischargers to obtain an effluent discharge permit. Because federal legislation has no effluent permitting system, federal agencies (i.e., Environment and Climate Change Canada and Fisheries and Oceans Canada) utilize the provincial permit process to communicate their specific requirements to the proponent. However, the proponent remains responsible for compliance with the general prohibitions of those federal laws (described further below), notwithstanding the presence of a provincial permit. The amended permit for the effluent discharge falls under the Waste Discharge Regulation (B.C. Reg. 154/2019), pursuant to the EMA.

In the EMA, pollution is defined as "the presence in the environment of substances or contaminants that substantially alter or impair the usefulness of the environment." The common expectations under the EMA are two-fold:

- Acutely lethal conditions should not exist at the point of discharge or within the initial dilution zone (IDZ) of the effluent.
- Chronic sublethal effects should not occur outside of the IDZ. A lack of chronic sublethal effects is reliably predicted when the parameter of concern has a concentration lower than applicable BC ambient water quality guidelines (WQGs) (BC ENV 2016). However, while WQGs are a convenient "first pass" benchmark of pollution, they do not reliably predict the actual presence of pollution. BC ENV offers alternatives to the BC WQGs to provide evidence that pollution has not occurred.

The IDZ is the three-dimensional zone around the point of discharge where mixing of the effluent and the receiving water occurs. For a large waterbody, the IDZ is commonly defined as a cylindrical body of water around the outfall with a lateral radius the lesser of 100 m from the outfall or 25% of the width of the body of water and extending upwards to the surface of the water column. However, the process for delineation of an IDZ is described in BC ENV 2019a and any new discharges would be expected to follow this technical guidance.

1.3.3 Fisheries Act

With respect to the *Fisheries Act*, a deleterious substance is a substance that, if added to water, would degrade, or alter or form part of a process of degradation of that water such that it would likely be rendered deleterious to fish or fish habitat, or the use by humans or fish that frequent that water. The specific properties defining a substance as being deleterious under the parent Act are up to interpretation by experts, except where sector-specific regulations have been developed, such as the MDMER. If a water of a certain quality is determined to be suitable for discharge in accordance with EMA, it is expected (but is also confirmed) that the water is also not a deleterious substance.

Fisheries and Oceans Canada also regulates fish habitat under the *Fisheries Act*. This includes, among other things, provisions for minimum flows; a prohibition against harmful alteration, disruption, or destruction (e.g., such as could occur if a watercourse were overloaded and scoured with too much flow); or the placement of physical structures into fish habitat (e.g., outfall).

1.3.4 Metal and Diamond Mining Effluent Regulations

The MDMER is a sector-specific regulation written under the authority of the *Fisheries Act*. The MDMER includes specific definition of what constitutes a deleterious substance in effluent from a metal mine. The MDMER also contains a requirement to undertake an environmental effects monitoring program. Undertaking an environmental effects monitoring program provides assurances that the technology-based effluent limits specified in the MDMER are sufficient to protect the aquatic receiving environment.

1.3.5 Water Sustainability Act

In BC, legislation of matters relating to the use of surface water and groundwater, and protection of water resources, are governed by the *Water Sustainability Act* (WSA; SBC 2014). The WSA was brought into force on February 29, 2016, replacing the *Water Act*. Five new regulations were introduced under the WSA, consisting of the Water Sustainability Regulation (BC Reg. 32/2023), the Water Sustainability Fees, Rentals and Charges Tariff Regulation (BC Reg. 37/2019), the new Groundwater Protection Regulation (BC Reg. 253/2022), the new Dam Safety Regulation (BC Reg. 32/2023), and the Water Districts Regulation (BC Reg. 38/2016). The Water Sustainability Regulation includes requirements for the licensing, diversion, and use of groundwater and surface water to protect water resources and ecosystems, while the Groundwater Protection Regulation specifically addresses protection of the groundwater resource and identifies requirements for the construction of wells.

MPMC currently holds three surface water licences, specifically:

- 5002458, which authorizes the non-power storage of Hazeltine Creek (500,000 m^3/yr).
- C101763, which authorizes Polley Lake water to be stored (1,000,352 m^3/yr) and used for processing ore (455 m^3/d).
- C111741, which allows Polley Lake water to be used for dust suppression (818 m^3/d) and work camps (36 m^3/d).

With the introduction of the WSA, these licences continue to be valid under the WSA rather than the former *Water Act*.

Section 11 of the WSA requires an authorization for Changes In and About a Stream, which includes a broader definition of “stream” in law than what is commonly understood to be a stream in ordinary use. There are certain activities that are authorized by regulation; however, the need for a written authorization will depend on the specific effluent discharge infrastructure being constructed.

1.4 Table of Concordance

A Table of Concordance serves as the single list of joint information requirements for a *Mines Act* (MA) permit application, issued by the Ministry of Energy, Mines and Low Carbon Innovation, and an effluent discharge permit application under the *Environmental Management Act*, by the Ministry of Environment and Climate Change Strategy. These joint information requirements, and how this WMP addresses those requirements, are listed in Table 1. The WMP and supporting documents are all prepared and/or reviewed by the Qualified Professionals presented in Table 2.

Table 1: Table of Concordance

Joint Application Information Requirements	Requirement Description	Water Management Plan Section
2. Baseline Information		
2.2. Meteorology and Climate	A summary of relevant meteorological and climate information will be provided, based on existing monitoring data. The baseline information will include parameters relevant for the design and construction of the Project, such as precipitation, snowpack, temperature, and evapotranspiration.	Section 3.2.1
2.6. Water Quantity		
2.6.1. Surface Water Quantity	The hydrology baseline information for the Project will be provided, with references to existing studies, where applicable, and previously published hydrological datasets. The baseline information will be summarized from data collection programs already in place.	Section 3.2.2
2.6.2. Groundwater Quantity	The groundwater baseline information for the Project will be provided, with references to existing studies, where applicable, and previously published groundwater datasets. The baseline information will be summarized from data collection programs already in place.	Sections 3.2.3 & 3.2.4
5. Modelling, Mitigation, and Discharges		
5.1. Summary	Qualitative hydrology and water quality assessments of the potential effects of the Project will be provided.	Sections 4.3, 4.4, & 4.6
5.3. Site-wide Water Balance Model	Quantitative model will be updated to reflect new LOM schedule. Updates include revisions to catchment boundaries, storage, and runoff impacted by mine development. Results will include facility level water volume and level projections and estimated discharge quantities from the site. Details on the operational efficiency and reliability of the WTP and a model sensitivity scenario that reflects recent operational data will be provided.	Section 4.3 (SWWBM) & Section 4.6 (WTP-details)
5.4. Surface Water Quality Model	Details on the operational efficiency and reliability of the WTP and a model sensitivity scenario that reflects recent operational data will be provided.	Section 4.4 (SWWQM) & Section 4.6 (WTP-details)

Table 1: Table of Concordance

Joint Application Information Requirements	Requirement Description	Water Management Plan Section
5.6 Mitigation Methods		
5.6.4. Water Treatment	Information/discussions on the anticipated changes to water quantity and quality as informed by the Surface Water Balance and Surface Water Quality Models, and how these predictions relate to the water treatment effectiveness and capacities will be provided. An update on water treatment technology and research development will be provided in the updated Water Management Plan submitted with the Application. This will include an implementation plan and schedule for water treatment technology development.	Sections 4.3 (SWWBM), 4.4 (SWWQM), 4.6.1 (Treatment Design Bases), & 4.6.2 (Treatment Technology Update)
5.6.4.1. Description	A description of the existing water treatment system will be provided in the Application.	Section 4.1 & Section 4.6.1
5.6.4.2. Location	The location of the existing water treatment system will be provided in the Application.	Figure 5 – Mine Site Layout
5.6.4.4. Treatment Effectiveness	Details on the operational efficiency and reliability of the WTP and a model sensitivity scenario that reflects recent operational data will be provided.	Section 4.6.1
5.6.4.6. Influent and Effluent Quality	Predictions for changes to WTP influent volume and quality resulting from the Project will be provided. Additionally, this section will provide details on proposed mitigation, including WTP capacity, performance, and adequacy in mitigating the discharge.	Section 4.6.1 & Section 4.6.2

LOM = Life of Mine; WTP = Water Treatment Plant.

2.0 PROJECT DESCRIPTION AND MINE PLAN

2.1 Approved Mine Plan

On November 6, 2015, MPMC submitted a *Mines Act* Permit M-200 amendment application (MPMC 2015) to mine the Phase 4 Cariboo-Springer Pit. On June 23, 2016, this application was approved by MEMPR, and an amendment to *Mines Act* Permit M-200 was received by MPMC, approving the return to full operations and use of the TSF. The required approval from BC ENV to resume deposition of tailings in the TSF, as required under EMA Permit 11678, was also received on June 23, 2016 (MEMPR 2016).

The approved mine plan included mining and processing (or stockpile) 27.8 Mt of ore from the Phase 4 Cariboo-Springer Pit over a four-year mine life. The approved mine plan also included transferring 5 Mt of tailings from the Springer Pit to the TSF. The TSF was planned to be constructed to a crest elevation of 970 metres (m; Tailings Coordinate Grid and Elevation Datum) to accommodate tailings transfer from the Springer Pit and new tailings.

2.2 Mine Plan Beyond 2023

Beyond 2023 the majority of mining will occur in the Springer and Cariboo Pit which is also the focus of the Springer Expansion LOM plan. The current plan has the life of mine concluding in 2031 then rehandled Potentially Acid Generating (PAG) material is placed back into the pit until end of 2033. The open pit mining operation mines on average 6.1 million tonnes of ore and 7.7 million tonnes of waste per annum (peaking at 35.5 million tonnes in 2025). The Springer Expansion which includes Phase 5, Phase 6, C2, WX will supplement ore production into the year 2031. A Life of Mine planned total material moved is presented in the Table 3 below and shown in Figure 3.

2.2.1 Surface Disturbances

The expansion of Springer Pit will require little stripping or preparation as the area has been previously disturbed mining the Bell, C2 and Cariboo pits. An inventory of areas disturbed to date, and projection of the land to be disturbed up to the projected end of mine life can be found in the Joint Application for the Springer Expansion application.

2.2.2 Pit Dewatering

The Springer Pit is currently mined to Phase 4 at a depth of 928m from surface. Dewatering from the Springer Pit will require establishing temporary sumps in the mine working usually at the lowest working bench. Electric or diesel pumps will convey water to a large sump located in the Cariboo pit. The Cariboo Pit will be pumped to the West collection ditch and then to the Perimeter Embankment Till Borrow Pond.

2.2.3 Assumptions

For the purposes of this WMP, WSP has assumed that the mine will be in operation for an additional mine life of approximately eight years (i.e., from May 2, 2023, to March 31, 2031). Ore will be processed at an average milling rate of 20,000 tonnes per day (tpd). Tailings from processing the ore will be pumped to the Tailing Storage Facility. Mining of the remainder of Phase 4 Cariboo-Springer Pit will require tailings (approximately 2.75 Mt) currently stored in the Springer Pit to be removed.

The TSF crest elevation is currently 970 m and additional TSF raises will continue beyond 2023 with an interim raise to 974 m planned to start in 2023 and then additional raises to the ultimate crest elevation of 987 m. The available tailings volume capacity for the 987 m crest elevation design is 62.8 Mt (based on a feasibility level design of the TSF to a dam crest elevation of 987 m) of which approximately 5.3 Mt has been used up since the resumption of operations in July 2022.

It has also been assumed that the waste rock generated during assumed future operations will be placed within the same footprint of the existing waste rock dumps and that the footprint of the pits will not significantly increase from the current configuration.

It should be recognized that the mine life duration, the production rate, the design of the mine facilities (e.g., TSF) have been assumed for the purposes of advancing this revised WMP and this will be confirmed or adjusted as part of the detailed mine plan being developed by MPMC. Details of the proposed amendments to the existing mine plan are anticipated to be presented in a *Mines Act* Permit M-200 amendment application.

2.3 Project Description

2.3.1 Project Development Phases

This section provides a description of the forecasted future mining phases associated with the Springer Expansion LOM Plan:

- **Future operational phase:** The Mine has resumed operation since June 2022 under the current EMA Permit 11678. The future operational phase is assumed for the period from May 2, 2023, through March 31, 2031, in line with the Springer Expansion LOM Plan. Future operations are anticipated to include the following:
  - Full mining and milling activities will resume, including deepening of the Cariboo and Springer pits (Phases 5, 6, C2, WX).
  - Tailings will be deposited into the TSF until March 2031 (subject to approvals for dam raises in the interim to 974 m and ultimately to 987 m).
- **Closure phase:** will begin when mining is finished and will include closure and reclamation activities as identified in the Reclamation and Closure Plan (RCP; MPMC 2022a) over the period of April 1, 2031, through March 31, 2041.
- **Post-closure phase:** will begin when the closure period is finished and will continue indefinitely. For the purposes of modelling and this WMP, post-closure has been assumed over the period of April 1, 2041, through March 31, 2131 (100 years including the closure phase). Pit lakes will develop in the combined Springer-Cariboo Pit and Wight Pit.

It should again be noted that these mine phase dates are assumed for the general purpose of modelling and that this mine life may change as a result of metal prices, new exploration, care and maintenance periods, revisions to the mine plan, and other factors that are common to mining operations.

2.3.2 Future Operational Phase

Under the future operational phase, tailings from milling operations will be discharged to the TSF from May 2, 2023, through 2031.

Outside of the TSF, mine contact water will either flow or be pumped to the SERDS (via West Ditch) and Long ditches, which flow to the Central Collection System (CCS). Water from the CCS reports by gravity to the PETBP, where it will be treated using the Veolia Actiflo system and discharged through the Quesnel Lake pipeline. When the inflows to the CCS exceed the discharge rate (typically during the freshet period), excess contact water will be pumped to the TSF for temporary detention.

Mine water inflows into the TSF will consist of:

- Water pumped with the tailings slurry.
- Precipitation and runoff into the TSF.
- Excess water pumped from the water management structures for temporary storage in the TSF during freshet and storm events.

Stored water in the TSF is reclaimed to meet process requirements. A minimum water volume of 1 M-m^3 is required to accommodate operation of barge pumps during operations. Makeup water would typically be required during dry years and on occasion during the winter. During these discrete periods, makeup water will be sourced from water collection sumps located in pits or other contact water sites.

2.3.3 Closure Phase and Post-closure

The SWWBM includes projection of water management into the closure and post-closure phases based on the Reclamation and Closure configuration update (MPMC 2022a), with adjusted closure dates to match the Springer Expansion LOM plan. The following objectives of the closure and post-closure phases have been identified:

- Long-term preservation of water quality within and downstream of decommissioned operations.
- Long-term stability of the TSF.
- Removal of all access roads, ponds, ditches, pipelines, structures, and equipment not required following mine closure.
- Long-term stabilization of all exposed materials that are susceptible to erosion.
- Establishment of a self-sustaining vegetative cover consistent with existing forestry, grazing, and wildlife needs.
- Natural integration of disturbed lands into the surrounding landscape and restoration of the natural appearance of the area.

As the closure phase ends and the post-closure phase begins, it is assumed that some catchments will produce non-contact water as areas are successfully remediated, and some sump pumping systems are assumed to be decommissioned to allow overflow from sumps and or pits directly into the environment rather than being pumped into the contact-water system for treatment. More details regarding the closure and post-closure assumptions regarding operating or decommissioned water management components within the mine facilities may be found in the Water Balance Model Report (Appendix A, WSP 2023a).

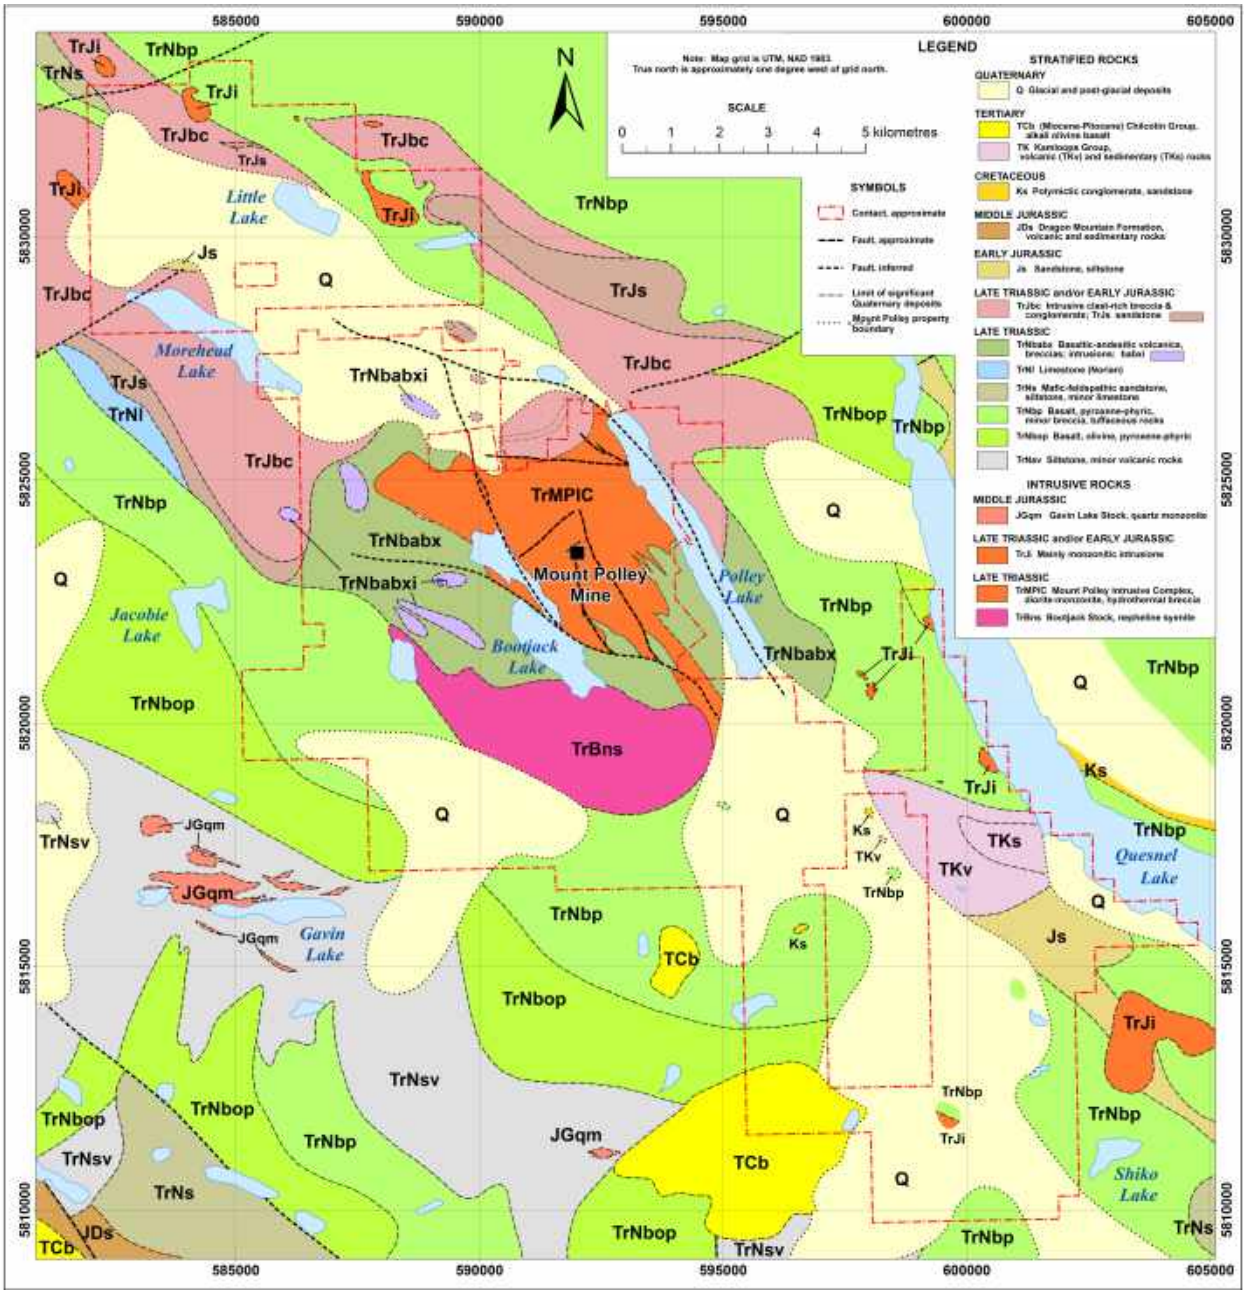
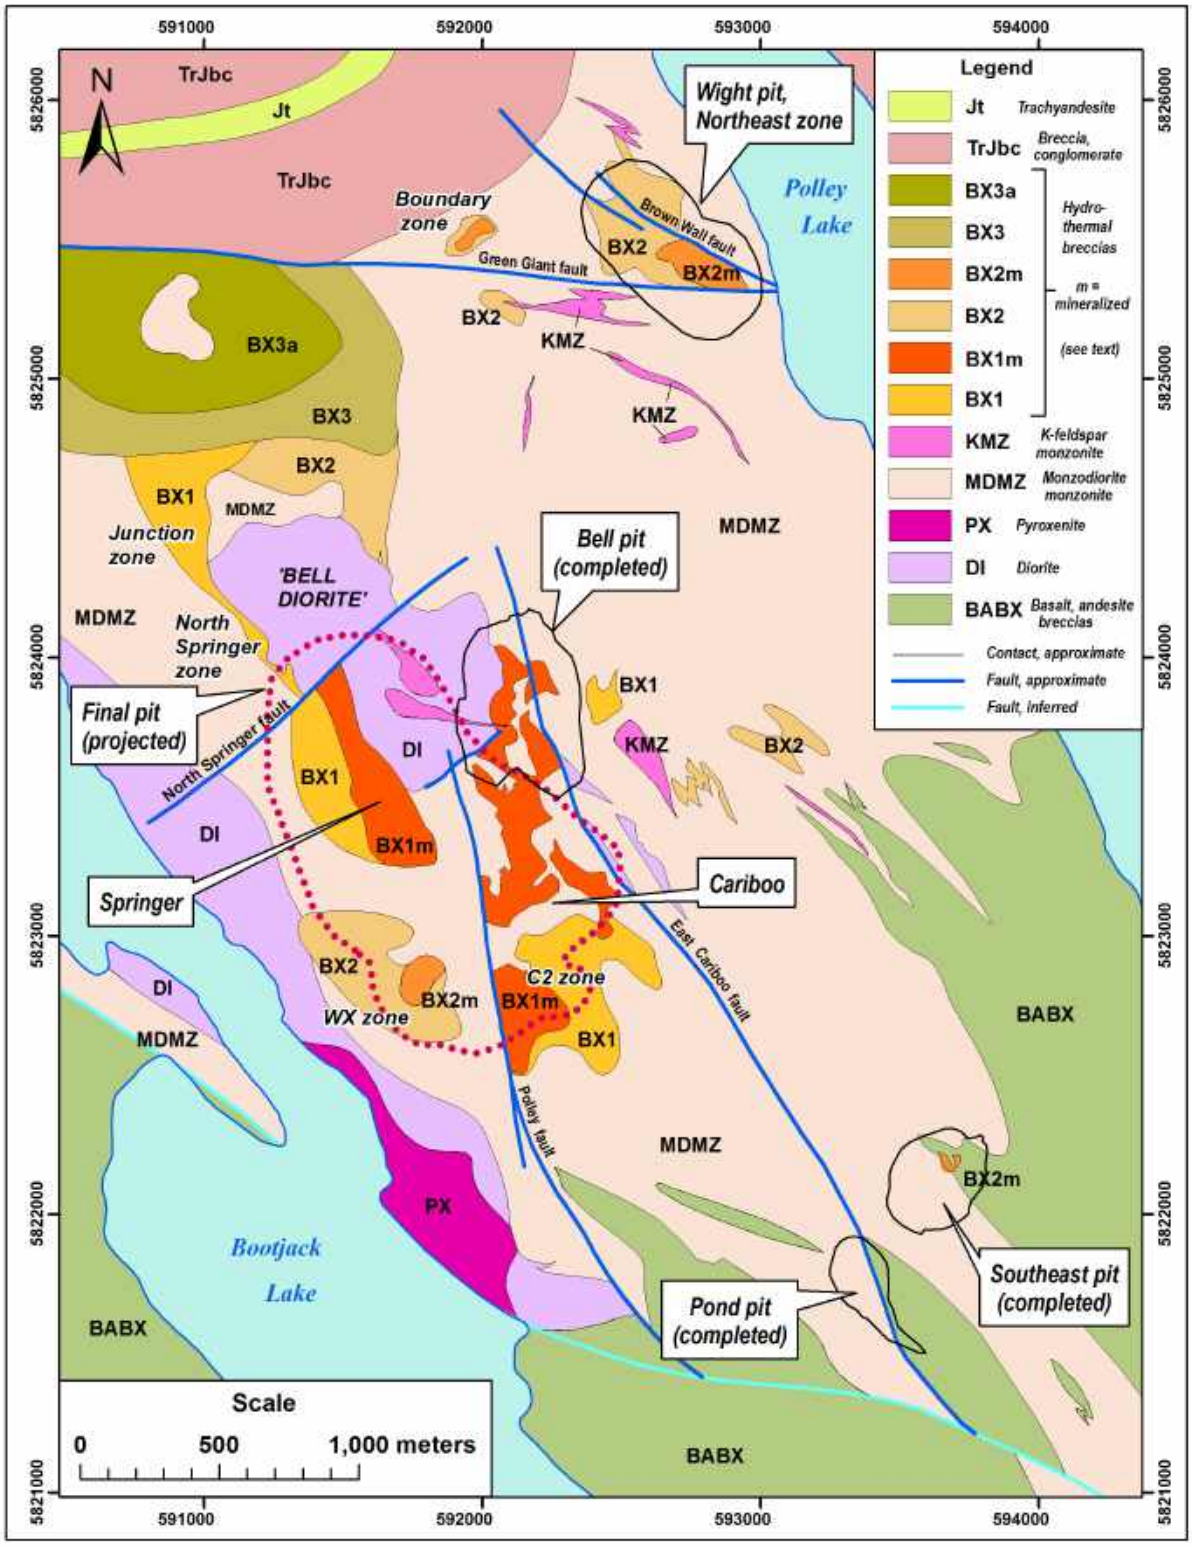
3.0 BASELINE INFORMATION



3.1 Geology

An understanding of the regional and local geology and the geochemical characteristics of the different mine materials (e.g., waste rock, ore) aids in developing an understanding of how these materials will weather, and to identify the processes that will control the release of constituents under ambient conditions. The following subsections (adapted from the TAR) provide a summary of the mine geology and geochemical characteristics that were subsequently used to derive the geochemical source terms (refer to Appendix C of the TAR, Golder 2016g; SRK 2015) for inclusion into the site-wide water quality model (refer to Appendix D of the TAR, Golder 2016g). The subsections of Section 3.1 were written by SRK Consulting (Canada) Inc. (SRK).

3.1.1 Regional Geology



The mine is in Quesnellia, an accreted terrane in the Intermontane Belt of the Canadian Cordillera. Quesnellia is characterized by Triassic to Jurassic volcanic, sedimentary, and mafic to intermediate intrusive rocks formed in a west-facing arc that developed west of the continental margin of ancestral North America. The mine is within the Mount Polley Intrusive Complex (MPIC), situated in the Central Quesnel Belt, a region of Quesnellia roughly between latitudes 51.5° and 53.5°N (Figure 6 and Figure 7). In this area, the arc and a marginal basin immediately to its east were obducted eastwards onto the then continental margin in the late Early Jurassic. Continued crustal shortening in the Middle Jurassic resulted in regional metamorphism and southwest-verging back-folding of the now coupled arc-marginal basin and continental margin assemblages. The mine lies in the core of a broad regional, northwest-trending upright syncline at the western limit of this Middle Jurassic folding. Regional metamorphic grade at the mine is no more than zeolite facies.

Stratified Triassic rocks surrounding the site are assigned to the Nicola Group, the type-area of which is in southern Quesnellia, where the Nicola hosts other porphyry copper deposits such as the Highland Valley, Copper Mountain, and New Afton mines. The arc stratigraphy in the Mount Polley district extends from the Middle and Late Triassic Nicola Group into the Early Jurassic. From the base, the Nicola Group consists of Middle to early Late Triassic sedimentary and minor volcanic rocks, overlain by a thick Late Triassic succession of submarine, trachybasaltic volcanics and related tuffaceous sediments and volcaniclastic breccias. The youngest assemblage, which extended into the Early Jurassic, consists of volcanic, plutonic, and sedimentary rocks representing a more mature stage of arc activity, and more differentiated magmatism, when the MPIC was formed. The youngest arc rocks are polymictic breccia and conglomerate that unconformably overlie the MPIC and are products of late arc uplift and erosion. In the southern part of the Mount Polley property, Nicola Group country rocks are covered by post-accretion units, including outliers of unnamed Cretaceous sandstone and conglomerate, early Tertiary andesitic volcanic and sedimentary rocks of the Kamloops Group, and Miocene-Pliocene basaltic volcanics of the Chilcotin Group.

Source: Rees 2013.

Figure 6: Regional Geology of the Mount Polley Property

Source: Rees 2013.

Figure 7: Simplified Geology of the Mount Polley Intrusive Complex

3.1.2 Deposit Geology

Geological details of the Mount Polley deposit are found in Rees 2013 and the findings are summarized below.

The MPIC hosts the Mount Polley copper-gold porphyry deposit (Figure 6 and Figure 7). It is a Late Triassic magmatic centre approximately 6 km by 4 km, elongated in a north-northwest direction. It consists of alkalic, marginally silica-undersaturated intrusions and magmatic-hydrothermal breccias. The age of the deposit is approximately 205 million years based on uranium-lead isotopic dating; there is close agreement between age determinations from MPIC intrusions and minerals associated with sulphide mineralization. Mineralization occurs in almost all constituent rock types of the MPIC, and thus occurred late in its formation. Nearly all economic mineralization is in breccias, or in mineralized stockwork veins in adjacent wall rock intrusion. Country rocks of the Nicola Group closest to the MPIC are mafic to intermediate volcanic and subvolcanic coherent rocks, and related breccias, and may form components of mineralized hydrothermal breccias in the periphery of the MPIC.

3.1.3 Metal Leaching/Acid Rock Drainage Geochemistry

Details of the characterization of metal leaching/acid rock drainage potential at the mine are provided in Appendix C of the TAR (Golder 2016g). Findings are summarized below.

The Mount Polley deposit is classified as an alkalic porphyry copper-gold deposit. With the exception of the distinctive small Pond Zone skarn deposit, it has been mined from several mineralized zones (Springer, Cariboo, Bell, Southeast, Northeast, Boundary) with common geological features including mainly a monzonitic plutonic host rock, association with breccia bodies in the intrusion, dominantly potassic hydrothermal alteration, lack of pronounced pyrite haloes, enrichment in copper and selenium relative to global norms, pervasive calcite, and natural oxide alteration. As a result, geochemical characteristics are consistent between zones, allowing a site-wide approach to geochemical characterization.

Potentially acid generating (PAG) and non-acid generating (NAG) waste rock materials occur locally as pyrite zones, but NAG rock dominates. Acid rock drainage potential has been used to segregate waste rock, with NAG waste rock being placed in several waste rock disposal sites and PAG waste rock either deposited in completed pits that are projected to flood at the closure of the mine (in accordance with the management practice of subaqueous disposal) or placed in the Temporary NW PAG Stockpile for final subaqueous disposal in the Springer Pit.

Tailings are classified as NAG based on operational monitoring and testing of tailings spilled into Hazeltine Creek in August 2014 (Appendix C of SRK 2015).

The metal leaching/acid rock drainage assessment was used to inform the development of geochemical source terms for use in the SWWQM. Major geochemical source terms were identified as waste rock stockpiles and tailings. Other sources included backfilled waste rock, ore processing, pit walls, ore stockpiles, and the sulphur and magnetite stockpiles. Source terms were mainly developed from conceptual geochemical models, then interpretation of rock geochemical characteristics and seepage data, rather than scale-up of laboratory kinetic test data. The reader is referred to Appendix C of SRK 2015 for details on the derivation of geochemical source terms and to Appendix D of the TAR (Golder 2016g) and Section 4.4 for how these source terms are applied in the model.

3.2 Climate and Hydrology

3.2.1 Climate

The Site is located 56 km northwest of Williams Lake, British Columbia (BC) near the eastern edge of the Fraser Plateau physiographic subdivision, approximately 10 km west of its boundary with the Quesnel Highland subdivision, as defined by Holland (1976).

Within the area of the Mine, the plateau has somewhat higher relief, with the Mine rising approximately 300 metres (m) above the surrounding terrain. Topographically, the Site area consists of north–south trending ridges of moderate elevation and relief. Local elevations range from 922 metres above sea level (masl) at Polley Lake to 1,266 masl at the top of Polley Mountain with an average elevation of 1,038 masl. The total surface area of the Site is 17.8 square kilometers (km^2).

In 2022, WSP updated the climate baseline data for the Site to include the most recent climate data. The climate of the mine site was characterized in the Baseline Climate Update Report (Golder 2022a) using historical measurements recorded at local climate stations, supported by data collected from five nearby regional Environment and Climate Change Canada (ECCC) climate stations. The baseline climate update report is summarized below, and more details can be found in Golder 2022a.

MPMC has operated climate stations on site since 1995, although the station data records are not continuous. From 1995 through 2012, MPMC maintained one climate station at the Mill Site that measured and recorded rainfall (1997 to 2012), temperature (1995 to 2012) and wind velocity and direction (1997 to 2003). In 2012, this station was replaced with two stations: one near the mill site (WS1) and one adjacent to the TSF (WS2). These new stations measure and record wind speed, relative humidity, solar radiation, temperature, and rainfall.

Five ECCC climate stations: Likely, Spokin Lake, Williams Lake, Barkerville, and Quesnel, were selected to support and extend the long-term climate dataset for the Site due to their proximity to the Site, length of record, elevation range, and concurrent period of record with the local climate stations at the Site. In addition, the ECCC Prince George climate station was added to include an additional station with solar radiation data. Historical records were retrieved from ECCC's Historical Climate Data web server (ECCC 2022a). More recent records were compiled through e-mail correspondence with ECCC staff (ECCC 2022b).

The details of these stations are shown in Table 6. The locations of the mine weather stations are shown in Figure 8.

Table 6: Local and Regional Climate Stations for the Mount Polley Mine

Station Name (ID)	Northing (m N)[(a)]	Easting (m E)[(a)]	Elevation (masl)	Approximate Distance to Site (km)	Data Type	Period of Record[(b)]

Air Temperature

Air temperature statistics for the Site were developed using historical data from the nearby ECCC climate station in Likely approximately 9 km northeast of the Site. The historical Likely data set was adjusted to the average elevation of the Mount Polley mine by applying the regional monthly lapse rate (Golder 2022a). Data gaps were infilled using data from the four regional ECCC climate stations in a prioritized sequence and applying the monthly temperature lapse rate to adjust for elevation.

Monthly and annual air temperature statistics for the Site (1974-2021) are presented in Table 8. The estimated mean annual temperature varies between 1.7°C and 6.3°C, with a long-term mean of 3.9°C. Mean monthly temperatures vary between -6.7°C in January and 15.1°C in July. The historical daily maximum and minimum air temperature from the derived long-term data set was 38.1°C in June 2021 (measured at the Site) and -39.8°C in December 1996, respectively.

Table 8: Derived Air Temperature (°C) Statistics for Mount Polley Mine, 1974 to 2021

Month	Temperature (°C)							
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile	Daily Maximum	Daily Minimum
January	-16.0	-6.7	-0.3	-8.7	-6.3	-4.0	11.2	-39.4
February	-13.0	-4.8	0.7	-7.7	-4.3	-2.1	13.6	-35.4
March	-6.7	-1.0	3.2	-2.2	-0.8	0.5	18.4	-32.7
April	-0.7	3.7	12.0	2.8	3.7	4.3	27.5	-16.7
May	5.2	8.5	13.1	7.5	8.3	9.6	33.1	-7.9

Annual	**1.7**	**3.9**	**6.3**	**3.2**	**3.9**	**4.5**	**38.1**	**-39.8**

Precipitation

The MPMC precipitation dataset was extended and infilled using the available data record from the five regional stations as described below to derive a daily and 24-hour long-term synthetic precipitation dataset for the Site. The Likely ECCC Station data were used to extend the precipitation record for the Site given the station's length of record and proximity to the Site.

Precipitation data gap infilling was completed following a priority sequence determined by analyzing measured daily rainfall from April to November for all climate stations; it was assumed that precipitation occurring between December and March occurred as snowfall. The regional climate station priority sequence considered the best-fit measured concurrent daily rainfall correlation (Rainfall Correlation), rainfall ranking correlation (Rainfall Rank), and percentage of time rain was recorded on the same day (Concurrent Daily Rain) between the raw data collected at the MPMC climate stations and each ECCC climate station (Golder 2022a).

A precipitation-elevation orographic factor was applied to adjust the raw precipitation data from the ECCC climate stations used to infill gaps. The adjustment was based on the April-to-November rainfall ranking factor of the raw ECCC climate station and Site rainfall records.

The Site experiences high summer precipitation due to summer storms, with the lowest monthly precipitation occurring in February. Precipitation typically occurs as snowfall starting in November and accumulates until March. Average annual precipitation at the Site is estimated to be 612 mm with a standard deviation of 118 mm. Frequency analyses of the derived long-term precipitation time series for the Site were undertaken to generate the variability in monthly and annual precipitation of the Site. Estimated annual wet and dry precipitation depths for a range of return periods are shown in Table 9.

Table 9: Long-Term Precipitation at the Mount Polley Mine Site

Month[a]	Precipitation (mm)				
	Average	1:200 Year Wet	1:25 Year Wet	1:25 Year Dry	1:200 Year Dry
January	49.4	74.3	66.5	33.2	28.2
February	35.8	54.0	48.3	24.1	20.5
March	29.7	44.7	40.0	20.0	16.9
April	44.7	67.3	60.2	30.1	25.5
May	49.9	75.2	67.2	33.6	28.5
June	70.8	107	95.4	47.7	40.4
July	63.6	95.8	85.7	42.9	36.3
August	50.6	76.2	68.1	34.1	28.8
September	52.3	78.8	70.5	35.2	29.9
October	58.1	87.5	78.2	39.1	33.1
November	49.8	75.0	67.1	33.5	28.4
December	57.6	86.8	77.7	38.8	32.9
Annual Total[b]	**612**	**922**	**825**	**412**	**349**

(a) Wet and Dry Monthly values assumed to follow the same monthly distribution as the Average.

(b) Annual total precipitation depths were rounded to the nearest mm for presentation purposes; therefore, it may appear the sum of the monthly values do not equal the annual total.

Relative Humidity

Relative humidity data are available for the Site from 2019 to 2021 and for ECCC climate stations Quesnel (1953 to 2021) and Williams Lake (1961 to 2021). The MPMC WS1 relative humidity record is more complete than WS2's record; therefore, WS1 data were used for the analysis and infilled with WS2 data where necessary and if available. However, relative humidity data for the Site are insufficient for characterizing long-term climatic conditions of the Site due to the short period of record. Therefore, data from Quesnel and Williams Lake stations were reviewed and analyzed to define a representative relative humidity estimate for the Site. A long-term relative humidity time series for the Site was developed using ECCC Williams Lake A data infilled with ECCC Quesnel A data with an adjustment factor of 1.13 and 1.04 (Golder 2022a).

Statistics for relative humidity are presented in Table 10. Mean annual relative humidity is 68.1%. Monthly mean values vary between 57.7% in April to 82.2% in December. The 25th and 75th percentiles for monthly relative humidity show little variation from the median indicating the Site experiences relatively constant relative humidity on a monthly basis from year to year.

Table 10: Derived Monthly and Annual Relative Humidity Statistics for the Site (1974-2021)

Month	Relative Humidity (%)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	69.2	81.3	90.1	78.9	81.7	84.0
February	65.5	75.0	84.8	72.0	75.6	77.8
March	55.4	64.9	76.2	61.0	64.0	68.3
April	47.9	57.7	69.4	54.9	57.4	60.5
May	45.6	58.1	70.3	54.1	57.8	61.5
June	44.2	60.4	72.4	54.4	60.2	67.7
July	42.2	59.0	72.9	52.6	58.6	65.9
August	48.4	60.2	81.2	55.0	58.8	63.6
September	47.5	66.4	79.1	61.3	66.1	71.3
October	54.3	72.3	86.7	69.7	72.0	76.1
November	61.4	80.1	87.8	77.6	80.4	83.5
December	70.8	82.2	89.3	78.9	82.6	85.0
Annual	**54.4**	**68.1**	**80.0**	**64.2**	**67.9**	**72.1**

Solar Radiation

Solar radiation data are available for the Site from 2001 to 2003 and 2019 to 2021, and for ECCC climate stations Williams Lake (1961 to 2001) and Prince George (1973 to 1995). Solar radiation data for the Site are insufficient for characterizing climatic conditions of the Site due to the short period of record, and as the data recorded in 2001 is incomplete and not concurrent with either ECCC climate station. Solar radiation statistics for the Site were determined from the ECCC Williams Lake data. Missing values were infilled by adjusting the Prince George records by a factor of 1.04 (Golder 2022a).

Statistics for solar radiation for the Site are presented in Table 11. Mean annual solar radiation is 135 W/m^2, with a minimum of 127 W/m^2 and maximum of 148 W/m^2. Mean monthly solar radiation varies between 20 W/m^2 in December to 257 W/m^2 in July following the same seasonal pattern for monthly air temperature. The 25th and 75th percentiles show greatest variation in solar radiation occurs in the summer months when solar radiation is greatest during the year, and less variation in winter months when solar radiation is lowest.

Table 11: Estimated Solar Radiation Statistics for the Site (1974-2001)

Month	Solar Radiation (W/m^2)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	16	27	40	23	27	32
February	37	60	86	54	61	67
March	85	114	152	108	113	123
April	143	180	215	161	179	201
May	196	230	275	214	227	250

December	12	20	27	18	20	23
Annual	**127**	**135**	**148**	**132**	**135**	**140**

Evaporation

Evaporation monitoring data are available for the Site from 2019 to 2021; however, the data are not continuous, and the length of record is not sufficient for characterizing the evaporation conditions at the Site. Therefore, a mathematical model (Morton 1983) was used to calculate evaporation and evapotranspiration (actual and potential) for the Site based on the long-term synthetic records for air temperature, relative humidity, and solar radiation. Evaporation is defined as free water evaporation, or the amount of evaporation from open/free water surfaces (i.e., the water is returned to the atmosphere from lakes, ponds, and watercourses). Potential evapotranspiration (PET) is the water loss that occurs from a vegetated natural surface if there is no deficiency of water in the soil for use by vegetation (Thornthwaite 1948). Actual evapotranspiration (AET) is the water loss that occurs from a vegetated natural surface considering the availability of water in the soil for use by vegetation. Estimated monthly and annual shallow lake evaporation, PET, and AET values are provided in Table 12, Table 13, and Table 14 respectively.

The mean annual shallow lake evaporation rate is estimated to be 673 mm, varying between 606 mm and 762 mm. Mean monthly evaporation rates vary between 0 mm in December to 138 mm in July. The 25th and 75th percentiles indicate that greatest variation in monthly evaporation occurs in July when evaporation is greatest, and lowest variation occurs in January and December when evaporation is lowest.

Table 12: Estimated Monthly and Annual Shallow Lake Evaporation Statistics for the Site (1974-2001)

Month	Shallow Lake Evaporation (mm)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	0	1	4	0	0	1
February	1	7	12	4	7	10
March	24	32	43	29	32	34
April	52	66	79	59	67	72
May	86	105	140	96	102	115
June	95	122	155	110	121	132
July	110	138	173	123	136	153
August	80	115	137	107	113	130
September	37	61	80	54	60	70
October	18	22	28	20	21	23
November	0	4	8	1	4	6
December	0	0	3	0	0	1
Annual	**606**	**673**	**762**	**648**	**663**	**699**

The mean annual PET rate is estimated to be 863 mm, varying between 744 mm and 1022 mm. Mean monthly PET rates vary between 1 mm in December and January to 171 mm in July. The 25th and 75th percentiles indicate that greatest variation in monthly PET occurs in July when PET is greatest, and lowest variation occurs in January and December when PET is lowest.

Table 13: Estimated Monthly and Annual PET Statistics for the Site (1974-2001)

Month	Potential Evapotranspiration (mm)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	0	1	5	0	0	2
February	1	7	11	4	7	10
March	24	41	59	34	42	45
April	68	92	112	83	93	102
May	103	134	178	120	131	149
June	113	150	195	125	155	174
July	124	171	240	151	166	191
August	84	151	199	135	152	174
September	54	89	117	71	89	108
October	17	24	40	20	23	26
November	0	4	9	1	4	6
December	0	1	4	0	0	1
Annual	**744**	**863**	**1022**	**815**	**856**	**925**

The mean annual AET rate is estimated to be 399 mm, varying between 319 mm and 449 mm. Mean monthly AET rates vary between 1 mm in December and January to 89 mm in July. The 25th and 75th percentiles indicate that greatest variation in monthly AET occurs in July when AET is greatest, and lowest variation occurs in January and December when AET is lowest. On an annual basis, AET at the Site is less than shallow lake evaporation and PET rates because AET is limited by the availability of water, particularly during the summer months when the air temperature is highest.

Table 14: Estimated Monthly and Annual AET Statistics for the Site (1974-2001)

Month	Actual Evapotranspiration (mm)					
	Minimum	Mean	Maximum	25th Percentile	50th Percentile	75th Percentile
January	0	1	5	0	0	2

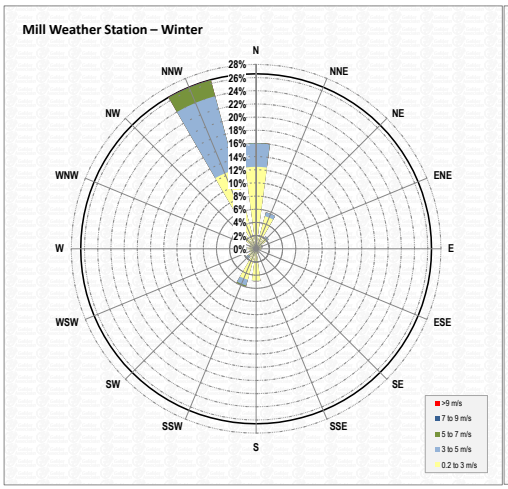
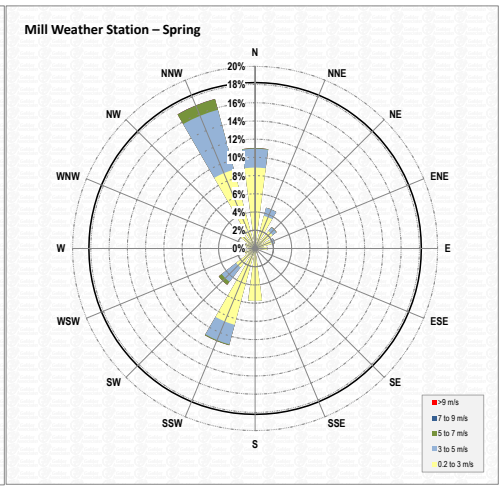
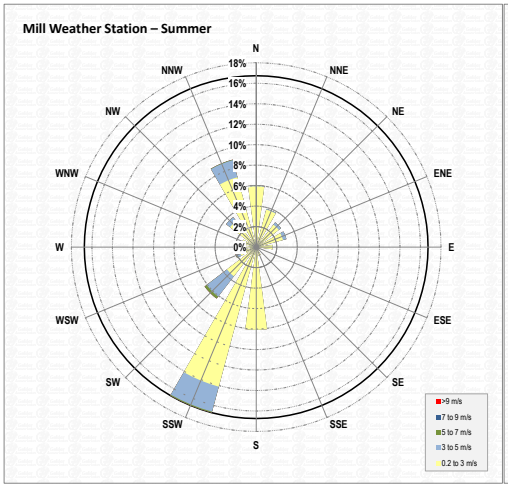
Wind Speed and Direction



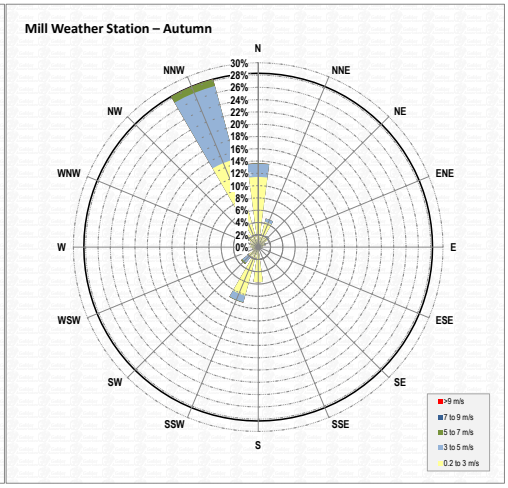
Hourly wind speed and direction data are available for the Site from 1997 to 2003, and daily wind speed data are available from 2019 to 2021; however, the data are not continuous. The hourly wind speed and direction data available from 1997 to 2003 were used to develop wind rose plots. A wind rose depicts the relative frequency of wind from a given direction on a 16-point compass. Each ring on the wind rose represents a frequency of 2% of the data period. The length of the shaded bars on each wind rose petal represents the frequency of wind recorded from a given direction within a defined wind speed range. A wind rose is provided for the period of August 1997 to November 2003, and seasonal wind roses are presented to display seasonal variability in wind patterns, where the seasons have been defined as follows:



- Winter – December to February
- Spring – March to May
- Summer – June to August
- Autumn – September to November



Daily wind data recorded from 2019 to 2021 from WS1 and WS2 were wind speed only, no direction. The period of record for WS2 in 2020 are incomplete and are not included in the analysis. The relative frequency (%) of the magnitude of the daily wind speed data recorded at WS1 for 2019 and 2021 were compared to the relative frequency (%) of wind speed magnitude of the data from 1997 to 2003.



A wind rose plot for the Site depicting the relative frequency of mean hourly wind speed and direction, and the seasonal distribution, between August 29, 1997, and November 27, 2003, is shown in Figure 9.

Spring = March, April, May; Summer = June, July, August; Autumn = September, October, November; Winter = December, January, February.

Figure 9: MPMC Station Monitoring Period and Seasonal Wind Roses – August 29, 1997, to November 27, 2003

Winds measured at the Site typically blew from the north-northwest, north, and south-southwest directions, with minimal winds from the east and the west. The spring, autumn, and winter seasonal wind roses were consistent with the wind rose pattern for the entire monitoring period; however, during the summer months, the majority of winds were from the south-southwest. Similarly, wind speeds in spring, autumn, and winter were generally consistent with the wind rose for the entire monitoring period, while wind speeds in summer were generally lower.

Wind speed measured and seasonal distributions at the Site from 2019 to 2021 were consistent with the relative frequency of wind speed magnitudes and the seasonal distributions recorded between August 29, 1997, and November 27, 2003 (Table 15). It is noted that the data from 2019 and 2021 are daily wind speed rather than hourly wind speed and only the relative frequency (%) of wind speed magnitude was compared.

Table 15: Comparison of Relative Frequency of Wind Speed from Mill Weather Station and Weather Station 1 for the Site

Wind Speed (m/s)	Mill Weather Station August 29, 1997, to November 27, 2003[(a)]	Weather Station 1 January 1, 2019, to December 31, 2021[(b)]
calm	35%	28%
0.2 to 3 m/s	50%	56%
3 to 5 m/s	14%	13%
5 to 7 m/s	2%	3%
7 to 9 m/s	0%	0%
>9 m/s	0%	0%

(a) Recorded as hourly wind speed.

(b) Recorded as daily wind speed.

Snow Cover Properties

Snow cover data at the Site are available monthly from manual measurements from 1997 to 2022, recorded as snow-water-equivalent (SWE). Measurements, although not continuous, are typically recorded at the beginning and end of a month, with the latter being representative of the monthly SWE. Snow cover monthly statistics, reported as SWE, are presented in Table 16. At 50% exceedance, snow begins accumulating in November and achieves its maximum in March, reducing to 0 mm in April. The 5th and 95th percentiles and standard deviation values demonstrate the variability in the amount of SWE at the Site, with March having the greatest variability from year to year.

Table 16: Snow Water Equivalent for the Site (1997-2021)

Month	Number of Measurements	Mean (mm)	Minimum (mm)	Percentile					Maximum (mm)	Standard Deviation (mm)
				5%	25%	50%	75%	95%		
January	22	147	76	88	120	139	164	327	339	56

3.2.2 Site Drainage and Surface Hydrology

The Mine is drained by three main watersheds: the Hazeltine Creek (30.2 km^2) at Quesnel Lake, the Edney Creek (87.4 km^2) at Quesnel Lake, and the Morehead Lake (62.7 km^2) watersheds (Figure 10). The Hazeltine Creek watershed includes Polley Lake and conveys all water from Polley Lake, the east side of the Mine, and the area surrounding the TSF. The Morehead Creek watershed includes the Bootjack Lake catchment area (11.2 km^2). The watershed areas listed here exclude the mine, which covers part of the original watersheds.

Both the Hazeltine Creek and the Morehead Creek watersheds were significantly altered by historical (i.e., pre-Mount Polley Mine) water diversions. Bootjack Creek, a small remnant of which now flows into Polley Lake via a constructed diversion channel, historically conveyed water from Bootjack Lake to Hazeltine Creek. In 1913, flow from Bootjack Lake was reversed by miners (not associated with MPMC) damming the east end of Bootjack Lake and digging a new outlet westward to Morehead Creek. Around the same time, a water control structure was also built at the outlet of Polley Lake (Hazeltine Creek), and Hazeltine Creek water was diverted to Bullion Pit to support hydraulic placer mining. Flow from Polley Lake to Hazeltine Creek was restored with the abandonment of mining at Bullion Pit during World War II. However, the flow from Bootjack Lake to Hazeltine Creek was never restored.

Prior to the breach of the TSF, Edney Creek and Hazeltine Creek converged just prior to discharging into Quesnel Lake. The mouths of the two creeks were separated following the breach and interim remediation works. As of late summer, 2020, Edney Creek and Hazeltine Creek have been reconnected, with in-stream habitat features installed, as part of the conclusion of habitat construction works in the lower Hazeltine Creek and Edney Creek area.

3.2.3 Pit Groundwater Hydrogeology

In 2016, Golder assessed groundwater flow for the following three open pits at the mine: Springer and Cariboo pits, Wight Pit, and Boundary Pit. The analysis for each pit was described in a series of technical memoranda in Appendix B of the TAR (Attachments C, D, E, and F; Golder 2016g). Hydrogeological assessments for the pits were conducted as part of the TAR to provide estimates of seepage into and out of the pits. Similarly, estimates of seepage into and out of the TSF was also assessed using a three-dimensional model (Golder 2016j).

A provision to update this Water Management Plan and provide an updated seepage assessment is included as part of the revision trigger and frequency table under the implementation plan and schedule in Section 5.0. A review of the existing hydrogeological pit model calibration is ongoing to determine whether existing model parameters remain valid. Based on the results of the pit model review and should any notable difference to parameter concentrations be identified, the hydrogeological parameters will be updated. Updated seepage parameters are not expected to alter the macro water balance results for the site or alter the water treatment quantity design basis; however, this will be confirmed once updated parameters are available. Should recalibration be required, an update to the hydrogeological parameters and associated seepage estimates will be completed in 2024.

The summary below is based on the previous (2016) hydrogeological assessments.

Springer and Cariboo Pits

During closure, the Springer Pit and the Cariboo Pit will be allowed to flood. Once the pit lake level is above approximately 1,028 m elevation, the pit lakes in these two pits will merge and form a single pit lake. The spillway elevation for this pit lake will be approximately 1,050 m elevation. PAG materials will be placed in the combined Cariboo-Springer Pit at closure and stored sub-aqueously to mitigate acid generation and metal leaching, in accordance with standard mine waste handling practices (MEND 2015).

A hydrogeological assessment was conducted to predict the quantity of long-term groundwater seepage from both the Springer and Cariboo pits towards Bootjack Lake for the Phase 4 Cariboo-Springer Pit mine plan (Golder 2016g). The analysis considered placement of waste rock in the pit prior to the pit lake formation. As the pit lake level increases to between 1,020 and 1,030 m elevation, seepage in the range of 10 to 100 m^3/d from the Springer Pit Lake into the subsurface was predicted to occur (Table 17). Seepage was found to gradually increase to approximately 400 m^3/d when the pit lake reaches the spillway elevation of 1,050 m. In the Cariboo Pit, seepage towards the Bootjack Lake of approximately 20 m^3/d was predicted to occur only when the pit lake level approaches 1,050 m elevation. At this elevation, the pit lake was predicted to act as a “flow-through” lake with groundwater recharge occurring from the uplands located northeast from both pits and recharge to groundwater occurring towards the southwest.

Table 17: Predicted Groundwater Flows for the Springer and Cariboo Pits

Pit Lake Elevation (masl)	Springer Pit		Cariboo Pit	
	Groundwater Flow (m^3/d)		Groundwater Flow (m^3/d)	
Base Case	**Into the Lake**	**Out of the Lake**	**Into the Lake**	**Out of the Lake**
880 (dewatered pit)	520	0	600[(a)]	0[(a)]
940	510	0	610	0
960	490	0	610	0
980	460	0	590	0

1,020	320	10	460	0
1,030	300	100	420	0
1,040	280	250	380	0
1,050	270	400	320	20
Upper Bound				
1,050	440	880	500	90
Lower Bound				
1,050	190	220	250	0

(a) These values represent conditions when the Cariboo Pit is fully dewatered (i.e., the base of the Cariboo Pit is at approximately 938 m elevation).

Source: Golder 2016g.

masl = metres above sea level.

Wight Pit

Hydrogeological modelling was carried out for the Wight Pit (Golder 2016g). The results from the hydrogeological model indicate that under steady-state conditions (Table 18), groundwater inflow to the Wight Pit is projected to gradually decrease from 2,600 m^3/d at an elevation of 880 m to 600 m^3/d at an elevation of 926 m (Golder 2016g).

Table 18: Predicted Groundwater Flows for the Wight Pit

Pit Lake Elevation (masl)	Groundwater Flow (m^3/d)	
	Into the Lake	**Out of the Lake**
Base Case		
880	2,600	0
900	2,500	0
910	2,100	0
920	800	0
926	600	500
Lower Bound		
926	400	300
Upper Bound		
926	700	800

Source: Golder 2016g.

masl = metres above sea level.

Boundary Pit

At present, hydrogeological data specific to the Boundary Pit are not available. However, MPMC indicated that during mining seepage was not observed along the pit walls. This is considered reasonable due to the relatively shallow depth of this pit and depth to water table measured at monitoring wells that were installed near other mine facilities. It is thus considered likely that the water table was located near or below the floor of the Boundary Pit before mining at this location commenced.

Although seepage to the Boundary Pit from the surrounding rock mass is not expected, seepage out of this pit could occur due to water entering the pit via surface water runoff and direct precipitation. An estimate of these potential seepage rates out of the pit was made to provide input to the pit water balance and to characterize a potential seepage pathway originating from this pit (Golder 2016g).

Seepage rates out of the Boundary Pit have been estimated from a Darcy's Law calculation that considers changes in the dimensions of the seepage area as the pit is being flooded. The estimated seepage rate from the Boundary Pit when the pit lake level is 5 m above its base (1,073 m) is approximately 59 m^3/d, with a potential range between 35 and 177 m^3/d due to uncertainty in bedrock permeability (Table 19). Seepage outflow is estimated to decrease as the height of water column above the pit bottom decreases as shown in Table 19.

Table 19: Estimated Seepage Outflows from the Boundary Pit

Water Level (masl)	Estimated Groundwater Outflow (m^3/d)		
	Lower Bound	Base Case	Upper Bound
1,068	2	3	10
1,069	6	10	29
1,070	12	20	61
1,071	16	26	79
1,072	32	53	159
1,073	35	59	177

masl = metres above sea level.

3.2.4 Seepage from the Tailings Storage Facility

WSP is currently designing a new upstream drainage system to accommodate the increase in the TSF water elevation (WSP 2023b). The new upstream drain system will capture water within the tailings above 970 m and convey it to the seepage collection system, downstream of the TSF embankment. WSP has estimated the water flows through the upstream drains based on the distance between the pond and the embankment (beach width). Estimation of flows have been made for each embankment:

- S1: South Embankment
- S2: Main Embankment
- S4: Corner 1 Embankment
- S5: Perimeter Embankment

Seepage flows from the TSF (S1 to S5) during operations were estimated using a two-dimensional numerical groundwater flow model to quantify anticipated seepage rates through the embankment and foundation. Seepage analyses were conducted for typical sections of the elevation of 987 m configuration of the South Embankment, Main Embankment, Perimeter Embankment, and Corner 1 Embankment under steady-state conditions. The analyses were conducted using GeoStudio 2021, developed by GEOSLOPE International Ltd. Seepage from the TSF has been defined to occur continuously without interruption in the SWWBM. Table 20 presents the estimated seepage flow rates through each embankment with dependency on the beach width.

Table 20: Seepage Flow Rates

Beach (m)	Seepage Flow Rate (L/s)			
	S1	S2	S4	S5
0	79	96	81	89
50	39	50	53	46
100	25	32	38	31
200	14	18	23	18
300	9	12	15	13

Note(s): Includes flows through upstream drains and embankment. All flows estimated for the 987 m raise.

The TSF contains both water and tailings. The term TSF water volume is used to describe the total amount of water within the TSF. The term TSF pond is also used, which describes the area of the TSF, mainly near the water surface elevation, where tailings are generally not placed and a water pond forms at the surface, typically with some water depth. The term TSF supernatant pond is also used and refers to the same pond. During operations, a pump barge is placed at the TSF pond to allow suction TSF water for process purposes and placing the pump intake at the pond allows drawing water without drawing tailings. The location of the TSF pond depends on how tailings are placed within the TSF and the pond can be shifted around the TSF through tailings placement. Nearing closure, the TSF pond will be shifted to a specific location within the TSF.

The progressive location of the TSF pond will depend on operational decisions during the deposition of tailings; thus, the change in beach widths have been assumed consistent for each embankment. Based on estimates of the TSF water volume and satellite imagery of the pond location since restart of operation in 2016, an estimation of embankment beach width has been made for different TSF water volume amounts. The estimates are provided in Table 21, which outline a conservative scenario, in terms of seepage flow quantities.

Table 21: Tailings Beach Width

TSF Water Volume (m^3)	Beach Width (m)			
	S1	S2	S4	S5
0	300	300	300	300
1,500,000	300	300	300	300
2,500,000	200	200	200	200
3,000,000	100	100	100	100
5,500,000	0	0	0	0

The model uses both Table 20 and Table 21 presented above to calculate the beach width and consequently the seepage flow rates through the embankments during operations. For every time step the model calculates the TSF water volume and consequently the beach width, and finally the seepage flow rate.

Starting from four months into closure (August 1, 2031), the TSF water volume reduces to 0.25 M-m^3 within two months due to the construction of the closure TSF spillway. This is estimated to increase the seepage flow rate on the perimeter embankment close to corner 1, as the TSF pond will be pushed to that corner. For modelling purposes, it is considered that the seepage flow rate in Table 22 will be in effect 6 months after the end of the operation phase and throughout the closure and post-closure phases.

Table 22: Tailings Beach Width at Last Year of Operation and Closure

Flow Rate (L/s)			
S1	S2	S4	S5
70	0	0	0

Note: Values start 6 months after end of operation. Maximum capacity of TSF water volume is limited to 250,000 m^3.

3.3 Characterization of Existing Water Quality

The characterization of existing surface water quality in Quesnel Lake has been updated as part of this WMP and is described below. The characterization of other receiving environments (Bootjack Lake, Hazeltine Creek, and Polley Lake) have not been updated in this WMP but have been previously characterized in Golder 2016g and Golder 2020e. Only the Quesnel Lake characterization has been updated as part of this WMP, as it is the sole discharge location permitted in the existing EMA permit, expected to continue through operations. This single discharge location may continue through closure or may share discharge with other distributed locations. Data from March 2015 to September 2023 collected in the West Basin, east of the sill near Cariboo Island, were summarized. These data represent the background water quality of Quesnel Lake, generally flowing into the West Basin.

The following summary statistics were calculated for Quesnel Lake to represent existing conditions:

- Number of samples.
- Number and percentage of samples with values below the method detection limit (MDL).
- Minimum, median, arithmetic mean, 95th percentile, and maximum concentrations.

Minimum, maximum, and median values were calculated using absolute values; that is, when the summary statistic corresponded to a non-detect value in the dataset, the MDL was reported. For values reported as less than the MDL, the MDL was substituted for calculation of the mean and 95th percentile. A mean was not calculated for parameters with greater than 50% non-detect values. A median was only reported where a mean was not calculated. A 95th percentile was not calculated for parameters with less than 10 measurements or with greater than 95% non-detect values.

Existing conditions were defined as arithmetic mean concentrations or median where a mean was not calculated. Data were compared to applicable BC drinking water guidelines and BC 30-day WQGs (BC ENV 2019b) protective of aquatic life; the maximum WQG was substituted where a 30-day WQG did not exist, as indicated in summary tables provided in Sections 3.3.1 through 3.3.4 in BC ENV 2019b. WQGs calculated based on toxicity modifying factors (e.g., hardness, pH, chloride, dissolved organic carbon) were calculated based on corresponding toxicity modifying factor values (i.e., minimum and maximum statistics) described in the summary statistics for each waterbody.

BC WQGs protective of the most sensitive receiving environment use (generally aquatic life) were used for screening water quality.

The average residence time of Quesnel Lake is approximately 10 years but is estimated to be 90 days within the West Basin (Laval et al. 2008). Quesnel Lake is oligotrophic, with low primary productivity and total dissolved solids (TDS). The West Basin has vertical mixing typical of temperate lakes, with thermal stratification for most of the year, interrupted by brief turnover periods in the spring and the fall when vertical density gradients are lowest. The physical limnology of the West Basin is described more fully in Laval et al. 2008 and Tetra Tech EBA Inc. (Tetra Tech 2015).

Levels of total suspended solids (TSS), turbidity, and total metals previously elevated in the West Basin as a result of the TSF foundation failure remained below WQGs from 2015 to 2023 east of Cariboo Island (Golder 2016a,c). All mean constituent concentrations were below applicable BC WQGs in Quesnel Lake baseline water quality measured east of Cariboo Island from 2015 to 2023 (Table 23). Figures comparing existing turbidity, TSS, total phosphorus and dissolved copper concentrations to corresponding water quality guidelines are presented in Figures 11 to 14, respectively.

Table 23: Summary of Water Quality Statistics for Quesnel Lake: Existing Conditions, East of Cariboo Island (2015 to 2023, from QUL-40A and QUL-120 Sampling Stations)

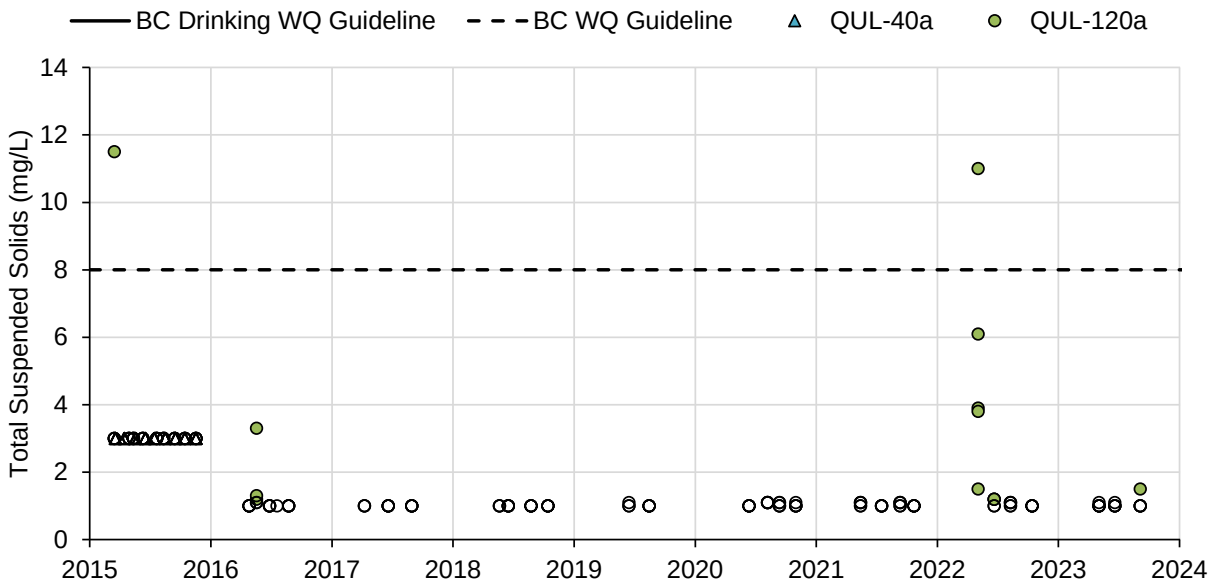
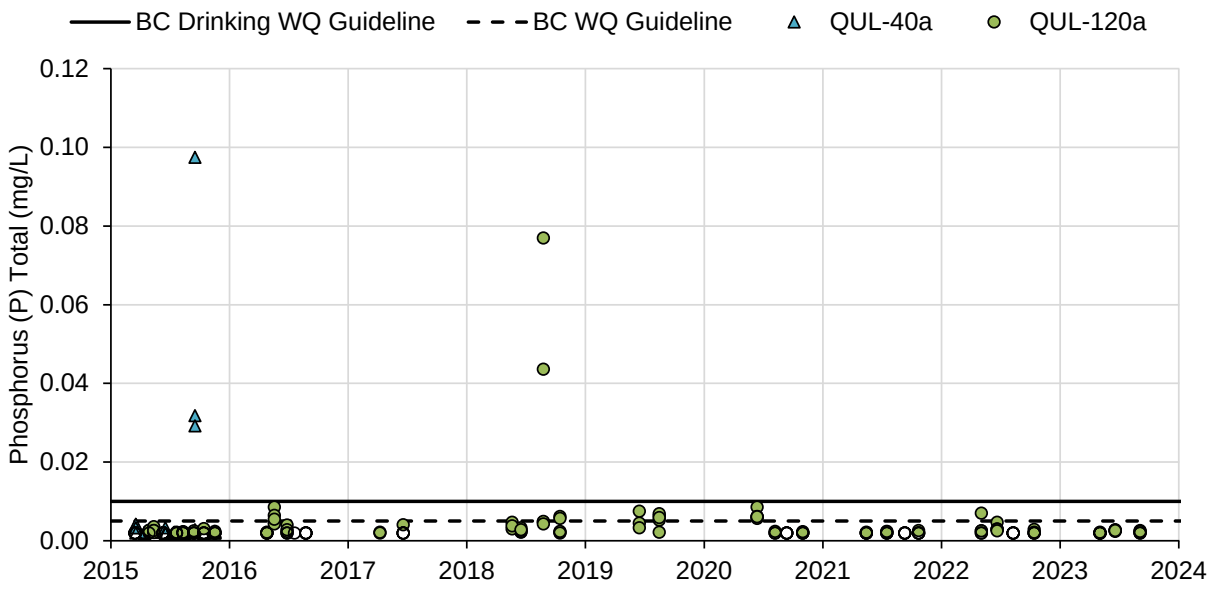
(a) BC WQ guideline for the protection of drinking water, available at https://www2.gov.bc.ca/gov/content/environment/air-land-water/water/water-quality/water-quality-guidelines/approved-water-quality-guidelines, accessed October 31, 2023.
(b) BC Water Quality Guidelines (BC WQG). Fresh Water Aquatic Life 30-day Guidelines used, except where noted (e.g., molybdenum, total aluminum). Maximum (Max) guidelines substituted where 30-d guidelines do not exist.
(c) For guideline comparison, Quesnel Lake background turbidity is assumed equal to 1 NTU and background TSS is equal to the MDL of 3.0 mg/L.
(d) Hardness dependent fluoride guideline: BC Max WQG (mg/L) = (-51.73+(92.57log10(hardness))*0.01), 0.4 at hardness 10 mg/L.
(e) Hardness dependent sulphate guideline: BC 30-d WQG (mg/L) = 128 at hardness <30 mg/L, 218 at hardness 31-75 mg/L, 309 at hardness 76-180 mg/L, 429 at hardness 181-250 mg/L, determined based on site water at hardness >250 mg/L.
(f) pH and temperature dependent ammonia guideline: values selected from Table 4 in BC WQG based on maximum temperature and pH.
(g) Chloride (Cl) dependent nitrite guideline: BC 30-d WQG (mg/L) = 0.02 at Cl <2 mg/L, 0.04 at Cl 2-4 mg/L, 0.06 at Cl 4-6 mg/L, 0.08 at Cl 6-8 mg/L, 0.10 at Cl 8-10 mg/L, 0.20 at Cl >10 mg/L.
(h) up to 4 – highly sensitive to acid inputs; 4 to 8 – moderately sensitive; over 8 – low sensitivity. Refer to alkalinity, the more restrictive of calcium or alkalinity applies.
(i) Max guideline is for hexavalent chromium.
(j) Hardness dependent lead guideline: BC 30-d WQG (mg/L) = (3.31 + exp(1.273*ln(hardness) - 4.704)) / 1000 at hardness >8 mg/L.
(k) Hardness dependent manganese guideline: BC 30-d WQG (mg/L) = 0.0044*hardness+0.605.
(l) Mercury BC 30-d WQG (mg/L) = 0.0001/(MeHg/THg), where MeHg is mass (or concentration) of methyl mercury and THg is total mass (or concentration) of mercury in a given water volume; assumed = 0.00001 at 1% MeHg.
(m) Hardness dependent nickel guideline: BC 30-d WQG (mg/L) = 0.025 at hardness <60 mg/L, (exp(0.76*ln(hardness)+1.06))/1000 at hardness <180 mg/L, 0.15 at hardness >180 mg/L.
(n) Hardness dependent silver guideline: BC 30-d WQG (mg/L) = 0.00005 at hardness ≤100 mg/L, 0.0015 at hardness >100 mg/L.
(o) pH dependent dissolved aluminum guideline: BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, exp(1.6-3.327*(median pH)+0.402*(median pH2)) at pH <6.5.
(p) Hardness dependent dissolved cadmium guideline: BC 30-d WQG (mg/L) = (exp(0.736*ln(hardness)-4.943))/1000.
(q) pH, dissolved organic carbon, and hardness dependent copper guideline was calculated using the BC copper biotic ligand model. BC 30-d WQG range calculated using minimum and maximum pH (6.4 – 8.9), dissolved organic carbon (1.3 to 13 mg/L), and hardness (44 – 58 mg/L) values.
(r) Hardness dependent zinc guideline: BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/1000.
(s) Minimum, maximum, and median were calculated using absolute values; that is, when the summary statistic corresponded to a non-detect (ND) value in the dataset, the MDL was reported.
(t) Mean was not calculated for parameters with greater than 50% non-detect values. A median was reported where a mean was not calculated.
(u) 95th percentile was not calculated for parameters with less than 10 samples.
(v) 95th percentile was not calculated for parameters with greater than 95% non-detect values.



Underlined value = exceeds maximum BC Drinking Water Quality Guidelines.
Shaded value = exceeds 30-day average BC Water Quality Guidelines.

A = approved guideline; W = working guideline; Max = maximum guideline used; Min = Minimum concentration requirement based on life stage; WW = wildlife water supply guidelines; NC = not calculated; "<" = reported value is less than method detection limit (MDL).



Note: Unfilled data points represent samples below detection limits.

4.0 WATER MANAGEMENT AND TREATMENT

4.1 Water Management Summary

A network of channels, ponds, and pumping systems is operated by MPMC for managing surface water at the mine. Contact (mine-affected) and non-contact water (non-mine-affected) systems are managed with the objective of avoiding the mixing of these waters.

The non-contact water system includes channels to divert runoff from undisturbed catchments away from mine infrastructure. Contact water from within the mine site is actively managed using on-site water management infrastructure and conveyed to the TSF or to the PETBP for re-use as part of mine operations or for treatment through the Water Treatment Plant (WTP) and subsequent discharge through a pipeline to Quesnel Lake.

The mine has a positive water balance, with discharge required during mine operations to prevent year-on-year accumulation of water. The only currently permitted discharge of treated contact water from site occurs through the existing WTP and the Quesnel Lake pipe and diffusers. Water management during operations will continue per the current water management infrastructure. The existing WTP (Actiflo patented high-rate ballasted coagulation and flocculation process) is considered the Best Achievable Technology (BAT, BC ENV 2015) for treatment and discharge through assumed future operations (Golder 2015g).

The treatment flow rate of the existing WTP varies between approximately 0.21 m^3/s and 0.31 m^3/s, pending operator control of the plant. The allowable maximum annual discharge volume from site is currently 10.59 M-m^3/year (average of 0.33 m^3/s), as per EMA Permit 11678. The design capacity of the WTP effluent pipeline and diffusers is 0.6 m^3/s (equivalent to the permitted maximum daily instantaneous rate).

The mine's water management plan assumes minimal storage of contact water on site, although during freshet (April through June) and extreme storm events, the volume of mine water runoff will exceed the discharge and treatment capacity, and temporary retention will be necessary to store water prior to discharge. Temporary water accumulation will occur in the TSF or in available pit volume(s). Temporary stored water will be discharged to the environment through the WTP following the freshet period or the storm event.

As the mine moves into closure and post-closure, the objectives of water management are to return the impacted land to pre-mining land functions. As the mine is constructed across a watershed divide, it is desired that during the post-closure period, drainages will be distributed back to their natural watersheds (i.e., to Bootjack Lake, Polley Lake, and Hazeltine Creek), provided that this can be achieved in an environmentally appropriate and permittable manner. MPMC has been proceeding with a program of evaluating and developing passive, semi-passive, and active water treatment technologies for their possible use during mine closure to support the goal of distributing discharge back into the pre-mining configuration. Two treatment options are considered the BAT for treatment during closure and post-closure: Option A – distributed passive/semi-passive treatment systems (applied to select sources), and Option B – pit-lake treatment followed by the centralized Actiflo plant (Golder 2016h). Option B is the current assumption for water treatment during closure/post-closure, but MPMC has also been progressing technology evaluations to support Option A.

This water management plan provides an update on expected water quantity and quality required for treatment during both operations and closure/post-closure (treatment design basis) and provides an update on treatment technology development considered for closure/post-closure (Section 4.7).

4.1.1 Short-term Water Management Strategy

Current water management practices have the objective to minimize mixing of contact and non-contact surface water sources where practicable. The flows from these sources are driven by direct precipitation, runoff, and snowmelt from the associated catchments. The majority of the contact water at the Site is collected along two ditches that run north to south along the western and eastern edges of the Mine: West Ditch and Long Ditch respectively. During large runoff events, the water management infrastructure is subject to increased runoff volumes that require careful planning to mitigate potential risk for discharging contact water to the receiving environment.

To address BC ENV recommendations, WSP is developing a short-term water management strategy, scheduled for completion in 2024, through staged analysis and reporting of surface water infrastructure and flow assessment for runoff and pumps and pipeline conveyance. The aim of the short-term water management strategy is reducing uncertainty during operational scenarios, providing tools for identifying/characterizing real-time events, and providing a decision-making framework for Site personnel during large runoff events.

4.2 Description of Source Inventory

Flow and water quality parameter inputs to the site water management tools, specifically the SWWBM and the SWWQM, are derived from a combination of measured data sources and assumed values based on established modelling practices and site knowledge. The primary objective of these water management tools is to predict the chemistry of water; in particular, the concentrations of constituents that have been identified in PE-11678 and how the loading behaves as water flows through disturbed and undisturbed landforms and constructed conveyance structures (e.g., ditches, pipelines, channels). The amount of loading (constituent concentrations) in contact water is generally influenced by the geochemistry of the source material (i.e., waste rock, ore) and the quantity of water. Non-contact water is not influenced by mine operations.

For the purposes of advancing the development of these water management tools, contact water flows can be classified as follows:

- **Waste rock contact water**—sourced primarily from waste dumps and ore stockpiles distributed throughout the mine.
- **Pit wall runoff**—sourced from the containment walls of excavated voids (i.e., pit shells).
- **Tailings Storage Facility**—sourced from the seepage collection system of the TSF.
- **Other**—site-wide sources for disturbed and undisturbed runoff and groundwater inflows.

As part of this WMP and water management framework, a source inventory (Table 24) has been compiled that identifies areas of the mine that generate mine-contact water. The inventory is intended to be a living database and may need to be updated as the mine layout changes over time or as the mine transition into closure becomes more defined. The source inventory is composed of the following data:

- Modelled or measured water quality data (i.e., station names, station UTM co-ordinates, number of samples, date range of samples).
- Modelled or measured flow (i.e., availability of flow records and a qualitative measure of how well the source is modelled in the SWWBM).

The water quality data from the source inventory is further defined and expanded upon in Section 4.4, where the water quality data are used to calibrate the SWWQM and provide context to the key findings from the model simulation results.

Table 24: Source Inventory

	Description	Water Quality			Data Source Coordinates	Water Quantity			
		Data Source[a]	Number of WQ Samples[b]	Period of Record (inclusive)	UTM Zone 10 (X/Y)[c]	Measured Flow Data	Period of Record (inclusive)	Number of Flow Records	Modelled Flows Available (Y = YES, N = NO; P = PARTIAL)[d]

(a) Boundary Dump SEEPS, SERDS SEEPS, and PAG Dump SEEPS contain multiple sampling points in the vicinity of the prescribed area.
(b) Samples collected before the period of record are excluded.
(c) UTM Zone 10 X and Y coordinates are approximate and represent the general location of the sampling point. Certain areas have multiple sampling points in the vicinity of the prescribed area.
(d) “Partial” designation indicates that the SWWBM only captures selected elements of the source category. Flows are not calibrated due to a lack of adequate flow records at preferred calibration points.
(e) Seepage stations beside the waste rock piles near Boundary Pit.
(f) Located east of the start of the Long Ditch in a clearing.
(g) Seepage stations located between the Northeast Zone Dump, the SERDS and the SERDS Ditch.
(h) Water quality inputs assigned to pit wall runoff were based on SRK source terms for wall rock lithologies and proportions instead of source terms calculated from pit water monitoring data.
(i) Located in the main embankment seepage collection pond.
(j) Water quality assigned from model predictions of the TSF instead of source terms calculated from pit water monitoring data.
(k) Located in Bootjack Creek above Hazeltine Creek.
(l) Located in the Northeast Edney Creek Tributary.
(m) GW12 sample stations located in the Springer Pit Well and NW of the Temporary PAG Dump. GW15 sample stations located the South and North Springer Pit Wells.

WQ = Water Quality; SEEPS = Seepage; JCP = Joe’s Creek Pipe; NAG = Non-potentially Acid Generating; NW = Northwest; SERDS = Southeast Rock Disposal Site; PAG = Potentially Acid Generating; TSF = Tailings Storage Facility; NA = Not Available; MTD = Main Toe Drain; GW = Groundwater; SWWBM = site-wide water balance model.

4.3 Water Balance

This section describes the SWWBM, including discussion of calibration to observed data, implementation of updates to reflect the Springer Expansion LOM Plan, and simulation results. The SWWBM represents a key water management tool that is used to confirm whether existing and proposed site Water Management Plans are adequate for supporting the joint permit application associated with the proposed Springer Expansion LOM plan.

4.3.1 Water Balance Model

An update to the existing SWWBM was carried out using GoldSim™ (Version 14.0). The SWWBM was originally developed for the TAR to support the effects predictions in the LTWMP for the mine and has since been calibrated on an annual basis (refer to WSP 2023e for 2022 annual calibration). WSP incorporated the Springer Expansion LOM Plan (MPMC 2023b) for the implementation of future operations scenario in the SWWBM.

The updated SWWBM simulates the site water circuitry (the logic driving water transfers, discharges, and flows on site) under the assumed future operations scenario. The model is built to project inflows and outflows to major storage locations and conveyance structures on-site. The SWWBM water quantity projections are then fed into the WQM to generate predictions on water quality parameter concentrations at selected locations of interest.

4.3.1.1 Model Software

GoldSim allows dynamic and complex water quantity interactions to be represented through a visual and highly modular framework. All input parameters and functions are defined by the user and are built as individual objects or elements linked together by mathematical expressions. GoldSim is widely used for mine water quantity studies and provides the following capabilities:

- Deterministic and probabilistic simulations can be run within the model, which allows statistics and probabilities to be assigned to the model outputs.
- Simulation periods can be varied within the same model.
- The model framework can be easily adjusted to account for evolving conditions on a mine site, which allows the model to be used as an operational planning tool.
- Water quantity and water quality modules can be directly linked within the model, which allows both modules to be updated simultaneously; this is particularly useful when evaluating a range of scenarios (e.g., alternative water management strategies).

4.3.1.2 Model Objectives

This SWWBM has the following objectives:

- Include a future operational phase that will extend from May 2, 2023, to March 31,2031.
- Include a closure phase extending from April 1, 2031, to March 31,2041.
- Include a post-closure phase commencing on April 1, 2041, and extending to March 31, 2131 (100 years including closure).
- Estimate the quantity of contact water collected on-site per the climate conditions.
- Estimate water retention requirements in major storage locations at site such as the TSF and pits.

- Estimate the quantity of contact water requiring treatment.
- Provide support for the assessment of future operations water quality and associated water treatment and/or discharge options.
- Provide a model that can be linked to a water quality module that assesses site water quality during forecasted future operations.

4.3.1.3 General Assumptions and Key Input Parameters

General assumptions applied to this model update are as follows:

- Continuation of mining of the Springer Pit and Cariboo Pit will not significantly increase the footprint of the pits.
- There is no seepage from the ponds or sumps other than the TSF (i.e., all ponds and sumps are assumed to be lined, or seepage is assumed to be negligible).
- Direct precipitation, evaporation, and seepage loss from ditches are assumed to be negligible.
- Precipitation occurs as snow from December to February and as rain or a mixture of rain and snow in all other months.
- Snowpack is represented by the cumulative precipitation depths over the months of December, January, and February, spanning a period of three months.
- Snowmelt occurs in the months of March, April, and May as a percentage of the maximum snowpack at the end of February (5% in March, 90% in April, and 5% in May).
- The closure and post-closure phases are included in the SWWBM, and the flow logic and model wiring for these phases are based on 2022 Reclamation and Closure Plan (RCP) (MPMC 2022a).

Key input parameter values and assumptions for the operational phase simulations are presented in Table 25.

Table 25: Key Input Parameter Values and Assumptions

Parameter	Value	Reference
TSF emergency spillway invert elevation at 987 m dam crest elevation during operations	985.8 m	WSP 2023g
Initial TSF water volume	2.84 M-m^3	TSF Weekly Report (MPMC 2023a)
Initial Springer Pit water level	970.66 m	TSF Weekly Report (MPMC 2023a)
Initial Cariboo Pit water level	954.72 m	TSF Weekly Report (MPMC 2023a)
Initial Wight Pit water level	912.87 m	TSF Weekly Report (MPMC 2023a)
Tailings stored in Springer Pit	2.00 M-m^3	TSF Weekly Report (MPMC 2023a)
Water Treatment Plant (WTP) treatment capacity	25,000 m^3/d (0.29 m^3/s)	Provided by MPMC (MPMC 2023c)

4.3.1.4 Model Scope and Flow Diagram

The scope and structure of the SWWBM is outlined in the conceptual flow diagram for forecasted future operations in Figure 15. The flow diagram illustrates the water circuitry at the Mine, including operational storage, conveyance, and discharge of water. The water management infrastructure modelled within the SWWBM is summarized in Table 26. The flow types that are programmed into the SWWBM are outlined in Table 27.

From closure and progressively to post-closure, certain Site areas will be reclaimed, and run-off will become non-contact water. Pumping rates for the Site will be reduced at the end of the closure period, as certain areas are assumed reclaimed. Closure and post-closure flow diagrams are shown in Figure 16 and Figure 17, respectively.

4.3.1.5 Climate Inputs

The following sections describe the climate inputs used in the SWWBM. The climate datasets are derived from local and site-based climate stations as described in Section 3.2.1.

Deterministic Climate Inputs

The model features a deterministic simulation mode, which allows the user to select from three predefined climate scenarios based on long-term ECCC and local data (as described in Section 3.2.1):

- average annual precipitation data (Table 9)
- 1:10-year wet annual precipitation (Table 6)
- 1:200-year wet annual precipitation (Table 6)

For each selected scenario, the associated annual precipitation is repeated for each year of the simulation period. Annual median lake evaporation is used for the deterministic mode, and snowpack is accumulated within the model based on the assumption that snow accumulates from December to February, with a 5%, 90%, and 5% melting in March, April, and May, respectively.

Stochastic Climate Inputs

GoldSim has stochastic elements, allowing uncertainty to be represented in model input data. GoldSim uses the Monte Carlo method to sample stochastic elements for probabilistic simulations. A stochastic generator is included in the model to probabilistically simulate natural climatic variation at the mine. The stochastic generator operates on an annual basis and generates random sequences of annual precipitation over the simulation period (one such random sequence is called a “realization”). This method of climate input is used to model a wide range of precipitation inputs and acts as a sensitivity analysis that can be easily viewed as results in the form of percentile values.

To simulate stochastic conditions, monthly precipitation data were fitted to a normal distribution. A normal distribution is a type of probability distribution (a mathematical representation of the relative likelihood of an uncertain variable having specific values). All distribution types use a set of arguments to specify the relative likelihood for each possible value. The arguments for normal distribution are the dataset’s mean and standard deviation. The mean and standard deviation for the monthly precipitation values were determined. The standard deviations were adjusted using a standard z-table, so that the annual mean of the stochastically generated results agreed with the mean of the historical data. The monthly input arguments (mean and standard deviation) are shown in Table 28.

The derived monthly means and standard deviations of the precipitation values, defined in the model as stochastic elements, were used to generate random values based on the normal distribution of the dataset. The stochastic generator was set to perform 2000 realizations to create a sample size that was sufficiently large to account for a range of conceivable climatic scenarios for the study period.

Table 28: Stochastic Climate Generator Log-normal Distribution Input Arguments

Month	Mean of the Monthly Precipitation Depths (mm)	Standard Deviation of the Monthly Precipitation Depths (mm)
January	49.4	30.9

Annual Total	**612.3**	**523.2**	**1064.1**	**2241.3**

(1) Average during the modeling period (2024 to 2131).

Climate Change

An ensemble of monthly temperature and precipitation projections were obtained from ClimateBC consisting of 8 Global Climate Models (UBC 2022) and two emissions scenarios (SSP2-4.5 and SSP5-8.5) covering mid to high emissions from the Sixth Intergovernmental Panel on Climate Change Assessment Report (IPCC 2021). A stochastic approach (outside the GoldSim model) was used to extend these projections from year 2100 to 2200 by resampling monthly data from 2071-2100 and relating projected changes in temperature and precipitation

climate variables to a set of extended greenhouse gas concentration pathways beyond year 2100 (van Vuuren et al. 2011). The range of projected temperature and precipitation values for each month was summarized across the ensemble of climate models and emissions scenarios using a range of values. The mean, and the upper bound, have been included in the SWWBM to analyze the effects of climate change. Lake evaporation, snow accumulation and snowmelt were calculated in the same way as for the average scenario.

4.3.1.6 Hydrology Inputs

The following sections describe the processes and inputs that define the SWWBM's hydrology.

Runoff Parameters

Runoff in the SWWBM is estimated using seasonal runoff coefficients. Runoff coefficients represent the proportion of rainfall that reports as runoff or seepage, accounting for losses due to evaporation, storage, and infiltration. Adjustment during the calibration process resulted in a 30% increase of the general runoff coefficients in cases where the monthly precipitation exceeds 50 mm. The runoff coefficients account for the following two seasonal climate periods:

- **General (July to February)**—mid-range coefficients to reflect soil moisture contents for intermittent runoff events.
- **Freshet (March to June)**—highest runoff coefficients to represent expected higher soil moisture content, and therefore greater runoff.

The seasonal runoff coefficients defined for the catchment types considered in the SWWBM are presented in Table 29.

Table 30: Seasonal Runoff Coefficients

Catchment Type	General	Freshet
Exposed tailings	0.6	0.9
Disturbed areas	0.3	0.9
Rock disposal site areas	0.1	0.6
Open pits	0.75	0.9
Undisturbed catchments	0.4	0.42
Haul roads and access roads	0.15	0.9
Mill site area	0.1	0.1

Catchment Areas

To model runoff, direct precipitation, and evaporation, the catchment areas for each storage element were defined in the model. The catchment/reporting area for each storage element remains consistent with the TAR (Golder 2016g). However, there's one exception: the TSF impoundment catchment at the projected 987 m crest. Any alterations would mainly affect the infrastructure downstream of the TSF, but these changes are expected to have minimal impact on the model results. The catchments are shown in Table 30 and illustrated in Figure 18.

Table 31: Current Catchment Areas for SWWBM Storage/Conveyance Elements

Storage or Conveyance Element	Total Reporting Area (m^2)
South Seepage Pond	385
Main Embankment Seepage Pond	376,900
TSF Upstream Catchment (External)	622,800
TSF Impoundment Catchment (Internal – current)	2,269,700
TSF Impoundment Catchment (Internal – projected at 987m raise)[(a)]	2,860,000
Perimeter Embankment Till Borrow Pond (PETBP)	524,300
Central Collection Sump (CCS)	438,600
Bootjack Creek Sump	175,200
SERDS Ditch[(b)]	1,537,600
Mill Site Sump	1,630
Mine Drainage Creek Sump	1,115,900
Long Ditch	2,494,000
Cariboo Pit	1,320,400
Springer Pit	651,900
NW Sump	330,200
9K Sump	698,700
Wight Pit	413,900
Boundary Pit	23,400
Total Reporting Area	**12,997,315**

(a) The raise of the TSF will affect the catchments producing runoff into the TSF. To consider the increase of the TSF impoundment catchment, the model interpolates the TSF impoundment catchments between the current state and the TSF raise to 987m. Changes in other catchments are minor.

(b) The current SERDS Tailings Co-disposal project does not affect the delineation of the catchment.

4.3.1.7 Storage Capacities

Free water volumes in storage ponds, sumps, and tailings facilities depend on a balance between their inflows and outflows. The stage (elevation) can be directly correlated to a specific storage volume using site bathymetric (sub-aqueous surface) and topographic (land surface) data. These relationships can be referred to as stage-storage curves.

Dynamic storage facilities such as the TSF, where tailings deposition changes the available storage, require regular survey updates to confirm whether existing stage storage curves are appropriate for projecting free water volumes. Stage-storage curves for the TSF up to a crest elevation of 987 m were developed from the 2020 TSF survey. These curves were obtained from preliminary tailings deposition modelling carried out in support of the design of the 987 m TSF.

The stage-storage curves projected up to a crest elevation of 987 m constitute a 2-D element that considers the tailings tonnage. These curves will interpolate according to the dry tailings volume across the Springer Expansion LOM schedule. Additionally, these curves are limited by the spillway invert stated in Table 25, serving as the upper boundary for the maximum TSF elevation.

- Springer Pit (November 7, 2019, bathymetry survey)
- Cariboo Pit (June 3, 2022, topographic survey)
- TSF (June 17, 2020, bathymetric survey tied-in with October 22, 2019, topographic survey)
- Wight Pit (January 13, 2022, bathymetric survey)

The estimated volume capacities for the facilities listed above and other storage locations are presented in Table 31.

Table 32: Maximum Capacities for Major Storage Facilities

Major Storage Facility	Estimated Capacity (M-m^3)
Springer Pit[(a)]	14.8
Cariboo Pit[(b)]	5.1
Combined Springer-Cariboo Pit final mine-out	30.3
TSF – 987 m crest elevation design	5.7[(b)]
Wight Pit	3.8
PETBP	0.17

(a) Represents current individual pit volumes (i.e., before pits are combined or further mined).

(b) Capacity at the final stage of the TSF, when tailings deposition ends.

4.3.1.8 Mine Plan

The mine plan for the Springer Expansion was updated in the SWWBM and assumed a milling operational end date of March 2031. Tonnage/volume of dry tailings during the project is provided in Table 32 (MPMC 2022b). It is assumed that 6.55 M-tons of dry tailings have been placed in the TSF between the mine plan start date of July 1, 2022, and the assumed SWWBM operations start date of May 2, 2023.

Table 33: Mine Plan (Annual Totals)

Year	Dry Tailings (tons)
2022[(a)]	3,530,469
2023	7,300,000
2024	7,300,000
2025	7,300,000
2026	7,300,000
2027	7,300,000
2028	7,300,000
2029	7,300,000
2030	7,300,000
2031[(b)]	860,381

(a) Mine plan starts on July 1, 2022.

(b) Mine plan ends on March 31, 2031.

4.3.1.9 TSF Water Volumes

Temporary detention of water in the TSF is necessary to manage large site runoff volumes that can be generated during freshet; however, a fundamental basis of the water management plan is to not accumulate water on-site year over year (including within the TSF) by treating and discharging water.

The minimum and maximum operational water volumes in the TSF under normal conditions are 1.5 M-m^3 and 1.7 M-m^3, respectively.

The water balance model activates and deactivates pumping flows. As a result, the TSF water volume is set at 1.5 M-m^3 prior to freshet and it returns to the specified normal operating range after freshet. TSF water volume conditions are presented in Table 33.

Table 34: TSF Water Volume Values

Condition	TSF Water Volume (M-m^3)
Minimum under normal conditions	1.5
Maximum prior to freshet (February-April)	1.5
Maximum after freshet and until freeze-up	1.7

4.3.1.10 Flow Derivation and Logic

This section describes the model logic for pumped flows, seepage (from the TSF), groundwater inflows and outflows, consumption, and transfer flows.

Pumped Flows

The most relevant transfer rates, including rates between TSF, Pits and PETBP; have been informed by MPMC (MPMC 2023c), while the remaining rates remain consistent with the TAR model and were based on engineering judgement (Golder 2016g). Maximum pumping rates for the operational, closure, and post-closure phases (2023 to 2131) are available in Appendix A.

It should be noted that the capacity set for transfer from TSF to Wight Pit (P30) was assumed at a capacity to avoid PETBP overflow during operations. Capacity set for transfer from CCS to Wight Pit (P35) during closure is a WSP assumption to allow suitable water transfer capacity between CCS and Wight Pit during the closure phase, and this future conveyance system will require design confirmation as the Site approaches closure.

PETBP Pumping Logic

The PETBP functions as attenuation pond for the WTP, with a storage capacity of 170,000 m^3. If this storage capacity is depleted, water is pumped to the TSF for temporary detention (P5).

Mill Process Flows

The mill process water requirements are based on 2.0 m^3/t of dry tailings. Interstitial water sequestered in the deposited tailings is based on 0.347 m^3/t of dry tailings deposited.

Tailings Storage Facility Seepage Flows

Seepage flows from the TSF (S1 to S5) were estimated using a two-dimensional numerical groundwater flow model to quantify anticipated seepage rates through the embankment and foundation. The analyses were conducted using GeoStudio 2021, developed by GEOSLOPE International Ltd. Seepage from the TSF has been defined to occur continuously without interruption in the SWWBM. The TSF seepage rates are presented in Section 3.2.4.

Consumption Flows

Consumption flows are system losses attributed to the operation of dust suppression equipment. Consumption flows were estimated by MPMC staff for operations (MPMC 2023c) and are modelled according to the following logic:

- Turbo-misters operate from May to September.
- Water trucks withdraw water at variable rates from May to September.

Consumption flow rates are presented in Appendix A.

4.3.2 Water Balance Calibration

Models are representations of systems, and as a result, accuracy will vary. Models are used to provide an indication of a system and how the system behaves under certain conditions. Calibration and validation exercises are used as an indicator of how well the model replicates conditions during the calibration period and provide the basis for future projections assuming that past behavior is an indicator of future behavior. The level of accuracy in model calibrations is dependent on the availability and quality of historical data and whether the logic for transferring or storing water is representative of actual conditions. If there are significant changes to the system that is being modelled, then those assumptions should be validated through additional model calibration as more monitoring data become available. The following sections provide information on the calibration process and the associated results.

4.3.2.1 Calibration Period

The calibration period is from January 1, 2017, to December 31, 2022. A 6-year period was selected to capture variable climatic, operational, and hydrological conditions that have been experienced on site.

4.3.2.2 Tailings Storage Facility Water Volume

The TSF represents the largest designated water storage facility at the mine. The large volume capacity of the facility, coupled with the availability of water level and survey data, and the TSF's role in the production mill reclaim water system, means the structure is a key indicator of large water volume changes on site, and with that, a good location for conducting a calibration check that is representative of the entire mine. A calibration check was carried out for the TSF water volume. Measured TSF water levels and operational water transfer data formed the primary inputs (e.g., water transfers to the Springer or Cariboo pits, production mill process flows, and water transfer to and from the PETBP). In addition, a global water balance check was performed to check that the difference between total water inflows and total water outflows was equal to the change in site storage.

Initial model simulation runs during the calibration period, without any adjustments, revealed poor agreement for selected periods. To account for these differences, general seasonal runoff coefficients (July to February) were assigned a 30% increase (scalar factor applied to the runoff coefficients for the applicable period) to represent higher antecedent moisture conditions if the previous month accumulated more than 50 mm of precipitation depth. In addition, general runoff coefficients were applied to what was defined as dry period in the TAR. Climate records obtained from a nearby ECCC station (Spokin Lake 4E; 1097646) appeared to support the hypothesis that rain-on-snow events, occurring for short and discrete periods, would have contributed to higher runoff conditions. The model was run again, and the results are shown in Figure 19.

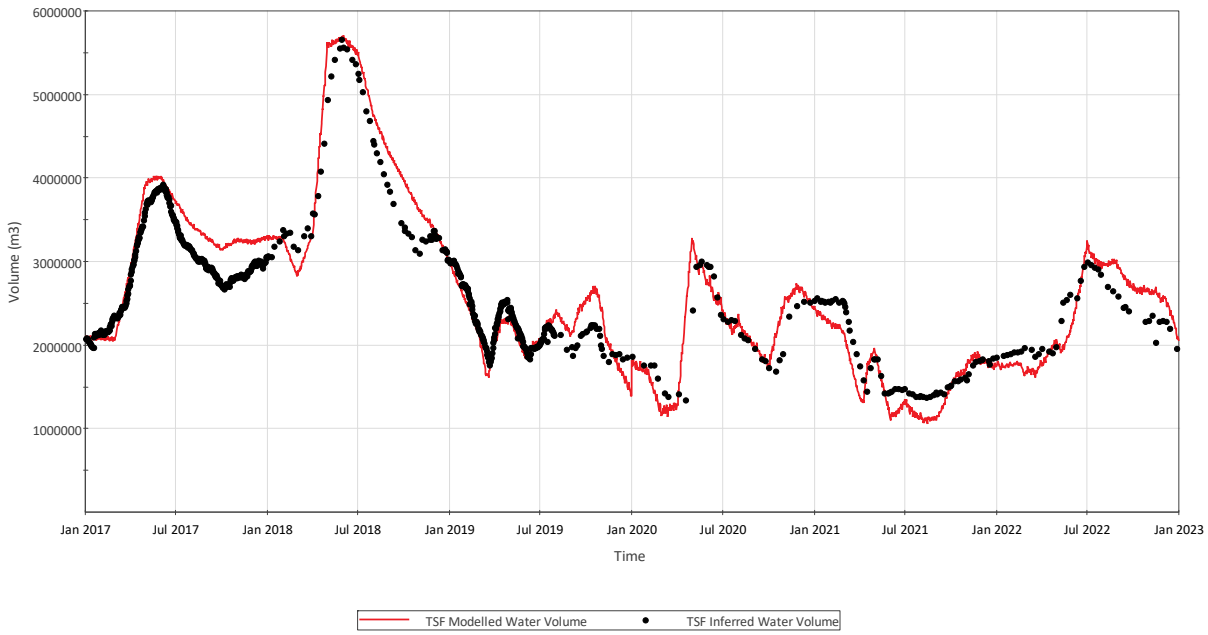

Figure 19: Tailings Storage Facility Water Volume Calibration from January 1, 2017, to December 31, 2022

As illustrated in Figure 19, the TSF modelled water volumes appear to demonstrate good agreement between modelled and inferred water volumes (water level measurements converted to a volume using interpolated stage-storage curves), with modelled volumes consistently tracking inflection points (change from accumulation to depletion or vice-versa). There are select periods where the calibrated model is slightly over-estimating or under-estimating the inferred volumes.

Remaining differences between modelled and inferred values may have several explanations:

- Variability in runoff coefficient throughout the year.
- Uncertainties in the climate data (e.g., snowpack surveys can miss intermittent snowmelt if conducted infrequently and the use of composite datasets may over or under-estimate actual conditions).
- Uncertainties in the TSF bathymetric survey (e.g., the transition between exposed tailings surface [i.e., beach] and free water can be complex).
- Uncertainties in the TSF storage curve after the start of tailings deposition.
- Potential inaccuracies in water level measurements.
- Gaps and/or inconsistent water level measurements.
- Potential inaccuracies and/or missing WTP discharge data.
- In general, the modelled results for the 2022 SWWBM calibration give a reasonable approximation of site conditions and are considered suitable for water management planning exercises.

4.3.3 Water Balance Results

The updated SWWBM results are intended to inform the water quality assessment for this WMP. The primary use of the water quantity and quality assessments are to predict whether the discharge water quality from the mine during operations will meet the parameter concentrations and discharge quantities and to anticipate water treatment requirements. This section provides an overview of the key results of the SWWBM. Full detailed SWWBM results can be found in Appendix A.

Quantity of Discharge

Throughout the entire planned future operations and closure periods to March 31, 2041, the maximum treatment capacity of the WTP in the model is assumed to be 25,000 m^3/day (0.29 m^3/s, 9.15 M-m^3/year). Excess water beyond this discharge rate is temporarily stored on-site until it can be treated and discharged.
Centralized collection and treatment of contact water is assumed during operations, closure, and post-closure. The Mine's current discharge permit authorizes an annual discharge volume of 10.59 M-m^3.

In year 2041, the assumed treatment capacity of the WTP in the model remains at 25,000 m^3/day (0.29 m^3/s). However, annual contact water requiring treatment is reduced over the post-closure phase as site areas are remediated and some runoff is considered non-contact water, as shown in Figure 17. The annual contact water treated discharge volume declines further in year 2051 when the South Seepage Pond and Main Embankment Seepage Pond catchments are considered remediated, commencing 10 years after the post-closure phase. At the end of the operations phase, contact water requiring treatment notably increases in 2031, as milling is assumed to terminate in 2031 and the demand for milling process water also terminates.

Estimated annual contact water volumes requiring treatment from operations to post-closure are presented in Table 34.

Table 35: WTP Annual Volume Requiring Treatment

Year	Annual Volume Requiring Treatment at WTP (M-m^3)		
	50th Percentile	90th Percentile	99.5th Percentile
2023[a]	3.90	4.57	5.72
2024	5.00	5.94	7.24
2025	3.50	4.97	6.79
2026	3.37	4.72	6.53
2027	3.35	4.79	6.60

Table 35: WTP Annual Volume Requiring Treatment

Year	Annual Volume Requiring Treatment at WTP (M-m³)		
	50th Percentile	90th Percentile	99.5th Percentile
2071	0.33	0.71	1.48
2091	0.32	0.69	1.60
2111	0.32	0.71	1.44
2131	0.02	0.03	0.05

(a) Model simulation start date: May 2, 2023.

(b) Closure starts on April 1, 2031.

(c) Post-closure starts on April 1, 2041.

Tailings Storage Facility

Temporary detention of water will be necessary to manage the large runoff volumes generated during freshet (typically April to June). The inflows during freshet will exceed treatment capacity, and detention volume is required to prevent uncontrolled release from the PETBP and to equalize the flow for treatment. The TSF is available to store excess freshet water until four months after the start of closure. At that time, the TSF water volume will decrease to a maximum of 0.25 M-m³, the maximum allowable water volume at closure. To create the reduced TSF water volume, a closure spillway will be constructed at the north abutment (Corner 5) of the TSF. Water will discharge from the TSF to the CCS, and then flow to the PETBP for treatment prior to discharge.

During closure and post-closure, the TSF is modelled to discharge annually via the spillway, and the TSF water volume will vary seasonally, limited by the spillway invert, to a maximum of approximately 0.25 M-m³. As from Figure 20, the water volume fluctuation follows a consistent pattern during both closure and post-closure periods, with minimum values occurring in winter and reaching maximum capacity during freshet (0.25 M-m³).

Figure 20 shows the water volume in the TSF throughout future operations and into closure until 10 years after post-closure. The TSF water volume pattern shown for the 2041-2051 post-closure period is continued for the remaining 80 years of post-closure (until 2131). Table 35 shows tabulated minimum, average, and maximum bounds for the three percentile trends shown in Figure 20.

Table 36: TSF Water Volume (m³)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	1,330,244	1,390,394	1,429,751
	Average	1,493,500	1,576,822	1,809,717
	Maximum	2,840,000	2,840,000	3,493,139

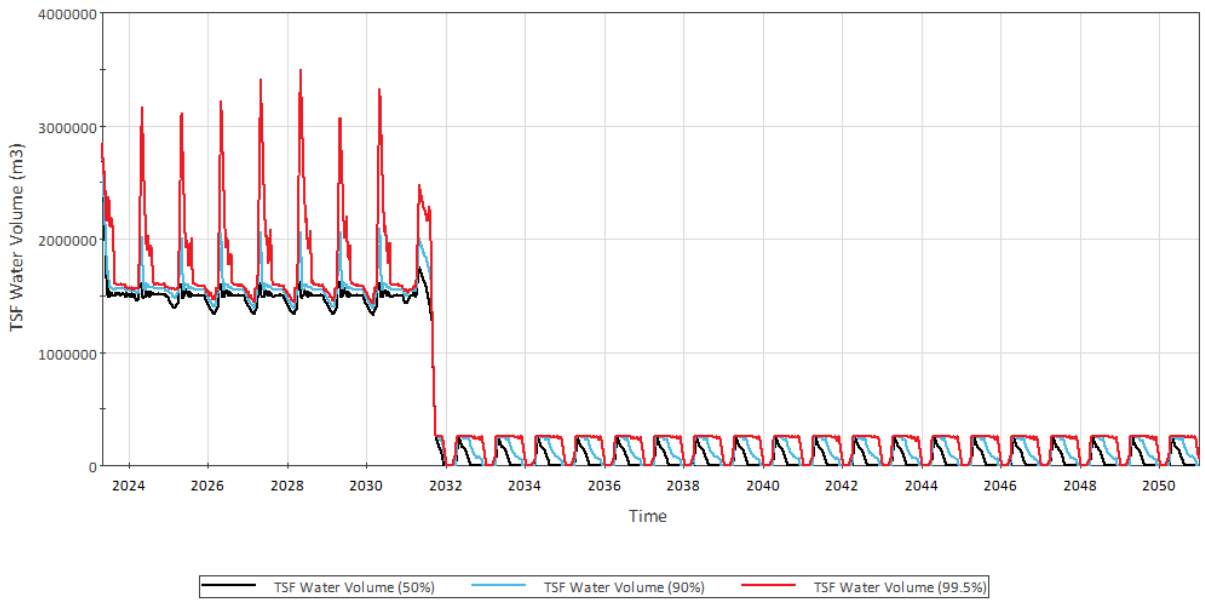

Figure 20: TSF Water Volume During Operations to 10 Years After Post-closure

Combined Springer-Cariboo Pit

Springer Pit and Cariboo Pit were modelled as a single pit for the closure and post-closure phases (starting April 1, 2031). A result comparison between different percentiles for Combined Springer-Cariboo Pit volume during closure and post-closure is provided in Figure 21 . Potentially Acid Generating (PAG) waste rock will be stacked uniformly to an elevation of 1,004 m in the base of the Combined Springer-Cariboo Pit at the end of the operations phase. Results of the simulations indicate that water levels within the pit will cover the PAG material placed in pit by approximately 2033 under the 99.5th percentile condition, while under the rest of the climate conditions it is estimated to cover the PAG material placed in pit by 2034. Under the 50th percentile results, the combined Springer-Cariboo Pit lake is estimated to start overflowing in 2058, while under the 90th percentile it is estimated to start overflowing in 2056, and in 2055 under the 99.5th percentile. The Water Quality Report (WSP 2023c) discusses modelled water quality of the Springer-Cariboo pit lake at the estimated time of overflow.

Table 37: Combined Springer-Cariboo Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Closure	Minimum	109,345	145,263	211,031
	Average	4,827,785	5,199,295	5,652,177
	Maximum	9,030,590	9,598,661	10,300,000
Post-closure	Minimum	9,032,744	9,600,627	10,300,000
	Average	20,033,811	20,167,573	20,287,305
	Maximum	21,100,000	21,100,000	21,100,000

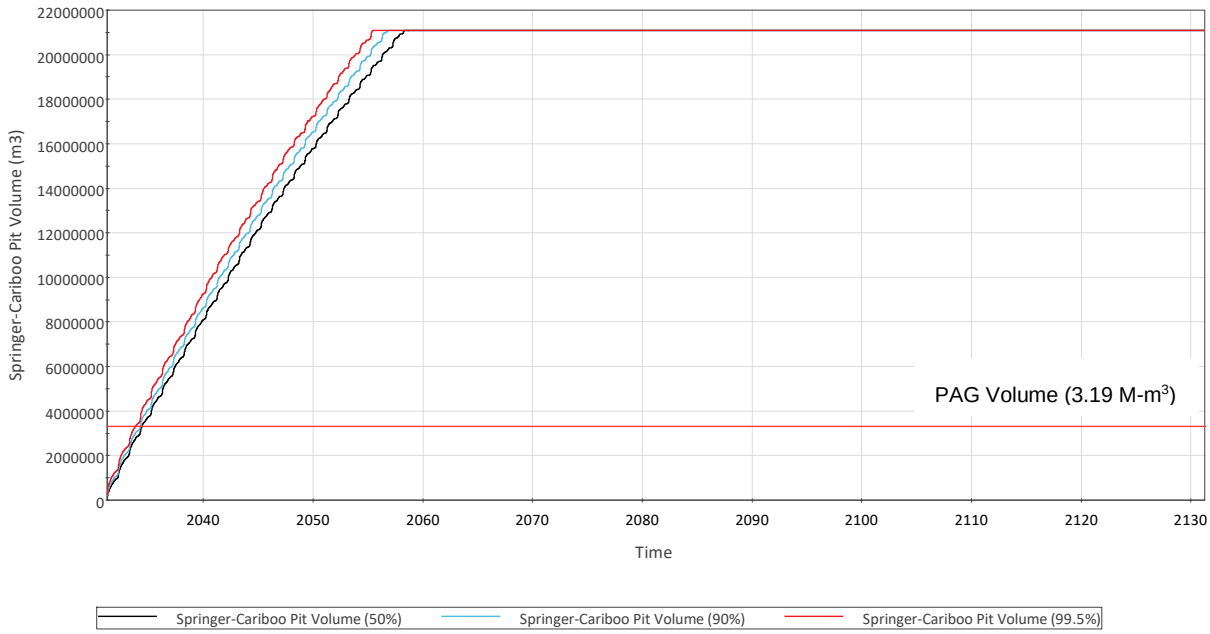

Figure 21: Combined Springer-Cariboo Pit Water Volume from Closure

The combined Springer-Cariboo Pit is modelled to fill to its maximum volume during post-closure. Following that time, additional volume collected in the combined pit will overflow from the pit's spillway and is assumed to direct discharge to the receiving environment in the SWWBM. Water quality and water treatment discussion is included under separate cover regarding this assumption of direct environmental discharge of pit lake overflow during post-closure.

Table 37 shows the modelled average annual overflow volume from the combined Springer-Cariboo Pit.

Table 38: Combined Springer-Cariboo Pit Annual Overflow (m^3)

Phase	Combined Springer-Cariboo Pit Annual Average Overflow (m^3)		
	50th Percentile	90th percentile	99.5th percentile
Post-Closure	469,711	1,051,048	2,249,910

Wight Pit

The water volume in Wight Pit is expected to increase during every freshet season. Four months into the closure phase, the TSF water volume will be reduced to a maximum of 0.25 M-m^3 within two months. Once the TSF can no longer provide freshet storage, Wight Pit will be used to store excess water. During post-closure, Wight Pit will no longer be used for freshet storage and will be allowed to fill. Wight Pit is projected to start overflowing in 2049 under the 50th percentile results, and in 2047 under the 90th and 99.5th percentile results. Overflow from Wight Pit during post-closure is assumed as direct environmental discharge to Polley Lake and the water quality implications of this assumption are discussed in the water treatment section of this WMP. Estimated volumes stored in Wight Pit from operations to 10 years after post-closure are presented in Figure 22 and the average annual post-closure overflow volumes are shown in Table 39.

Table 39: Wight Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0
	Average	459,747	650,947	1,128,389
	Maximum	3,427,576	3,483,974	3,495,141
Closure	Minimum	0	0	0
	Average	80,815	373,440	1,188,190
	Maximum	490,123	1,153,040	2,326,346
Post-Closure	Minimum	0	0	0
	Average	4,835,386	4,841,820	4,849,597
	Maximum	4,984,114	4,984,114	4,984,114

Post-closure	466,741	617,692	993,214

4.3.4 Water Balance Model Summary

The SWWBM was updated to reflect the Springer Expansion LOM plan during the operational phase and incorporates closure and post-closure phases for the Mount Polley Mine. The SWWBM supports water management planning and the assessment of water quality and associated water treatment and discharge options.

The model was run from May 2, 2023, to March 31, 2131, and included the following LOM phases:

- Operational phase extending from May 2, 2023, to March 31, 2031.
- Closure phase extending from April 1, 2031, to March 31, 2041.
- Post-closure phase commencing on April 1, 2041, and extending, for the purposes of this analysis, to 2131.

The model was run stochastically for 2000 realizations to present 50th, 90th, and 99.5th percentile model results. The results for the modelling during the operational phase are presented as follows:

- The average annual treated discharge for the 50th percentile is approximately 3.65 M-m^3 between 2023 and 2031, while the milling process water demand exists.
- The maximum annual treated discharge for the 99.5th percentile is 7.21 M-m^3 in 2031.
- The maximum TSF water volume during the operational phase is approximately 3.49 M-m^3 for 99.5th percentile, and 1.62 M-m^3 for the 50th percentile results (excluding 2023 when the TSF is initially set to 2.84 M-m^3 in the model).
- During the operational phase, the volume in Springer Pit and Cariboo Pit are both decreased to empty before each freshet, and temporary storage will occur during the freshet.
- There are no overflows from the PETBP under the simulated conditions during the operational phase.

The conclusions for the modelling during closure and post-closure phases are as follows:

- The average annual treated discharge for the 50th percentile result is approximately 0.95 M-m^3.
- The TSF water volume will vary seasonally, limited by the spillway invert, to a maximum of approximately 0.25 M-m^3.
- The combined Springer-Cariboo Pit Lake is estimated to start overflowing between 2055 and 2058, with an average annual 50th percentile overflow volume of approximately 0.47 M-m^3.
- PAG material placed in the combined Springer-Cariboo Pit is estimated to be inundated and covered by the pit lake between 2033 and 2034.
- During closure, the volumes in PETBP are reduced to the minimum volume before each freshet, and temporary storage will occur during the freshet under each of the climate conditions simulated. During closure and post-closure phases, the PETBP does not have sufficient storage capacity to prevent overflow during freshet for the 99.5th percentile condition; however, these overflow volumes are included with the annual treatment requirement volumes. System modifications will occur during closure to prevent overflow of contact water requiring treatment.
- The Wight Pit is expected to initiate spilling between 2047 and 2049, with an average annual 50th percentile overflow volume of approximately 0.47 M-m^3.

4.4 Water Quality

The Site Wide Water Quality Model Report (SWWQM), developed in GoldSim for the TAR (Appendix D; Golder 2016g) and linked to the SWWBM, was updated as part of this WMP. The complete description of the model setup, inputs, assumptions, calibration and model results are presented in the Springer Expansion water quality model report (Appendix B, WSP 2023c). The objectives of the SWWQM are as follows:

- Hindcast concentrations of constituents in the influent to the WTP (i.e., water quality in the PETBP) and at other Mine facilities (i.e., CCS, Springer Pit, Cariboo Pit, 9K Sump, NW Sump, Mine Drainage Creek Sump, Bootjack Creek Sump, South Embankment Seepage Collection Pond, Main Embankment Seepage Collection Pond, TSF supernatant pond, and seepage from all ore stockpiles) for the calibration period.
- Forecast concentrations of constituents during operations, closure and post-closure as part of the permit application for the Springer Expansion LOM.

The model simulation included four time periods:

- **Calibration** (1 January 2017 to 31 December 2022) – the calibration period includes operations (1 January 2017 to 1 May 2019), care and maintenance of the Mine site (2 May 2019 to 31 October 2021) and the beginning of resumed operations (starting 1 November 2021). During the calibration period, water in the Perimeter Embankment Till Borrow Pond (PETBP) is treated at the water treatment plant (WTP) and discharged to Quesnel Lake.
- **Resumed Operations** (1 May 2023 to 31 March 2031) – the resumed operations period when, similar to the calibration period, water in the PETBP is treated at the WTP and discharged to Quesnel Lake.
- **Closure** (April 1,2031, to March 31, 2041) – a ten-year active closure period is assumed, during which potentially acid generating (PAG) stockpile material from the Temporary Northwest (NW) PAG stockpile is deposited into the Springer-Cariboo Pit and other facilities are reclaimed. The closure phase will include reclamation activities as identified in the RCP (MPMC 2022a). The WTP is assumed to be in operation through all of the closure period. Details on the closure and post-closure management of mine facilities are provided in the MPMC 2022a.
- **Post-closure** (April 1, 2041, to April 1, 2131) – this period includes filling of pits, discharge, and establishment of steady-state conditions for the drainage from mine facilities. Results are presented for two periods within post-closure:
  - Early post-closure (April 1, 2041, to March 31, 2051) – Represents the first ten years of post-closure during which drainage from Mine facilities is assumed to progressively return to undisturbed water quality. The WTP is assumed to be in operation during this period.
  - Long-term post-closure (April 1, 2051, to April 1, 2131) – this time period has been selected to represent steady-state conditions after all closure and post-closure changes have taken place. The need for treatment during long-term post-closure will be confirmed as MPMC approaches this phase and may be achieved through distributed passive or semi-passive treatment systems if required.

Uncertainty exists regarding the exact timing of these transitions. The time periods are intended to show, at a conceptual level, the difference in site drainage quality as the site progresses through the post-closure period; it is not intended to imply that the transitions will occur on precisely those dates.

4.4.1 Constituents in the Model

The constituents in the SWWQM include physical parameters, major ions, nutrients, and dissolved metals and metalloids (Table 40). The dissolved fractions of metals and metalloids are used in all mixing calculations in the model. The total concentrations of metals and metalloids are calculated by adding particulate fractions to the dissolved concentrations as described in the Particulate Addition and Total Metals section that follows the table.

Table 41: Constituents in the Site-wide Water Quality Model

Category	Constituent
Physical parameters	Total dissolved solids (calculated), hardness (calculated).
Major ions	Calcium, chloride, fluoride, magnesium, potassium, sodium, sulphate.
Nutrients	Nitrate, nitrite, total ammonia, total phosphorus.
Dissolved metals and metalloids	Aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, titanium, uranium, vanadium, zinc.

Particulate Addition and Total Metals

The process of calculating particulate fractions of constituents and total metals and metalloids concentrations was described in Appendix D of the TAR (Golder 2016g). Predictions of total metals and metalloids were calculated by adding empirical particulate fractions to the predicted dissolved metals and metalloids concentrations. Particulate fractions were calculated for two periods:

1) **Operations and Closure:** Monitoring data in the SERDS Ditch and Long Ditch between 2008 and 2023 were used to establish the empirical particulate metal concentrations during operations and closure because these facilities are expected to contribute the majority of particulate load to site flows. The model assumes that total suspended solids (TSS) will be settled to 15 mg/L during operations and closure (i.e., the maximum permitted discharge concentration) before being discharged.

2) **Post-closure:** Monitoring data from Edney Creek was used to establish the empirical particulate metal concentrations because data from this location is considered representative of undisturbed (i.e. reclaimed) surface runoff. The model assumes that TSS will be settled to 3 mg/L (i.e., the 95th percentile of TSS from monitoring data at Edney Creek from 2016 to 2022).

4.4.2 Model Set-up

The model simulated concentrations on a daily time step from January 2017 to December 2022 (calibration period), May 2023 to March 2031 (operations) and from April 2031 to March 2131 (closure and post-closure). Probabilistic climate and water quality inputs were used to run the model stochastically for 2000 simulations:

- **Climate Inputs:** The SWWQM was run with probabilistic monthly climate inputs during operations, closure and post-closure as described in Section 4.3.1.5. Monthly precipitation data in the Mount Polley Mine Climate Baseline Update (Golder 2022a) were fitted to a log-normal probability distribution. The calibration period used historical climate data for the climate inputs.

- **Water Quality Inputs:** For each realization, a unique concentration for each parameter was selected based on randomly sampled values from within a statistical probability distribution function that was derived from each input.

To interpret the results, median and 95th percentile concentrations were calculated for each Mine facility. To put the results in context, a 95th percentile prediction indicates the maximum concentration that is likely to be reached over the duration of the simulation, with a 95% likelihood that concentrations will be at or below that concentration (it does not suggest that concentrations will exceed this value 5% of the time).

4.4.3 Model Inputs

Water quality inputs in the SWWQM were derived from site monitoring data. A summary of the water quality inputs assigned to each flow in the SWWQM is presented in Table 42 and described below.

Site Water Quality Monitoring Data

Site water quality monitoring data from 2006 to 2023 (depending on the input) were used to develop water quality inputs in the SWWQM. For each constituent, water quality inputs were represented in the model by probability distribution functions. The same standardized process described in the TAR (Appendix D, Golder 2016g) was used to fit probability distribution functions to the monitoring data. A summary of the distributions selected, maximum, 95th percentile, and mean values used for each constituent, and number of samples for each water quality input are presented in in the Springer Expansion SWWQM Report (WSP 2023c).

Geochemical Source Terms

Water quality inputs derived from geochemical source terms developed by SRK Consulting Canada were applied to the SWWQM as an additional scenario in the 2016 Long Term Water Management Plan (Golder 2016). Updates to these geochemical source terms were completed by SRK consulting (SRK 2023). An alternative model scenario was completed using the geochemical source terms as water quality inputs in place of inputs calculated from monitoring data. The results of the two scenarios (using monitoring data or geochemical inputs) were compared. Consistent with the previous geochemical source terms provided by SRK for the 2016 TAR (Golder 2016g) and the 2020 WMP (Golder 2020e), the SRK inputs were considered more conservative than the monitoring data inputs and produced generally higher concentrations in the SWWQM. The results presented in this report are from the scenario that utilized the water quality inputs that were calculated from monitoring data (Section 2.6.3). The results from the geochemical source term scenario are not presented because the model predictions were considered overly conservative for most parameters and because the model was calibrated using the inputs calculated from monitoring data.

Table 42: Summary of Water Quality Inputs

Category	Description	Model Input		
		Calibration Period and Operations	Closure	Post-closure
Rock Disposal Site Contact Water	RDS Runoff to Boundary Pit	Boundary Dump Seep station water quality data (n = 70, June 2013 – July 2022)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	RDS Seepage to Boundary Pit	Boundary Dump Seep station water quality data (n = 70, June 2013 – July 2022)		
	RDS Runoff to Wight Pit	Joe's Creek Pipe station (from North Bell Dump) water quality (n = 66, August 2014 to February 2023)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	RDS Seepage to Wight Pit	Joe's Creek Pipe station (from North Bell Dump) water quality (n = 66, August 2014 to February 2023)		
	NAG Waste Rock Runoff	East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep station water quality (n = 523, May 2013 to October 2022)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	NAG Waste Rock Seepage	East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep station water quality (n = 523, May 2013 to October 2022)		
	Temporary NW PAG Stockpile Runoff	PAG Dump Seep station water quality (n = 140, May 2013 – January 2023)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	Temporary NW PAG Stockpile Seepage	PAG Dump Seep station water quality (n = 140, May 2013 – January 2023)	NAG Waste Rock: East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep station water quality (n = 523, May 2013 to October 2022)	
Pit Wall Runoff	Boundary Pit Wall Runoff	Boundary Pit station water quality (n = 16, February 2016 – July 2023)		
	Wight Pit Wall Runoff	Wight Pit (Station E10) water quality (n = 71, January 2016 – February 2023)		
	Springer Pit Wall Runoff	Springer Pit (Station E11) water quality (n = 53, January 2016 – August 2022)		
	Cariboo Pit Wall Runoff	Cariboo Pit (Station E8) water quality (n = 40, January 2016 – February 2023)		
Tailings Storage Facility	TSF Beach, Impoundment, and Embankment Runoff	TSF supernatant (Station E1a) water quality (n = 157, May 2011 to February 2023)		Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	Unsaturated TSF Seepage	TSF Main Embankment Seepage Collection Pond (Station E4) water quality (n = 144, January 2006 – February 2023)		
	Saturated TSF Seepage	Predicted concentration in the TSF		
Other	Haul Road Runoff	NAG Waste Rock: East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep station water quality (n = 523, May 2013 to October 2022)		Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	Disturbed Runoff	W4 and W5 site monitored data (n = 256, January 2014 to February 2023)		
	Undisturbed Runoff	W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)		
	Groundwater Inflow to Springer-Cariboo Pit	GW12-1/2, GW15-1/2 site monitored data		
		(n = 253, June 2013 to January 2023)		

NW Sump = Northwest Sump; MDCS = Mine Drainage Creek Sump; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond; PAG = potentially acid-generating; NAG = Non-potentially acid-generating; RDS = Rock Disposal Site; TSF = Tailings Storage Facility; SERDS = Southeast Rock Disposal Site.

4.4.4 Model Assumptions

The key assumptions that have been made in the SWWQM are:

- The input water qualities used in the SWWQM are representative of their respective input sources and will continue to be representative over the modelled timeframe. Water quality data for model inputs were selected from available lab testing and field monitoring, augmented by professional judgement where necessary.
- Concentrations of parameters from monitoring data that were lower than the analytical detection limit were set equal to half the detection limit.
- Concentrations of parameters in direct precipitation onto the water surface of water management facilities were assumed to be zero. No mass was removed or added to modelled systems through evaporation or direct precipitation. These processes affected water quantity only and did not affect mass of modelled parameters in the system.
- All open pits, ponds, and sumps are fully mixed systems. No stratification is considered over the modelled timeframe. All inputs are mixed with existing water volumes to calculate concentrations of parameters.
- All parameters are assumed to behave conservatively. That is, they are assumed to not settle, precipitate, sorb, degrade, or undergo any other process that would reduce concentrations. This assumption is likely to have negligible effects on major ion predictions but may lead to over-estimation of some nutrients and metals.
- All PAG waste rock will be disposed sub-aqueously in the Springer-Cariboo Pit at closure to mitigate onset of acid generation. Acid generation is not expected to occur prior to subaqueous disposal, and disposal in the Springer-Cariboo Pit Lake will prevent acid onset in the future by limiting oxidation in the waste rock. Geochemical characterization studies estimate the time to the onset of acid generation varies between decades and 100 years (MPMC 2022a).
- The combined Springer-Cariboo Pit is assumed to be empty at the start of closure.
- Rock disposal sites (RDS) are assumed to be reclaimed in post-closure. Following revegetation, the runoff from these facilities is assumed to return to undisturbed runoff quality over the course of ten years.
- Diffusive flux from the submerged PAG waste rock into the Springer-Cariboo Pit Lake water cap was not modelled.
- Accumulation and flushing of oxidation products from weathered PAG material prior to subaqueous disposal was not modelled.
- Ice formation and melting were not considered in pits, ponds, and ditches that retain water.

4.4.5 Model Calibration

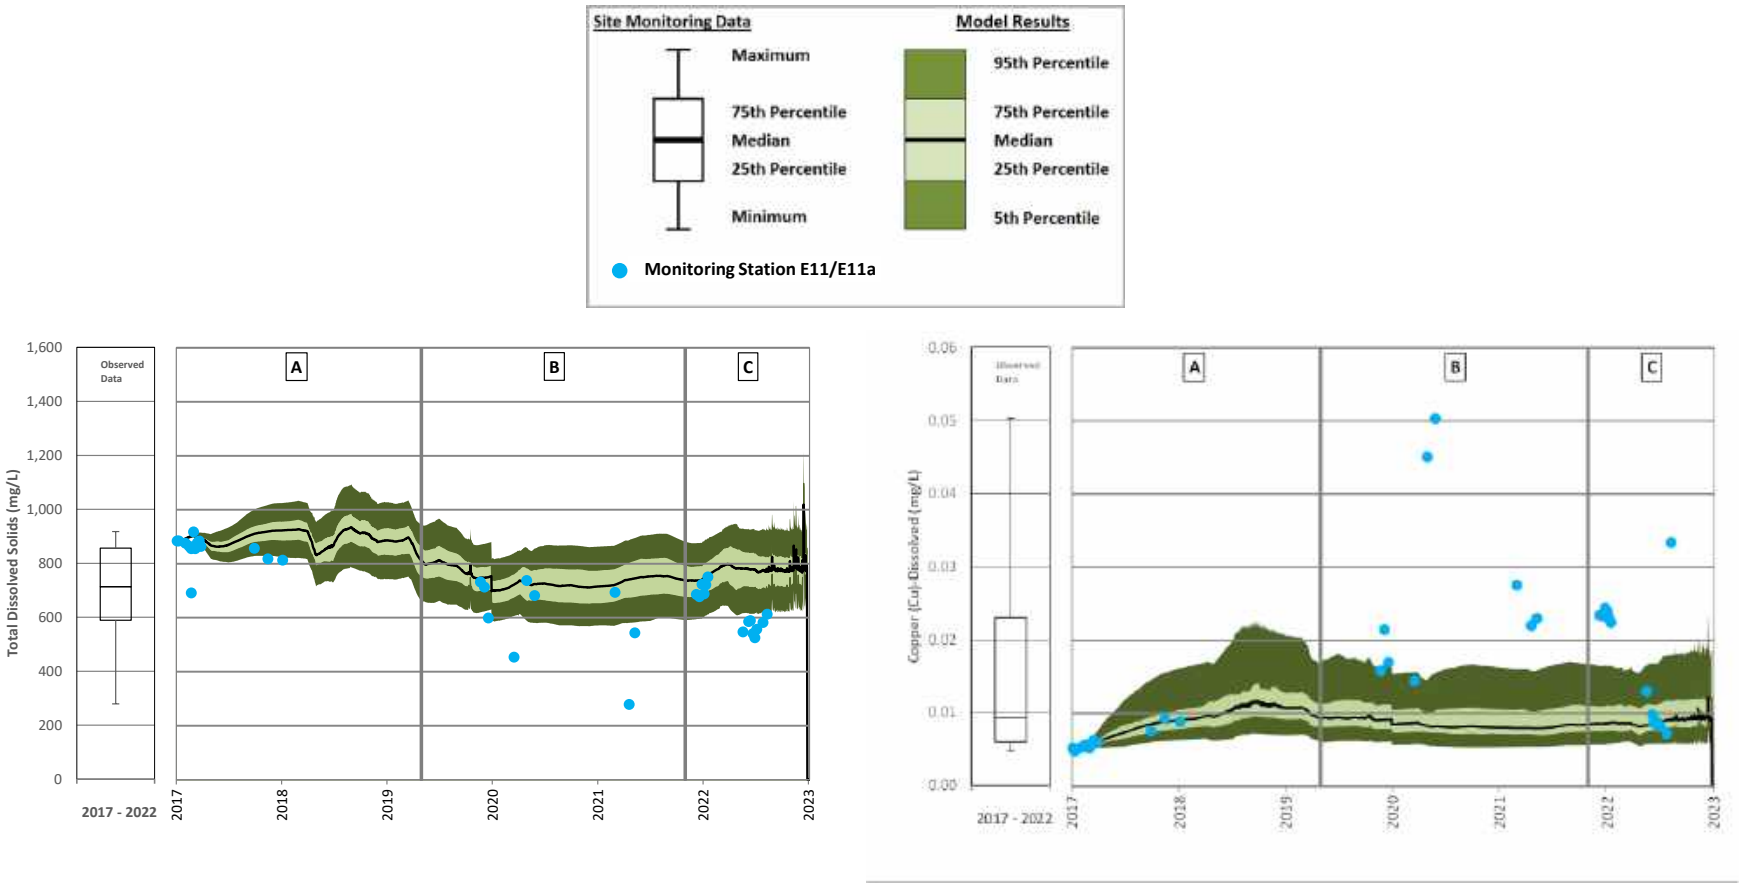
The SWWQM was set up to hindcast concentrations from January 1, 2017, to December 31, 2022, at seven locations:

- Springer Pit
- Cariboo Pit
- Wight Pit
- CCS
- PETBP
- TSF
- NW Sump

Where discrepancies between model results and monitoring data existed, the model was adjusted to better reflect monitoring data. The same adjustments, made during calibration of the SWWQM in the 2020 Water Management Plan (Golder 2020e) and during the calibration of the SWWQM in the 2022 Reclamation and Closure Plan (MPMC 2022a), were maintained in this update to achieve calibration with monitoring data:

- Adjusting the proportion of Wight Pit runoff and groundwater inflows that are assigned a waste rock contact water input based on storage of waste rock in the pit.
- Adjusting the proportion of runoff from waste rock that is assigned an undisturbed water quality input.
- In the TSF, applying calibration factors greater than 1.0 to improve the model calibration for chloride, fluoride, potassium, sodium, nitrite, dissolved antimony, dissolved arsenic, dissolved barium, dissolved lithium, dissolved molybdenum, and dissolved vanadium. These calibration factors are applied during periods when tailings are deposited to the TSF.

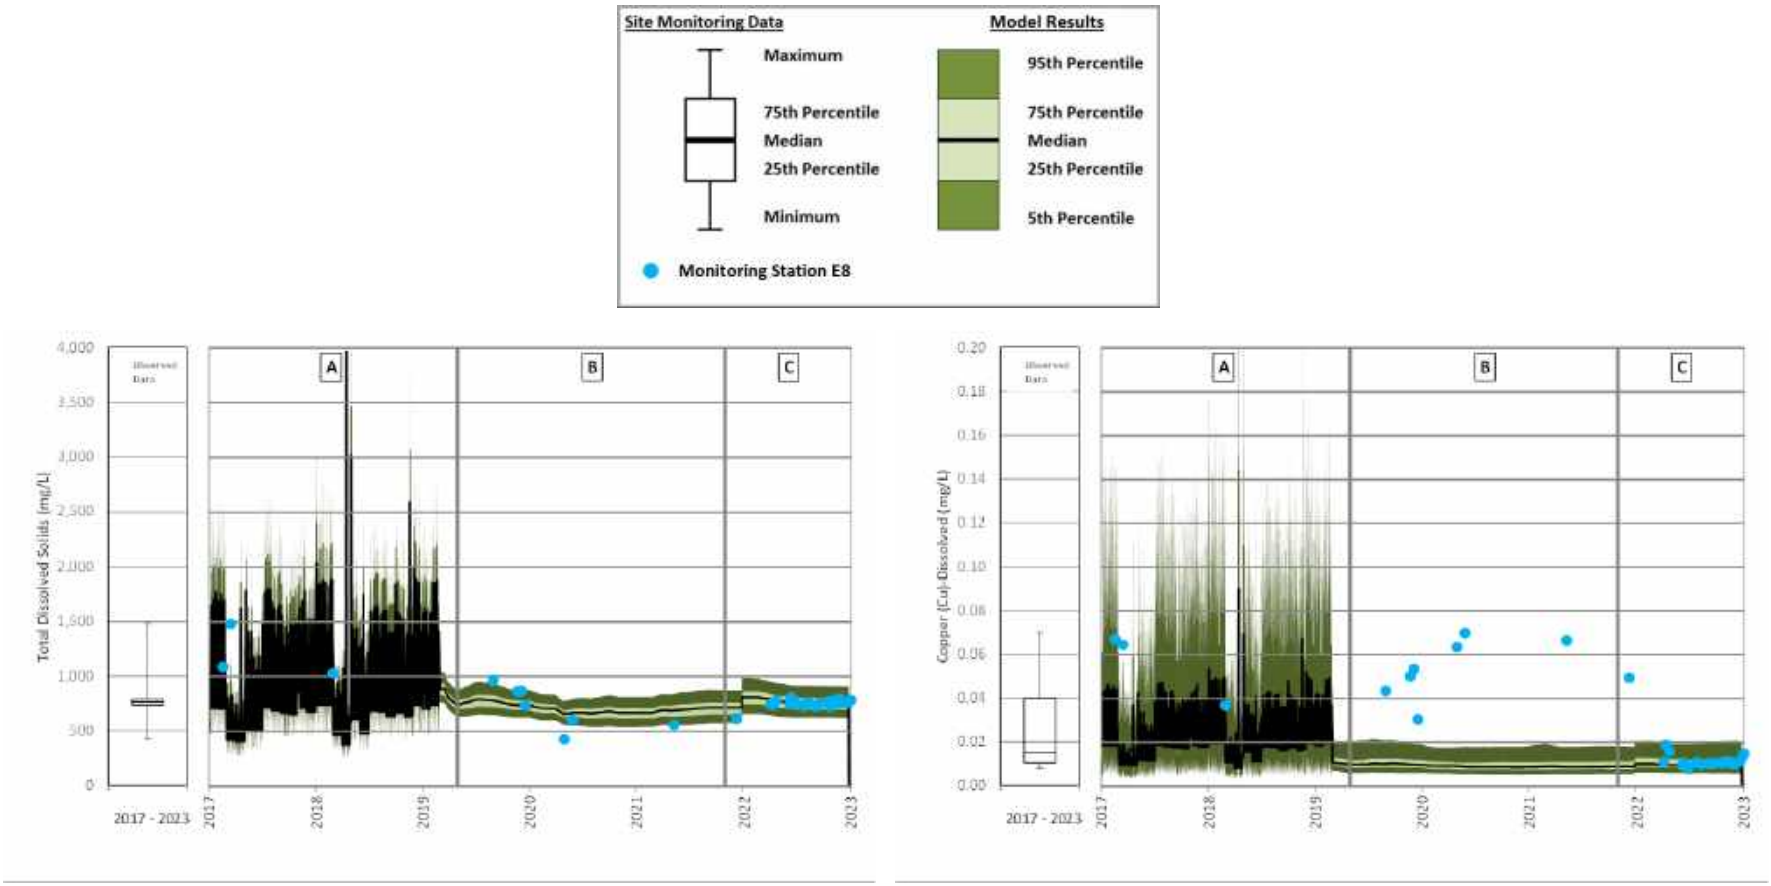
Calibration Results



Model calibration results are shown compared to monitoring data for total dissolved solids and dissolved copper in Figure 23 through Figure 29. Model calibration results for all parameters and locations are provided in the Springer Pit Expansion SWWQM Report (Appendix B, WSP 2023c). Monitoring data were generally between the projected 5th and 95th percentile model calibration results for all parameters. However, several parameters (e.g., dissolved copper) were underpredicted during periods in 2018, 2020, and 2021. The source of the increased concentrations in the monitoring data for these parameters is thought to be due to the discharge of leachate to the TSF from the onsite test heap leach facility (Golder 2022f). These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process.

Where monitoring data fell within the 5th and 95th percentile model calibration results, the model was considered to be in good agreement with monitoring data. The good agreement indicates that model inputs were well characterized and that these parameters had low sensitivity to assumptions or model conditions not matching site conditions.

Where monitoring data were consistently below the 5th percentile predictions, the model was considered to be over predicting concentrations. Possible reasons why the model may be over-predicting concentrations are:



- The model was developed to predict water quality conservatively; where uncertainty exists in model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected. For example, seepage from RDSs was assigned a NAG water quality for the entire model simulation period, which is a conservative assumption.
- Metal concentrations that are far below detection limits may be skewed upward by model inputs where half-detection limits were applied.
- Settling of particulate material is not accounted for in the model.
- Geochemical processes, such as precipitation and adsorption, are not accounted for in the model.

Although these factors may lead to over-prediction of concentrations, the model is considered valid for the purpose of predicting concentrations of parameters on the Mine and in the influent to the WTP because deviations in model predictions from monitoring data in this category tend toward additional environmental protection.

A = Operations; B = Care and Maintenance; C = Resumed Operations.

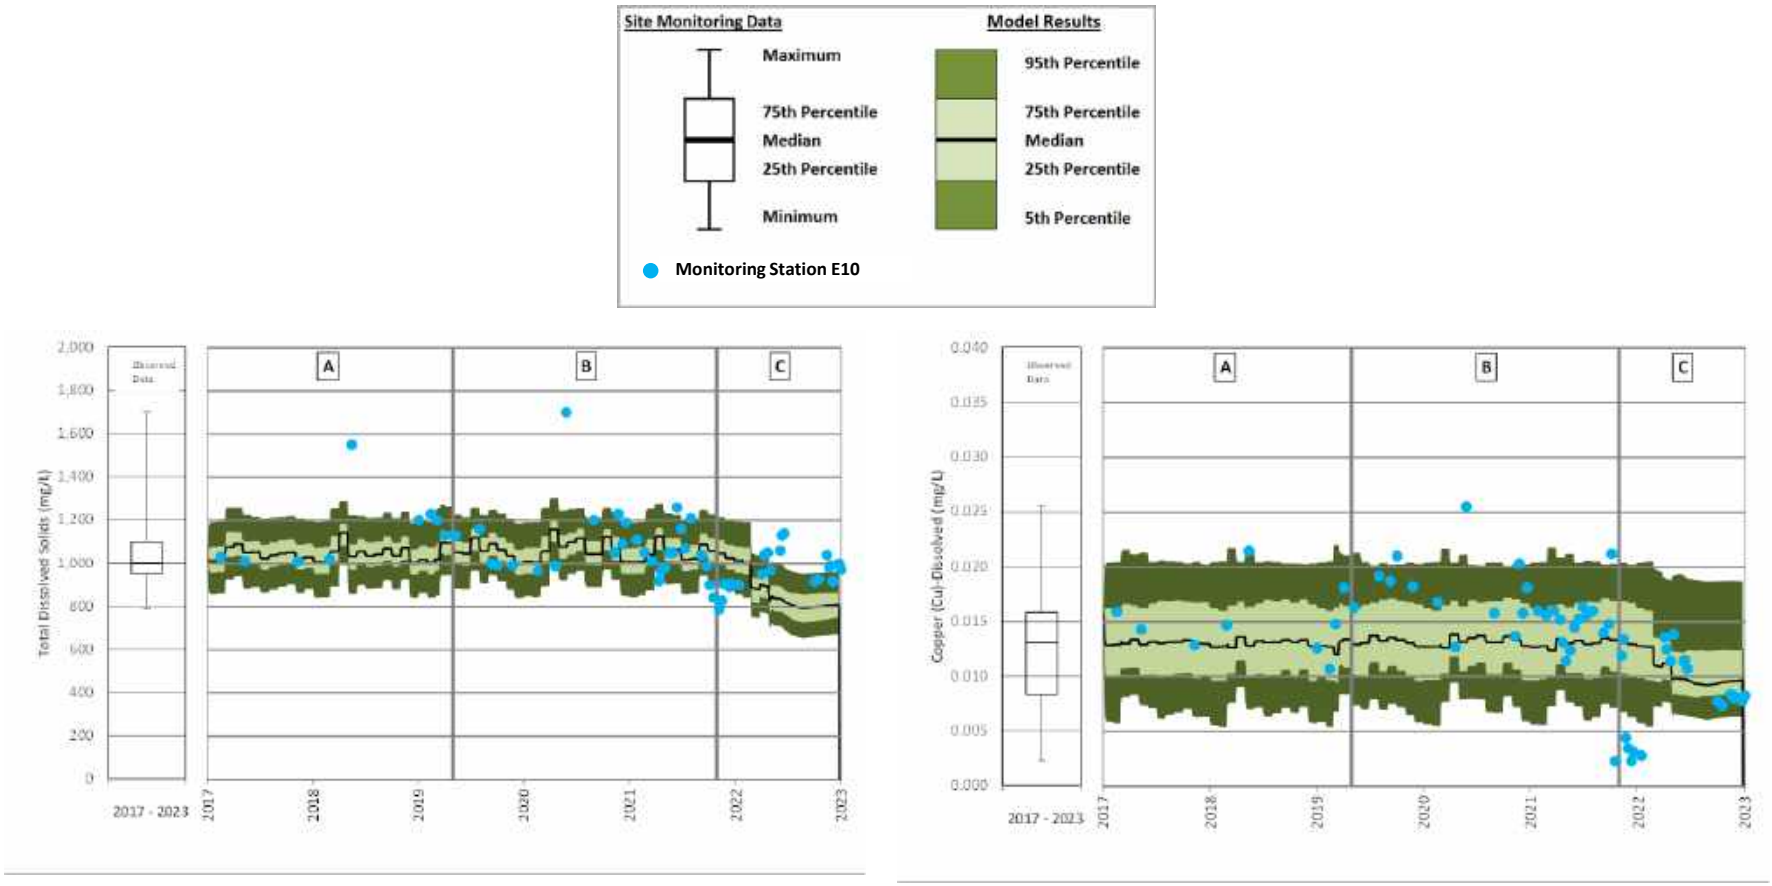


Figure 23: Springer Pit Calibration – Total Dissolved Solids and Dissolved Copper

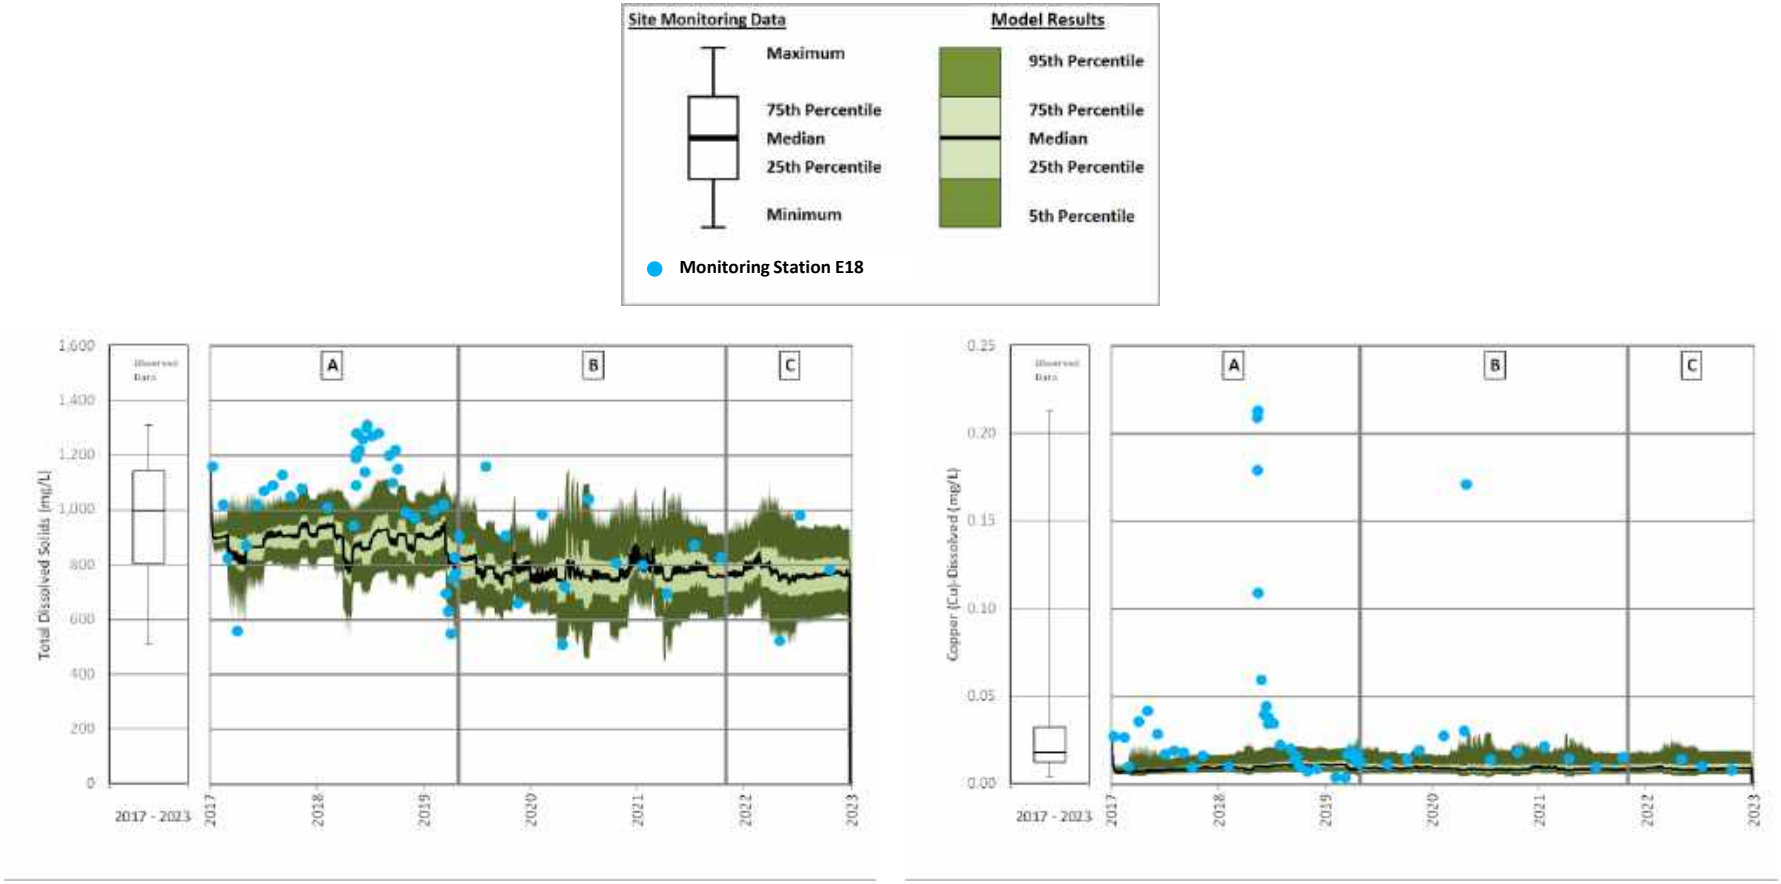
A = Operations; B = Care and Maintenance; C = Resumed Operations.



Note(s): Cariboo Pit is a flow-through system from the beginning of the model simulation to March 2019, which results in a wide range in predicted concentrations. After March 2019, Cariboo Pit stores water, which reduces the range in predicted concentrations. The source of increased copper concentrations in 2019, 2020 and 2021 monitoring data is due to the discharge of leachate from the onsite test heap leach facility to the TSF, which is then pumped to Cariboo Pit). These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process (Golder 2022a).

A = Operations; B = Care and Maintenance; C = Resumed Operations.

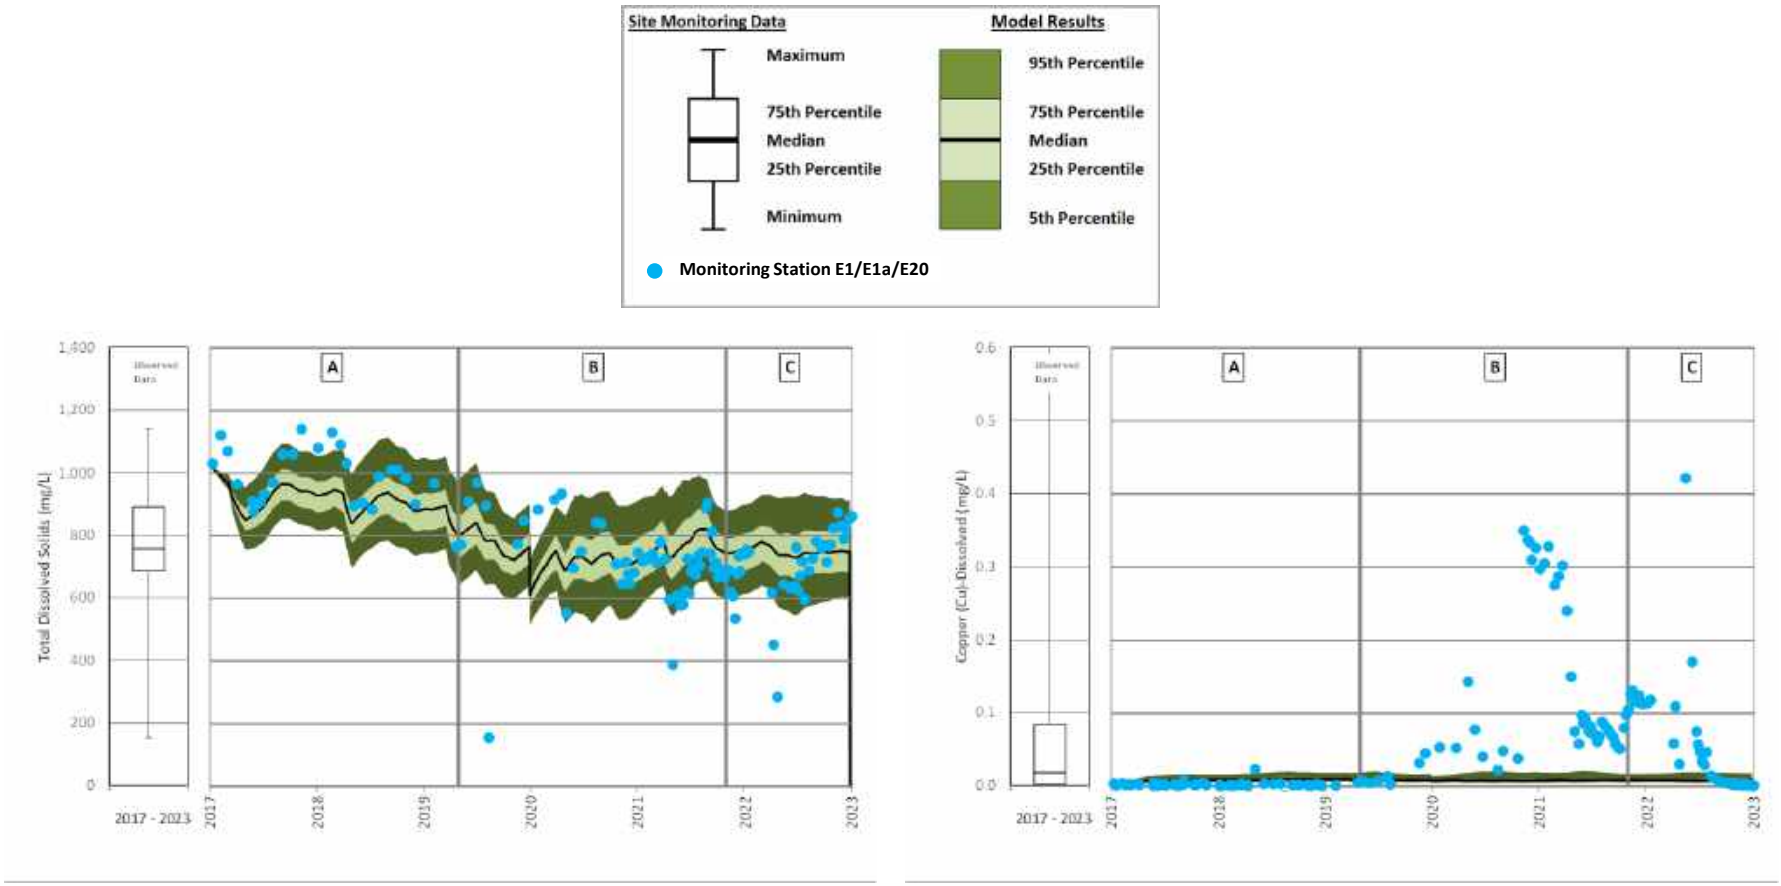

Figure 25: Wight Pit Calibration – Total Dissolved Solids and Dissolved Copper

A = Operations; B = Care and Maintenance; C = Resumed Operations.

Note(s): The source of increased dissolved copper concentrations in the Central Collection Sump 2018 monitoring data is due to discharge of leachate from the onsite test heap leach facility to the TSF, which is then pumped to the CCS. These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process (Golder 2022a).

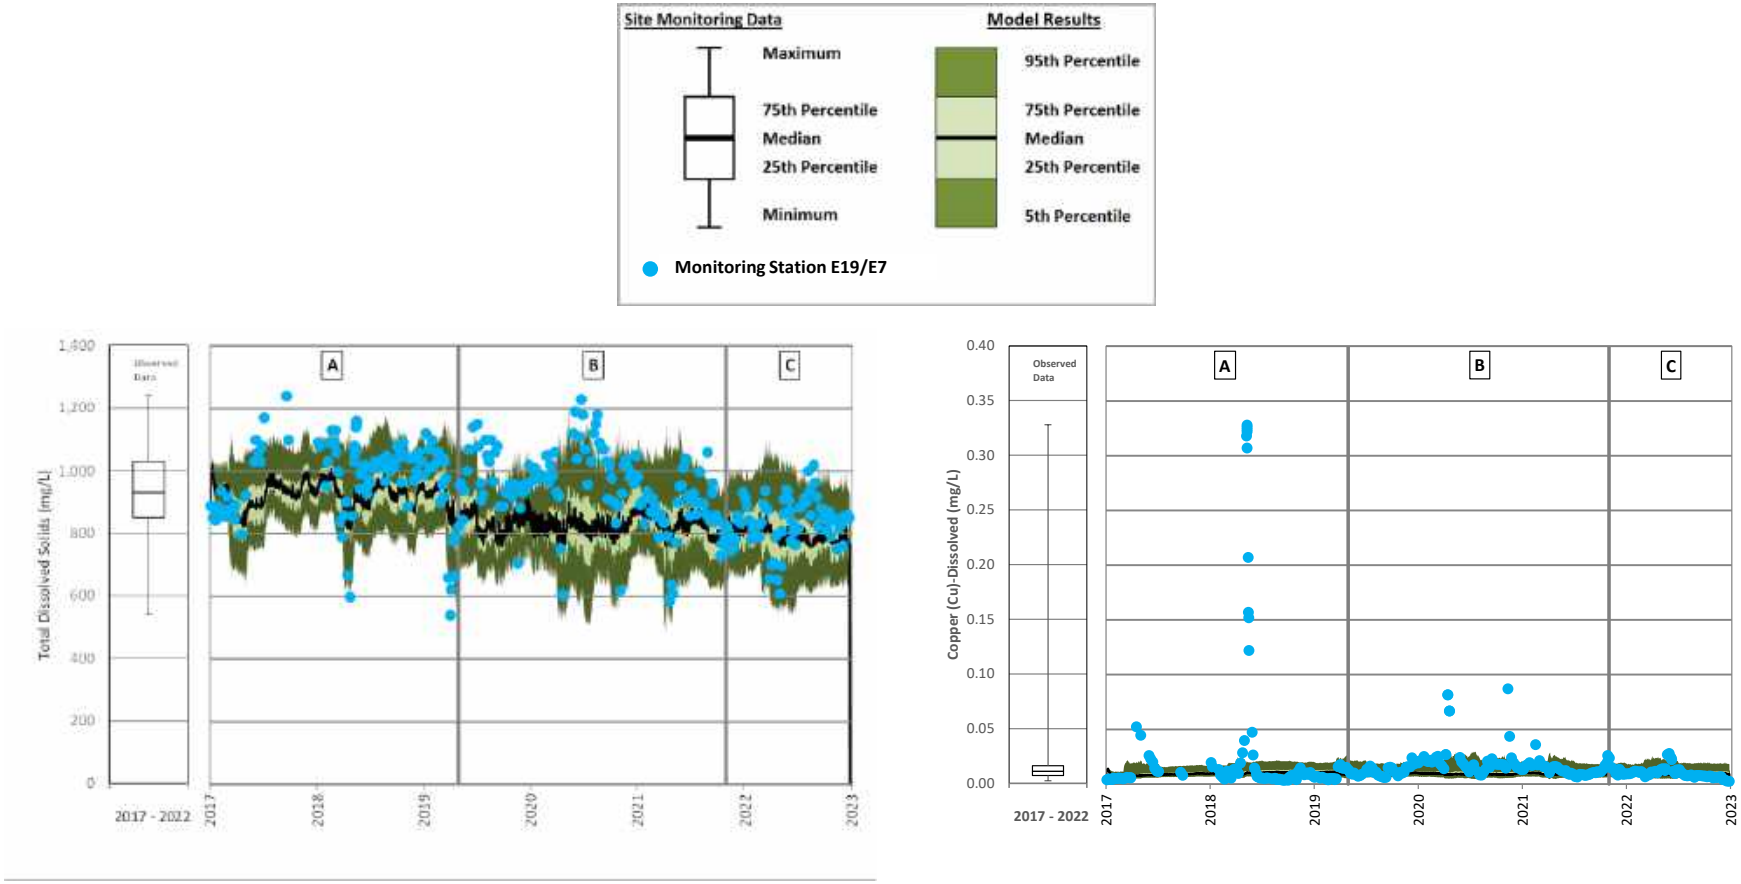

Figure 26: Central Collection Sump Calibration – Total Dissolved Solids and Dissolved Copper

A = Operations; B = Care and Maintenance; C = Resumed Operations.

Note(s): The source of increased copper concentrations in 2018 and from 2020 to 2022 in the monitoring data of the Tailings Storage Facility (TSF) is due to the discharge of leachate to the TSF from the onsite test heap leach facility. These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process (Golder 2022a).

Figure 29: Northwest Sump – Total Dissolved Solids and Dissolved Copper

4.4.6 Model Simulation

After the model calibration was completed, model simulations were performed for the following periods:

- Operations (January 1, 2024, to March 31, 2031)
- Closure (April 1, 2031, to March 31, 2041)
- Post-closure (April 1, 2041, to April 1, 2131)

For most parameters, peak concentrations of parameters occur in operations or closure. Concentrations decrease during closure and post closure as Site areas are reclaimed. Runoff inflows from reclaimed areas are assigned the undisturbed runoff water quality input. Some parameters (for example, dissolved aluminum and dissolved chromium) increase in concentration from operations to closure and post-closure because the statistical distributions assigned to undisturbed runoff water quality have higher concentrations than the statistical distributions assigned to the contact areas of the Site (disturbed runoff areas, TSF beach runoff areas, NAG waste rock areas and PAG waste rock areas).

The following sections present time series of predicted concentrations of several key parameters (copper and selenium) for the PETBP, the Springer-Cariboo Pit Sump, Wight Pit and Long Ditch (which receives contact water from the SERDS). Maximum of median and 95th percentile predicted concentrations are presented for all modelled parameters in these locations. Time series and maximum concentrations for all modelled parameters and locations are presented in the SWWQM report (Appendix B).

4.4.6.1 Perimeter Embankment Till Borrow Pond

During operations, closure and the first ten years of post-closure, the PETBP is the assumed influent water to the WTP, which discharges to Quesnel Lake. Maximum of the daily median and maximum of the daily 95th percentile concentrations in the PETBP are presented in Table 42. Time series for predicted copper and selenium concentrations in the PETBP are presented in Figure 30.

In general, concentrations in the PETBP are predicted to remain relatively consistent during operations until the end of pumping from the mill processing plant in 2031. This consistency is due to the assumption that the entire surface areas of the RDS are accounted for at the beginning of the model simulation. Therefore, the runoff and seepage volumes from the RDS do not change. Changes in predicted concentrations in the PETBP are due to:

- Variable pumping from the TSF to the Mine Drainage Creek Sump (MDCS) during operations. During periods when the TSF is pumped to the MDCS, concentrations of most parameters increase in the MDCS. Concentrations decrease in the MDCS when there is no pumping from the TSF. Changes in MDSC water quality reach the PETBP through the pathway connecting the MDCS to the PETBP:
  - TSF → MDCS → SERDS Ditch → Long Ditch → CCS → PETBP.
- Surface runoff at the mine site causes fluctuations in concentrations depending on the proportions of the catchment areas flowing into the facilities (e.g., RDS areas, disturbed areas, undisturbed areas). Parameter concentrations reach steady-state during the winter months because surface runoff is low.

Discharge from the PETBP may be directed to Hazeltine Creek in closure if distributed discharge can be achieved. This discharge may also include overflow and seepage from the TSF, as well as runoff from surrounding catchment areas of the PETBP, TSF, and CCS.

Predicted concentrations in the PETBP change from operations to closure and into early post-closure because of the staggered reclamation of the TSF beach and impoundment areas which are then assigned an undisturbed water quality once the areas are reclaimed. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows to the PETBP. In closure and post-closure, concentrations in the PETBP follow two patterns:

1) Decrease from operations because the statistical distributions assigned to undisturbed runoff water quality have lower concentrations than the statistical distributions assigned to the TSF beach runoff and the NAG waste rock runoff quality (e.g., sulphate, nitrate and dissolved copper).

2) Increase from operations because the statistical distributions assigned to undisturbed runoff water quality have higher concentrations than the statistical distributions assigned to the TSF beach runoff and the NAG waste rock runoff quality (e.g., total phosphorus, dissolved chromium and dissolved iron).

Predicted concentrations in the PETBP reach a steady state approximately 10 years after the start of post-closure when all mine site areas have been reclaimed.

(a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure.

Note(s): The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 30: Predicted Dissolved Copper and Dissolved Selenium Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

4.4.6.2 Springer-Cariboo Pit

At closure, the PAG material from the Temporary NW PAG Stockpile will be placed in the Springer-Cariboo Pit, and a pit lake will form. The pit will fill passively with groundwater and surface runoff from the pit catchment area. The groundwater inflow to the pit is assumed to flow into the stored PAG material in closure and post-closure. The surface runoff includes runoff and seepage from North Bell RDS, East RDS, and the haul roads. These facilities will be reclaimed during closure. The pit lake is predicted to completely fill between 2059 (99.5th percentile of the 2000 water balance model simulations) and 2063 (mean of the 2000 water balance model simulations), at which point, overflow from the pit will discharge to Bootjack Lake.

Maximum of the daily median and maximum of the daily 95th percentile concentrations in the Springer-Cariboo Pit are presented in Table 43. Time series for predicted copper and selenium concentrations in the Springer-Cariboo Pit are presented in Figure 31. Peak concentrations for most parameters are predicted to occur during the closure period because:

- The PAG material in the Springer-Cariboo Pit contains pore water with a NAG Seep water quality.
- The groundwater inflow to the pit, which has a groundwater water quality (Table 24), is assumed to flow into the PAG material and displace the pore water upwards into the forming pit lake.
- The displacement of pore water from the PAG material into the pit lake causes pit lake concentrations to peak in closure.

The only parameters with predicted maximum concentrations greater in post-closure than closure are aluminum, chromium, iron, and lead. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to a greater proportion of the total inflows to the Springer-Cariboo pit.

(a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure.

Note: The change in concentrations during closure and post-closure is caused by reclamation of mine site areas and the filling of the combined Springer-Cariboo Pit.

Figure 31: Predicted Dissolved Copper and Dissolved Selenium Concentrations in the Springer-Cariboo Pit – Operations, Closure and Post-closure

4.4.6.3 Wight Pit

Towards the last year of operation, the TSF water volume will be progressively reduced to a maximum of 0.25 M-m^3. During that time and continuing into closure, the Wight Pit will be used to store excess water. During post-closure, Wight Pit will no longer be used for storage and will be allowed to fill. A pit lake will form in Wight Pit as the mined-out pit refills passively with groundwater, seepage from Boundary Pit, surface runoff from pit walls, disturbed areas, and haul roads in the Wight Pit catchment. Wight Pit is projected to start overflowing in 2048 under the mean results and in 2046 under 99.5th percentile, at which point overflow will be directed to Polley Lake. Reclamation of the disturbed areas and haul roads is assumed to occur during closure. Runoff water quality from these facilities is predicted to return to undisturbed water quality.

Maximum of the daily median and maximum of the daily 95th percentile concentrations in Wight Pit are presented in Table 44. Time series for predicted copper and selenium concentrations in the Wight Pit are presented in Figure 32.

Predicted concentrations of parameters in Wight Pit are generally stable 10 years after the start of post-closure. Concentrations of most parameters decrease slightly through early post-closure after the pit has filled and is flushed with runoff from reclaimed disturbed areas and haul roads in the Wight Pit catchment area.

Some parameters are predicted to have higher concentrations in post-closure than closure (for example, dissolved copper). The increase in concentration for these parameters is caused by either:

a) Higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows into Wight Pit.

b) Increased proportions of the total inflows to Wight Pit from pit wall runoff that is assigned the Wight Pit wall runoff during post-closure.

(a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure.

Note(s): The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 32: Predicted Dissolved Copper and Dissolved Selenium Concentrations in the Wight Pit – Operations, Closure and Post-closure

4.4.6.4 Long Ditch

In closure, the Long Ditch continues to receive flow from the SERDS Ditch and overflow from Bootjack Creek Sump (via SERDS Ditch). Discharge from the Long Ditch is assumed to be directed to Polley Lake during post-closure. The combined catchment area for the Long Ditch, the SERDS Ditch, and Bootjack Creek includes the SERDS RDS, NEZ RDS, and East RDS along with haul roads, disturbed areas, and undisturbed catchment area. Tailings co-disposal to the SERDS location will include a soil cover during closure that will remediate runoff from the tailings deposition area to that runs off to SERDS Ditch. However, seepage water quality from the SERDS tailings are assumed to remain unchanged through closure and post-closure. The proportion of seepage assigned tailings water quality is calculated based on the total proportions of tailings relative to waste rock deposited (3.5% tailings and 96.5% waste rock; (MPMC 2022b).

Maximum of the daily median and maximum of the daily 95th percentile concentrations in Long Ditch are presented in Table 45. Time series for predicted copper and selenium concentrations in the Long Ditch are presented in Figure 33.

Peak concentrations in Long Ditch are predicted to occur during operations, representing runoff and seepage from un-reclaimed RDS areas within the combined catchment area for the Long Ditch, the SERDS Ditch, and Bootjack Creek. These facilities are reclaimed throughout closure, at which point runoff is assigned undisturbed water quality. Most parameter concentrations in Long Ditch are predicted to decrease through closure, reaching steady state conditions 10 years after the start of post-closure.

Seasonal peak concentrations in winter are driven by seepage from the RDS area within the watershed which is assigned the NAG water quality in perpetuity. During winter months, when precipitation occurs as snowfall, RDS seepage represents a higher proportion of the total flow to the Long Ditch and causes concentrations to peak.

Some parameters are predicted to have higher concentrations in post-closure than closure. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows into Bootjack Creek Sump, SERDS Ditch, and Long Ditch which causes concentrations of some parameters, such as aluminum, to increase.

(a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure.

Note(s): The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 33: Predicted Dissolved Copper and Dissolved Selenium Concentrations in the Long Ditch – Operations, Closure and Post-closure

4.5 Description of Discharge Options Inventory

4.5.1 Restoration of Watercourses

There are few ecologically productive watercourses that have been changed as a result of mining activity. Hazeltine Creek and a lower portion of Edney Creek were changed extensively as a result of the August 2014 foundational failure and resulting TSF breach. The restoration of those watercourses began to take place as soon as safe access was possible following that breach. Historical changes to the natural drainage patterns occurred well before the Mount Polley Mine was developed. Bootjack Creek drainage and Hazeltine Creek drainages were modified to support hydraulic placer mining.

The primary driver behind watercourse restoration at Mount Polley is aquatic productivity / productive capacity of aquatic habitats, rather than the use of a watercourse as a discharge conveyance system [1]. However, some amount of flows within Hazeltine Creek could potentially augment the amount of habitat available, particularly during seasonally dry periods (e.g., August). Currently, the weir at the confluence of Hazeltine Creek and Polley Lake is being used to mute the peak flows and to provide flow nourishment to Hazeltine Creek.

Other streams affected by mine development include Bootjack Creek and Mine Drainage Creek. MPMC has determined that Bootjack Creek cannot maintain its current alignment while still functioning as fish habitat. Impacts to Bootjack Creek will be addressed through the development of offset habitat in accordance with Fisheries and Oceans Canada's fish habitat policy. Mine Drainage Creek is currently captured as contact water in Mine Drainage Creek sump and pumped to the west ditch for management and treatment. However, rainbow trout spawning was recorded previously in the lower reach of the creek (~25 m upstream of Bootjack Lake), and restoration of this watercourse could be considered as part of future planning.

Should additional drainages need to be constructed at closure, they will be constructed with the objective of developing those watercourses as aquatic habitats where feasible. Feasibility evaluations will include the stream gradient, access and connectivity to other habitats, habitat enhancement objectives, stream bed characteristics (i.e., the stream bed must be capable of maintaining surface water) and the cost to construct as a habitat. Where it is not feasible to construct a drainage feature as an aquatic habitat, hydraulic engineering design principles (Chow 1959) will be used to provide drainage features that are built to sustain themselves without maintenance following closure. The details of such drainages will be identified as closure designs are developed in advance of the mine going into closure.

4.5.2 Watercourses Available to Receive Discharge

Over 2015 and 2016, Golder assessed the capacity of the following receiving environments around the Mine to receive treated effluent discharge (Golder 2015a, Golder 2016b, Appendix G of the TAR – Golder 2016g):

- Polly Lake outlet
- Hazeltine Creek at the mouth
- Bootjack Lake outlet
- Edney Creek at the mouth
- Quesnel River at Likely

[1] Note: Prior to Hazeltine Creek being made accessible to fish, it was temporarily used to convey treated water flows to Quesnel Lake while the current pipeline and diffuser were being constructed.

Based on the far-field volumetric dilution values for the mean seven-day low flow condition, concentrations of constituents in the treated effluent discharge were calculated such that concentrations at the potential effluent discharge locations would meet WQGs. The concentrations of constituents in the treated effluent discharge to meet WQGs were compared to monitoring data at station HAD-3 to determine if additional water treatment would be required.

Based on median concentrations from monitoring data, additional water treatment would be required to meet WQGs for several constituents (sulphate, nitrate, nitrite, dissolved aluminum, dissolved copper, and total selenium) if considering discharge to the receiving environments listed above.

In Golder (2016g), two potential discharge locations were presented for long-term discharge at the mine in operations:

- Pipeline to Quesnel River
- Pipeline to Quesnel Lake

Based on the hydrologic and chemical assimilative capacities of potential receiving environments, a pipeline to Quesnel Lake was ranked to provide the best assimilative capacity for discharge from the Mount Polley Mine during operations. A pipeline from the WTP to Quesnel Lake was constructed, including submerged diffuser at the pipeline terminus, to convey treated mine contact water to this selected receiving environment. This discharge location remains as the single permitted discharge location for the mine, which is anticipated to continue through operations and potentially into closure/post-closure.

A detailed description of this receiving environment assessment and results are provided in the 2020 Water Management Plan (Golder 2020e) and not duplicated in full here.

4.6 Water Treatment

This section provides details regarding water treatment for the Mine to identify the design basis for current (operations) and potential future (closure/post-closure) water treatment options. This section also provides updates on the progression of water treatment technology development.

4.6.1 Design Basis

The flows and associated water quality that require treatment during the operational and closure periods are described in this section and form the design basis for the current treatment system and the design basis for identification of water treatment technologies for closure.

Flow Rate

Operations

The treatment flow rate of the existing WTP varies between approximately 0.21 m^3/s and 0.31 m^3/s, pending operator control of the plant. The allowable maximum annual discharge volume from site is currently 10.59 M-m^3/year (average of 0.33 m^3/s), as per EMA Permit 11678. The design capacity of the WTP effluent pipeline and diffusers is 0.6 m^3/s (equivalent to the permitted maximum daily instantaneous rate).

The SWWBM has assumed a maximum WTP treatment capacity of 0.29 m^3/s for modelling purposes and this flow rate results in sufficient treatment of all contact water required for discharge from Site for the predicted operations period (WSP 2023a). The SWWBM has predicted that the 50th percentile average annual treated water discharge from Site is 3.72 M-m^3 during operations (average of 0.12 m^3/s). Stochastic results from the SWWBM were also used to predict 90th percentile annual volume requirements for treated water discharge during operation, resulting in an annual average volume of 4.64 M-m^3 (average of 0.15 m^3/s) Given these volume predictions and the modelled WTP capacity, the treatment capacity of the existing WTP has been assumed sufficient for the remainder of the LOM operations period.

Closure and Post-closure

For closure and post-closure, the SWWBM was again used to predict annual treatment volumes for the period of 2031 to 2131. For the closure period of 2031 to 2041, results showed an annual average treatment volume of approximately 5.50 M-m^3 for 50th percentile climate conditions and 6.53 M-m^3 for the 90th percentile climate conditions, which results in an average treatment flow rate of 0.17 m^3/s and 0.21 m^3/s, respectively (WSP 2023a). For the post-closure period of 2041 to 2131, results showed an annual average treatment volume of approximately 0.80 M-m^3 for 50th percentile climate conditions and 1.16 M-m^3 for the 90th percentile climate conditions, which results in an average treatment flow rates of 0.03 m^3/s and 0.04 m^3/s, respectively.
The treatment flow rate design basis is selected as the 90th percentile average requirement of 0.21 m^3/s during closure and 0.04 m^3/s during post-closure.

The combined Springer-Cariboo Pit and Wight Pit are both modelled to become pit lakes during post-closure and are assumed to fill and overflow directly to the environment without treatment. Overflow is predicted to occur between 2047 and 2049 for Wight Pit and between 2055 and 2058 for Springer-Cariboo pit. Annual overflow volume from these pits is predicted to be 0.62 M-m^3 for Wight Pit and 1.05 M-m^3 for Springer-Cariboo Pit for the 90th percentile climate scenario. Water quality and treatment requirements for pit overflow water is discussed in the closure/post-closure water quality section. If overflow from both pits is included in the annual treatment volume, then the design basis for water treatment during post-closure would increase to 0.09 m^3/s.

Water Quality and Targets

Operations

The SWWBM was used to predict water quality at the PETBP during operations (the current influent source to the WTP). Table 46 provides a list of constituents of interest determined following review of modelled water quality predictions during operations (WSP 2023c). Table 46 compares the current EMA Permit 11678 WTP discharge limits with the predicted 95th percentile parameter concentrations in the PETBP.

Table 47: Predicted Water Quality Concentrations and Permit Limits for Treatment During Operations

Parameter	Unit	EMA Permit 11678 WTP Discharge Limit	PETBP – Maximum of 95th Percentile Predicted Concentrations
Major Ions			
Total Sulphate	mg/L	1,100	681
Nutrients			
Total Ammonia	mg/L (as N)	1.30	0.06
Total Nitrate	mg/L (as N)	34	23
Total Phosphorus	mg/L	0.09	0.03

Table 47: Predicted Water Quality Concentrations and Permit Limits for Treatment During Operations

Parameter	Unit	EMA Permit 11678 WTP Discharge Limit	PETBP – Maximum of 95th Percentile Predicted Concentrations
Total Metals			
Arsenic	mg/L	0.028	0.003
Chromium	mg/L	0.004	0.001
Copper	mg/L	0.033	**0.190**
Iron	mg/L	1.00	0.58
Manganese	mg/L	3.4	0.26
Molybdenum	mg/L	0.36	0.28
Selenium	mg/L	0.075	0.074
Zinc	mg/L	0.059	0.019
Dissolved Metals			
Cadmium	mg/L	0.00034	**0.00036**
Copper	mg/L	No EMA Permit Limit	0.030

Note(s): **Bold and underlined** values exceed permitted discharge limits. These EMA Permit 11678 discharge limits apply to the effluent of the WTP, and not to the PETBP (WTP influent). PETBP water quality predictions are shown to demonstrate the requirement for treatment of a water quality parameter. The SWWBM was developed to predict water quality conservatively; where uncertainty exists in the model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected.

Table 46 shows that total copper and dissolved cadmium are predicted to require treatment during operations. Total Suspended Solids (TSS), not listed in Table 46, is also required for treatment during operations. The existing WTP has been shown to effectively treat TSS for historical operating conditions (discussed in more detail in Golder 2022b). WTP influent and effluent quality were assessed over six years between 2016 and 2021, showing effluent TSS consistently below permit limit (Golder 2022b).

The existing WTP has been able to effectively treat total copper for the majority of historic operating conditions, as demonstrated in Figure 34, which shows total copper concentration in the WTP influent and effluent over the period of 2016 through 2023. Also shown in the figure is the total copper EMA permit limit for the WTP effluent (0.033 mg/L). The SWWQM predicted maximum of the 95th percentile concentration for total copper of 0.190 mg/L in the WTP influent shown in Table 46 is a conservative prediction and the average WTP influent total copper illustrated in Figure 34 is significantly lower at a value of 0.025 mg/L (between 2016 and 2023). Figure 34 shows that the existing WTP is able to maintain WTP effluent total copper below the permit limit with only occasional occurrences of total copper above the permit limit. These occurrences are managed by halting WTP discharge and temporary WTP recirculation until copper concentration is below permit limit. This process is managed through MPMC's Trigger Response Plan, further discussed in Golder 2022b.

There is one instance of high historic total copper that is not seen on Figure 34 due to the axis limits in the figure. In May 2018, specific conditions occurred on-site to produce a WTP influent total copper concentration of 0.933 mg/L. The Trigger Response Plan was initiated for this occurrence to manage the high copper instance. This particular event is an outlier occurrence and is further discussed in Appendix B (Section 3.1) when discussing total copper model predictions.

A full record of the tabulated Figure 34 monitoring data is not provided due to the number of records; however, statistics of the monitoring data are provided in Table 48.

The EMA Permit also includes a Numeric Performance Metric (NPM) for total copper at a value of 0.012 mg/L (annual average). The existing WTP is able to meet this NPM, and the annual average of total copper in the WTP effluent during 2022 and 2023 was 0.012 mg/L and 0.010 mg/L, respectively.

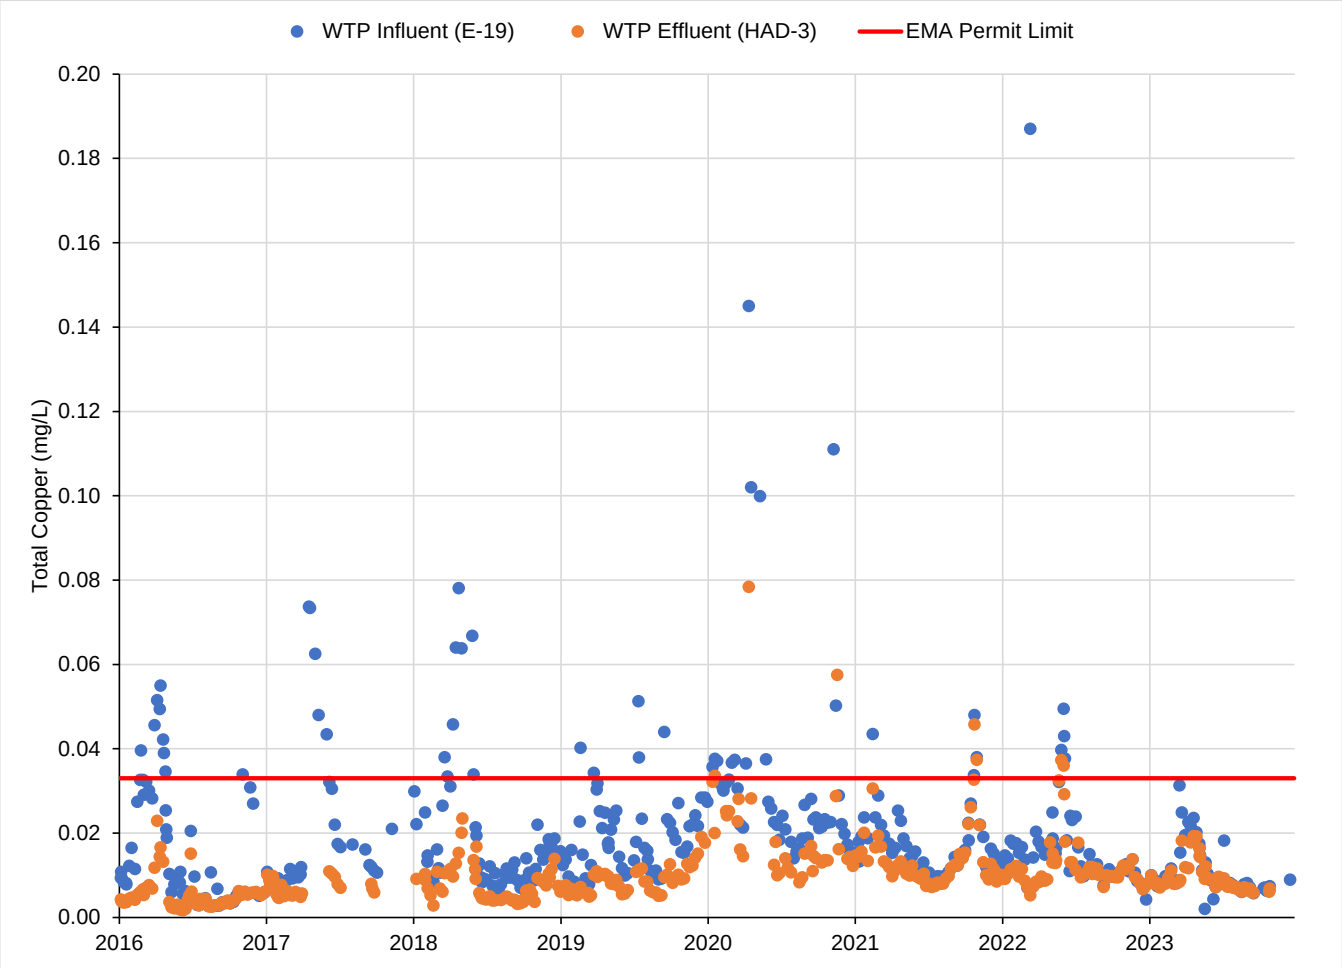

Figure 34: Historical Total Copper in WTP Influent and WTP Effluent from 2016 through 2023

Table 48: Historical Total Copper Trend Statistics (WTP Influent and WTP Effluent from 2016 through 2023)

	E-19 (WTP Influent) Total Copper (mg/L)	HAD-3 (WTP Effluent) Total Copper (mg/L)
Minimum	0.002	0.002
Maximum	0.933	0.282
Average	0.025	0.012
Median	0.015	0.009
Standard Deviation	0.065	0.019

Total selenium is not predicted to require treatment during operations, as shown by the 95th percentile PETBP concentration shown in Table 46. Even though predictions show that PETBP total selenium concentration is near the permit limit, monitoring data has shown actual total selenium in the PETBP consistently below the permit limit (Golder 2022b). The water treatment system during operations has not required selenium treatment and it is not anticipated to require selenium treatment for the remainder of operations. The Selenium Management Plan (SeMP, Golder 2016i) lists in-pit treatment along with biological treatment as two of the measures that may be employed to mitigate selenium if required.

Table 46 shows that dissolved cadmium is predicted to require treatment during operations. This modelled 0.36 µg/L concentration is a conservative estimate from the model, and monitoring data from existing operation does not show dissolved cadmium in concentrations requiring treatment. The existing WTP does not target dissolved cadmium as a constituent of concern (COC), but similar to copper and selenium, total cadmium is partially removed through TSS removal at the WTP.

Closure and Post-closure

The SWWBM was used to predict water quality at the PETBP during closure/post-closure. Central collection to the PETBP may not be the final post-closure water treatment configuration (particularly if distributed treatment and discharge can be permitted), but collection to this location has been assumed as the closure base case as it represents the currently permitted system configuration and is one of the two BAT options identified for closure. Table 47 provides a list of constituents of interest and the maximum of the 95th percentile predicted concentrations in the PETBP during closure and post-closure (WSP 2023c). Table 47 also compares predicted PETBP water quality to MPMC's current EMA Permit 11678 WTP discharge limits. These WTP discharge limits have been assumed for closure/post-closure as they represent the currently permitted treatment requirements. Distributed treatment during closure/post-closure may discharge to different receiving environments with different discharge limits than the existing EMA Permit, but the current limits have been assumed for closure/post-closure for the purposes of this Water Management Plan.

Table 49: Predicted Water Quality Concentrations at Perimeter Embankment Till Borrow Pond During Closure/Post-closure

Parameter	Unit	EMA Permit 11678 WTP Discharge Limit	PETBP – Maximum of 95th Percentile Predicted Concentrations – Closure	PETBP – Maximum of 95th Percentile Predicted Concentrations – Post-closure

Zinc	mg/L	0.059	0.011	0.003

Table 49: Predicted Water Quality Concentrations at Perimeter Embankment Till Borrow Pond During Closure/Post-closure

Parameter	Unit	EMA Permit 11678 WTP Discharge Limit	PETBP – Maximum of 95th Percentile Predicted Concentrations – Closure	PETBP – Maximum of 95th Percentile Predicted Concentrations – Post-closure
Dissolved Metals				
Cadmium	mg/L	0.00034	0.00009	0.00005

Note(s): **Bold and underlined** values exceed permitted discharge limits. These EMA Permit 11678 discharge limits apply to the effluent of the WTP, and not to the PETBP (WTP influent). PETBP water quality predictions are shown to demonstrate the requirement for treatment of a water quality parameter. The SWWBM was developed to predict water quality conservatively; where uncertainty exists in the model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected.

Table 47 shows that total copper is predicted to require treatment during closure and post-closure. TSS, not listed in Table 47, is also required for treatment during closure/post-closure. Total selenium is not predicted to require treatment in closure/post-closure but is still considered as a potential COC for these phases.

The assumed BAT treatment system during closure/post-closure is pit-lake treatment (for selenium treatment if required) followed by the centralized Actiflo plant (existing WTP), with the possibility of distributed passive/semi-passive treatment if systems are environmentally appropriate and permittable. TSS treatment is assumed to be required through closure and post-closure and will be achieved with the Actiflo plant. Total copper treatment is predicted to be required through closure and post-closure and will be achieved with a combination of the Actiflo plant (total copper removal through TSS removal), and future trimercapto-striazine trisodium salt (TMT) pre-treatment, if required (for dissolved copper precipitation).

Total selenium is considered a potential COC during closure and post-closure, though not predicted to require treatment. Existing monitoring data has consistently shown total selenium in Site contact water to be below discharge limits. If required, the assumed method of selenium treatment is semi-passive pit-lake pre-treatment for dissolved selenium (active dosing of carbon source to pit-lake), followed by treatment by the Actiflo plant for TSS and particulate selenium removal. MPMC has also been progressing the development of multiple passive and semi-passive closure treatment technologies that target selenium in order to potentially reduce the complexity and operating footprint of long-term treatment system during post-closure.

At mine closure, three major zones are in long-term contact with waste rock: the combined Springer-Cariboo Pit, Wight Pit, and the SERDS which drains into Long Ditch. Table 48 provides a list of constituents of interest and the maximum of the 95th percentile predicted concentrations in the Springer-Cariboo Pit, Wight Pit, and Long Ditch during closure and post-closure (WSP 2023c). Predicted parameters are shown post-2041 for Wight Pit and Long Ditch, the period in closure they have been assumed to discharge directly to environment in the SWWBM. Predicted parameters are shown post-2055 for Springer-Cariboo, the period in closure that the pit is assumed to overflow directly to the environment in the SWWBM.

Table 50: Predicted Water Quality Concentrations at Springer-Cariboo Pit, Wight Pit, and Long Ditch During Closure/Post-closure

Parameter	Unit	Springer-Cariboo Pit – Maximum of 95th Percentile Predicted Concentrations – Post-closure (post-2055)	Wight Pit – Maximum of 95th Percentile Predicted Concentrations – Post-closure (post-2041)	Long Ditch – Maximum of 95th Percentile Predicted Concentrations – Post-closure (post-2041)
Major Ions				
Total Sulphate	mg/L	510	187	317
Nutrients				
Total Ammonia	mg/L (as N)	0.02	0.01	0.01
Total Nitrate	mg/L (as N)	3	2	4
Total Phosphorus	mg/L	0.03	0.03	0.04
Total Metals				
Arsenic	mg/L	0.001	0.005	0.002
Chromium	mg/L	0.001	0.001	0.002
Copper	mg/L	0.028	0.007	0.019
Iron	mg/L	0.30	0.24	0.45
Manganese	mg/L	0.19	0.07	0.14
Molybdenum	mg/L	0.11	0.05	0.06
Selenium	mg/L	0.056	0.008	0.034
Zinc	mg/L	0.008	0.010	0.006
Dissolved Metals				
Cadmium	mg/L	0.00014	0.00002	0.00010

Note: The SWWBM was developed to predict water quality conservatively; where uncertainty exists in the model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected.

Direct discharge of the Table 48 catchments to the environment during post-closure is assumed in the SWWBM, but this will not occur until appropriate permit limits are established and when actual water quality near post-closure is confirmed. Copper and selenium concentrations in these drainages will be monitored through operations and closure. If copper treatment is required during post-closure for these drainage sources, then centralized or distributed TMT pre-treatment and/or TSS settling could be employed to reduce total copper to below established limits. Other technologies being considered for closure may also address copper reduction. If selenium treatment is required during post-closure, then centralized pit-lake or distributed passive/semi-passive treatment could be employed to reduce total selenium to below established limits.

Details on modelled water quality concentrations for all parameters and mine phases at various site locations (in addition to the locations discussed here) can be found in Appendix B.

4.6.2 Water Treatment Technology Development

Good engineering practice typically requires a project to follow a standardized engineering design process for the selection and progressive refinement of the final project concept. A project progresses from a pre-concept phase for the identification of multiple treatment options, through concept, pre-feasibility, and feasibility phases to project execution. Generally, the engineering studies performed for each of these project phases are supported by test work that progresses from proof-of-concept and detailed bench-scale testing to pilot-scale and demonstration-scale test work. Some of the treatment technologies tested may not progress to the next stage of development. For example, a treatment technology may be eliminated if its treatment capacity is insufficient to treat the forecast volumes. This framework takes a staged approach, such that input assumptions, design,

and cost for the total system can be refined as each stage is completed and the information that the plan relies on becomes more certain. This allows input assumptions to be less conservative as they become more accurate with accumulated knowledge. Additional details regarding this project development framework and how it aligns with the BC Ministry of Environment and Climate Change Strategy's BAT policy is provided in Golder 2020e.

A generic model for such a project development framework is provided in Figure 35. This framework also approximates the sequence of steps outlined in BC ENV's BAT policy (BC ENV 2015).

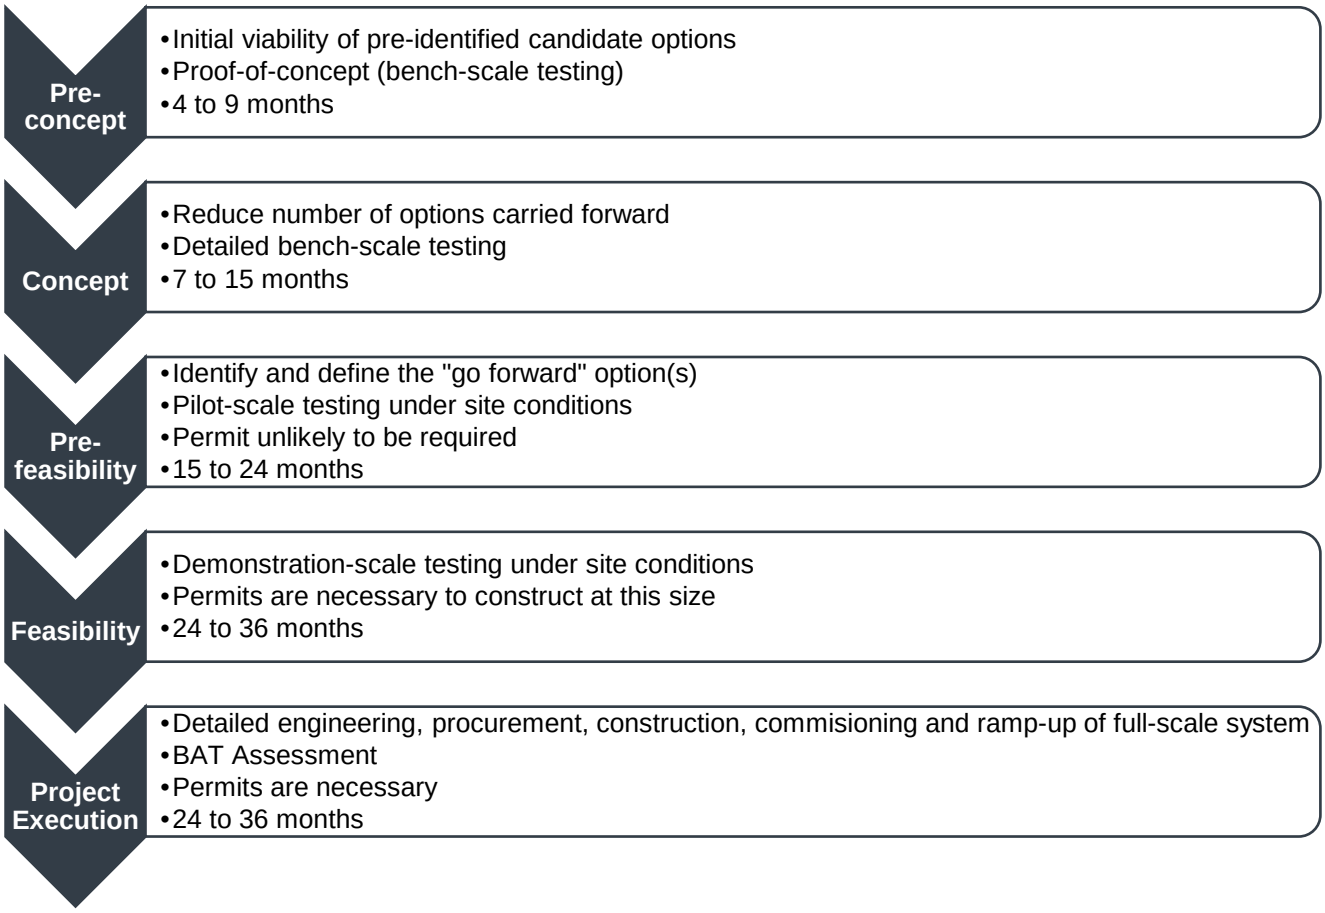

Figure 35: Project Development Framework

MPMC has been progressing and evaluating multiple technologies under this project development framework to support the treatment of identified COCs and to support potential decentralized treatment and discharge during closure/post-closure. Various studies and trials have been completed to support these efforts as an important component of water management planning and closure refinement. An inventory of treatment technologies and a summary of their development is presented in Table 49.

This Water Management Plan assumes that the reader is familiar with the technologies presented in Table 49; this document only provides updates on work completed by MPMC since circa 2017 to support the development of these technologies. Detailed descriptions of these technologies and associated process flow schematics can be found in Golder 2020e.

Table 51: Treatment Technology Inventory and Stage of Development

Technology/ Stage of Development	Targeted COCs	Proof-of-Concept Bench-Scale Testing	Detailed Bench-Scale Testing	Pilot-Scale Testing	Demo-Scale Testing	Full-Scale Execution	Work Completed
Actiflo	TSS, total copper					→	Bench and full-scale testing. Flocculant Management Plan.
Lime Treatment	Dissolved copper					→	N/A
TMT Treatment	Dissolved copper	→	→	→	→		Bench and full-scale testing. Toxicity evaluation.
Pit-Lake Treatment	Selenium, nitrate	→	→	→			Preliminary concept design and proof-of-concept bench-scale testing. Pilot-scale testing workplan.
Saturated Rock Fill (SRF)	Selenium, nitrate	→	→				Concept design, proof-of-concept bench-scale testing, detailed bench-scale testing workplan, and long-term substrate leach testing. Wight Pit SRF assessments.
Packed Bed Reactor (PBR)	Selenium, nitrate	→	→				Concept design, proof-of-concept bench-scale testing, and detailed bench scale testing workplan.
Biochemical Reactor (BCR)	Selenium, nitrate	▬	▬				Concept design and proof-of-concept bench-scale testing.
Submerged Sand Reactor (SSR)	Selenium, nitrate	▬					Screening analysis.
Constructed Wetland Treatment (CWT)	Selenium, nitrate	→	→	→			Concept design, bench-scale testing, and on-site pilot scale testing (by others).

Implemented → Under Consideration → Eliminated/Paused ▬

Actiflo

Actiflo, the tradename of a technology supplied by Veolia, is the technology currently in use as the Site's WTP and is considered the BAT for TSS removal during operations and closure/post-closure. The main targeted COC of this technology is TSS, with total copper removal also occurring via TSS removal. Polyaluminum chloride (PAC) is dosed into the influent water in the Actiflo process, which produces aluminum hydroxide precipitates that adsorb to copper complexes, thus removing copper during the solids-liquids separation step of the process. The Actiflo technology is currently implemented at full-scale on-site, as indicated in Table 49.

Concept design, bench-scale, and full-scale testing have been completed for the Actiflo technology, including assessment and optimization of PAC and various chelating agent dosages (including TMT) to assist copper removal (Golder 2016k, Golder 2017a, Golder 2018a, Golder 2019a, Golder 2019b, Golder 2020f). A Flocculant Management Plan for the Actiflo WTP was also recently completed (WSP 2023d) to address recent EMA Permit requirements, which describes the Actiflo process and associated flocculant use in detail, including PAC, polymer, and microsand. Golder 2022b also provides a detailed summary of recent WTP performance regarding TSS, total copper, and total selenium removal.

Actiflo treatment is currently operating as the core component of the treatment system during operations and is currently assumed as the base case core component of treatment during closure/post-closure.

Lime Treatment

Active treatment with lime is currently in use at the site, where existing mill process plant infrastructure is used to dose lime, raise contact water pH, resulting in the precipitation of metal hydroxides, particularly dissolved copper. Precipitated copper is then removed via TSS removal in the Actiflo system. The main targeted COC of this technology is dissolved copper. Lime treatment is currently implemented on-site, as indicated in Table 49, and used as a pre-treatment step of the Actiflo water treatment system to target dissolved copper removal. Use of this technology is well known to industry and technology development to support this has not been required.

Lime treatment, when required, is currently a component of the water treatment system during operations.

TMT Treatment

TMT is a chelating agent that aids with dissolved copper precipitation that allows copper treatment through TSS removal. The main targeted COC of this technology is dissolved copper.

Bench-scale test work completed showed that TMT is able to effectively precipitate dissolved copper (Golder 2016k, Golder 2017a, Golder 2018a) and the full-scale trials completed showed that the existing Actiflo treatment system was able to remove the copper bound with TMT to below the permit limit (Golder 2019a, Golder 2019b, Golder 2020f). Full-scale trials also showed that copper removal to lower concentrations (total copper <0.012 mg/L) was challenging for Actiflo with TMT treatment, not due to limitations in dissolved copper precipitation but due to limitations in Actiflo TSS removal to low concentrations. TMT was effective in precipitating dissolved copper, but the Actiflo system was not effective in subsequently removing the precipitate to result in low effluent copper concentrations. The toxicity of TMT has also been evaluated and showed that its use would not result in an acutely lethal effluent (Golder 2018b).

TMT treatment is still being considered for full-scale implementation during closure/post-closure if required.

Pit-Lake Treatment

Pit-lake treatment targeting COCs of selenium and nitrate is an in-situ technology that requires nutrient and carbon source dosing to create conditions for biological treatment within the pit-lake.

A conceptual assessment of full-scale pit-lake selenium treatment was completed (Golder 2017b) and the technology was deemed a cost-effective approach to managing selenium and was recommended for further bench and pilot-scale testing. Proof-of-concept bench-scale testing for pit-lake selenium treatment was also completed and showed effective removal of selenium and nitrate, with further pilot-scale testing recommended (Golder 2019c). A pilot-scale study for pit-lake treatment was designed for Cariboo Pit (Golder 2020d), but the pit is being dewatered to support future mining activities and this work has not yet been completed. A pit-lake trial is also not currently available in Wight Pit, as the pit is providing required water storage during storm and freshet operations and will not remain at a steady volume required for the trial.

Pit-lake treatment targeting selenium and nitrate is still being considered for full-scale implementation and is currently assumed as part of the treatment system during closure/post-closure if required.

Saturated Rock Fill (SRF)

SRF treatment is a fixed-film anaerobic system targeting the treatment of selenium and nitrate and ideally utilizes a mined open pit as a bioreactor operated in a horizontal flow configuration.

A concept study for SRF treatment was completed (Golder 2020g) and SRF was recommended for further bench-scale and pilot-scale testing. Proof-of-concept bench-scale testing for SRF was also completed (Golder 2021), which showed effective removal of selenium and nitrate, but also indicated metal leaching. Detailed bench-scale testing and waste rock SRF substrate metal leach testing was recommended following completion of the proof-of-concept work. Bench-scale leach testing using anticipated SRF substrate waste rock from site was completed (Golder 2022c), which monitored leached metals over a long-term test period of 52 weeks. Results showed that metal leaching varies over time and differs between metals and must be considered during the start-up phase of SRF implementation (and may lead to additional required polishing treatment steps downstream of the SRF). Detailed bench-scale testing for SRF has been proposed and a test plan has been submitted to MPMC (Golder 2022d). Geotechnical and geochemical substrate characterization for SRF media waste rock is currently ongoing and anticipated for completion in 2023. It is anticipated that geochemical substrate characterization will be conducted by MPMC's geochemical consultant SRK.

SRF treatment is still being evaluated for full-scale implementation and is currently considered a technology option for semi-passive treatment of selenium and nitrate during closure/post-closure if required.

Packed Bed Reactor (PBR)

PBR treatment is another fixed-film anaerobic system targeting the treatment of selenium and nitrate. PBR treatment differs from SRF treatment through the use of a vertical flow (top to bottom) reactor.

Proof-of-concept bench-scale testing was completed (Golder 2019d) and PBR treatment was shown to be effective in reducing selenium and nitrate. Further detailed bench-scale and pilot-scale testing was recommended following completion of the initial testing. Detailed bench-scale testing for PBR has been proposed and a test plan has been submitted to MPMC (Golder 2022e).

PBR treatment is still being evaluated for full-scale implementation and is currently considered a technology option for semi-passive distributed treatment of selenium and nitrate during closure/post-closure if required.

Biochemical Reactor (BCR)

BCR treatment is another fixed-film anaerobic treatment technology that consists of a lined pond filled with a submerged organic substrate media mix. The main targeted COCs of this technology are selenium and nitrate. BCR treatment is passive and does not involve continuous dosing of a carbon source to the media bed.

Proof-of-concept bench-scale testing was completed (Golder 2019d) and BCR treatment was shown to be effective in reducing selenium and nitrate, but redox sensitive metals were present in the BCR effluent.

Upon review of the BCR technology in comparison to other passive and semi-passive technologies, MPMC decided to not proceed with further development of this technology (MPMC 2021) for the following reasons:

- Limited lifespan of BCR passive treatment systems based on the availability of a carbon source that is encapsulated in the system during construction – this needs to be replaced periodically at significant cost.
- Emission of elevated levels of biochemical oxygen demand (BOD) from the system during commissioning and start-up of operation that exceed standards for discharge to the environment.
- Persistent emission of phosphorus from the BCR during operation that will likely exceed plausible standards for discharge to the environment.

BCR treatment is no longer being developed as a passive treatment technology option during closure/post-closure.

Submerged Sand Reactor (SSR)

SSR is similar to other anaerobic reactor technologies, with the use of the existing tailings as media for the bioreactor. The main targeted COCs of this technology are selenium and nitrate.

A concept study was completed for SSR (Golder 2020g), as well as proof-of-concept bench-scale testing (Golder 2019d). Use of MPMC tailings as SSR bioreactor media or use of the site's TSF as an in-situ SSR was not recommended for further investigation. Bench-scale testing resulting in metal release in the reactor effluent when using site tailings as the reactor media. The concept study also concluded that further investigation of SSR was not warranted, based on a review of literature, an evaluation of historical water quality monitoring data, and an evaluation of the feasibility of utilizing the TSF from a hydrogeological and permitting perspective.

SSR treatment is no longer being developed as a treatment technology option during closure/post-closure.

Constructed Wetland Treatment (CWT)

MPMC retained Ensero Solutions Inc. (Ensero), formerly known as Contango Strategies Ltd., to conduct a detailed assessment and evaluation of the feasibility of a CWT system for passive/semi-passive treatment during closure/post-closure. The main targeted COCs of this technology are selenium and nitrate.

Pilot-scale design, sizing, and testing for CWT was completed by Ensero (Ensero 2020), and the technology demonstrated successful results for treatment of targeted COCs; however other passive/semi-passive technologies have indicated improved treatment capability in comparison. MPMC may choose to proceed with demonstration-scale on-site testing of CWT once the pilot-scale results have been fully understood and if the performance of competing technologies (SRF and others) indicates an advantage for CWT.

CWT is still being evaluated for full-scale implementation and is currently considered a technology option for passive/semi-passive and distributed treatment of selenium and nitrate during closure/post-closure if required.

5.0 WATER MANAGEMENT PLAN REVISION TRIGGERS

Operational events (i.e., triggers) that may result in updates to the WMP being required are listed in Table 50 as part of the revision process. These triggers cover changes to the mine plan or changes to site catchments or the TSF that would likely have a material impact on how water is conveyed, stored, and treated at the mine.
When one of the operational events occur, it is expected that an update will be required to the WMP to address changes to the water management approach. Triggers and proposed timelines for a WMP update are included in Table 50.

The need for changes to water treatment will be evaluated for each operational trigger. If it is determined that an operational trigger requires a change to the water treatment approach, the required engineering design process will be followed for the selection and progressive refinement of options as described in Figure 35.

Table 52: Water Management Plan: Revision Process for Potential Future Updates to Water Management Plan

Revision Trigger	Applicable Regulatory Body and Permit	WMP Update	Anticipated WMP Update Submission (revision trigger + X months)	Additional Notes
Mine plan update: a change to the permitted mine plan or implementation schedule that results in modifications to the water management systems.	MEMPR; M-200 EMA; PE-11678	Full update	10 months	Update to water balance (including water quality model) and implementation schedule. Updates to groundwater/hydrogeological models may be required.
Tailings Storage Facility: a change to the permitted configuration (i.e., dam crest elevation, water storage volume, or tailings volumes) of the TSF that impacts water storage and discharge requirements.	MEMPR; M-200 EMA; PE-11678	Full update	6 months	Update to water balance (including water quality model) and implementation schedule. Updates to groundwater/hydrogeological models may be required.
Catchment areas: change in the site footprint of more than 10% increase or decrease in runoff volume attributed to changes in the permitted and modified mine areas.	MEMPR; M-200 EMA; PE-11678	Partial update	3 months	Update will be composed of a calibration and sensitivity exercise on the existing water balance (including water quality model). Updates to groundwater/hydrogeological models may be required.
Requirement to update WMP by the Engineer of Record or the Independent Engineering Review Panel.	MEMPR; HSRC	Level of update depends on requirement of Engineer of Record or Independent Engineering Review Panel	6 months	To be determined; however, it may include an update to water balance (including water quality model) and implementation schedule. Updates to groundwater/hydrogeological models may be required.
Requirement to update the WMP by the Statutory Decision Maker of MEMPR or BC ENV.	MEMPR; M-200 EMA; PE-11678	Level of update depends on requirement of statutory decision maker	6-10 months	To be determined; however, it may include an update to water balance (including water quality model) and implementation schedule. Updates to groundwater/hydrogeological models may be required.

WMP = Water Management Plan; TSF = Tailings Storage Facility; EMA = *Environmental Management Act*; MEMPR = Ministry of Energy, Mines, and Petroleum Resources; HSRC = Health, Safety and Reclamation Code for Mines in British Columbia; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy.

6.0 CLOSURE

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this report.

We trust the above meets your present requirements. If you have any questions or comments, please contact the undersigned.

Springer Expansion LOM SWWBM Inputs

APPENDIX B
Flow Diagrams and 2022 Water Management Infrastructure

APPENDIX C
SWWBM Results

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) is currently submitting a permit application for the new Springer Expansion phase, extending assumed operations until March 31, 2031. The Site Wide Water Balance Model (SWWBM) presented in this report is a critical component, essential to support the Water Management Plan required for the Springer Expansion permit application. It should be noted that the specific operation, closure, and post-closure dates in this report have been assumed for the purpose of modelling. There are many factors that exist that can alter these dates, such as delays on the mine production as a result of metal prices, new exploration, care and maintenance periods, revisions to the mine plan. Thus, these time frames should not be considered static.

The SWWBM was originally developed for the Technical Assessment Report (TAR) to support the effects predictions in the Mount Polley Mine Long Term Water Management Plan (Golder 2016a) for the Mount Polley Mine (the Mine) and has since been calibrated on an annual basis (refer to WSP 2023a for the latest 2022 annual calibration). This report presents the SWWBM based on the Springer Expansion Life-of-Mine (LOM) Plan informed by MPMC (MPMC 2022), to a crest elevation of 987 m of the TSF.

The work presented in this report is as follows:

- A summary of the physical setting at the Site (Section 2.0)
- An overview of the climate and hydrology at the Site (Section 3.0)
- A description of the SWWBM, including inputs and assumptions (Section 4.0)
- A presentation of SWWBM results, including operational, closure, post-closure phases (Section 5.0)
- Tabular inputs of the SWWBM (APPENDIX A)
- Flow Diagrams and 2022 Water Management Infrastructure Drawing (APPENDIX B)

This report has been prepared in accordance with the “Study Limitations,” which are presented at the beginning of the report. The reader’s attention is specifically drawn to this information for reference during use of this report.

2.0 BACKGROUND

2.1 General Information

Mount Polley Mine is a copper and gold mine operated by MPMC, a subsidiary of Imperial Metals Corporation. The Mine is located approximately 56 km northeast of Williams Lake, British Columbia (BC), and is located between Polley Lake and Bootjack Lake. Within the area of the Mine, the plateau has somewhat higher relief, with the Mine rising approximately 300 metres (m) above the surrounding terrain. Topographically, the Site area consists of north–south trending ridges of moderate elevation and relief. Local elevations range from 922 metres above sea level (masl) at Polley Lake to 1,266 masl at the top of Polley Mountain with an average elevation of 1,038 masl. The total surface area of the Site is 17.8 square kilometers (km^2).

MPMC is applying for a permit for the new Springer Expansion phase, which extends operations until 2031. Updating the SWWBM to reflect the Springer Expansion LOM plan is required to support the Water Management Plan for this permit application. The updated SWWBM will generate results throughout the operational phase to a crest level of 987 m of the TSF (to be completed before the end of operations), extending into the closure and post-closure phases.

3.0 CLIMATE AND HYDROLOGY

3.1 Climate

In 2022, WSP Canada Inc. (WSP) updated the climate baseline data for the Mine. The climate of the Mine was characterized in the Baseline Climate Update Report (Golder 2022b) using historical measurements from local climate stations, supported by data obtained from five nearby regional Environment and Climate Change Canada (ECCC) climate stations. During the winter, snowpack is measured at four snow course sites at a minimum frequency of once per month, with more frequent measurements typically being taken during the melt phase. Detailed climate information can be viewed in Golder 2022b. The climate inputs for the SWWBM are presented in Section 4.5.1.

3.2 Site Drainage and Surface Hydrology

A network of ditches, sumps, and pumping systems are operated by MPMC to manage surface water at the Mine. The current water management infrastructure of Mount Polley is presented in the MPMC 2022 Water Management Infrastructure Drawing provided in APPENDIX B. Surface water is separated between contact (mine affected) and non-contact (non mine affected) sources of runoff. The two water sources can be characterized as follows:

- Contact water: water that may have come into direct contact with mining and milling activities. This water generally requires treatment before release to the environment.
- Non-contact water: runoff originating from areas unaltered by mining activity that does not contact mining areas. It is typically diverted to the maximum extent practicable and allowed to discharge directly to the receiving environment.

The objective of current water management practices is to minimize the mingling of contact and non-contact surface water sources whenever possible. These flows originate from direct precipitation, runoff, and snowmelt from catchments. Contact water is mainly collected along two ditches running north to south along the Site: West Ditch and Long Ditch. A block flow diagram provides a conceptual overview of the sumps and their respective connections across the Mine area presented in Figure 1.

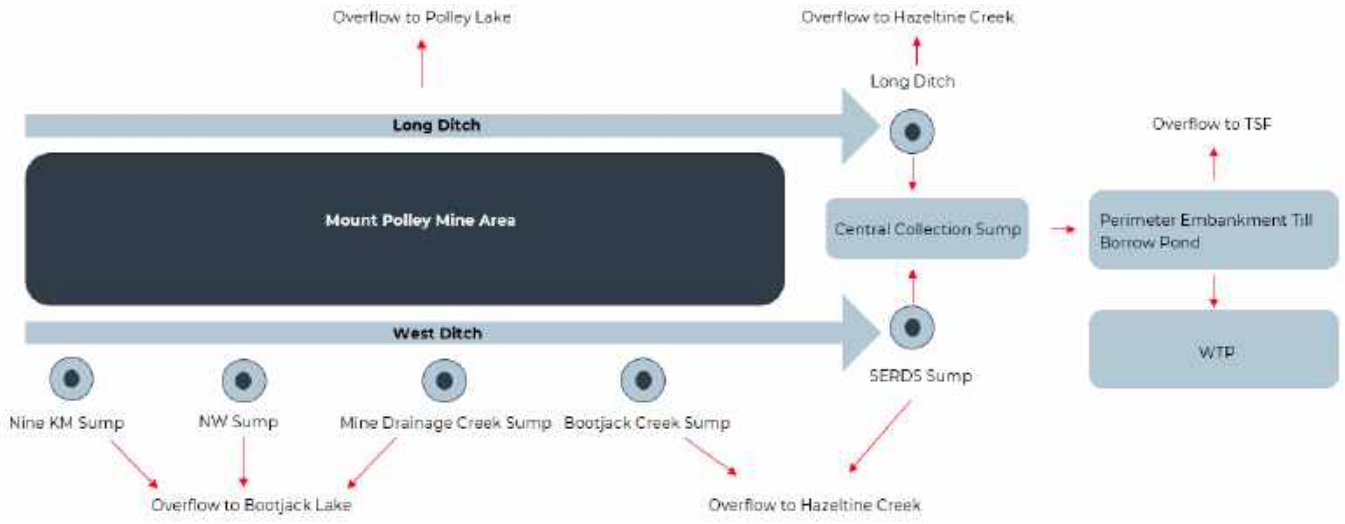

Figure 1: Conceptual Block Flow Diagram of Mount Polley Mine Contact Water Management Infrastructure

The West Ditch system collects contact water starting from the west side of the Site, progressing from the Nine KM Sump to the SERDS Sump. Components of the West Ditch system include various sumps, ditches, and pumping systems.

Similarly, the Long Ditch system manages contact water from the east side of the Site, extending from below the site access road to the Central Collection Sump. This system also comprises various sumps, ditches, and pumping systems.

3.3 Pit Groundwater Hydrogeology

Groundwater flow has been assessed for the following open pits at the mine: Springer Pit, Cariboo Pit, Wight Pit, and Boundary Pit. The analysis for each pit is described in a series of technical memoranda in Appendix B of the TAR (Attachments C, D, E, and F; Golder 2016a).

Hydrogeological assessments for the pits were conducted as part of the TAR to estimate groundwater seepage into and out of the pits. Seepage estimates have not been updated for the WBM results presented in this document, which relies on the estimates completed in the 2016 TAR. WSP is currently updating these seepage estimates for the Mine pits, the seepage estimates will be updated in the SWWBM when available. Results will be assessed to identify any notable changes to the seepage estimate. Updated seepage parameters are not expected to alter the water balance results for the site or alter the water treatment quantity design basis; however, this will be confirmed once updated parameters are available. Groundwater inputs for the SWWBM are presented in Section 4.5.3.

3.4 Tailings Storage Facility

Flows from the TSF have been discussed in the TAR (Golder 2016a). WSP is currently designing a new upstream drainage system within the TSF to accommodate the increase in the TSF pond elevation (WSP 2023e). Updated estimations of seepage flow rates have been developed for each embankment as part of the TSF embankment crest at elevation 987 m design and are provided in Section 4.5.7.5.

4.0 SITE WIDE WATER BALANCE MODEL

An update to the existing SWWBM was carried out using GoldSim™ (Version 14.0). This section presents SWWBM software, model objectives, general assumptions, processes, and inputs.

4.1 Model Software

GoldSim allows dynamic and complex water quantity interactions to be represented through a visual and highly modular framework. All input parameters and functions are defined by the user and are built as individual objects or elements linked together by mathematical expressions. GoldSim is widely used for mine water quantity studies and provides the following capabilities:

- Deterministic and probabilistic simulations can be run within the model, which allows statistics and probabilities to be assigned to the model outputs.
- Simulation periods can be varied within the same model.
- The model framework can be easily adjusted to account for evolving conditions on a mine site, which allows the model to be used as an operational planning tool.
- Water quantity and water quality modules can be directly linked within the model, which allows both modules to be updated simultaneously; this is particularly useful when evaluating a range of scenarios (e.g., alternative water management strategies).

4.2 Model Objectives

This SWWBM was updated to include the future operational phase, in line with the assumed Springer Expansion LOM plan. Additionally, it has been updated to reflect changes in the closure and post-closure phases since the Reclamation and Closure Model update completed in 2022 (Golder 2022a).

This SWWBM has the following objectives:

- Include a future operational phase that will extend from May 2, 2023, to March 31, 2031.
- Include a closure phase extending from April 1, 2031, to March 31, 2041.
- Include a post-closure phase commencing on April 1, 2041, and extending to March 31, 2131 (100 years including closure).
- Estimate the quantity of contact water collected on-site per the climate conditions.
- Estimate water retention requirements in major storage locations at site such as the TSF and pits.
- Estimate the quantity of contact water requiring treatment.
- Enable assessment of future operations water quality and associated water treatment and/or discharge options.
- Provide a model that can be linked to a water quality module that assesses site water quality during forecasted future operations.

4.3 Assumptions and Key Input Parameter Values

General assumptions applied to this model are as follows:

- Continuation of mining of the Springer Pit and Cariboo Pit will not significantly increase the footprint of the pits.
- There is no seepage from the ponds or sumps other than the TSF (i.e., all ponds and sumps are assumed to be lined, or seepage is assumed to be negligible).
- Direct precipitation, evaporation, and seepage loss from ditches are assumed to be negligible.
- Precipitation occurs as snow from December to February and as rain or a mixture of rain and snow in all other months.
- Snowpack is represented by the cumulative precipitation depths over the months of December, January, and February, spanning a period of three months.
- Snowmelt occurs in the months of March, April, and May as a percentage of the maximum snowpack at the end of February (5% in March, 90% in April, and 5% in May).
- The closure and post-closure phases are included in the SWWBM, and the flow logic and model wiring for these phases are based on the 2022 Reclamation and Closure Plan (RCP) (Golder 2022a). Flow diagrams for closure and post-closure phases are also presented in Appendix B.

Key input parameter values and assumptions for the operational phase simulations are presented in Table 1.

Table 1: Key Input Parameter Values and Assumptions

Parameter	Value	Reference
TSF emergency spillway invert elevation at 987 m dam crest elevation during operations	985.8 m	WSP 2023c
Initial TSF water volume	2.84 M-m^3	TSF Weekly Report (MPMC 2023a)
Initial Springer Pit water level	970.66 m	TSF Weekly Report (MPMC 2023a)
Initial Cariboo Pit water level	954.72 m	TSF Weekly Report (MPMC 2023a)
Initial Wight Pit water level	912.87 m	TSF Weekly Report (MPMC 2023a)
Tailings stored in Springer Pit	2.00 M-m^3	TSF Weekly Report (MPMC 2023a)
Water Treatment Plant (WTP) treatment capacity	25,000 m^3/d	Provided by MPMC (MPMC 2023b)

4.4 Model Domain

A description of the model flows is provided in APPENDIX A. The domain and structure of the SWWBM is outlined in the conceptual flow diagrams for the forecasted operational, closure and post-closure phases in Appendix B. The flow diagrams illustrate the assumed water circuit system at the Site during operations, closure, and post-closure, including the storage and conveyance of water. The water management infrastructure within the SWWBM for the operational phase is summarized in Table 2 and flow types are outlined in Table 3.

From closure and progressively to post-closure, certain Site areas will be reclaimed, and run-off will become non-contact water and the volume of annual contact water will reduce. Pumping rates for the Site will be reduced at the end of the closure period, as certain areas are assumed reclaimed. The progression of flow routes and discharges to the environment are shown on the flow diagrams presented in Appendix B.

Table 2: Water Management Infrastructure during Operations

Major Ditches	Sumps and Minor Ponds	Major Ponds and Storage Facilities
▪ Long Ditch ▪ SERDS Ditch (lower portion of West Ditch)	▪ South Seepage Pond ▪ Main Embankment Seepage Pond ▪ Central Collection Pond ▪ Bootjack Creek Sump ▪ Mill Site Sump ▪ Mine Drainage Creek Sump ▪ NW Sump ▪ 9K Sump ▪ Boundary Pit	▪ TSF ▪ Cariboo Pit ▪ Springer Pit ▪ Wight Pit ▪ Perimeter Embankment Till Borrow Pond

SERDS=Southeast Rock Disposal Site; TSF = Tailings Storage Facility

Table 3: Types of Flows Represented in the SWWBM

Site Inflows	Site Outflows or Transfers
▪ Direct precipitation ▪ Runoff ▪ Seepage (includes baseflows)	▪ Water consumption flows (turbo-misters, and water trucks) ▪ Water treatment discharge ▪ permanent, unrecoverable storage in tailings (interstitial water) ▪ Open water evaporation ▪ Pumped flows between facilities ▪ Transfer flows (gravity flows between facilities) ▪ Groundwater flows

4.5 Model Inputs

4.5.1 Climate Inputs

The following sections describe the climate inputs used in the SWWBM.

4.5.1.1 Precipitation

The SWWBM was run with probabilistic monthly climate inputs for this assessment. To develop probabilistic inputs, monthly precipitation data in the Mount Polley Mine Climate Baseline Update (Golder 2022b) were fitted to a log-normal probability distribution. The mean and standard deviation for the monthly precipitation values are shown in Table 4.The model is run using a daily time step, which represents better variation between months such as the water volume in the TSF or the pits.

The derived monthly means and standard deviations of the precipitation values, defined in the model as stochastic elements, were used to generate random values based on the distribution of the dataset. The stochastic generator was set to perform 2000 realizations to create a sample size that was sufficiently large to account for a range of conceivable monthly climatic precipitation scenarios for the study period. The results of these 2000 realizations were compiled to generate probability distributions that yield percentile values. To represent average and extreme climate scenarios, results for the 50th, 90th and 99.5th percentiles are presented in Section 5.0.

Table 4: Stochastic Climate Generator Log-Normal Distribution Input Arguments

Month	Mean of the Monthly Precipitation Depths (mm)	Standard Deviation of the Monthly Precipitation Depths (mm)
January	49.4	30.9
February	35.8	24.2
March	29.7	13.9
April	44.7	43.6
May	49.9	20.2
June	70.8	32.9
July	63.6	55.1
August	50.6	31.2
September	52.3	30.1
October	58.1	27.9
November	49.8	28.9
December	57.6	32.7

4.5.1.2 Evaporation

The median annual shallow lake evaporation rate is estimated to be 670 mm. Monthly evaporation rates vary between 0 mm in December to 136 mm in July. Estimated median monthly and annual shallow lake evaporation from 1974 to 2001 are presented in Table 5.

Table 5: Median Monthly and Annual Shallow Lake Evaporation Statistics for the Site (1974-2001)

Month	Median Shallow Lake Evaporation (mm)
January	0
February	7
March	32
April	67
May	102
June	121
July	136
August	113
September	60
October	21
November	4
December	0
Annual	**663**

4.5.1.3 Climate Change

An ensemble of monthly temperature and precipitation projections were obtained from ClimateBC consisting of 8 Global Climate Models (UBC 2022) and two emissions scenarios (SSP2-4.5 and SSP5-8.5) covering mid to high emissions from the Sixth Intergovernmental Panel on Climate Change Assessment Report (IPCC 2021). A stochastic approach (outside the GoldSim model) was used to extend these projections from year 2100 to 2200 by resampling monthly data from 2071-2100 and relating projected changes in temperature and precipitation climate variables to a set of extended greenhouse gas concentration pathways beyond year 2100 (van Vuuren et al. 2011). The range of projected temperature and precipitation values for each month was summarized across the ensemble of climate models and emissions scenarios using a range of values. The mean, and the upper bound, have been included in the SWWBM to analyze the effects of climate change. Lake evaporation, snow accumulation and snowmelt were calculated in the same way as for the average scenario.

4.5.2 Hydrology Inputs

The following sections describe the hydrologic processes and inputs used in the SWWBM.

4.5.2.1 Runoff Parameters

Runoff in the SWWBM is estimated using seasonal runoff coefficients. Runoff coefficients represent the proportion of rainfall that reports as runoff or seepage, accounting for losses due to evaporation, storage, and infiltration. Adjustment during the calibration process resulted in a 30% increase of the general runoff coefficients in cases where the monthly precipitation exceeds 50 mm. The runoff coefficients account for the following two seasonal climate periods:

- **General (July to February)** – mid-range coefficients to reflect soil moisture contents for intermittent runoff events.
- **Freshet (March to June)** – highest runoff coefficients to represent expected higher soil moisture content, and therefore greater runoff.

The seasonal runoff coefficients defined for the catchment types considered in the SWWBM are presented in Table 6.Runoff coefficients are adjusted during the annual SWWBM calibration to align estimated runoff volumes with Site monitoring data.

Table 6: Seasonal Runoff Coefficients

Catchment Type	General	Freshet
Exposed tailings	0.6	0.9
Disturbed areas	0.3	0.9
Rock disposal site areas	0.1	0.6
Open pits	0.75	0.9
Undisturbed catchments	0.4	0.42
Haul roads and access roads	0.15	0.9
Mill site area	0.1	0.1

Source: Golder 2020

4.5.2.2 Catchment Areas

To model runoff, direct precipitation, and evaporation, the catchment areas for each storage element were defined in the model. The catchment/reporting area for each storage element remains consistent with the TAR (Golder 2016a). However, there's one exception: the TSF impoundment catchment at the projected 987 m crest. Any alterations would mainly affect the infrastructure downstream of the TSF, but these changes are expected to have minimal impact on the model results. The catchments are shown in Table 7. Subdivision of catchments areas by land type are presented in Table A-1 in APPENDIX A.

Table 7: Current Catchment Areas for SWWBM Storage/Conveyance Elements

Storage or Conveyance Element	Total Reporting Area (m^2)
South Seepage Pond	385
Main Embankment Seepage Pond	376,900
TSF Upstream Catchment (External)	622,800
TSF Impoundment Catchment (Internal – current)	2,269,700
TSF Impoundment Catchment (Internal – projected at 987m raise) [(a)]	2,860,000
Perimeter Embankment Till Borrow Pond (PETBP)	524,300
Central Collection Sump (CCS)	438,600
Bootjack Creek Sump	175,200
SERDS Ditch[(b)]	1,537,600
Mill Site Sump	1,630
Mine Drainage Creek Sump	1,115,900
Long Ditch	2,494,000
Cariboo Pit	1,320,400
Springer Pit	651,900
NW Sump	330,200
9K Sump	698,700
Wight Pit	413,900
Boundary Pit	23,400
Total Reporting Area	**12,997,315**

Source: Golder 2016a. Update on TSF impoundment based on TSF projections.

(a) The raise of the TSF will affect the catchments producing runoff into the TSF pond. To consider the increase of the TSF impoundment catchment, the model interpolates the TSF impoundment catchments between the current state and the TSF raise to 987m. Changes in other catchments are minor.

(b) The current SERDS Tailings Co-Disposal project does not affect the delineation of the catchment.

After finishing operations, some mining features become remediated during closure and become non-contact water during post-closure. This is modelled by changing the land types, from disturbed to not disturbed areas. The land types define the runoff coefficients (Table 6) and the water quality, which is analyzed in the Water Quality Report (WSP 2023d). The model logic to convert the land types it is as follows (all timeframes are from start of closure on April 1, 2031 – assumed for the purpose of modelling):

- Roads:
  - 14% of total road area switch to disturbed at year 3.
  - 21% of total road area (additional 7%) switch to disturbed at year 4.
  - Negligible amount of road surface is fully reclaimed (no undisturbed road area ever).
- Dump areas transition to disturbed at the following rate:
  - Closure + year 1 = 22%.
  - Closure + year 2 = 37%.
  - Closure + year 3 = 61%.
  - Closure + year 4 = 100%.
- Mill site
  - Areas switch to disturbed at year 2.
- All Disturbed areas, not including unreclaimed roads, will transition to undisturbed at the following schedule:
  - year 5 = 25%.
  - year 10 = 50%.
  - year 15 = 75%.
  - year 20 = 100%.

After this time all areas will be undisturbed except Pit areas and unreclaimed roads.

4.5.3 Groundwater Inputs

Groundwater flow has been assessed for the following open pits at the mine: Springer Pit, Cariboo Pit, Wight Pit, and Boundary Pit. Groundwater flows with dependency on the water level of the pits are presented in Appendix B of the TAR (Attachments C, D, E, and F; Golder 2016a) and repeated in Appendix A of this report.

4.5.4 Storage Capacities

Free water volumes in storage ponds, sumps, and the TSF depend on a balance between their inflows and outflows. The stage (elevation) can be directly correlated to a specific storage volume using bathymetric and topographic data. These relationships are referred to as stage-storage curves.

Dynamic storage facilities such as the TSF, where tailings deposition changes the available storage, require regular survey updates to confirm whether existing stage storage curves are appropriate for projecting free water volumes. Stage-storage curves for the TSF up to a crest elevation of 987 m were developed from the 2020 TSF survey. These curves were obtained from preliminary tailings deposition modelling carried out in support of the design of the 987 m TSF.

The stage-storage curves projected up to a crest elevation of 987 m constitute a 2-D element that considers the tailings tonnage. These curves will interpolate according to the dry tailings volume across the Springer Expansion LOM schedule. Additionally, these curves are limited by the spillway invert stated in Table 1, serving as the upper boundary for the maximum TSF elevation. The stage-storage curves up to a crest elevation of 987 m crest in this report are provided in APPENDIX A.

Stage-storage curves were available for the following major storage elements and are provided in APPENDIX A:

- Springer Pit (November 7, 2019, bathymetry survey)
- Cariboo Pit (June 3, 2022, topographic survey)
- TSF (June 17, 2020, bathymetric survey tied-in with October 22, 2019, topographic survey)
- Wight Pit (January 13, 2022, bathymetric survey)

The estimated volume capacities for the facilities listed above and other storage locations are presented in Table 8.

Table 8: Maximum Capacities for Major Storage Facilities

Major Storage Facility	Estimated Capacity (M-m^3)
Springer Pit[(a)]	14.8
Cariboo Pit[(a)]	5.1
Combined Springer-Cariboo Pit final mine-out	30.3
TSF – 987 m crest elevation design	5.7[(b)]
Wight Pit	3.8
PETBP	0.17

(a) Represents current individual pit volumes (i.e., before pits are combined or further mined.)

(b) Capacity at the final stage of the TSF, when tailings deposition ends.

When the embankment reaches an elevation of 987 m, the TSF pond will be pushed towards the north abutment. The TSF will be available to store freshet water until four months after the start of the closure phase (July 31, 2031) in order to capture the last freshet period during the operations phase. Commencing August 1, 2031, TSF volume will be progressively reduced to 0.25 M-m^3 over the course of two months due to construction of the closure spillway.

4.5.5 Mine Plan

The mine plan for the Springer Expansion was updated in the SWWBM and assumed a milling operational end date of March 2031. Tonnage/volume of dry tailings during the project is provided in Table 9 (MPMC 2022). It is assumed that 6.55 M-tons of dry tailings have been placed in the TSF between the mine plan start date of July 1, 2022, and the assumed SWWBM operations start date of May 2, 2023.

Table 9: Mine Plan (Annual Totals)

Year	Dry Tailings (tons)
2022[(a)]	3,530,469
2023	7,300,000
2024	7,300,000
2025	7,300,000
2026	7,300,000
2027	7,300,000
2028	7,300,000
2029	7,300,000
2030	7,300,000
2031[(b)]	860,381

(a) Mine plan starts on July 1, 2022.

(b) Mine plan ends on March 31, 2031.

4.5.6 TSF Pond Volumes

Temporary detention of water in the TSF is necessary to manage large site runoff volumes that can be generated during freshet; however, a fundamental basis of the water management plan is to not accumulate water on-site year over year (including within the TSF) by treating and discharging water.

The minimum and maximum operational water volumes in the TSF under normal conditions are 1.5 M-m^3 and 1.7 M-m^3, respectively.

The water balance model activates and deactivates pumping flows. As a result, the TSF pond volume is set at 1.5 M-m^3 prior to freshet and it returns to the specified normal operating range after freshet. TSF volume conditions are presented in Table 10.

Table 10: TSF Pond Volume Values

Condition	TSF Pond Volume (M-m^3)
Minimum under normal conditions	1.5
Maximum prior to freshet (February-April)	1.5
Maximum after freshet and until freeze-up	1.7

Note: M-m^3 = 1 × 10^6 m^3

4.5.7 Flow Derivation and Logic

This section describes the model logic for pumped flows, seepage (from the TSF), groundwater inflows and outflows, consumption, and transfer flows.

In general, the model localizes the outflows of the TSF and pits and ponds; based on demand priorities using modeling elements known as "allocators." When water is present in storage, the allocator calculates evaporation as the first priority, followed by all pumping flows depending on the configured priorities. The maximum pumping capacity is utilized when water is available. If the total outflow is restricted, a lower or zero pumping rate is applied.

4.5.7.1 Pumped Flows

The most relevant transfer rates, including rates between TSF, Pits and PETBP; have been informed by MPMC (MPMC 2023b), while the remaining rates remain consistent with the TAR model and were based on engineering judgement (Golder 2016a). Maximum pumping rates for the operational, closure, and post-closure phases (2023 to 2131) are shown in APPENDIX A.

It should be noted that the capacity set for transfer from TSF to Wight Pit (P30) was assumed at a capacity to avoid PETBP overflow during operations. Capacity set for transfer from CCS to Wight Pit (P35) during closure is a WSP assumption to allow suitable water transfer capacity between CCS and Wight Pit during the closure phase, and this future conveyance system will require design confirmation as the Site approaches closure.

4.5.7.2 PETBP Pumping Logic

PETBP will begin pumping water to the TSF when the water elevation at the PETBP surpasses 923.25 m or when the TSF water volume drops below the minimum threshold by 50,000 m^3 or more.

4.5.7.3 Mill Process Flows

The mill process water requirements are based on 2.0 m^3/t of tailings. Interstitial water sequestered in the deposited tailings is based on 0.347 m^3/t of tailings deposited.

4.5.7.4 Consumption Flows

Consumption flows are system losses attributed to the operation of dust suppression equipment. Consumption flows were estimated by MPMC staff for operations (MPMC 2023b) and are modelled according to the following logic:

- Turbo-misters operate from May to September.
- Water trucks withdraw water at variable rates from May to September.

Consumption flow rates are presented in APPENDIX A.

4.5.7.5 Tailings Storage Facility Flows

WSP is currently designing a new upstream drain system to accommodate the increase in the TSF pond elevation (WSP 2023e). The new upstream drain system will capture water within the tailings above 970 m and convey it to the seepage collection system, downstream of the TSF embankment. WSP has estimated the water flows through the upstream drains based on the distance between the pond and the embankment (beach width).

Estimation of flows have been made for each embankment:

- S1: South Embankment
- S2: Main Embankment
- S4: Corner 1 Embankment
- S5: Perimeter Embankment

Seepage flows from the TSF (S1 to S5) during operations were estimated using a two-dimensional numerical groundwater flow model to quantify anticipate seepage rates through the embankment and foundation. Seepage analyses for typical sections of the elevation of 987 m configuration of the South Embankment, Main Embankment, Perimeter Embankment, and Corner 1 Embankment under steady-state conditions. The analyses were conducted using GeoStudio 2021, developed by GEOSLOPE International Ltd. Seepage from the TSF has been defined to occur continuously without interruption in the SWWBM. Table 11 presents the estimated seepage flow rates through each embankment with dependency on the beach width.

Table 11: Seepage Flow Rates

Beach (m)	Flow Rate (L/s)			
	S1	S2	S4	S5
0	79	96	81	89
50	39	50	53	46
100	25	32	38	31
200	14	18	23	18
300	9	12	15	13

Note: includes flows through upstream drains and embankment. All flows estimated for the 987 m raise.

The progressive location of the TSF pond will depend on operational decisions during the deposition of tailings; thus, the change in beach widths have been assumed consistent for each embankment. Based on estimates of the TSF pond volume and satellite imagery of the pond location since restart of operation in 2016, an estimation of embankment beach width has been made for different pond sizes. The estimates are provided in Table 12, which outline a conservative scenario, in terms of seepage flow quantities.

Table 12: Tailings Beach Width

TSF Pond Volume (m^3)	Beach Width (m)			
	S1	S2	S4	S5
0	300	300	300	300
1,500,000	300	300	300	300
2,500,000	200	200	200	200
3,000,000	100	100	100	100
5,500,000	0	0	0	0

The model uses both Table 11 and Table 12 presented above to calculate the beach width and consequently the seepage flow rates through the embankments during operations. For every time step the model calculates the TSF volume and consequently the beach width, and finally the seepage flow rate.

Starting from four months into closure (August 1, 2031), the TSF pond reduces its volume to 0.25 M-m^3 within two months due to the construction of the closure TSF spillway. This is estimated to increase in the seepage flow rate on the perimeter embankment close to corner 1, as the TSF pond will be pushed to that corner. For modelling purposes, it is considered that the seepage flow rate in Table 13 will be in effect 6 months after the end of the operation phase and throughout the post-closure phase.

Table 13: Tailings Beach Width at Last Year of Operation and Closure

Flow Rate (L/s)			
S1	**S2**	**S4**	**S5**
70	0	0	0

Note: Values start 6 months after end of operation. Maximum capacity of TSF pond is limited to 250,000 m³.

5.0 WATER BALANCE RESULTS

The following sections present major model results for the operational and closure phases, and partial results for post-closure phase. Full extension of post-closure results are presented in Appendix C.

5.1 WTP Treatment Capacity

Throughout the entire planned future operations and closure periods to March 31, 2041, the maximum treatment capacity of the WTP in the model is assumed to be 25,000 m^3/day (0.29 m^3/s, 9.15 M-m^3/year). Excess water beyond this discharge rate is temporarily stored within the TSF until it can be treated and discharged. Centralized collection and treatment of contact water is assumed during operations, closure, and post-closure. The Mine's current discharge permit authorizes an annual discharge volume of 10.59 M-m^3.

In year 2041, the assumed treatment capacity of the WTP in the model remains at 25,000 m^3/day (0.29 m^3/s). However, annual contact water requiring treatment is reduced over the post-closure phase as site areas are remediated and some runoff is considered non-contact water, as shown in the flow diagram Figure B-3 provided in Appendix B. The annual contact water treated discharge volume declines further in year 2051 when the South Seepage Pond and Main Embankment Seepage Pond catchments are considered remediated, commencing 10 years after the post-closure phase. At the end of the operations phase, contact water requiring treatment notably increases in 2031, as milling is assumed to terminate in 2031 and the demand for milling process water also terminates.

Estimated annual contact water volumes requiring treatment from operations to post-closure are presented in Table 14, and Figure 2 illustrates daily WTP discharge rates from operations to 10 years after post-closure.

Table 14: WTP Annual Volume Requiring Treatment (M-m^3)

Year	Annual Volume Requiring Treatment at WTP (M-m^3)		
	50th Percentile	90th percentile	99.5th percentile
2023[a]	3.90	4.57	5.72
2024	5.00	5.94	7.24
2025	3.50	4.97	6.79
2026	3.37	4.72	6.53
2027	3.35	4.79	6.60
2028	3.36	4.80	6.70
2029	3.39	4.78	6.46
2030	3.31	4.75	6.56
2031[b]	3.93	4.39	5.04
2032	5.56	6.68	7.82
2033	5.54	6.57	7.57
2034	5.50	6.54	7.49
2035	5.42	6.42	7.44
2036	5.43	6.44	7.36

Table 14: WTP Annual Volume Requiring Treatment (M-m^3)

Year	Annual Volume Requiring Treatment at WTP (M-m^3)		
	50th Percentile	90th percentile	99.5th percentile
2041[(c)]	2.36	2.88	4.04
2046	1.80	2.27	3.31
2051	0.46	0.83	1.39
2071	0.33	0.71	1.48
2091	0.32	0.69	1.60
2111	0.32	0.71	1.44
2131	0.02	0.03	0.05

(a) Model simulation start date: May 2, 2023.
(b) Closure starts on April 1, 2031.
(c) Post-closure starts on April 1, 2041.

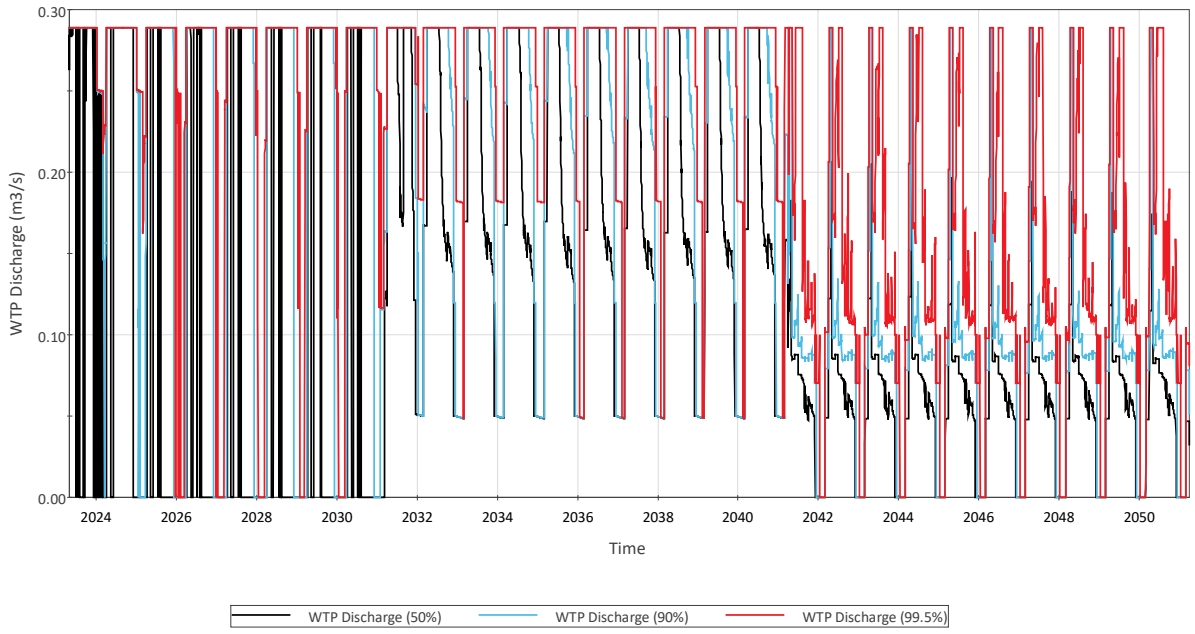

Figure 2: WTP Discharge Rate from Operations to 10 years after Post-Closure

5.2 Tailings Storage Facility

Temporary detention of water will be necessary to manage the large runoff volumes generated during freshet (typically April to June). The inflows during freshet will exceed treatment capacity, and detention volume is required to prevent uncontrolled release from the PETBP and to equalize the flow for treatment. The TSF is available to store excess freshet water until four months after the start of closure. At that time, the TSF pond will decrease its volume to 0.25 M-m³, the maximum allowable volume at closure.

To create the reduced TSF pond, a closure spillway will be constructed at the north abutment (Corner 5) of the TSF. Water will discharge from the TSF to the CCS, and then flow to the PETBP for treatment prior to discharge.

During closure and post-closure, the TSF pond is modelled to discharge annually via the spillway, and the TSF pond volume will vary seasonally, limited by the spillway invert, to a maximum of approximately 0.25 M-m^3. As from Figure 3, the volume fluctuation follows a consistent pattern during both closure and post-closure periods, with minimum values occurring in winter and reaching maximum capacity during freshet (0.25 M-m^3).

Figure 3 shows the water volume in the TSF throughout future operations and into closure until 10 years after post-closure. The TSF volume pattern shown for the 2041-2051 post-closure period is continued for the remaining 80 years of post-closure (until 2131). Table 15 shows tabulated minimum, average, and maximum bounds for the three percentile trends shown in Figure 3.

Table 15: TSF Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	1,330,244	1,390,394	1,429,751
	Average	1,493,500	1,576,822	1,809,717
	Maximum	2,840,000	2,840,000	3,493,139
Closure	Minimum	0	0	0
	Average	119,248	188,149	265,076
	Maximum	1,756,506	2,012,120	2,479,271
Post-Closure	Minimum	0	0	0
	Average	50,710	116,082	182,881
	Maximum	252,571	252,571	252,571

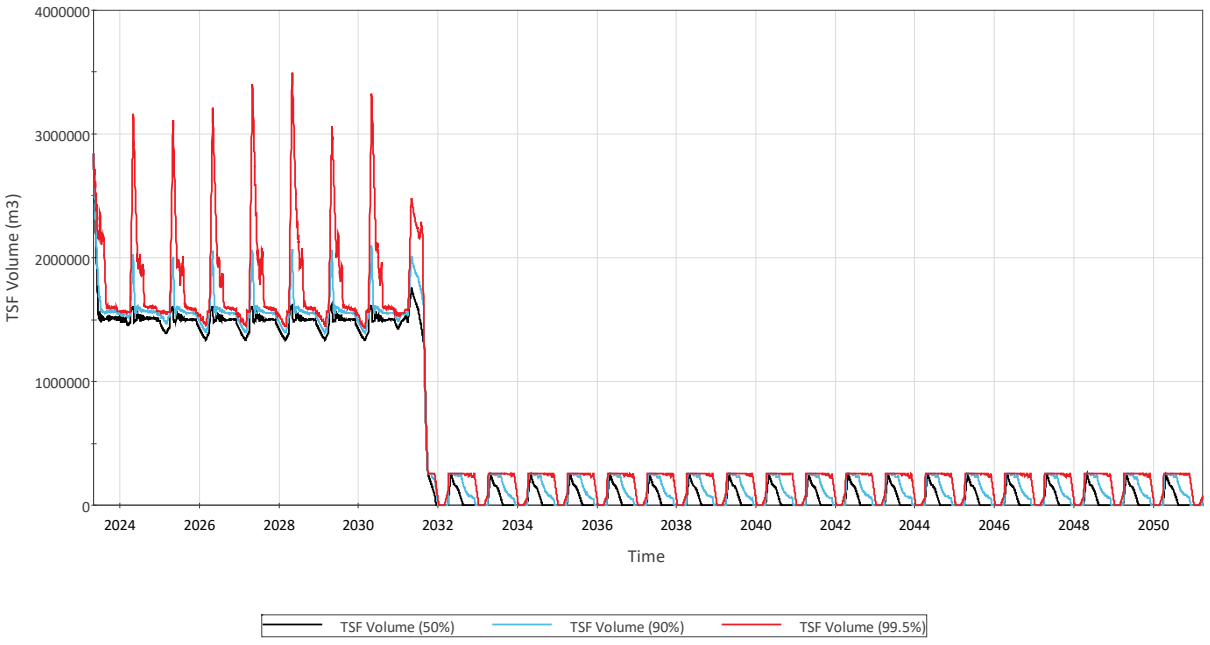

Figure 3: TSF Water Volume from Operations to 10 Years after Post-Closure

5.3 Springer Pit

The simulated Springer Pit water volume during the operational phase is shown in Figure 4 for the 50th, the 90th, and the 99.5th percentiles. The simulations were run from an initial Springer Pit storage volume of 0 m^3 on May 2, 2023. During the operational phase, the volume in Springer Pit is reduced to the minimum volume before each freshet, and temporary storage will occur during the freshet, as freshet inflow exceeds pit dewatering pumping capacity.

Springer Pit and Cariboo Pit are modelled as a single pit in the closure phase, using the stage-storage curve based on the ultimate projected topography, as detailed in Section 5.5.

Table 16: Springer Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0
	Average	8,620	35,720	117,745
	Maximum	74,124	169,623	361,074

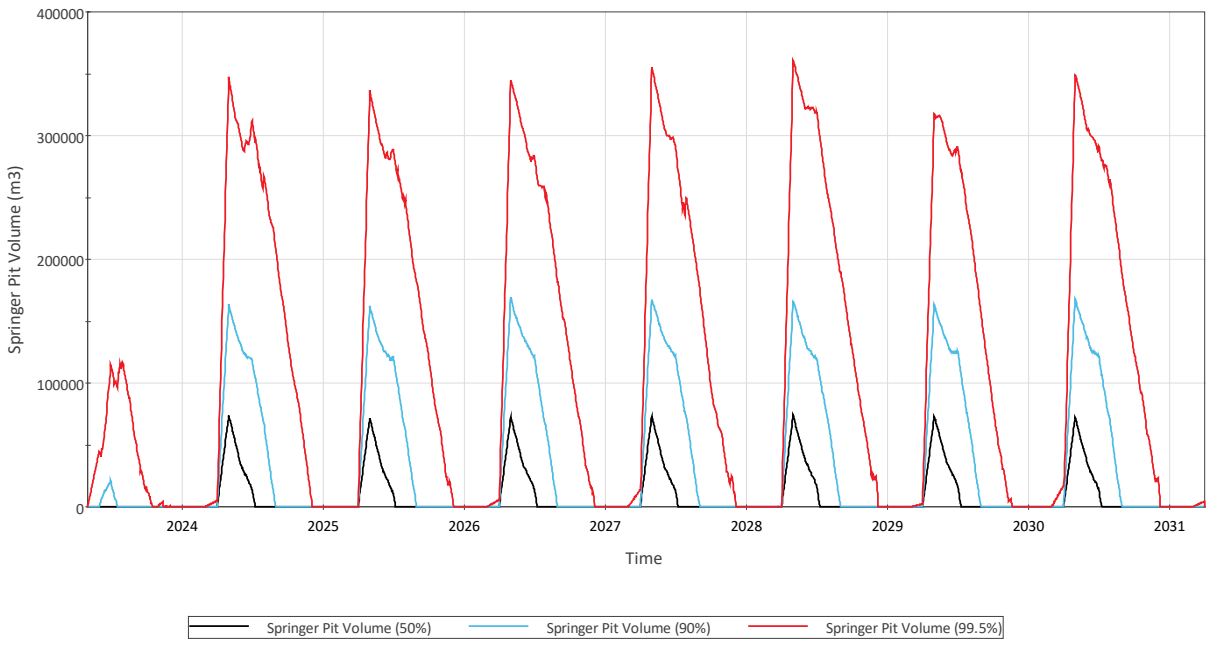

Figure 4: Springer Pit Water Volume during Operations

5.4 Cariboo Pit

Simulated Cariboo Pit water volumes during the operational phase are shown in Figure 5 for the 50th, the 90th, and the 99.5th percentiles. The simulations were run from an initial Cariboo Pit storage volume of 0.24 M-m^3 on May 2, 2023. During the operational phase, the volume in Cariboo Pit is reduced to the minimum volume before each freshet, and temporary storage will increase to its maximum volume of 0.26 M-m^3 during the freshet. Springer Pit and Cariboo Pit have been modelled as one combined pit in the closure phase as explained in Section 5.3.

Table 17: Cariboo Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0
	Average	81,256	112,813	169,463
	Maximum	259,249	259,249	259,249

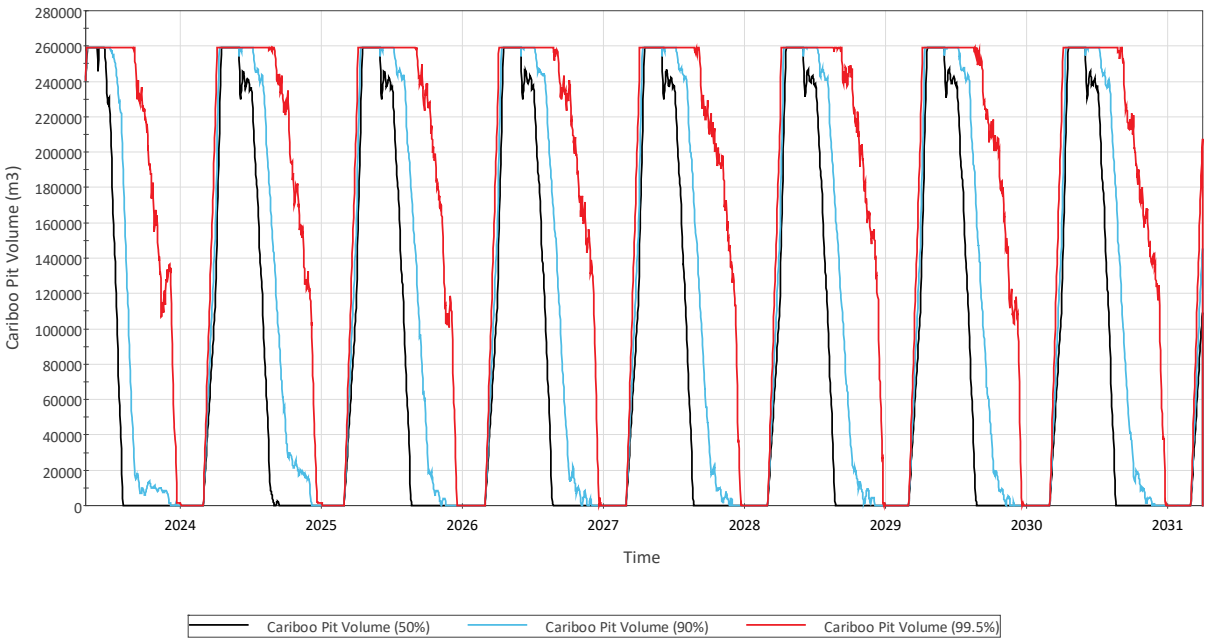

Figure 5: Cariboo Pit Water Volume during Operations

Table 18 shows the modelled average annual overflow volume from the Cariboo Pit during operations, and these overflow volumes are included in the total annual volumes required for treatment shown in Table 14.

Table 18: Cariboo Pit Annual Overflow (m^3)

Phase	Cariboo Pit Annual Average Overflow (m^3)		
	50th Percentile	90th percentile	99.5th percentile
Operations	283,897	574,260	1,221,920

5.5 Combined Springer-Cariboo Pit

Springer Pit and Cariboo Pit were modelled as a single pit for the closure phase (starting April 1, 2031). A result comparison between different percentiles for Combined Springer-Cariboo Pit volume during closure and post-closure is provided in Figure 6 . Potentially Acid Generating (PAG) waste rock will be stacked uniformly to an elevation of 1,004 m in the base of the Combined Springer-Cariboo Pit at the end of the operations phase. Results of the simulations indicate that water levels within the pit will cover the PAG material placed in pit by approximately 2033 under the 99.5th percentile condition, while under the rest of the climate conditions it is estimated to cover the PAG material placed in pit by 2034. Under the 50th percentile results, the combined Springer-Cariboo Pit lake is estimated to start overflowing in 2058, while under the 90th percentile it is estimated to start overflowing in 2056, and in 2055 under the 99.5th percentile. The Water Quality Report (WSP 2023d) discusses modelled water quality of the Springer-Cariboo pit lake at the estimated time of overflow.

Table 19: Combined Springer-Cariboo Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Closure	Minimum	109,345	145,263	211,031
	Average	4,827,785	5,199,295	5,652,177
	Maximum	9,030,590	9,598,661	10,300,000
Post-Closure	Minimum	9,032,744	9,600,627	10,300,000
	Average	20,033,811	20,167,573	20,287,305
	Maximum	21,100,000	21,100,000	21,100,000

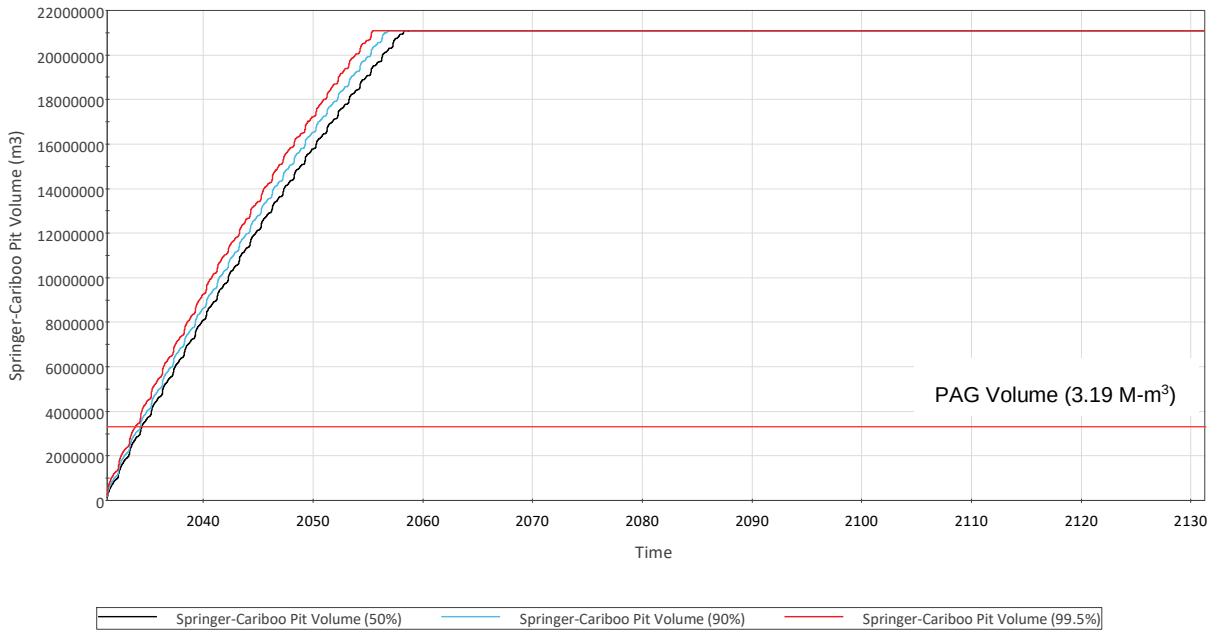

Figure 6: Combined Springer-Cariboo Pit Water Volume from Closure

The combined Springer-Cariboo Pit is modelled to fill to its maximum volume during post-closure. Following that time, additional volume collected in the combined pit will overflow from the pit's spillway and is assumed to direct discharge to the receiving environment in the SWWBM. Water quality and water treatment discussion is included under separate cover regarding this assumption of direct environmental discharge of pit lake overflow during post-closure.

Table 20 shows the modelled average annual overflow volume from the combined Springer-Cariboo Pit.

Table 20: Combined Springer-Cariboo Pit Annual Overflow (m^3)

Phase	Combined Springer-Cariboo Pit Annual Average Overflow (m^3)		
	50th Percentile	90th percentile	99.5th percentile
Post-Closure	469,711	1,051,048	2,249,910

5.6 Perimeter Embankment Till Borrow Pond (PETBP)

The PETBP serves as the final component of the centralized water management infrastructure, collecting water from the entire site. From this point, the water is pumped back to the mine for reuse, storage, or treated and discharged through the adjacent WTP. The current maximum capacity of the PETBP is 170,000 m^3. When the water volume in the PETBP exceeds 121,700 m^3 during the operations phase, modelled pumps to the TSF are activated to prevent overflow.

The 50th percentile results show that the maximum volume in the pond approaches 125,000 m^3 during the freshet. There are no occurrences of overflow from the PETBP under the simulated conditions during the future operational phase. During closure and post-closure, less storage is available in the overall water management system, and the PETBP reaches higher maximum volumes during freshet periods and does not have the capacity to prevent overflow for the 99.5th percentile results (as shown in PETBP overflow volumes listed in Table 22). The SWWBM predicts that the PETBP will have sufficient capacity to prevent overflow for the 50th and 90th percentile climate conditions. It is assumed that sufficient storage will be implemented during closure to prevent any unwanted overflow of contact water requiring treatment during the closure phase. The volumes listed in Table 22 are included in the total annual volumes required for treatment shown in Table 14.

Estimated storage volumes in the Perimeter Embankment Till Borrow Pond (PETBP) from operations to 10 years after post-closure are presented in Figure 7, with minimum, average, and maximum bounds of those trends shown in Table 21.

Table 21: PETBP Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	57,800	57,800	57,800

2131	0	0	0

(a) Model simulation start date: May 2, 2023.
(b) Closure starts on April 1, 2031.
(c) Post-closure starts on April 1, 2041.

5.7 Wight Pit

The water volume in Wight Pit is expected to increase during every freshet season. Four months into the closure phase, the TSF pond will be reduced to 0.25 M-m^3 within two months. Once the TSF can no longer provide freshet storage, Wight Pit will be used to store excess water. During post-closure, Wight Pit will no longer be used for freshet storage and will be allowed to fill. Wight Pit is projected to start overflowing in 2049 under the 50th percentile results, and in 2047 under the 90th and 99.5th percentile results. Overflow from Wight Pit during post-closure is assumed as direct environmental discharge to Polley Lake and the water quality implications of this assumption are discussed under separate cover. Estimated volumes stored in Wight Pit from operations to 10 years after post-closure are presented in Figure 8 and the average annual post-closure overflow volumes are shown in Table 24.

Table 23: Wight Pit Water Volume (m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0

6.0 SUMMARY

The SWWBM was updated to reflect the Springer Expansion LOM plan during the operational phase and incorporates closure and post-closure phases for the Mount Polley Mine. The SWWBM supports water management planning and the assessment of water quality and associated water treatment and discharge options.

The model was run from May 2, 2023, to March 31, 2131, and included the following LOM phases:

- operational phase extending from May 2, 2023, to March 31, 2031.
- closure phase extending from April 1, 2031, to March 31, 2041.
- post-closure phase commencing on April 1, 2041, and extending, for the purposes of this analysis, to 2131.

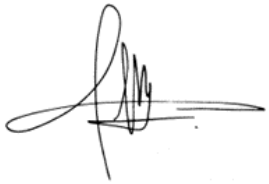
The model was run stochastically for 2000 realizations to present 50th, 90th, and 99.5th percentile model results. The results for the modelling during the operational phase are presented as follows:

- The average annual treated discharge for the 50th percentile is approximately 3.65 M-m^3 between 2023 and 2031, while the milling process water demand exists.
- The maximum annual treated discharge for the 99.5th percentile 7.21 M-m^3 in 2031.
- The maximum TSF pond volume during the operational phase is approximately 3.49 M-m^3 for 99.5th percentile, and 1.62 M-m^3 for the 50th percentile results (excluding 2023 when the TSF is initially set to 2.84 M-m^3 in the model).
- During the operational phase, the volume in Springer Pit and Cariboo Pit are both decreased to empty before each freshet, and temporary storage will occur during the freshet.
- There are no overflows from the PETBP under the simulated conditions during the operational phase.

The conclusions for the modelling during closure and post-closure phases are as follows:

- The average annual treated discharge for the 50th percentile result is approximately 0.95 M-m^3.
- The TSF pond volume will vary seasonally, limited by the spillway invert, to a maximum of approximately 0.25 M-m^3.
- The combined Springer-Cariboo Pit Lake is estimated to start overflowing between 2055 and 2058, with an average annual 50th percentile overflow volume of approximately 0.47 M-m^3.
- PAG material placed in the combined Springer-Cariboo Pit is estimated to be inundated and covered by the pit lake between 2033 and 2034.
- During closure, the volumes in PETBP are reduced to the minimum volume before each freshet, and temporary storage will occur during the freshet under each of the climate conditions simulated. During closure and post-closure phases, the PETBP does not have sufficient storage capacity to prevent overflow during freshet for the 99.5th percentile condition; however, these overflow volumes are included with the annual treatment requirement volumes.
- The Wight Pit is expected to initiate spilling between 2047 and 2049, with an average annual 50th percentile overflow volume of approximately 0.47 M-m^3.

7.0 CLOSING



This report summarizes the SWWBM to support the water management information requirements for the Springer Expansion LOM plan.

We trust that this report satisfies your current requirements. Please contact the undersigned should you have any questions.

A3.0 FLOW RATES

A3.1 Pumped Flows

Except for P13 and P15, which were measured at 545 m^3/d and 2.5 m^3/d, respectively (Golder 2016a), all maximum pumping rates have been assumed. Among these rates, P4b, P5, T6, P9b, P17b, P21, P30, and P32 were provided by MPMC (MPMC 2023b), while the remaining rates remain consistent with the TAR model and were based on Golder's engineering judgement (Golder 2016a).

Maximum pumping rates for operational flows are shown in Table A-3, and maximum pumping rates for closure flows are shown in Table A-4. It should be noted that any pumped flows shown in Table A-3, but not shown in Table A-4, are assumed to be decommissioned with zero transfer capacity.

Table A-3: Maximum Pumping Rates for Operational Flows

Flow ID	From	To	Flow Rate (m^3/day)	Reference
P4b	Cariboo Pit	PETBP	13,000	MPMC 2023b
P5	PETBP	TSF	100,000	Golder 2016a
P6	South Seepage Pond	Main Embankment Seepage Pond	8,640	Golder 2016a

(a) No maximum pumping rate applied. This pumping demand is dynamic and depend on the required pumping rate to dewater the Mine Drainage Creek Sump.

(b) Based on measured flow rates (Golder 2016a).

(c) 14,088 m3/day effective starting September 2023.

(d) Capacity assumed to avoid PETBP overflow during operation. See Section 4.5.7.1 in the main report.

(e) No maximum pumping rate applied. These are defined based on the process flow requirements from the Mill, where P27 is defined as process water (including interstitial water) in addition to tailings solids, and P28 is defined as process water demand.

(a) Active to use Wight Pit to store water when TSF is not available for storage during closure. See Section 4.5.7.1 in the main report.

A3.2 Consumption Flows

The flow parameters for the turbomisters are shown in Table A-5 and Table A-6.

Table A-5: Operational Hours per Day for Turbomisters

Flow ID	From	Hours per Day				
		May	June	July	August	September
C1	Main Embankment Seepage Collection Pond	10	10	10	10	10
C10	Wight Pit	10	10	10	10	10

Table A-6: Operational Flow Rates for Turbomisters

Flow ID	From	Evaporation Rates (m^3/hr)	
		May and June	July to September
C1	Main Embankment Seepage Collection Pond	5.5	12.7
C10	Wight Pit	5.5	12.7

The flow parameters for water trucks are shown in Table A-7 and Table A-8 below.

Table A-7: Operational Days per Month for Water Trucks

Flow ID	From	Days per Month				
		May	June	July	August	September
C4	Wight Pit	0	0	20	20	15
C8	CCS	4.5	19	12.6	21.5	10.6

Table A-8: Operational Flow Rates for Water Trucks

Flow ID	From	Flow Rates (m^3/day)
C4	Wight Pit	818
C8	CCS	818

A3.3 Transfer Flows

The flow rates for the transfer flows were defined in the model as described in Table A-9.

Table A-9: Transfer Flows

Flow ID	From	To	Flow Definition/Rates
T1	Long Ditch	Central Collection Sump	Flow rates determined by runoff and baseflow from the Long Ditch catchment.
T2	SERDS Ditch	Central Collection Sump	Flow rates determined by runoff and baseflow from the SERDS ditch catchment.
T3	Central Collection Sump	PETBP	Modelled as the overflow rate from the CCS.
T6[(a)]	PETBP	Water Treatment Plant	Maximum capacity 25,000 m^3/day during operations until post-closure.

(a) Provided by Maximum pumping rates provided by MPMC (MPMC 2023b).

A3.4 Groundwater inputs

Springer Pit

A hydrogeological assessment was conducted to predict the quantity of long-term groundwater seepage from both the Springer and the Cariboo pits towards Bootjack Lake (Golder 2016b). The analysis considered placing waste rock in the ultimate pit prior to the pit lake formation. As the pit lake level increases between 1,020 masl and 1,030 masl, seepage in the range of 10 to 100 m^3/d from the Springer Pit Lake into the subsurface was predicted to occur (Table A-10). Seepage was found to gradually increase to approximately 400 m^3/d when the pit lake reaches the spillway at 1,050 masl.

Table A-10: Springer Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Flow (m^3/d)	
	Into the Pit	Out of the Pit
880	520	0
940	510	0
960	490	0
980	460	0
1000	420	0
1020	320	10
1030	300	100
1040	280	250
1050	270	400

Cariboo Pit

Predicted groundwater flows of Cariboo Pit remain consistent from Golder 2016b. In the Cariboo Pit, seepage towards the Bootjack Lake of approximately 20 m^3/d was predicted to occur only when the pit lake level approaches 1,050 masl.

Table A-11: Cariboo Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Flow (m^3/d)	
	Into the Pit	Out of the Pit
880	600	0
940	610	0
960	610	0
980	590	0
1000	540	0
1020	460	0
1030	420	0
1040	380	0
1050	320	20

Wight Pit

Groundwater inflow to the Wight Pit is projected to gradually decrease from 2,600 m^3/d at of 804 masl, to 600 m^3/d at 935 masl (Golder 2015). Table A-12 shows the predicted groundwater flows for Wight Pit.

Table A-12: Wight Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Flow (m^3/d)	
	Into the Pit	Out of the Pit
804	2600	0
880	2600	0
900	2500	0
910	2100	0
920	800	0
926	600	500
930	600	500
935	600	500

Boundary Pit

MPMC reported that seepage was not observed along the pit walls during mining. However, seepage out of the pit could still occur due to water entering via surface water runoff and direct precipitation. Potential seepage rates out of the pit were estimated to incorporate them into the pit water balance and to characterize a possible seepage pathway originating from this pit (Golder 2016c).

Seepage rates out of the Boundary Pit were estimated from a Darcy's Law calculation that considers changes in the dimensions of the seepage area as the pit is being flooded. The estimated seepage rate from the Boundary Pit when the pit lake surface level is 5m above its base (1,072 masl) is approximately 59 m^3/d, with a potential range between 35 m^3/d and 177 m^3/d due to uncertainty in bedrock permeability. Seepage outflow is estimated to decrease as the height of water column above the pit bottom decreases as shown in Table A-13.

Table A-13: Boundary Pit Predicted Groundwater Flows

Pit Lake Elevation (masl)	Groundwater Outflow (m^3/d)
1067	3
1068	10
1069	20
1070	26
1071	53
1072	59
1073	59

C3.0 TOTAL ANNUAL RUNOFF VOLUME FROM STOCKPILES/DUMPS

C3.1 Temp PAG Stockpile

The total annual runoff volume during operations for Temp PAG Stockpile is shown in Table C-5. The runoff was generated over the catchment area, which was broken down by different land types (i.e., waste rock, disturbed, undisturbed, and haul road). This catchment area breakdown was inserted as input into SWWBM. Table C-4 presents the distribution of these land types.

Table C-4: Temp PAG Stockpile Catchment Area Breakdown by Land Type

Land Type	Catchment Area (m^2)
Waste Rock Area	703,147
Disturbed Area	120,945
Undisturbed Area	140,272
Haul Road Area	63,800

Table C-5: Temp PAG Stockpile Annual Runoff Volume during Operations (m^3)

Year	50th Percentile	90th percentile	99.5th percentile
2023	122,711	226,570	445,588
2024	248,347	421,842	768,449

2029	249,343	422,660	755,345
2030	248,572	425,593	777,709
2031	26,050	41,089	68,748

C3.2 SERDS

The total annual runoff volume during operations for SERDS is shown in Table C-7. The runoff was generated over the catchment area, which was broken down by different land types (i.e., waste rock, disturbed, undisturbed, haul road, and mill site). This catchment area breakdown was inserted as input into SWWBM. Table C-6 presents the distribution of these land types.

Table C-6: SERDS Catchment Area Breakdown by Land Type

Land Type	Catchment Area (m^2)
Waste Rock Area	401,235
Disturbed Area	313,059
Undisturbed Area	383,918
Mill Site Area	273,919
Haul Road Area	165,456

Table C-7: SERDS Annual Runoff Volume during Operations (m^3)

Year	50th Percentile	90th percentile	99.5th percentile
2023	192,874	365,010	738,562
2024	360,384	625,704	1,163,887
2025	359,170	627,159	1,167,189
2026	359,541	635,520	1,138,079
2027	359,635	632,119	1,195,850
2028	360,975	631,021	1,198,955
2029	361,394	625,581	1,140,716
2030	360,604	629,622	1,172,763
2031	34,619	54,596	91,336

C3.3 NEZ Dump

The total annual runoff volume during operations for NEZ Dump is shown in Table C-9. The runoff was generated over the catchment area, which was broken down by different land types (i.e., waste rock, disturbed, undisturbed, and haul road). This catchment area breakdown was inserted as input into SWWBM. Table C-8 presents the distribution of these land types.

Table C-8: NEZ Dump Catchment Area Breakdown by Land Type

Land Type	Catchment Area (m^2)
Waste Rock Area	199,116
Disturbed Area	237,889
Undisturbed Area	202,646
Haul Road Area	261,421

Table C-9: NEZ Dump Annual Runoff Volume during Operations (m^3)

Year	50th Percentile	90th percentile	99.5th percentile
2023	134,053	250,501	499,643
2024	261,170	448,211	824,647

EXECUTIVE SUMMARY

Background

The Mount Polley Mine (the Mine, or Site) is a copper and gold mine operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. The Mine is located 56 km northeast of Williams Lake, British Columbia (BC), and is located between Polley Lake and Bootjack Lake.

MPMC began production at the mine in 1997 and operated until October 2001 when operations were suspended temporarily for economic reasons. In March 2005, the Mine restarted production and it was in continuous operation until 4 August 2014 when a subsurface failure of the Tailings Storage Facility (TSF) foundation resulted in mining and milling operations being suspended. MPMC was subsequently issued with a Pollution Abatement Order (Order #107461) by the BC Ministry of Environment and Climate Change Strategy (BC ENV). Containment infrastructure for collection of drainage from the breached section of the TSF was constructed by 4 September 2014, and all contact water was subsequently directed to and contained within the Springer Pit. This measure was implemented as part of the emergency response and was considered a temporary Water Management Plan to deal with changed conditions arising from the breach.

On 9 July 2015, MPMC was provided approval by the Ministry of Energy, Mines and Petroleum Resources (MEMPR) to return to restricted operations for a one-year period using the Springer Pit for tailings deposition and subject to the conditions stated in the M-200 Permit (Mine No. 1101163). On 23 June 2015, MPMC was provided approval by MEMPR to return to normal operations using the TSF for tailings deposition under an approved four-year mine plan as stated in the M-200 Permit.

MPMC has been in care and maintenance since May 31, 2019, which has resulted in an extension to the operational period needed to develop the permitted Phase 4 Cariboo-Springer Pit. In addition to this, the results of exploration and strong resource prices have provided the basis for an extended life of mine plan that will result in mining activity beyond Phase 4 Cariboo-Springer Pit, to include additional phases that will expand Springer Pit to consolidate Springer and Cariboo pits adding approximately 8 years to the life of the mine.

For the purposes of this report, WSP Canada Inc. (WSP) has assumed that the mine will be in operation until 31 March 2031, followed by a closure phase from 1 April 2031 to 31 March 2041, and a post-closure phase from 1 April 2041 to 31 March 2131. It should be recognized that this mine life may change as a result of metal prices, new exploration, care and maintenance periods, revisions to the mine plan, and other factors that are common to mining operations. These are only assumed mine phase dates to allow completion of modelling and should not be considered by regulators as static dates.

MPMC has a permit to discharge treated effluent from the Mine under the *Environmental Management Act* (EMA; SBC 2003) as Permit 11678. The permit was issued on 30 May 1997 and most recently amended through a Consent Order on 18 September 2020. An interim extension to Section 1.2.3 of PE-11678 was granted by BC ENV in 2022, allowing the existing discharge to Quesnel Lake to continue until 30 June 2025. The (2022) TAR provided an update on, among other things, receiving environment data and, in aggregate, provided scientific rationale to support the view that the discharge is not causing pollution. Under section 1.2.3 of Permit 11678, the “authorized discharge period” for discharge of effluent to Quesnel Lake expires on June 30, 2025. This discharge period is anticipated to support the permitted Phase 4 Cariboo-Springer Pit. However, MPMC is pursuing an extension to the life of the Mount Polley mine with the development of the Springer Expansion Project, which will add approximately 8 years of operational mining life.

Approval of this project will be sought through a Joint Application through the Ministry of Energy, Mines, and Low Carbon Innovation and the Ministry of Environment and Climate Change Strategy, with the request to BC ENV being an extension of the discharge period beyond 2025.

Section 2.10 of EMA Permit 11678 requires the development of a water management plan (WMP) that addresses future Water Management Plans beyond the end of 2022 and during mining operations. The WMP seeks to provide a practical plan for managing mine water for the proposed life of mine and to do so in a manner that reflects the requirements of Section 2.10 of the permit, based on information available at the time of writing. It also proposes an implementation schedule and revision process for the WMP.

In support of the WMP, the site wide water quality model was updated to reflect predicted mine site conditions during operations, closure, and post-closure (this report). This included updates to the water balance inputs and water quality inputs based on monitoring data. Updated geochemical source terms were also modelled in an alternative scenario (in place of inputs calculated from monitoring data) and were compared to model results that used monitoring data to calculate the water quality inputs. The model results from the scenario that used the geochemical source terms were considered overly conservative and are not presented in this report.

The updated predicted concentrations during operations, closure and post-closure in the mine site are similar to those presented in previous iterations of the water quality model including the 2016 Long Term Water Management Plan (Golder 2016) and the 2020 Water Management Plan (Golder 2020). For some parameters, the maximum predicted concentrations of total metals are lower during post-closure in this update of the water quality model. This change in predicted total metal concentrations is due to an adjustment to the particulate addition calculation during post-closure that now assumes a total suspended solids concentration that is representative of a reclaimed water quality input. Changes in concentrations from operations to closure and post-closure are caused by reclamation of mine site areas that are complete during post-closure. Predicted concentrations reach a steady state during post-closure after reclamation of the mine site areas is complete and the Springer Expansion pit is filled. Treatment and mitigation strategies during operations, closure and post- closure are addressed in the treatment section of the WMP (WSP 2023a).

STUDY LIMITATIONS

WSP Canada Inc. (WSP) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by WSP for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents WSP's professional judgement based on the knowledge and information available at the time of completion. WSP is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to WSP by MPMC, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by WSP are considered its professional work product and shall remain the copyright property of WSP. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

APPENDICES

APPENDIX A
Water Quality Model Calibration Results

APPENDIX B
Water Quality Model Results - Operations, Closure and Post-closure

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) retained WSP Canada Inc. (WSP) to update the Site Wide Water Quality Model (SWWQM) to support the joint permit amendment application for the new Springer Expansion life-of-mine (LOM) plan that will extend operations until 31 March 2031 (current estimates).

The SWWQM was developed as part of the Mount Polley Mine (Mine) Resumed Operations and Closure Water Management Plan Permit Amendment Application and Technical Assessment Report (Golder 2016a) to model water quality across the site. The SWWQM was updated in 2020 as part of the Water Management Plan that addressed water management through future operations (Golder 2020). The SWWQM was also updated as part of the Five Year Mine and Reclamation Plan (RCP) to include the closure and post-closure phases for the period of 1 September 2024 to 1 September 2124 (Golder 2022a).

This report presents the updates made to the SWWQM to predict parameter concentrations within the mine site during operations, closure and post-closure as part of the permit application for the Springer Expansion LOM plan. Included here is a summary of the model, assumptions, model inputs and results.

2.0 MODEL APPROACH

A site wide surface water balance model (SWWBM; WSP 2023a) was developed to predict flow quality at the Mine and potential discharges to the receiving environment during operations, closure and post-closure, and comprises the underlying framework for evaluating mass transfers in the SWWQM. The SWWQM is directly linked to the reclamation and closure SWWBM and includes mass transfers for each flow.

The SWWQM model does not include water treatment or mixing in the receiving environment. Rather, water quality was simulated in Mine facilities so that treatment technologies can be selected and applied, as described in the Water Management Plan that was prepared along with this report (WSP 2023b).

2.1 Model Platform

The model was developed using GoldSim Version 14.0 (GoldSim 2021). GoldSim is a graphical, object-oriented mathematical modelling program where all input parameters and functions are defined by the user and are built as individual objects or elements linked together by mathematical expressions. The object-based nature of the program is designed to facilitate an understanding of the various factors that control an engineered or natural system and to predict potential changes in the system.

GoldSim was selected for the current assessment for the following reasons:

- It facilitates probabilistic simulations, allowing descriptive statistics and probabilities to be assigned to the model outputs.
- The model framework can be easily adjusted to account for changing/future conditions on a mine site, allowing the model to be used as a planning tool.
- Water quantity and water quality models can be directly linked, allowing both models to be updated simultaneously when conducting sensitivity scenarios for alternate water management strategies.

2.2 Model Simulation Period

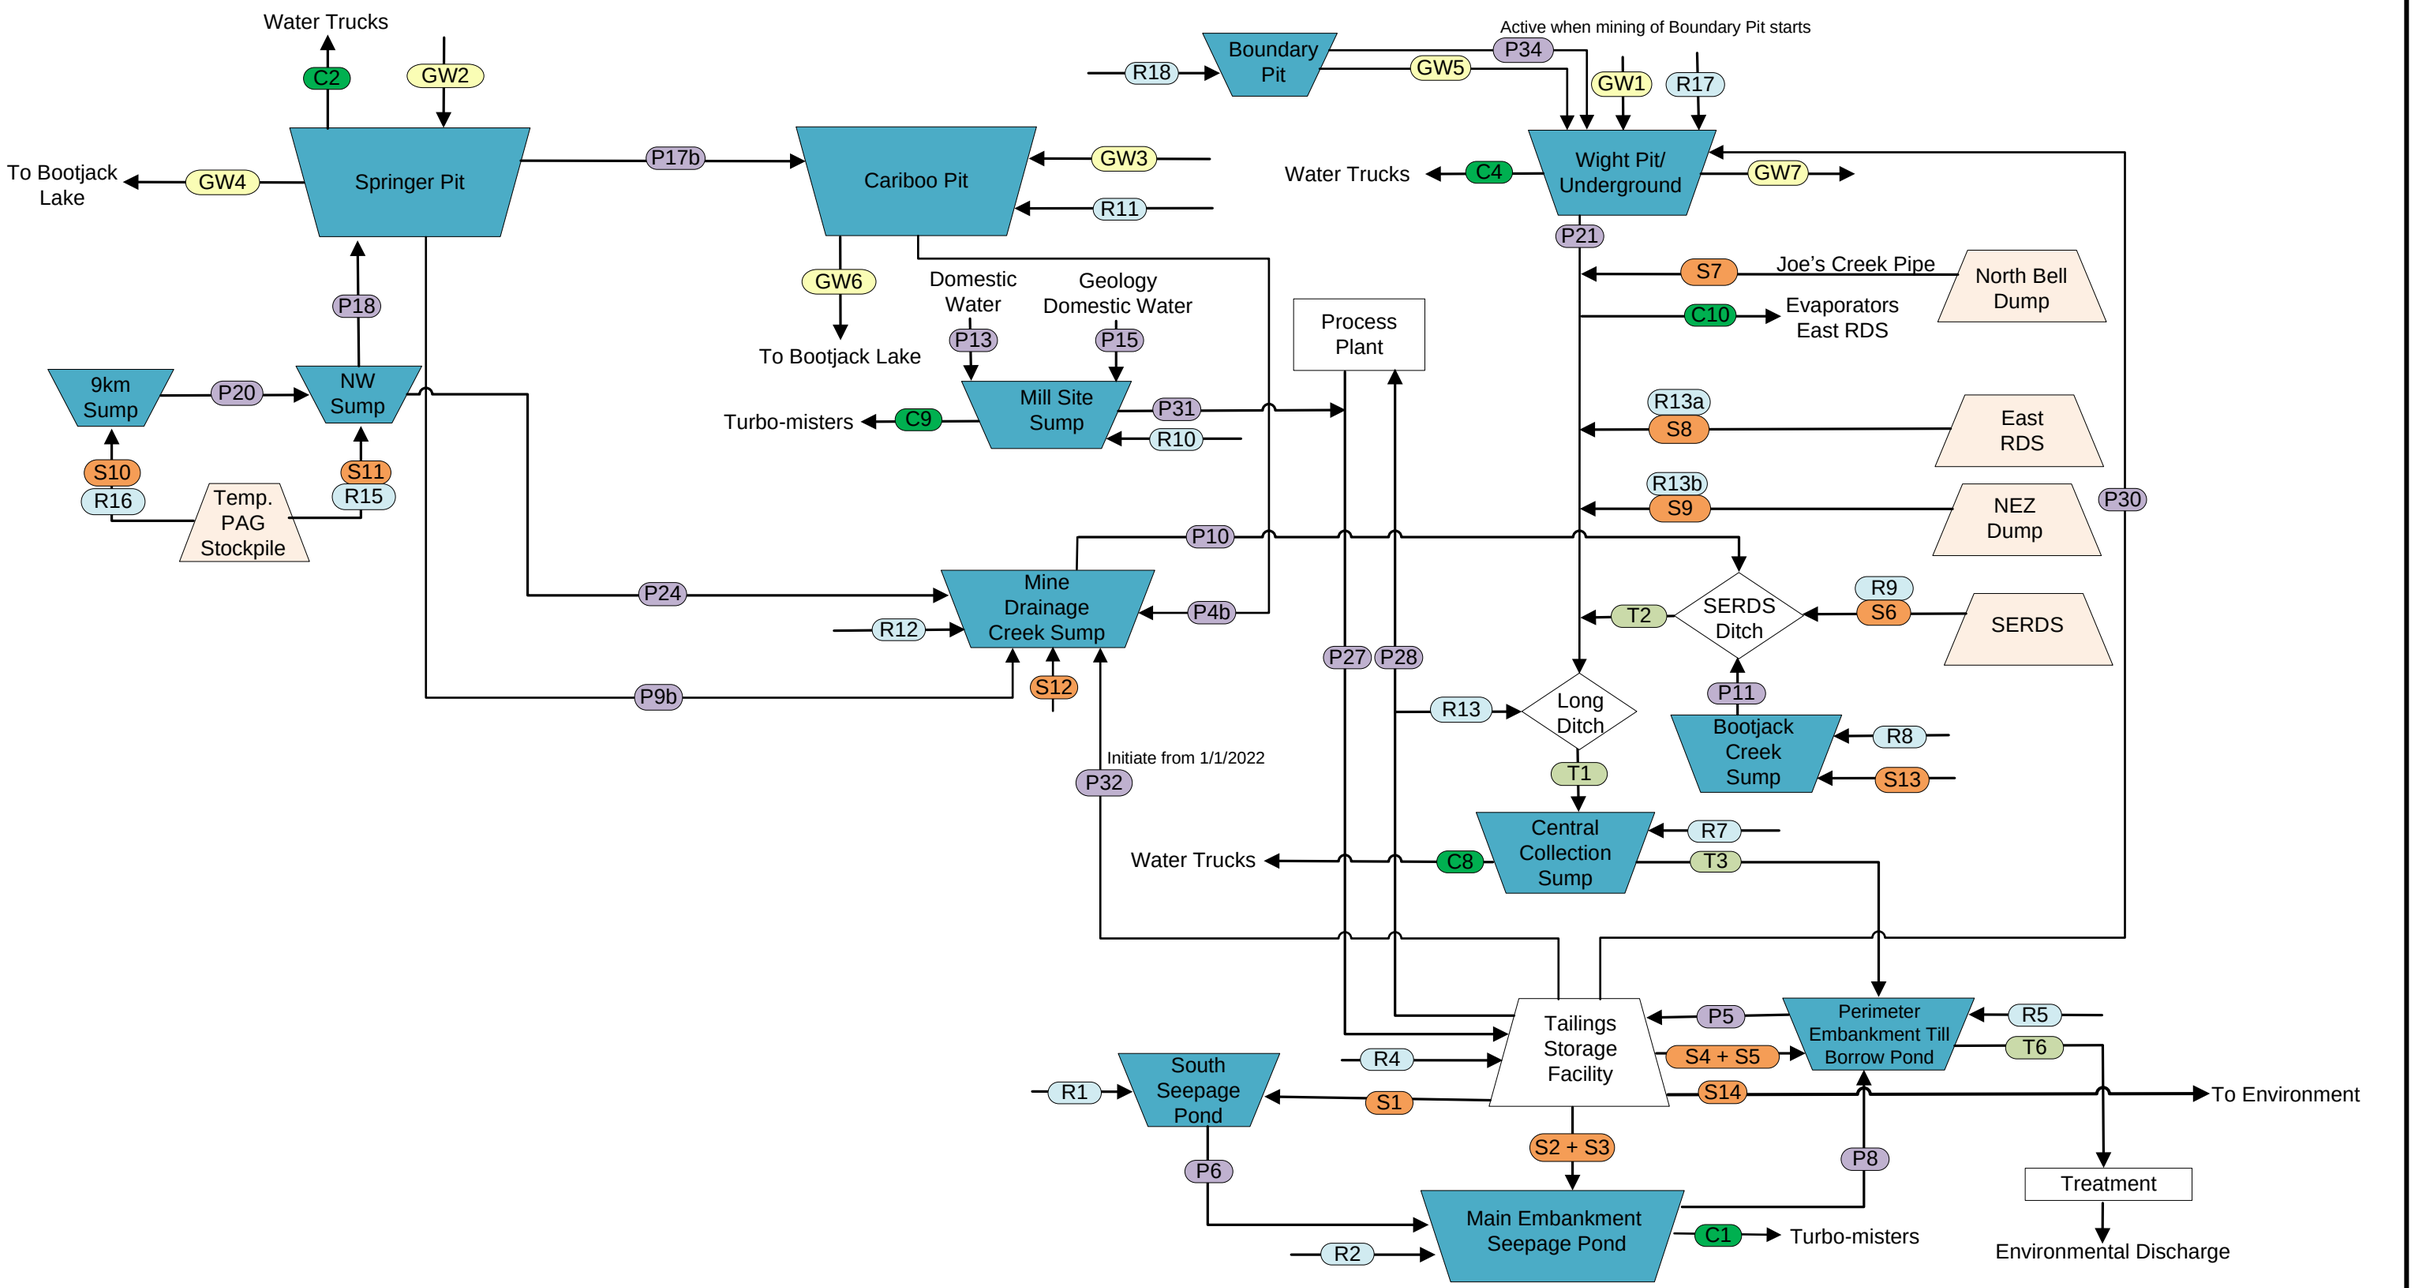
The model simulations included four time periods:

- **Calibration** (1 January 2017 to 31 December 2022) – the calibration period includes operations (1 January 2017 to 1 May 2019), care and maintenance of the Mine site (2 May 2019 to 31 October 2021) and the beginning of resumed operations (1 November 2021). During the calibration period, water in the Perimeter Embankment Till Borrow Pond (PETBP) is treated at the water treatment plant (WTP) and discharged to Quesnel Lake.
- **Resumed Operations** (1 May 2023 to 31 March 2031) – the resumed operations period when, similar to the calibration period, water in the PETBP is treated at the WTP and discharged to Quesnel Lake.
- **Closure** (1 April 2031 to 31 March 2041) – a ten-year active closure period is assumed, during which potentially acid generating (PAG) stockpile material from the Temporary Northwest (NW) PAG stockpile is deposited into the Springer-Cariboo Pit and other facilities are reclaimed. The closure phase will include reclamation activities as identified in the WMP. The WTP is assumed to be in operation through all of the closure period. Details on the closure and post-closure management of mine facilities are provided in the SWWBM Report (WSP 2023a).
- **Post-closure** (1 April 2041 to 1 April 2131) – this period includes filling of pits, discharge, and establishment of steady-state conditions for the drainage from mine facilities. Results are presented for two periods within post-closure:
  - Early post-closure (1 April 2041 to 31 March 2051) – Represents the first ten years of post-closure during which drainage from Mine facilities is assumed to progressively return to undisturbed water quality. The WTP is assumed to be in operation during this period.
  - Long-term post-closure (1 April 2051 to 1 April 2131) – this time period has been selected to represent steady-state conditions after all closure and post-closure changes have taken place. The need for treatment during long-term post-closure will be confirmed as MPMC approaches this phase and may be achieved through distributed passive or semi-passive treatment systems if required.

Uncertainty exists regarding the exact timing of these transitions. The time periods are intended to show, at a conceptual level, the difference in site drainage quality as the site progresses through the post-closure period; it is not intended to imply that the transitions will occur on precisely those dates.

2.3 Facilities

The SWWQM includes the following facilities (grouped into five categories):



- **Open Pits**: Springer-Cariboo Pit, Wight Pit, and Boundary Pit.
- **Sumps**: NW Sump, 9K Sump, Mine Drainage Creek Sump (MDCS), Bootjack Creek Sump (BCS), Central Collection Sump (CCS), Perimeter Embankment Till Borrow Pond (PETBP), South Embankment Seepage Collection Pond (SESCP), and Main Embankment Seepage Collection Pond (MESCP).
- **Ditches/Drains**: Long Ditch and Southeast Rock Disposal Site (SERDS) Ditch.

- **Rock Disposal Sites (RDSs)**: East RDS, SERDS, Northeast Zone (NEZ) RDS, North Bell RDS, and Boundary RDS.
- **Other Facilities**: Tailings Storage Facility (TSF), TSF Quarry, Temporary NW PAG Stockpile, and haul roads.

2.4 Mine Site Flows

The SWWBM accounts for mine waste and water management plans, which are described in detail in the Springer Expansion Model SWWBM Report (WSP 2023b). During the calibration and operations periods, the Mine facilities are used to manage water within the Mine site and the only Mine discharge to the receiving environment is from the WTP (Table 1 and Figure 1). During closure, water will continue to be managed within the Mine facilities and the combined Springer-Cariboo Pit will be allowed to fill before discharging to Bootjack Lake (Table 2 and Figures 2 and 3). To the extent possible, flows from the Mine site will be returned to pre-disturbance watershed flows as the facilities are reclaimed during closure (Table 3).

During post-closure, most site catchment areas are expected to drain directly to their pre-disturbance watersheds; this applies to 9K Sump, NW Sump, Springer-Cariboo Pit, Mine Drainage Creek, Wight Pit, Joe's Creek, SESCP, and the MESCP. Some sumps, ponds, and ditches are expected to flow together and to be discharged as a combined flow to their pre-disturbance watersheds; Long Ditch discharge will include flow from SERDS Ditch and Bootjack Creek Sump, and PETBP discharge will include overflows from the TSF and CCS (Table 3).

Table 3: Facility Flows during Post-Closure.

Facility	Inflows to the Facility	Discharge Destinations
9K Sump	Runoff and seepage from the Temporary NW PAG Stockpile, North Bell RDS, disturbed, and undisturbed watershed areas.	Bootjack Lake
NW Sump	Runoff and seepage from the Temporary NW PAG Stockpile, disturbed, and undisturbed watershed areas.	
Springer-Cariboo Pit Lake	Pit wall runoff, groundwater inflow, disturbed, and undisturbed watershed areas.	
MDCS	Runoff and seepage from haul roads, disturbed, undisturbed and RDS areas.	
Wight Pit Lake	Pit wall runoff, groundwater inflow, and runoff and seepage from haul roads, undisturbed, disturbed area, and RDS areas.	Polley Lake
Long Ditch	SERDS Ditch overflow and runoff and seepage from the East RDS, NEZ RDS, SERDS RDS, haul roads, disturbed and undisturbed watershed areas.	
SESCP	TSF seepage and minimal runoff from undisturbed watershed areas.	Edney Creek
MESCP	TSF seepage, runoff from the TSF embankment, and runoff and seepage from undisturbed watershed areas.	
PETBP	TSF pond overflow (via CCS), TSF seepage, runoff from TSF impoundment, and runoff and seepage from haul roads, disturbed, and undisturbed watershed area.	Influent to the water treatment plant and Hazeltine Creek

Note: NW Sump = Northwest Sump; MDCS = Mine Drainage Creek Sump; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond; PAG = potentially acid-generating; NAG = Non-potentially acid-generating; RDS = Rock Disposal Site; TSF = Tailings Storage Facility; Central Collection Sump = CCS; SERDS = Southeast Rock Disposal Site.

2.5 Mine Plan

The SWWQM predicts concentrations based on water quality concentrations assigned to runoff from surface areas (Section 2.5.1), scheduled water management pumping and waste rock/tailings production from mine operations according to the mine plan presented in Section 2.5.2 (WSP 2023a).

2.5.1 Mine Site Surface Areas

The SWWQM and SWWBM assumes the entire surface area of the RDS, disturbed runoff areas and undisturbed runoff areas are accounted for at the beginning of operations. Therefore, the runoff and seepage volumes do not change until closure and post-closure when remediation of mine surface areas begin. The total surface areas are presented in the Springer Expansion Model Water Balance Report (WSP 2023a).

2.5.2 Waste Rock and Tailings Deposition

The mine plan for the Springer Expansion was updated in the SWWBM and assumed a milling operational end date of March 2031. Tonnage of dry tailings during the project is provided in Table 4 (MPMC 2023). Tailings are deposited into either the TSF or the SERDS Tailings Co-disposal site. The tailings beach area increases during operations until deposition is complete in 2031. The tailings and waste rock excavated from Springer Pit are to be deposited in the SERDS Tailings Co-disposal site according to the 3-year schedule presented in Table 5 (WSP 2022a).

Table 4: Annual Tonnes of Dry Tailings Deposited

Year	Dry Tailings (tonnes)
2022[(a)]	3,530,469
2023	7,300,000
2024	7,300,000
2025	7,300,000
2026	7,300,000
2027	7,300,000
2028	7,300,000
2029	7,300,000
2030	7,300,000
2031[(b)]	860,381

(a) Mine plan starts on 1 July 2022.

(b) Mine plan ends on 31 March 2031.

Table 5: Annual Tonnes of NAG Waste Rock and Tailings Deposited in the SERDS (MPMC 2022)

Year	Non-acid Generating Waste Rock (dry tonnes)	Tailings (dry tonnes)
May 2022	1,849,434	0
June 2022	1,533,187	0
July 2022	1,646,190	0
August 2022	1,876,485	0

September 2024	2,151,911	0
October 2024	1,712,150	0
November 2024	1,911,993	0
December 2024	1,921,593	0
Total	58,253,223	3,635,000

2.6 Model Setup

The model simulated concentrations on a daily time step from January 2017 to December 2022 (calibration period), May 2023 to December 2034 (operations) and from January 2035 to January 2135 (closure and post-closure). Probabilistic climate and water quality inputs were used to run the model stochastically for 2000 simulations:

- **Climate Inputs:** The SWWQM was run with probabilistic monthly climate inputs during operations, closure and post-closure as described in Appendix H of the WMP. Monthly precipitation data in the Mount Polley Mine Climate Baseline Update (Golder 2022b) were fitted to a log-normal probability distribution. The calibration period used historical climate data for the climate inputs.
- **Water Quality Inputs:** For each realization, a unique concentration for each parameter was selected based on randomly sampled values from within a statistical probability distribution function that was derived from each input.

To interpret the results, median and 95th percentile concentrations were calculated for each Mine facility. To put the results in context, a 95th percentile prediction indicates the maximum concentration that is likely to be reached over the duration of the simulation, with a 95% likelihood that concentrations will be at or below that concentration (it does not suggest that concentrations will exceed this value 5% of the time).

2.6.1 Modelled Parameters and Particulate Addition

The parameters in the SWWQM include physical parameters, major ions, nutrients, and dissolved metals and metalloids (Table 6). The dissolved fractions of metals and metalloids are used in all mixing calculations in the model. The total concentrations of metals and metalloids are calculated by adding particulate fractions to the dissolved concentrations as described below.

Table 6: Parameters in the Site Wide Water Quality Model

Category	Parameters
Physical parameters	Total dissolved solids (calculated), hardness (calculated)
Major ions	Calcium, chloride, fluoride, magnesium, potassium, sodium, sulphate
Nutrients	Nitrate, nitrite, total ammonia, total phosphorus
Dissolved metals and metalloids	Aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, titanium, uranium, vanadium, zinc

Total metal predictions were calculated using dissolved metal predictions and empirical particulate metal concentrations for Operations and Closure (Section 2.6.1.1) and Post-closure (Section 2.6.1.2).

2.6.1.1 Particulate Addition – Operations and Closure

Monitoring data from the SERDS Ditch and Long Ditch were used to establish the empirical particulate metal concentrations because these facilities are expected to contribute the majority of particulate load to site discharges during operations and closure. The model assumes that TSS will be settled/removed to 15 mg/L (i.e., the current average authorized discharge concentrations) prior to discharge.

Monitored data for total and dissolved metals were used to calculate observed particulate metal concentrations in the SERDS Ditch and Long Ditch. The strength of correlation of measured particulate metal concentrations to TSS concentrations was calculated using linear regressions. An empirical particulate metal concentration for each parameter was established by grouping each parameter into the following categories:

- Correlated parameters ($R^2 \geq 0.75$)—a particulate concentration using 15 mg/L during operations/closure was calculated using the regression equation, and this concentration was added to both the maximum median and 95th percentile dissolved metal predictions to calculate a total metal concentration.
- Poorly-correlated parameters ($0.25 < R^2 < 0.75$)—median and 95th percentile particulate concentrations were calculated based on observed data for samples with a TSS below 15 mg/L, and these concentrations were added to the maximum median and 95th percentile dissolved metal concentrations, respectively.
- Non-correlated parameters ($R^2 \leq 0.25$)—median and 95th percentile particulate concentrations were calculated based on all observed data, and these concentrations were added to the maximum median and 95th percentile dissolved metal concentrations, respectively.

A summary of the correlated and non-correlated parameters and the particulate concentrations used for operations and closure in the model are presented in Table 7.

Table 7: Particulate Metal Concentrations – Operations and Closure

Parameter	Coefficient of Determination (R^2)	Category	Median Particulate Concentration (mg/L)	95th Percentile Particulate Concentration (mg/L)
Aluminum	0.82	Correlated	0.46	0.46
Antimony	0.021	Non-correlated	0.000020	0.00014
Arsenic	0.87	Correlated	0.00019	0.00019
Barium	0.74	Poorly-correlated	0.0015	0.0083
Beryllium	0.39	Poorly-correlated	-	-
Boron	0.001	Non-correlated	0.0040	0.031
Cadmium	0.37	Poorly-correlated	0.0000017	0.000073
Chromium	0.76	Correlated	0.00049	0.00049
Cobalt	0.84	Correlated	0.00032	0.00032
Copper	0.024	Non-correlated	0.0090	0.16
Iron	0.85	Correlated	0.49	0.49
Lead	0.86	Correlated	0.00013	0.00013
Lithium	0.51	Poorly-correlated	0.00020	0.0010
Manganese	0.79	Correlated	0.014	0.014
Mercury	0.016	Non-correlated	-	-
Molybdenum	0.0071	Non-correlated	-	0.011
Nickel	0.84	Correlated	0.00047	0.00047
Selenium	0.0087	Non-correlated	-	0.0056
Silver	0.63	Poorly-correlated	-	0.000005
Strontium	0.0029	Non-correlated	0.017	0.34
Thallium	0.41	Poorly-correlated	-	-
Tin	0.22	Non-correlated	-	0.000080
Titanium	0.81	Correlated	0.022	0.022
Uranium	0.008	Non-correlated	0.000023	0.00031
Vanadium	0.84	Correlated	0.0012	0.0012
Zinc	0.77	Correlated	0.0014	0.0014

2.6.1.2 Particulate Addition – Post-closure

Monitoring data from Edney Creek was used to establish the empirical particulate metal concentrations because data from this location is considered representative of undisturbed (i.e., reclaimed) surface runoff. The model assumes that TSS will be settled to 3 mg/L (i.e., the 95th percentile of TSS from monitoring data at Edney Creek from 2016 to 2022).

Monitored data for total and dissolved metals were used to calculate observed particulate metal concentrations in Edney Creek. The strength of correlation of measured particulate metal concentrations to TSS concentrations was calculated using linear regressions. Measured particulate metal concentrations were not correlated to TSS ($R^2 \leq 0.25$) for all parameters. Median and 95th percentile particulate concentrations were calculated based on all observed data, and these concentrations were added to the maximum median and 95th percentile dissolved metal concentrations, respectively (Table 8).

Table 8: Particulate Metal Concentrations – Post-closure

Parameter	Coefficient of Determination (R^2)	Category	Median Particulate Concentration (mg/L)	95th Percentile Particulate Concentration (mg/L)
Aluminum	0.012	Non-correlated	0.028	0.12
Antimony	0.0048	Non-correlated	0	0
Arsenic	0.0083	Non-correlated	0.00003	0.00011
Barium	0.00008	Non-correlated	0.00038	0.0015
Beryllium	-[a]	Non-correlated	0	0
Boron	0.028	Non-correlated	0	0.002
Cadmium	0.02	Non-correlated	0.0000012	0.0000078
Chromium	0.0000024	Non-correlated	0.00011	0.00052
Cobalt	0.000022	Non-correlated	0	0.000076
Copper	0.0046	Non-correlated	0.00034	0.0016
Iron	0.0051	Non-correlated	0.044	0.18
Lead	0.0012	Non-correlated	0	0.00002
Lithium	0.0078	Non-correlated	0	0.00016
Manganese	0.0039	Non-correlated	0.0038	0.016
Mercury	-[a]	Non-correlated	0	0
Molybdenum	0.046	Non-correlated	0.00003	0.00045
Nickel	0.0055	Non-correlated	0.00007	0.00031
Selenium	0.006	Non-correlated	0.000022	0.00012
Silver	0.038	Non-correlated	0	0.0000066
Strontium	0.0015	Non-correlated	0.0029	0.023
Thallium	-[a]	Non-correlated	0	0
Tin	0.0077	Non-correlated	0	0
Titanium	-[a]	Non-correlated	0	0
Uranium	0.00018	Non-correlated	0.000001	0.00004
Vanadium	0.00047	Non-correlated	0.00015	0.00039
Zinc	0.0057	Non-correlated	0	0

a) Coefficients of determination could not be calculated for beryllium, mercury, thallium and titanium because concentrations in the Edney Creek monitoring data were all below detection limits.

2.6.2 Water Quality Calculations

In the SWWQM, Mine facilities were grouped into four categories: open pits, water management ponds sumps and ditches, RDSs, and TSF. The concentrations of parameters at each Mine facility were estimated as described below.

2.6.2.1 Pits, Ponds and Ditches

Conveyance facilities on site (Long Ditch and SERDS Ditch) that are flow-through systems (i.e., they do not retain water for more than a single timestep) were modelled by assigning a water quality to each inflow and calculating a mixed water quality based on the proportions of each inflow (Equation 1). For pits, sumps, and ponds where water can be stored (9K Sump, NW Sump, Springer-Cariboo Pit, MDCS, Wight Pit, SESCP, MESCP and the PETBP), the concentration and volume retained from the previous time step is included in the calculation (Equation 2).

$$C_{pond} = \frac{\sum C_i Q_i}{\sum Q_i}$$ Equation 1

Where:

C_{pond} = concentration in facility
C_i = concentration in inflow *i*
Q_i = flow rate of inflow *i*

$$C_{pond} = \frac{C_x V_x + \sum C_i Q_i - \sum C_x Q_o}{V_x + \sum Q_i - \sum Q_o}$$ Equation 2

Where:

C_{pond} = concentration in facility
C_i = concentration in inflow *i*
Q_i = flow rate of inflow *i*
C_x = concentration in facility in previous timestep *x*
V_x = volume of water in facility in previous timestep *x*
Q_o = flow rate of outflow *o*

Evaporation from water surfaces was included as a decrease in total volume (V_i); in other words, evaporation was a water quantity reduction only and did not remove mass of modelled parameters from the system.

2.6.2.2 Rock Disposal Sites and Tailings Storage Facility

Runoff and seepage volumes from RDSs and the TSF were predicted by the SWWBM and input water quality was assigned to these flows based on site monitoring data. Concentrations at these Mine facilities were calculated using Equation 1.

2.6.2.3 SERDS Tailings Co-Disposal

Water quality modelling of seepage from the SERDS Tailings Co-disposal Facility was consistent with the modelling presented in the 2022 Permit Amendment Application (MPMC 2022). Seepage from the SERDS Tailings Co-disposal Facility into SERDS Ditch is assigned a combination of unsaturated TSF seepage water quality and NAG waste rock seepage water quality (Equation 3; Table 8). Source terms for waste rock were not modified upwards to reflect co-disposal with tailings because concentrations in the waste rock are a function of solubility rather than oxygen penetration (MPMC 2022).

$$C_{SERDS} = \left(C_{Tailings} \times \frac{\sum M_{Tailings}}{\sum M_{Tailings} + \sum M_{NAG}}\right) + \left(C_{NAG} \times \frac{\sum M_{NAG}}{\sum M_{Tailings} + \sum M_{NAG}}\right)$$ Equation 3

Where:

C_{SERDS} = concentration of SERDS runoff or seepage during mine operations

$C_{Tailings}$ = unsaturated tailings water quality input (Table 8)

$\Sigma M_{\text{Tailings}}$ = cumulative mass of tailings deposited in the SERDS Tailings Co-disposal Facility

ΣM_{NAG} = cumulative mass of waste rock deposited in the SERDS Tailings Co-disposal Facility

$C_{Tailings}$ = NAG waste rock seepage water quality input (Table 8)

2.6.3 Model Inputs

Water quality inputs in the SWWQM were derived from site water quality monitoring data. A summary of the water quality inputs assigned to each flow in the SWWQM is presented in Table 9 and described below. Site water quality monitoring data from 2006 to 2023 (depending on the input) were used to develop water quality inputs in the SWWQM. For each parameter, water quality inputs were represented in the model by probability distribution functions. The development of the distribution inputs is described in Section 2.6.3.1. A summary of the distributions selected, the maximum and mean values used for each parameter, and the number of samples for each water quality input are presented in Table 10.

As areas in the mine site are reclaimed, the assigned water quality inputs are adjusted in the SWWQM (Table 6):

- Before reclamation of the RDS facilities, the water quality of runoff is assigned either PAG, non-potentially acid-generating (NAG), Boundary Dump (in the Boundary Pit RDS runoff), or Joe' s Creek Pipe (in the Wight Pit RDS runoff) water quality depending on the RDS location. The water quality of runoff is assumed to be equal to disturbed runoff while the facilities are being reclaimed, and then gradually return to undisturbed watershed runoff.
- Seepage from the RDS facilities is conservatively assumed to remain as contact water in perpetuity.
- For Wight Pit and Boundary Pit, the pit wall runoff is assigned the same water quality input during the calibration, operations, closure and post-closure periods. The water quality input assigned to runoff from each of the pit walls is calculated using monitoring data from the corresponding pit (e.g., the water quality distribution assigned to pit wall runoff into Wight Pit is calculated using monitoring data from Wight Pit).
- Pit wall runoff into the Springer-Cariboo Pit during calibration, operations, closure and post-closure is assigned water quality from two source terms:
  - For pit walls of the former Springer Pit, the source term is calculated based on observed data from Springer Pit. This assumes no acid generation or change in pit wall runoff water quality over time.
  - For pit walls of the former Cariboo Pit, the source term is calculated based on observed data from Cariboo Pit. This assumes no acid generation or change in pit wall runoff water quality over time.
- During the calibration, operations, closure and post-closure periods, disturbed areas are assigned a water quality input calculated using monitoring data from the North Dump Creek and Bootjack Creek (Stations W4 and W5).

- During the calibration, operations, closure and post-closure periods, undisturbed areas are assigned a water quality input calculated using monitoring data from undisturbed runoff (Stations W8 and W8z).
- During the calibration, operations and closure periods, runoff from the TSF beach, impoundment and embankment is assigned a water quality input calculated using monitoring data from the TSF supernatant (Stations E1 and E1a). The water quality of TSF beach, impoundment and embankment runoff is assumed to be equal to undisturbed runoff once the area has been reclaimed in post-closure.
- The proportion of seepage from saturated and unsaturated tailings in the TSF during closure and post-closure are based on hydrogeologic modelling of seepage from the facility (Appendix F). Seepage from unsaturated tailings is assigned the water quality input calculated using monitoring data from the MESCP (Stations E4 and E5). Seepage from the saturated tailings is assigned predicted water quality from the TSF.
- Runoff from the Haul Road is assigned NAG water quality until it is reclaimed in post-closure. Once the Haul Road is reclaimed, runoff from this area is assigned the undisturbed water quality input.
- During the calibration, operations, closure and post-closure periods, groundwater inflow into the combined Springer-Cariboo Pit is assigned a water quality input calculated using monitoring data from Springer Pit Wells (Stations GW12-1/2 and GW15-1/2).

Table 9: Site-Wide Water Quality Model Inputs

Category	Description	Model Input		
		Calibration Period and Operations	Closure	Post-closure
Rock Disposal Site Contact Water	RDS Runoff to Boundary Pit	Boundary Dump Seep station water quality data (n = 70, June 2013 – July 2022)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	RDS Seepage to Boundary Pit	Boundary Dump Seep station water quality data (n = 70, June 2013 – July 2022)		
	RDS Runoff to Wight Pit	Joe's Creek Pipe station (from North Bell Dump) water quality (n = 66, August 2014 to February 2023)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	RDS Seepage to Wight Pit	Joe's Creek Pipe station (from North Bell Dump) water quality (n = 66, August 2014 to February 2023)		
	NAG Waste Rock Runoff	East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep water quality (n = 523, May 2013 to October 2022)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	NAG Waste Rock Seepage	East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep station water quality (n = 523, May 2013 to October 2022)		
	Temporary NW PAG Stockpile Runoff	PAG Dump Seep station water quality (n = 140, May 2013 - January 2023)	Disturbed Runoff: W4 and W5 site monitored data (n = 256, January 2014 to February 2023)	Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	Temporary NW PAG Stockpile Seepage	PAG Dump Seep station water quality (n = 140, May 2013 - January 2023)	NAG Waste Rock: East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep station water quality (n = 523, May 2013 to October 2022)	

Table 9: Site-Wide Water Quality Model Inputs

Category	Description	Model Input		
		Calibration Period and Operations	Closure	Post-closure
Pit Wall Runoff	Boundary Pit Wall Runoff	Boundary Pit station water quality (n = 16, February 2016 - July 2023)		
	Wight Pit Wall Runoff	Wight Pit (Station E10) water quality (n = 71, January 2016 - February 2023)		
	Springer Pit Wall Runoff	Springer Pit (Station E11) water quality (n = 53, January 2016 - August 2022)		
	Cariboo Pit Wall Runoff	Cariboo Pit (Station E8) water quality (n = 40, January 2016 - February 2023)		
Tailings Storage Facility	TSF Beach, Impoundment, and Embankment Runoff	TSF supernatant (Station E1a) water quality (n = 157, May 2011 to February 2023)		Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	Unsaturated TSF Seepage	TSF Main Embankment Seepage Collection Pond (Station E4) water quality (n = 144, January 2006 - February 2023)		
	Saturated TSF Seepage	Predicted concentration in the TSF		
Other	Haul Road Runoff	NAG Waste Rock: East Rock Disposal Site station, Northeast Zone Dump station, SERDS Seep station water quality (n = 523, May 2013 to October 2022)		Undisturbed Runoff: W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)
	Disturbed Runoff	W4 and W5 site monitored data (n = 256, January 2014 to February 2023)		
	Undisturbed Runoff	W8 and W8z site monitored water quality (n = 224, January 2006 to January 2023)		
	Groundwater Inflow to Springer-Cariboo Pit	GW12-1/2, GW15-1/2 site monitored data (n = 253, June 2013 to January 2023)		

Note: NW Sump = Northwest Sump; MDCS = Mine Drainage Creek Sump; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond; PAG = potentially acid-generating; NAG = Non-potentially acid-generating; RDS = Rock Disposal Site; TSF = Tailings Storage Facility; SERDS = Southeast Rock Disposal Site.

Zinc	mg/L	Delta-lognormal	0.0076	1.8	0.027	251

Note: Standard deviation calculated as $\sigma = \sqrt{\frac{\sum(x_i - \mu)^2}{n}}$ where σ = standard deviation; x_i = individual sample from distribution dataset; μ = mean of dataset distribution; n = number of samples from distribution dataset.

2.6.3.1 Development of Water Quality Inputs

The following standardized process was used to develop a statistical distribution for each parameter (Table 7):

- Step 1: Determine if data are available and if values are less than the method detection limit (MDL). Except for special cases listed below under Step 5, values below the MDL were set equal to half of the MDL.
- Step 2: Examine time-series of available data to select the most representative range of data to use for input:
  - The following general rules were used to select the data used for input to the model:
    - Where no trend was apparent in the monitoring data over time, the whole data set was used as input to the model.
    - Where a decreasing trend was observed in the monitoring data, the whole data set was used, including the earlier, higher values, thereby adding conservatism and representing a potential return to conditions that led to higher concentrations (without specifying what those conditions were).
    - Where an increasing trend was observed in the monitoring data, input data were limited to the range of data most representative of current or recent conditions.
- Step 3: Remove outliers from selected data:
  - Three statistical tests were used to identify outliers. These included the three times standard deviation (3σ) rule, the Hampel identifier, and combined Rosner-Dixon test. A data point was considered an outlier only if it was flagged by all three tests. By using multiple tests, the possibility of misdiagnoses was reduced (Beckman and Cook 1983; Jain 1981; Kottegoda 1984; Pearson 2001).
- Step 4: Fit suitable statistical distributions to the resulting data:
  - The probability distributions considered for the water quality data were normal, lognormal, or delta-lognormal, as these are typical distributions for water quality data (AEP 1995; US EPA 1991). To identify which distribution best described a constituent, all three distributions were initially fitted to the available data. Statistical goodness of fit tests, consisting of the Chi-squared test, the Kolmogorov-Smirnov test and the squared correlation coefficient (Sokal and Rohlf 1981) were used to determine which distribution was most appropriate.
- Step 5: Process data with a single value:
  - Where all data were at a single value a constant input was used equal to this value.
  - Where all data were below the MDL, a constant input was used at half the MDL.

    - Where dissolved mercury data were not available for a location, a constant input was used equal to half the lowest detection limit measured on site, consistent with other locations.

- Step 6: Determine the minimum and maximum bounds to define a reasonable range for the selected distribution:
    - When possible, the maximum observed value was used as the maximum bound of all distributions. In cases where the maximum observed value was too low to result in a fitted distribution, the lowest maximum value acceptable for a fitted distribution was used as the maximum bound. The maximum is considered reasonable because there is a large dataset of mine water chemistry and parameter concentrations in drainage water are not expected to increase significantly from the period of observed data to closure.

The minimum value of a distribution was set to zero for the normal distribution, a value very close to zero (e.g., 0.00000001) for the lognormal distribution, or half the detection limit for the delta-lognormal distribution.

2.6.4 Geochemical Source Terms

Water quality inputs derived from geochemical source terms developed by SRK Consulting Canada were applied to the SWWQM as an additional scenario in the 2016 Long Term Water Management Plan (Golder 2016). Updates to these geochemical source terms were completed by SRK consulting (SRK 2023). An alternative model scenario was completed using the SRK geochemical source terms as water quality inputs in place of inputs calculated from monitoring data. The results of the two scenarios (using monitoring data or SRK geochemical inputs) were compared. Consistent with the previous geochemical source terms provided by SRK for the 2016 TAR (Golder 2016) and the 2020 WMP (Golder 2020), the SRK inputs were considered more conservative than the monitoring data inputs and produced generally higher concentrations in the SWWQM. The results presented in this report are from the scenario that utilized the water quality inputs that were calculated from monitoring data (Section 2.6.3). The results from the geochemical source term scenario are not presented because the model predictions were considered overly conservative for most parameters and because the model was calibrated using the inputs calculated from monitoring data.

2.6.5 Initial Water Quality

Concentrations in ponds, sumps, and pits at the beginning of the calibration period are based on monitoring data in January 2017. Concentrations in ponds, sumps, and pits at the beginning of the operations period are based on monitoring data in May 2023.

2.7 Model Assumptions

Assumptions that have been made in the SWWQM are:

- The input water qualities used in the SWWQM are representative of their respective input sources and will continue to be representative over the modelled timeframe. Water quality data for model inputs were selected from available lab testing and field monitoring, augmented by professional judgement where necessary.
- Concentrations of parameters from monitoring data that were lower than the analytical detection limit were set equal to half the detection limit.

- Concentrations of parameters in direct precipitation onto the water surface of water management facilities were assumed to be zero. No mass was removed or added to modelled systems through evaporation or direct precipitation. These processes affected water quantity only and did not affect mass of modelled parameters in the system.
- All open pits, ponds, and sumps are fully mixed systems. No stratification is considered over the modelled timeframe. All inputs are mixed with existing water volumes to calculate concentrations of parameters.
- All parameters are assumed to behave conservatively. That is, they are assumed to not settle, precipitate, sorb, degrade, or undergo any other process that would reduce concentrations. This assumption is likely to have negligible effects on major ion predictions but may lead to over-estimation of some nutrients and metals.
- All PAG waste rock will be disposed sub-aqueously in the Springer-Cariboo Pit at closure to mitigate onset of acid generation. Acid generation is not expected to occur prior to subaqueous disposal, and disposal in the Springer-Cariboo Pit Lake will prevent acid onset in the future by limiting oxidation in the waste rock. Geochemical characterization studies estimate the time to the onset of acid generation varies between decades and 100 years (MPMC 2022).
- The combined Springer-Cariboo Pit is assumed to be empty at the start of closure.
- Rock disposal sites are assumed to be reclaimed in post-closure. Following revegetation, the runoff from these facilities is assumed to return to undisturbed runoff quality over the course of ten years.
- Diffusive flux from the submerged PAG waste rock into the Springer-Cariboo Pit Lake water cap was not modelled.
- Accumulation and flushing of oxidation products from weathered PAG material prior to subaqueous disposal was not modelled.
- Ice formation and melting were not considered in pits, ponds, and ditches that retain water.

3.0 MODEL CALIBRATION

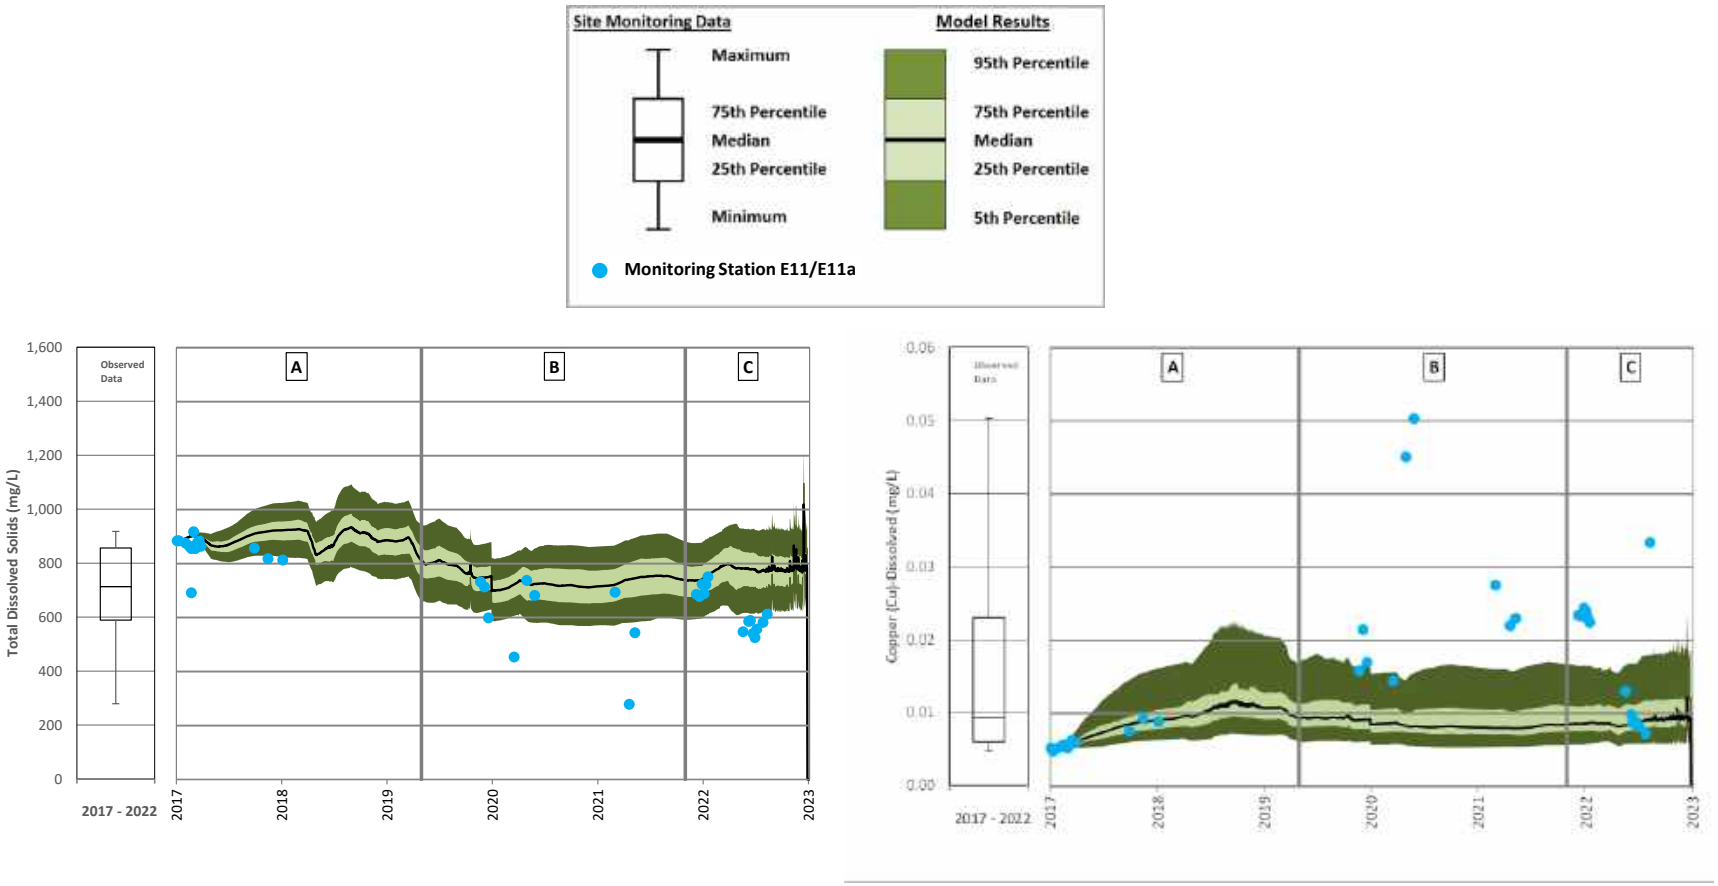
The SWWQM was set up to hindcast concentrations from 1 January 2017 to 31 December 2022 at seven locations:

- Springer Pit
- Cariboo Pit
- Wight Pit
- CCS
- PETBP
- TSF
- NW Sump

Where discrepancies between model results and monitoring data existed, the model was adjusted to better reflect monitoring data. The same adjustments, made during calibration of the SWWQM in the 2020 Water Management Plan (Golder 2020) and during the calibration of the SWWQM in the 2022 Reclamation and Closure Plan (WSP 2022), were maintained in this update to achieve calibration with monitoring data:

- Adjusting the proportion of Wight Pit runoff and groundwater inflows that are assigned a waste rock contact water input based on storage of waste rock in the pit.
- Adjusting the proportion of runoff from waste rock that is assigned an undisturbed water quality input.
- In the TSF, applying calibration factors greater than 1.0 to improve the model calibration for chloride, fluoride, potassium, sodium, nitrite, dissolved antimony, dissolved arsenic, dissolved barium, dissolved lithium, dissolved molybdenum, and dissolved vanadium. These calibration factors are applied during periods when tailings are deposited to the TSF.

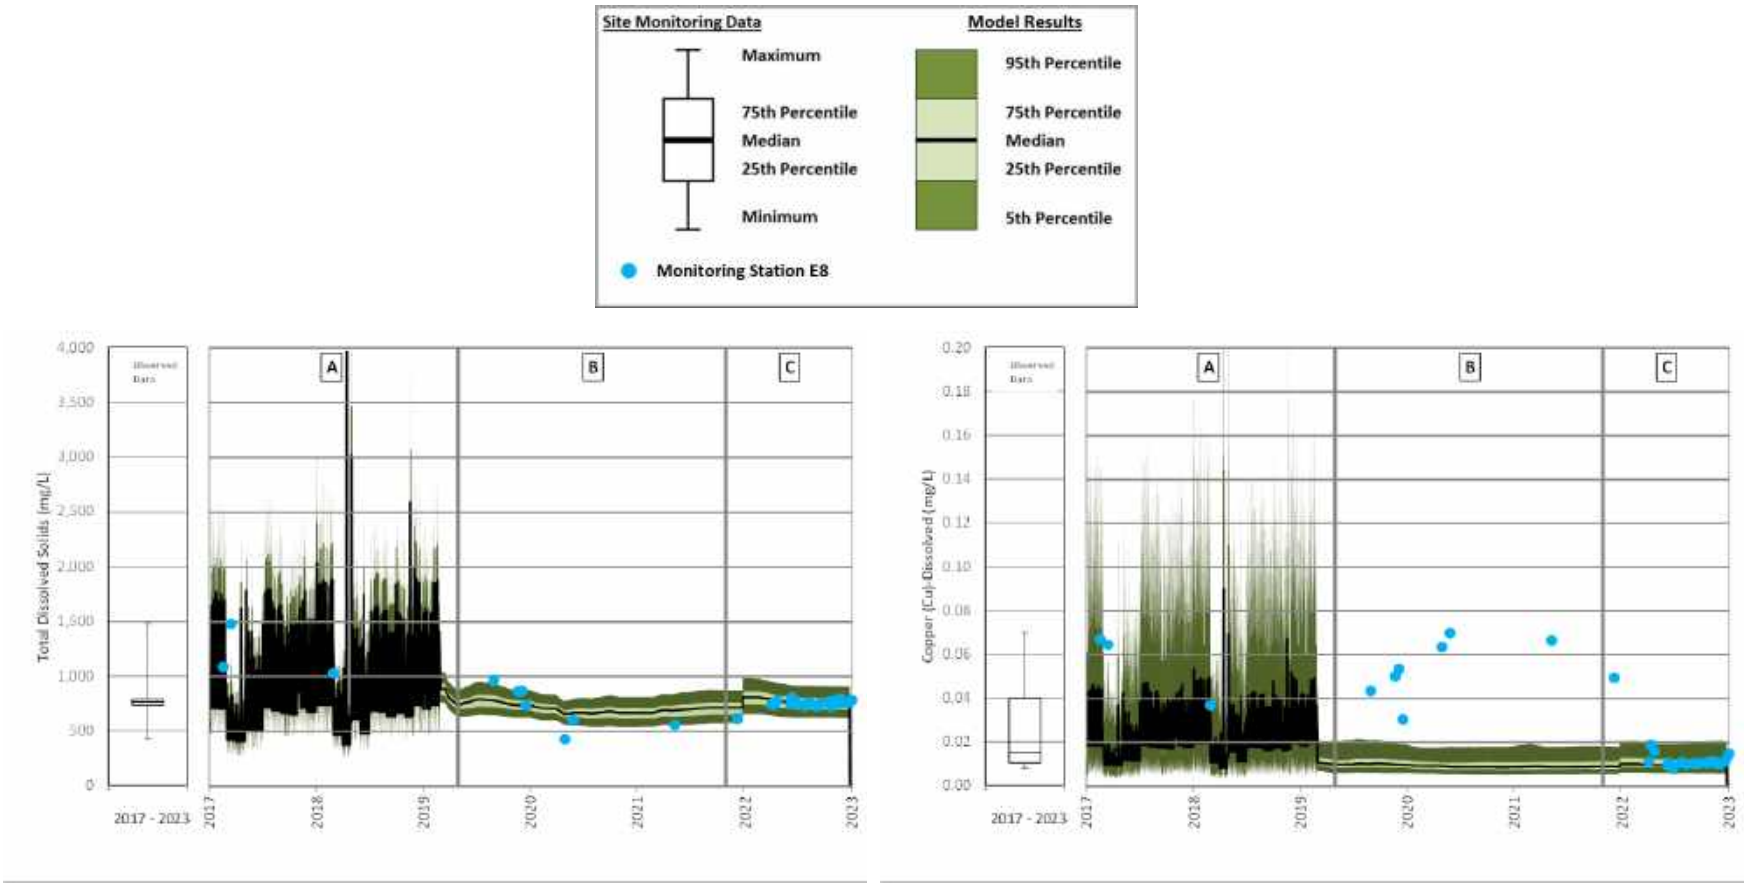
3.1 Calibration Results



Model calibration results are shown compared to monitoring data in Figures 4 to 9 (model calibration results for all parameters and locations are provided in Appendix A). Monitoring data were generally between the projected 5th and 95th percentile model calibration results for all parameters. However, several parameters (e.g., dissolved copper) were underpredicted during periods in 2018, 2020, and 2021 (Figure 5, Figure 7, Figure 8 and Figure 9). The source of the increased concentrations in the monitoring data for these parameters is thought to be due to the discharge of leachate to the TSF from the onsite test heap leach facility (Golder 2022c). These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process.

Where monitoring data fell within the 5th and 95th percentile model calibration results, the model was considered to be in good agreement with monitoring data. The good agreement indicates that model inputs were well characterized and that these parameters had low sensitivity to assumptions or model conditions not matching site conditions.

Where monitoring data were consistently below the 5th percentile predictions, the model was considered to be over predicting concentrations. Possible reasons why the model may be over-predicting concentrations are:



- The model was developed to predict water quality conservatively; where uncertainty exists in model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected. For example, seepage from RDSs was assigned a NAG water quality for the entire model simulation period, which is a conservative assumption.
- Metal concentrations that are far below detection limits may be skewed upward by model inputs where half-detection limits were applied.
- Settling of particulate material is not accounted for in the model.
- Geochemical processes, such as precipitation and adsorption, are not accounted for in the model.

Although these factors may lead to over-prediction of concentrations, the model is considered valid for the purpose of predicting concentrations of parameters on the mine site and in the influent to the WTP because deviations in model predictions from monitoring data in this category tend toward additional environmental protection.

A = Operations; B = Care and Maintanence; C = Resumed Operations

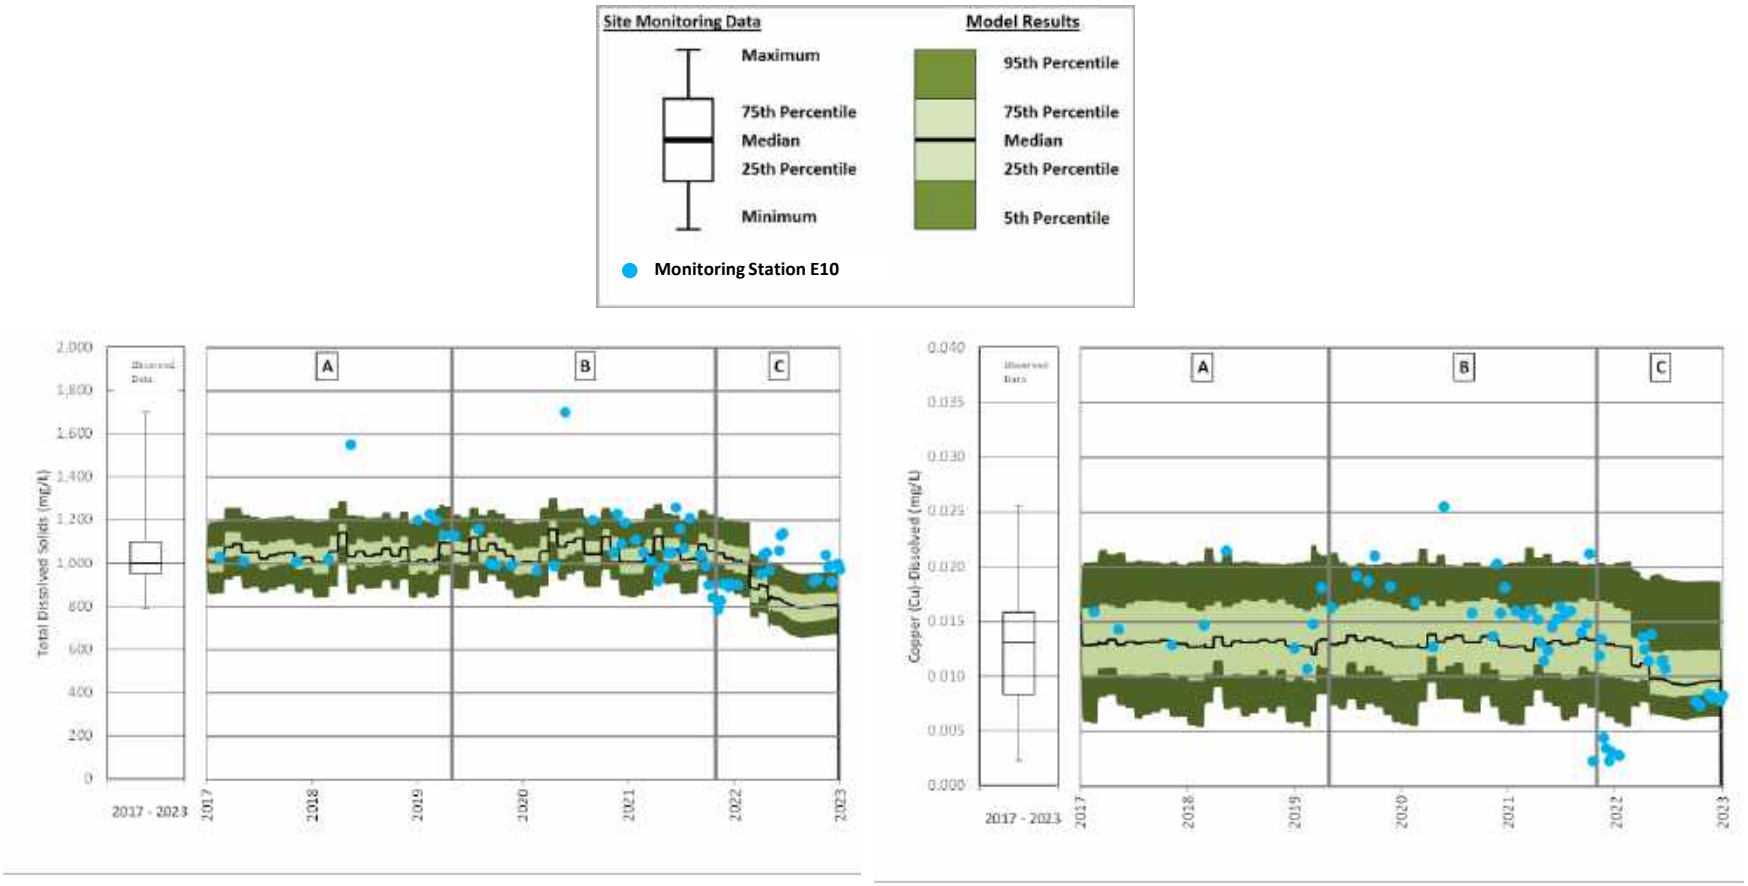


Figure 4: Springer Pit Calibration – Total Dissolved Solids and Dissolved Copper

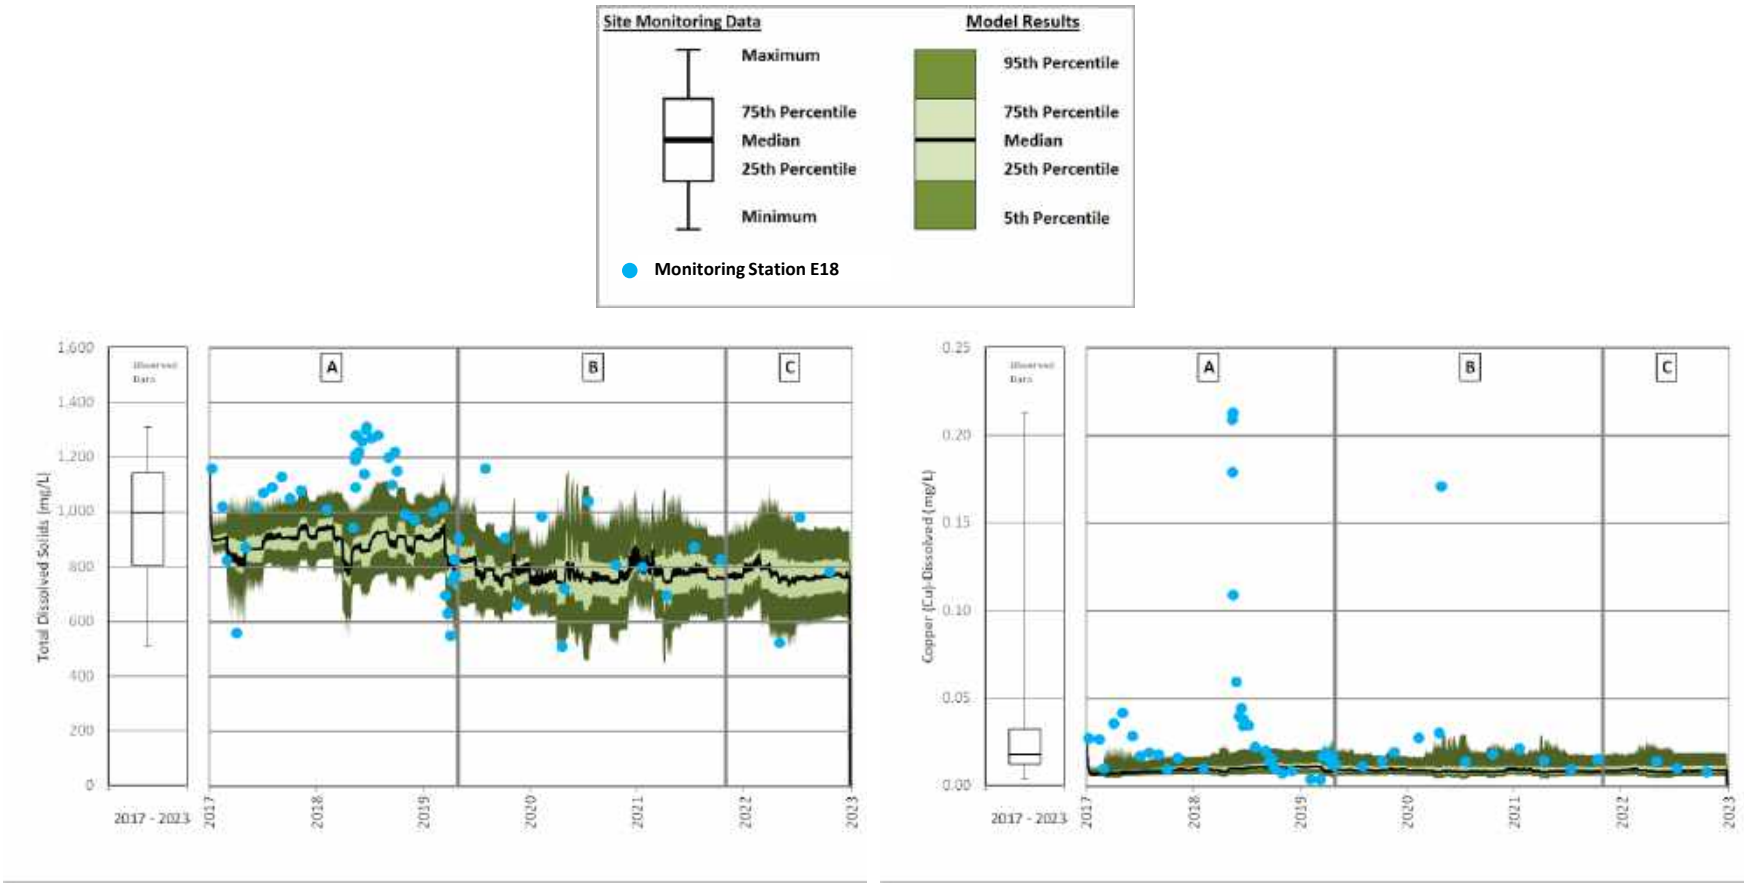
A = Operations; B = Care and Maintanence; C = Resumed Operations



Note: Cariboo Pit is a flow-through system from the beginning of the model simulation to March 2019, which results in a wide range in predicted concentrations. After March 2019, Cariboo Pit stores water, which reduces the range in predicted concentrations. The source of increased copper concentrations in 2019, 2020 and 2021 monitoring data is due to the discharge of leachate from the onsite test heap leach facility to the TSF, which is then pumped to Cariboo Pit). These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process (Golder 2022c).

A = Operations; B = Care and Maintanence; C = Resumed Operations

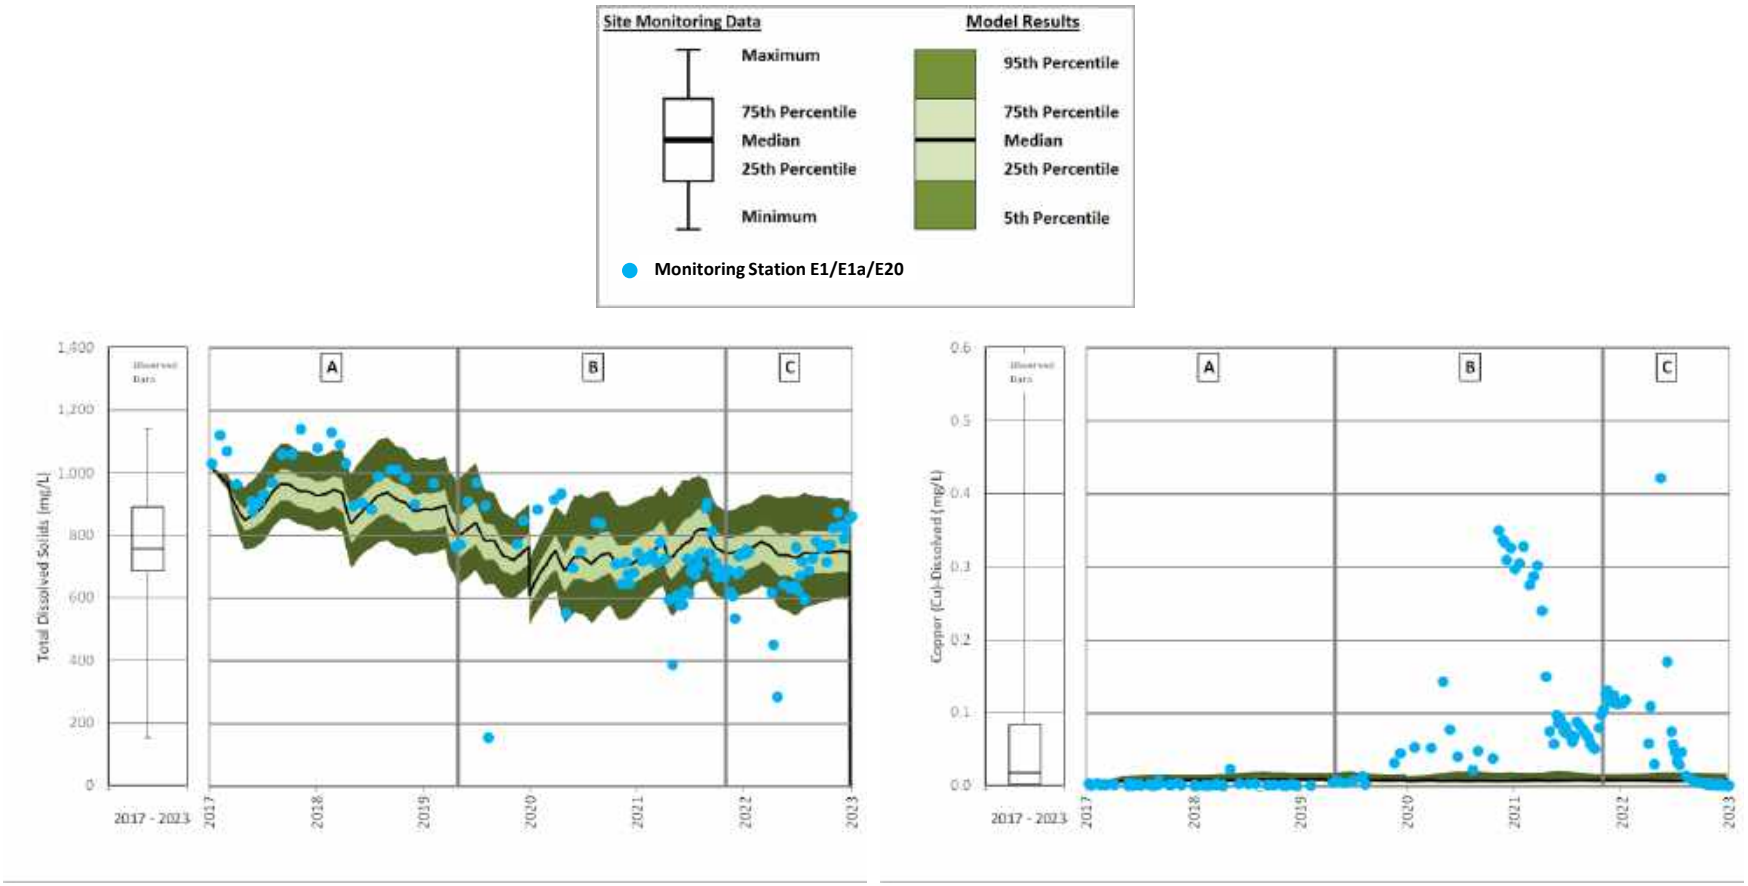

Figure 6: Wight Pit Calibration – Total Dissolved Solids and Dissolved Copper

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: The source of increased dissolved copper concentrations in the Central Collection Sump 2018 monitoring data is due to discharge of leachate from the onsite test heap leach facility to the TSF, which is then pumped to the CCS. These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process (Golder 2022c).

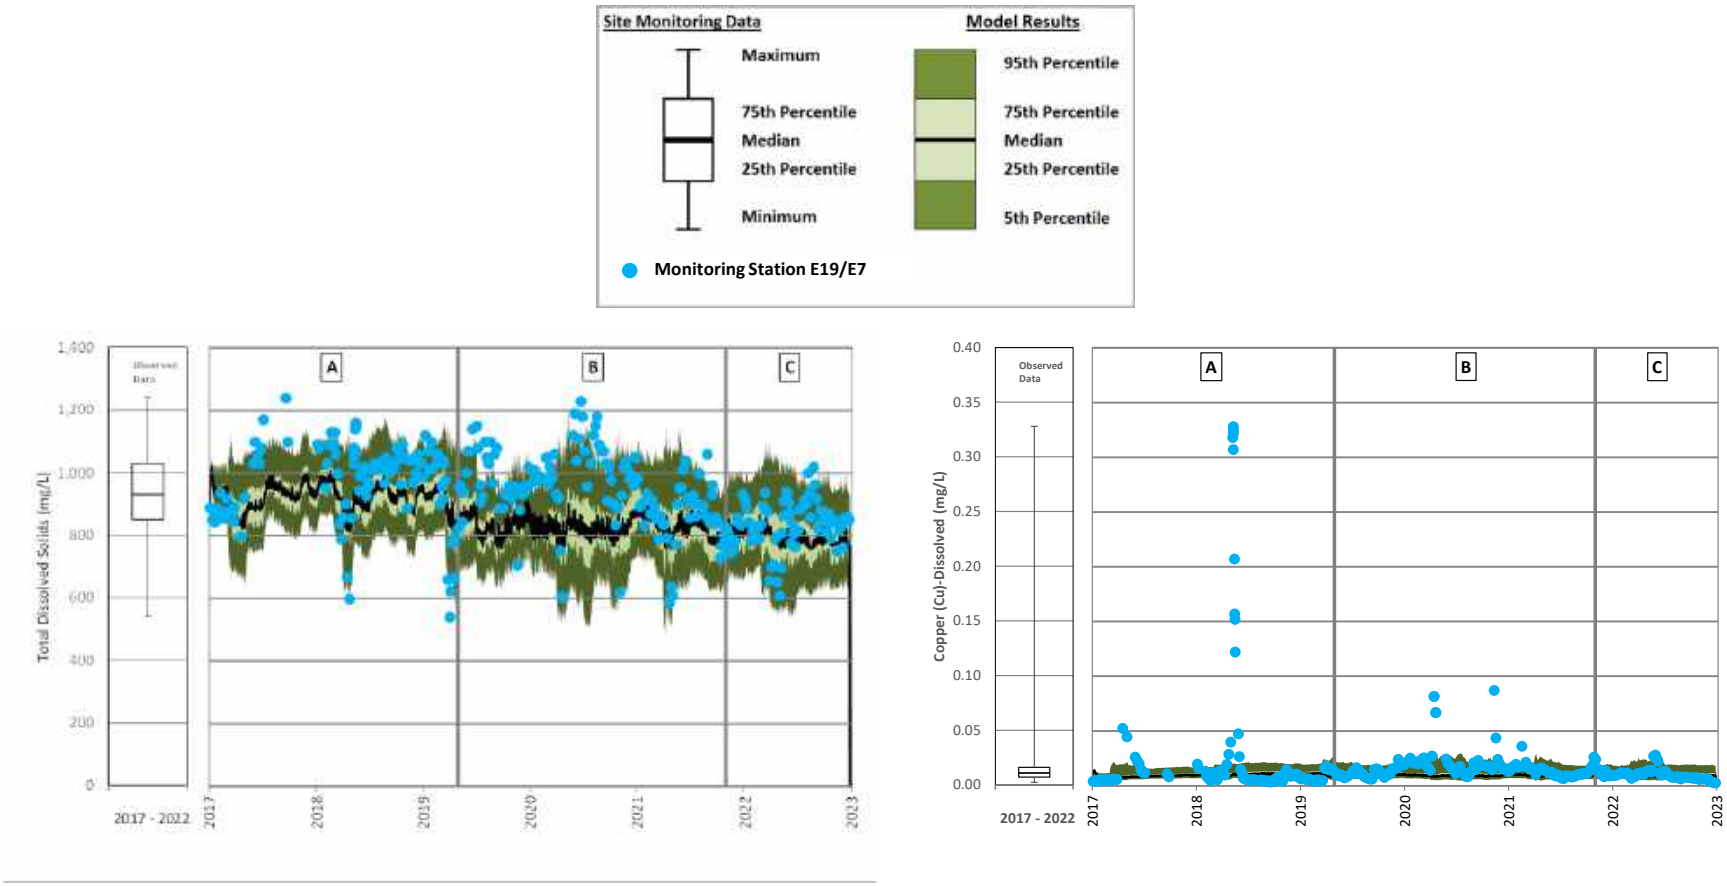

Figure 7: Central Collection Sump Calibration – Total Dissolved Solids and Dissolved Copper

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: The source of increased copper concentrations in 2018 and from 2020 to 2022 in the monitoring data of the Tailings Storage Facility (TSF) is due to the discharge of leachate to the TSF from the onsite test heap leach facility. These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process (Golder 2022c).

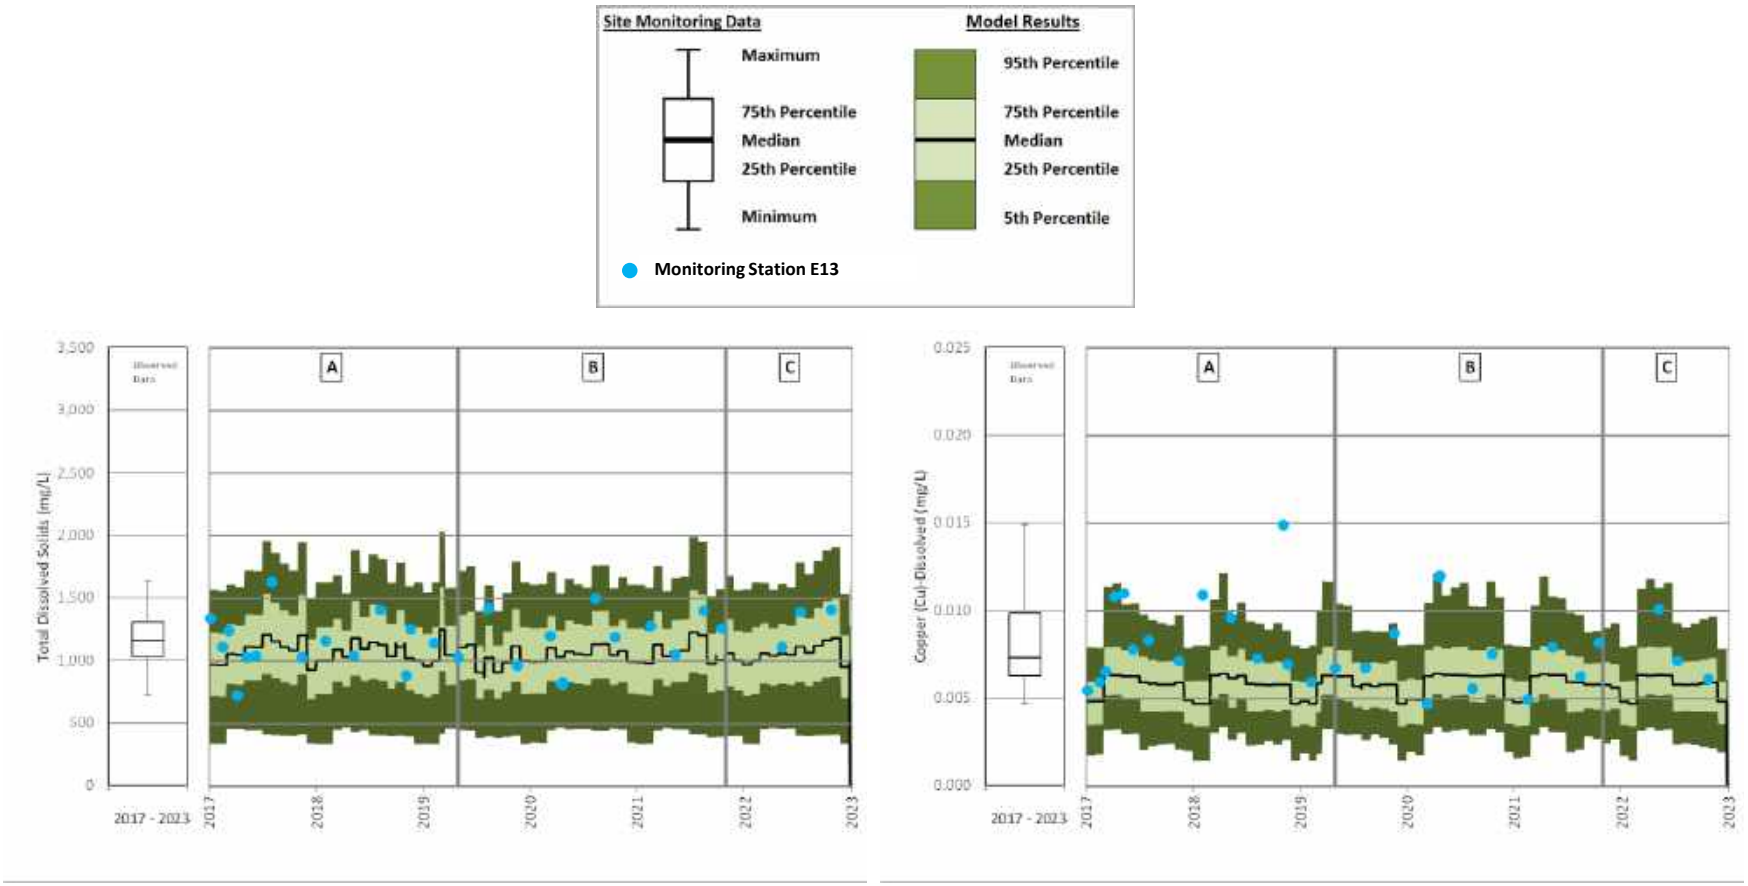

Figure 8: Tailings Storage Facility Supernatant Pond – Total Dissolved Solids and Dissolved Copper

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: The source of increased dissolved copper concentrations in the Perimeter Embankment Till Borrow Pond 2018 monitoring data is due to discharge of leachate from the onsite test heap leach facility to the TSF, which is then pumped to the PETBP. These concentrations were not observed throughout the operational phases of the mine and are considered atypical. These conditions are not expected to persist during future operational phases as the leachate will be managed exclusively through the milling process (Golder 2022c).

4.0 MODEL RESULTS

After the model calibration was completed, model simulations were performed for the following periods:

- Operations (1 January 2024 to 31 March 2031)
- Closure (1 April 2031 to 31 March 2041)
- Post-closure (1 April 2041 to 31 March 2131)

The following sections present predicted discharge concentrations for the PETBP in operations, which represents predicted WTP influent concentrations, and each of the nine discharge locations in closure and post-closure that discharge to receiving environments (Section 2.4):

- PETBP
- 9 km Sump
- NW Sump
- Springer-Cariboo Pit Sump
- MDCS

- Long Ditch
- SESCP
- MESCP

Maximum of median and 95th percentile predicted concentrations are presented for all modelled parameters. Time series of predicted dissolved concentrations are presented for parameters with permit limits. Time series predictions are also compared to historical observed data for each facility in the model as a quality control check.

4.1 Perimeter Embankment Till Borrow Pond

During operations, closure and the first ten years of post-closure, the PETBP is the influent water to the WTP, which discharges to Quesnel Lake. Maximum of the daily median and maximum of the daily 95th percentile concentrations in the PETBP are presented in Table 11. Predicted total concentrations in the PEBTP are based on a TSS concentration of 15 mg/L. Time series for predicted concentrations in the PETBP are presented for parameters with permit limits in Figures 10 to 15.

In general, concentrations in the PETBP are predicted to remain relatively consistent during operations until the end of pumping from the mill processing plant in 2031. This consistency is due to the assumption that the entire surface areas of the RDS are accounted for at the beginning of the model simulation. Therefore, the runoff and seepage volumes from the RDS do not change. Changes in predicted concentrations in the PETBP are due to:

- Variable pumping from the TSF to the MDCS during operations. During periods when the TSF is pumped to the MDCS (P100 booster pumping in Figure 1), concentrations of most parameters increase in the MDCS. Concentrations decrease in the MDCS when there is no pumping from the TSF. Changes in MDSC water quality reach the PETBP through the pathway connecting the MDCS to the PETBP:
  - TSF → MDCS → SERDS Ditch → Long Ditch → CCS → PETBP
- Surface runoff at the mine site causes fluctuations in concentrations depending on the proportions of the catchment areas flowing into the facilities (e.g., RDS areas, disturbed areas, undisturbed areas). Parameter concentrations reach steady-state during the winter months because surface runoff is low.

Discharge from the PETBP will be directed to Hazeltine Creek in closure. This discharge includes overflow and seepage from the TSF, as well as runoff from catchment areas of the PETBP, TSF, and CCS.

Predicted concentrations in the PETBP change from operations to closure and into early post-closure because of the staggered reclamation of the TSF beach and impoundment areas which are then assigned an undisturbed water quality once the areas are reclaimed. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows to the PETBP. In closure and post-closure, concentrations in the PETBP follow two patterns:

1) Decrease from operations because the statistical distributions assigned to undisturbed runoff water quality have lower concentrations than the statistical distributions assigned to the TSF beach runoff and the NAG waste rock runoff quality (e.g., sulphate, nitrate and dissolved copper).
2) Increase from operations because the statistical distributions assigned to undisturbed runoff water quality have higher concentrations than the statistical distributions assigned to the TSF beach runoff and the NAG waste rock runoff quality (e.g., total phosphorus, dissolved chromium and dissolved iron).

Predicted concentrations in the PETBP reach a steady state approximately 10 years after the start of post-closure when all mine site areas have been reclaimed.

Table 11: Predicted Maximum Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. The increase in total ammonia concentrations during the first ten years of post-closure is caused by the pumping from the MESCP which ends in 2051. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

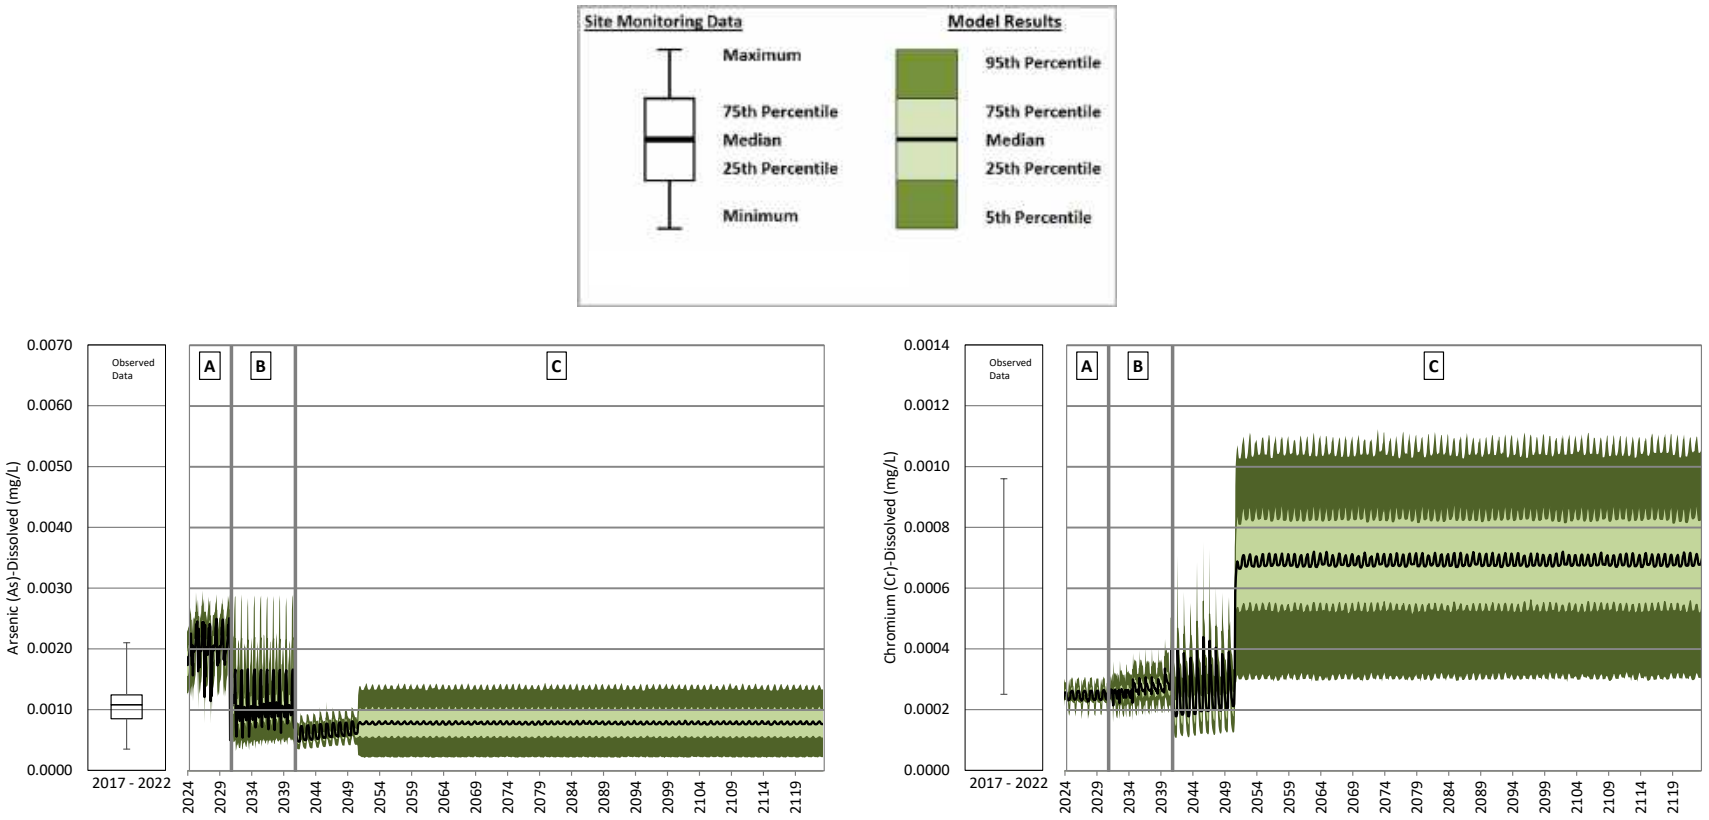

Figure 11: Predicted Sulphate and Total Ammonia Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

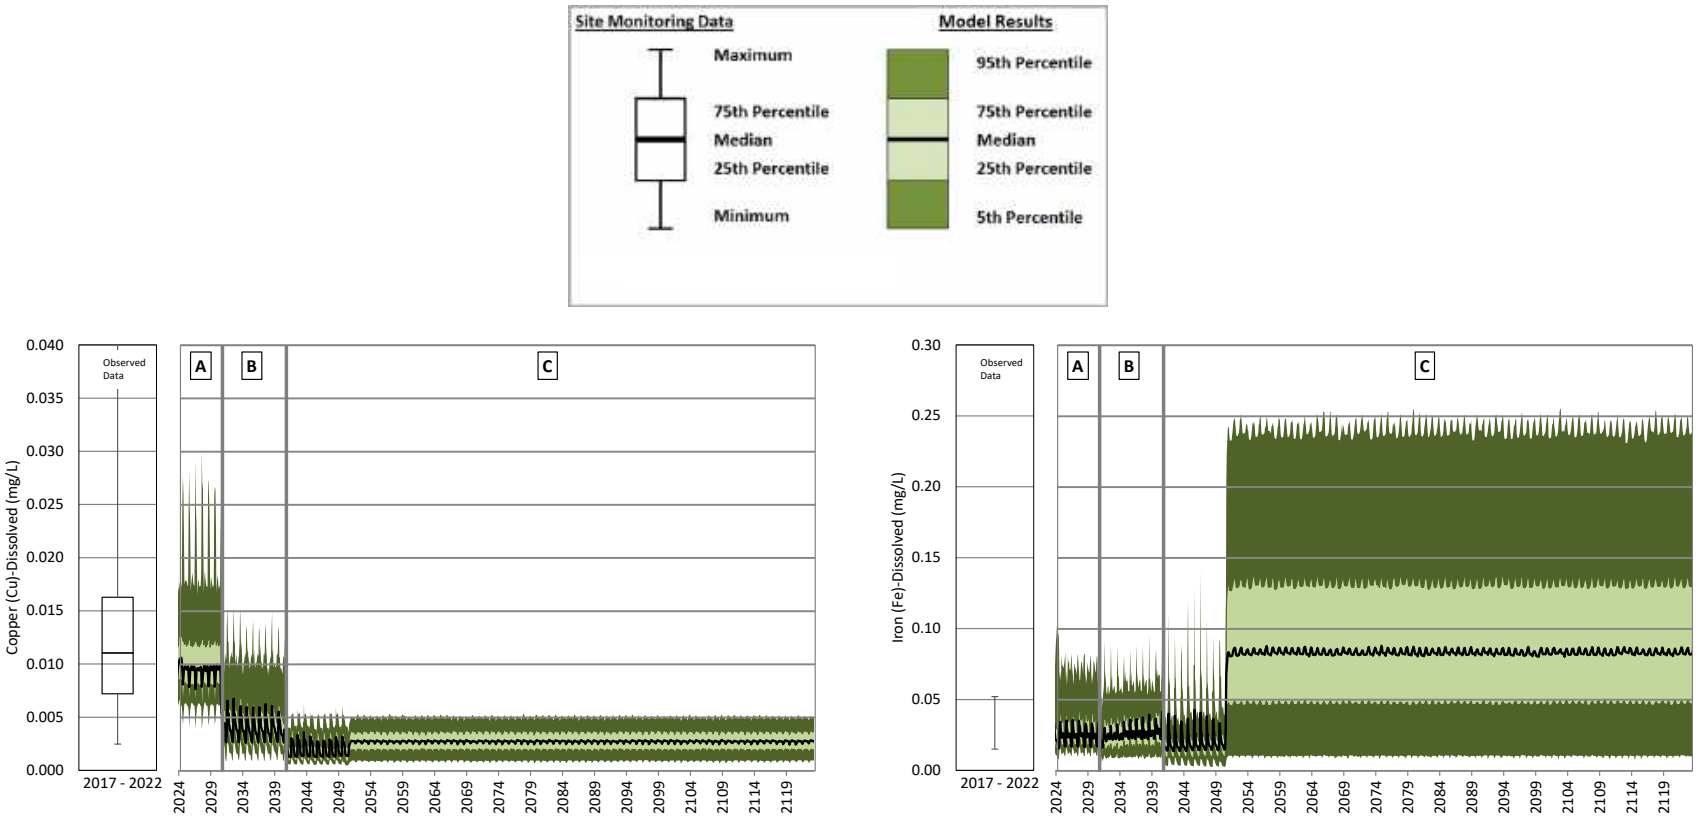

Figure 12: Predicted Nitrate and Total Phosphorus Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

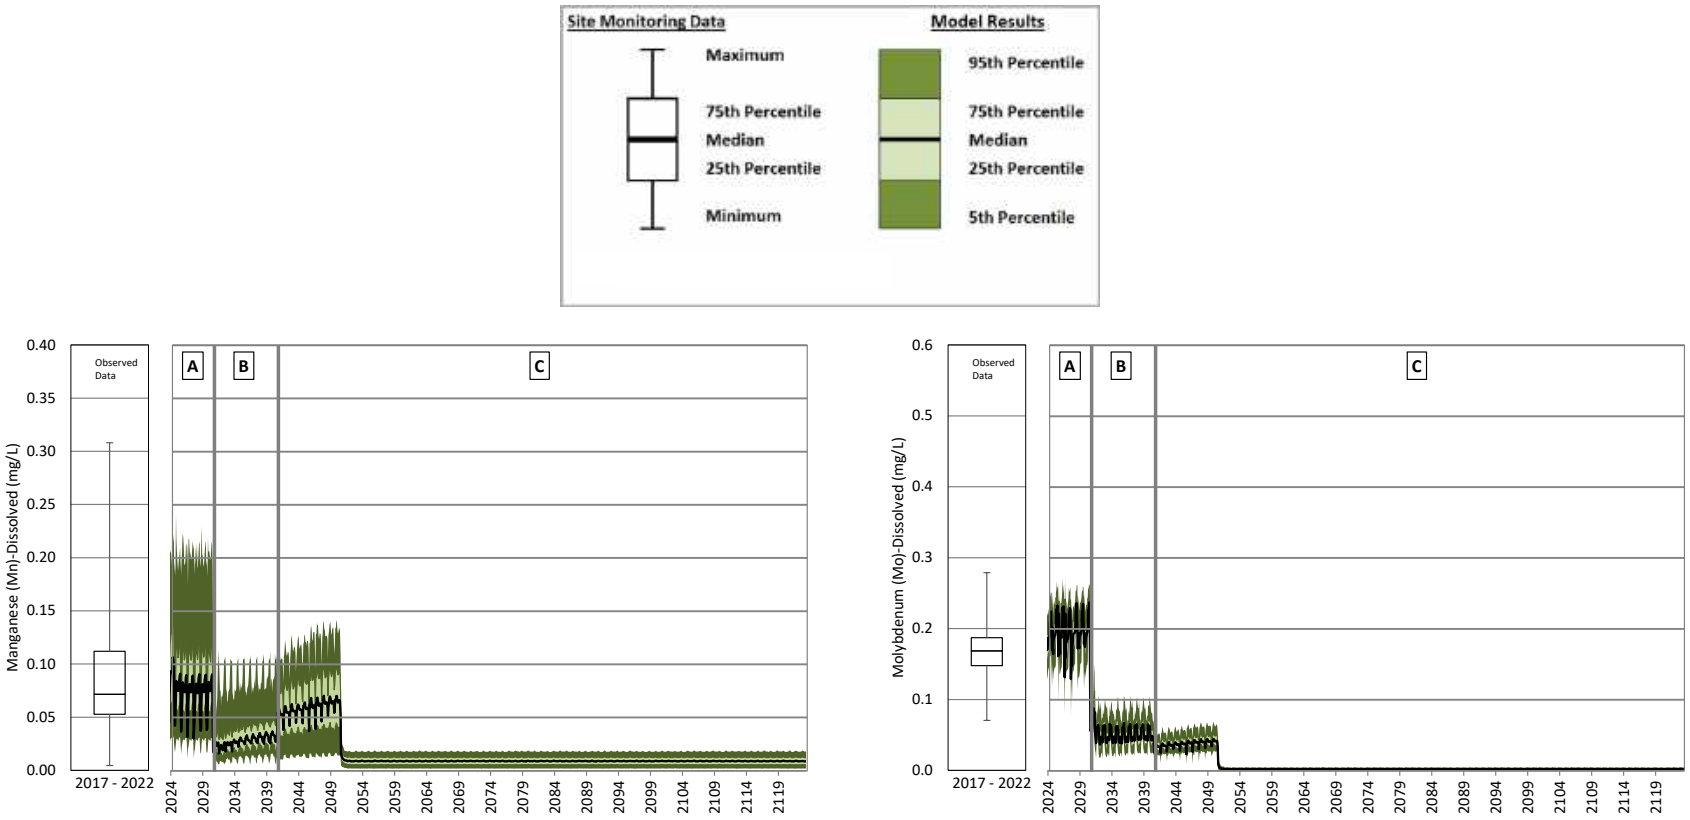

Figure 13: Predicted Dissolved Arsenic and Dissolved Chromium Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

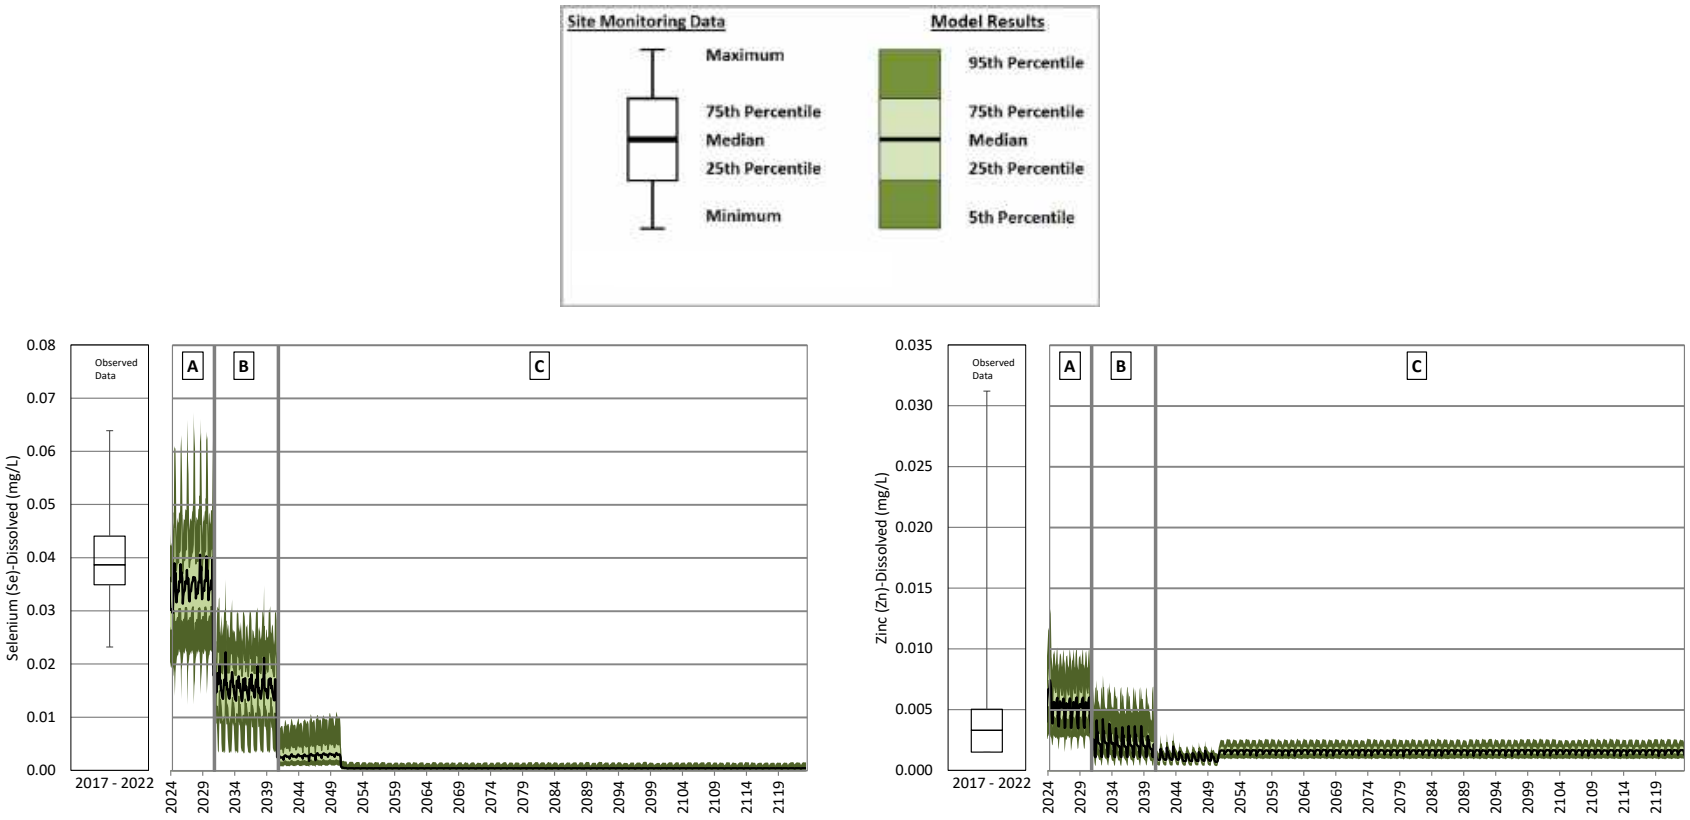

Figure 14: Predicted Dissolved Copper and Dissolved Iron Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. The increase in manganese concentrations during the first ten years of post-closure is caused by the pumping from the MESCP which ends in 2051. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 15: Predicted Dissolved Manganese and Dissolved Molybdenum Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 16: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in the Perimeter Embankment Till Borrow Pond – Operations, Closure and Post-closure

4.2 9 km Sump and Northwest Sump

The 9 km (9K) Sump and the NW Sump receive drainage from undisturbed and disturbed areas in their catchment areas, as well as runoff and seepage from the Temporary NW PAG Stockpile and East RDS. Discharge from the 9K Sump and NW Sump is assumed to be directed to Bootjack Lake during post-closure.

Time series plots for key parameters in the 9K Sump for operations, closure and post-closure are shown in Figures 17 to 22. Time series plots for key parameters in the Northwest Sump for closure and post-closure are shown in Figures 23 to 28. Maximum of median and 95th percentile predictions are presented in Tables 12 and 13 for the 9K Sump and NW Sump, respectively.

Changes in concentrations in the 9K and Northwest Sumps from operations to closure and post-closure are due to remediation of the catchment areas. Trends for all key parameters reach steady state conditions in the 9K Sump and NW Sump 10 years after the start of post-closure when the runoff areas are assumed to be reclaimed (Figures 16 to 21 for the 9K Sump; Figures 22 to 27 for the NW Sump). Concentrations of most parameters gradually decrease as runoff water qualities from all facilities reporting to the 9K Sump are predicted to return to undisturbed water quality (Table 9). After the PAG material has been removed from the 9K Sump catchment area, runoff from the Temporary NW PAG Stockpile is assigned the disturbed runoff water quality and returns to undisturbed after ten years, which causes concentrations of most parameters to decrease.

Seasonal concentration peaks during winter are associated with continued seepage through the reclaimed Temporary NW PAG Stockpile. During winter months, the relative flow contribution of seepage from the Temporary NW PAG Stockpile is high compared to runoff because snowfall is assumed to accumulate on the stockpile and not melt until spring. Seepage from the Temporary NW PAG Stockpile is assigned a PAG water quality input during reclamation and then a NAG water quality input in perpetuity once reclamation is complete. The NAG and PAG water quality in the seepage flows during the winter results in the seasonal winter peaks in concentrations.

The only parameters with predicted maximum concentrations greater in post-closure than closure are total phosphorus, aluminum, arsenic, chromium, iron, lead, silver and silicon. These parameters have higher concentrations in the statistical distributions assigned for undisturbed runoff water quality than the statistical distributions assigned for PAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more flows on the Mine site, which results in predicted concentrations of aluminum, arsenic, chromium, iron, lead, silver and silicon to be higher in post-closure than closure.

a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

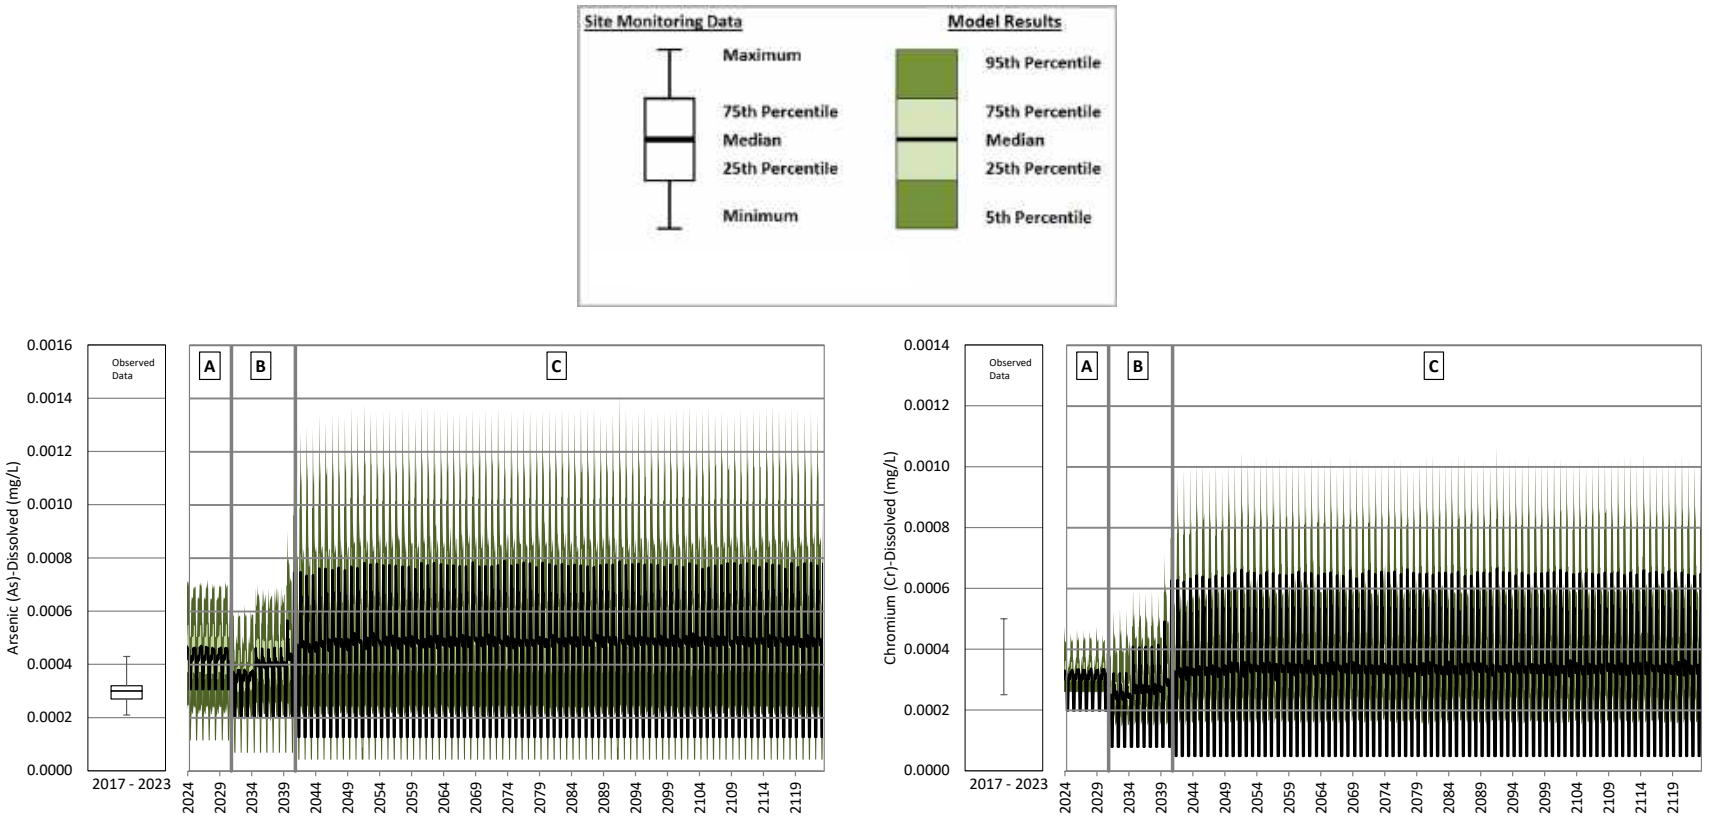

Figure 17: Predicted Sulphate and Total Ammonia Concentrations in the 9K Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

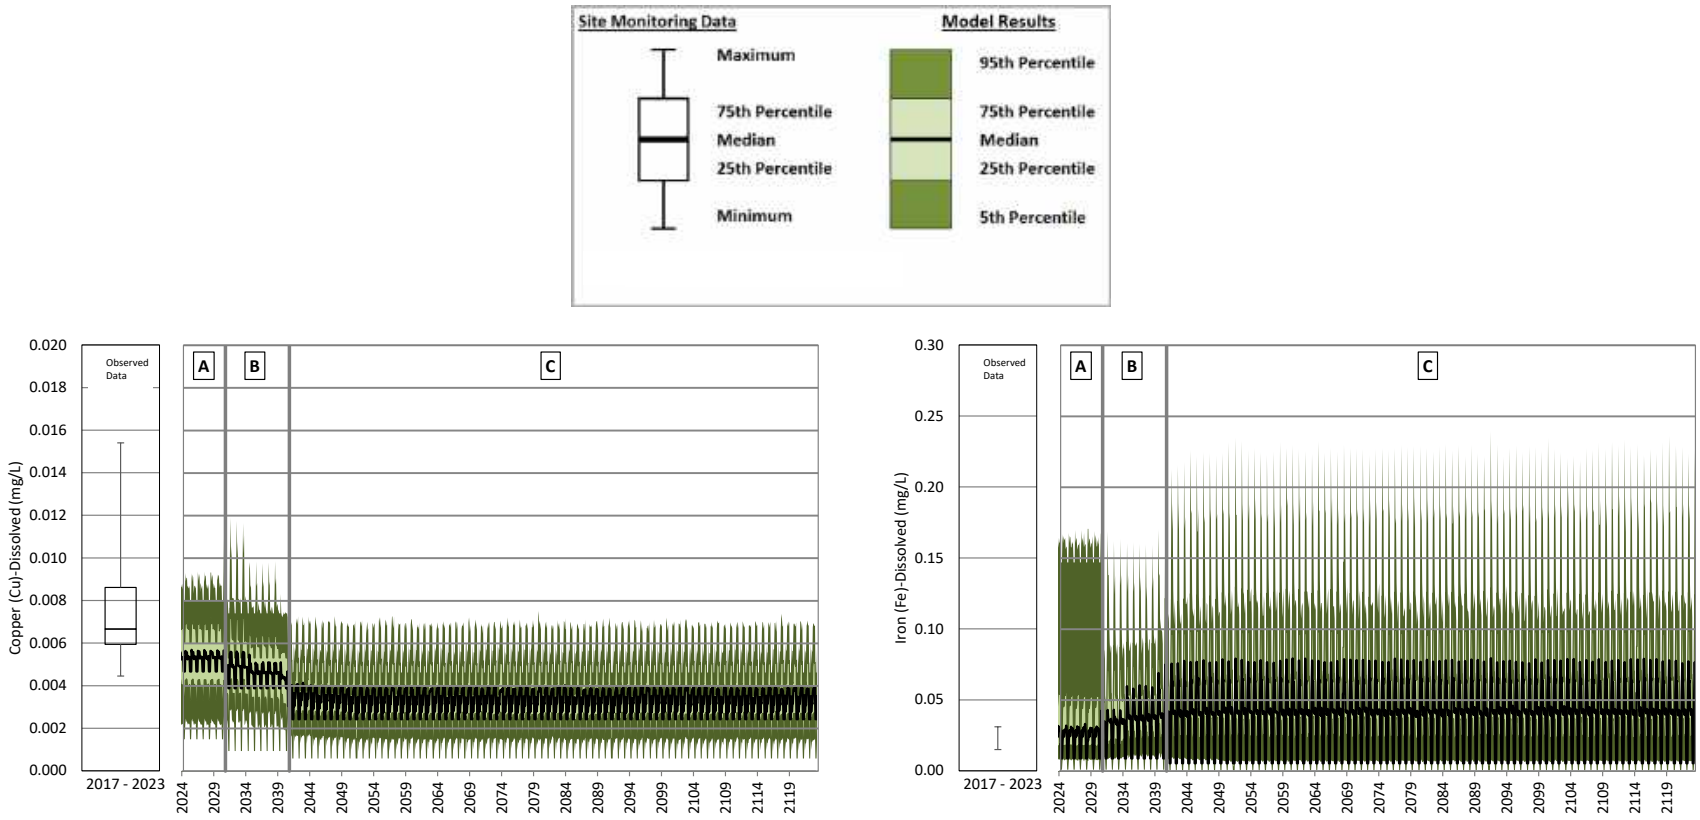

Figure 18: Predicted Nitrate and Total Phosphorus Concentrations in the 9K Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

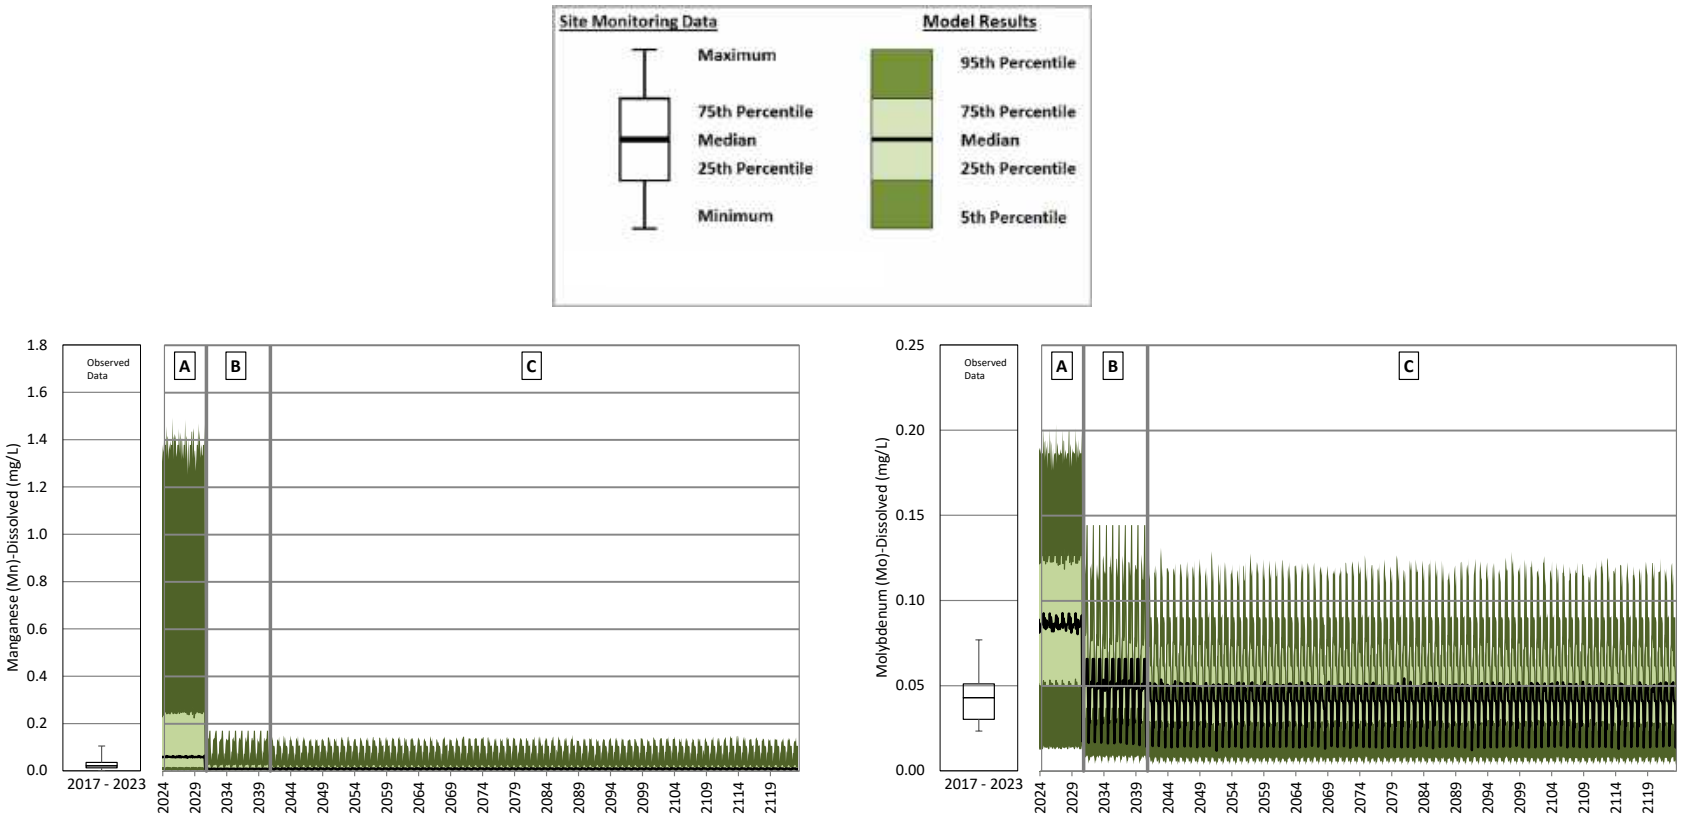

Figure 19: Predicted Dissolved Arsenic and Dissolved Chromium Concentrations in the 9K Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

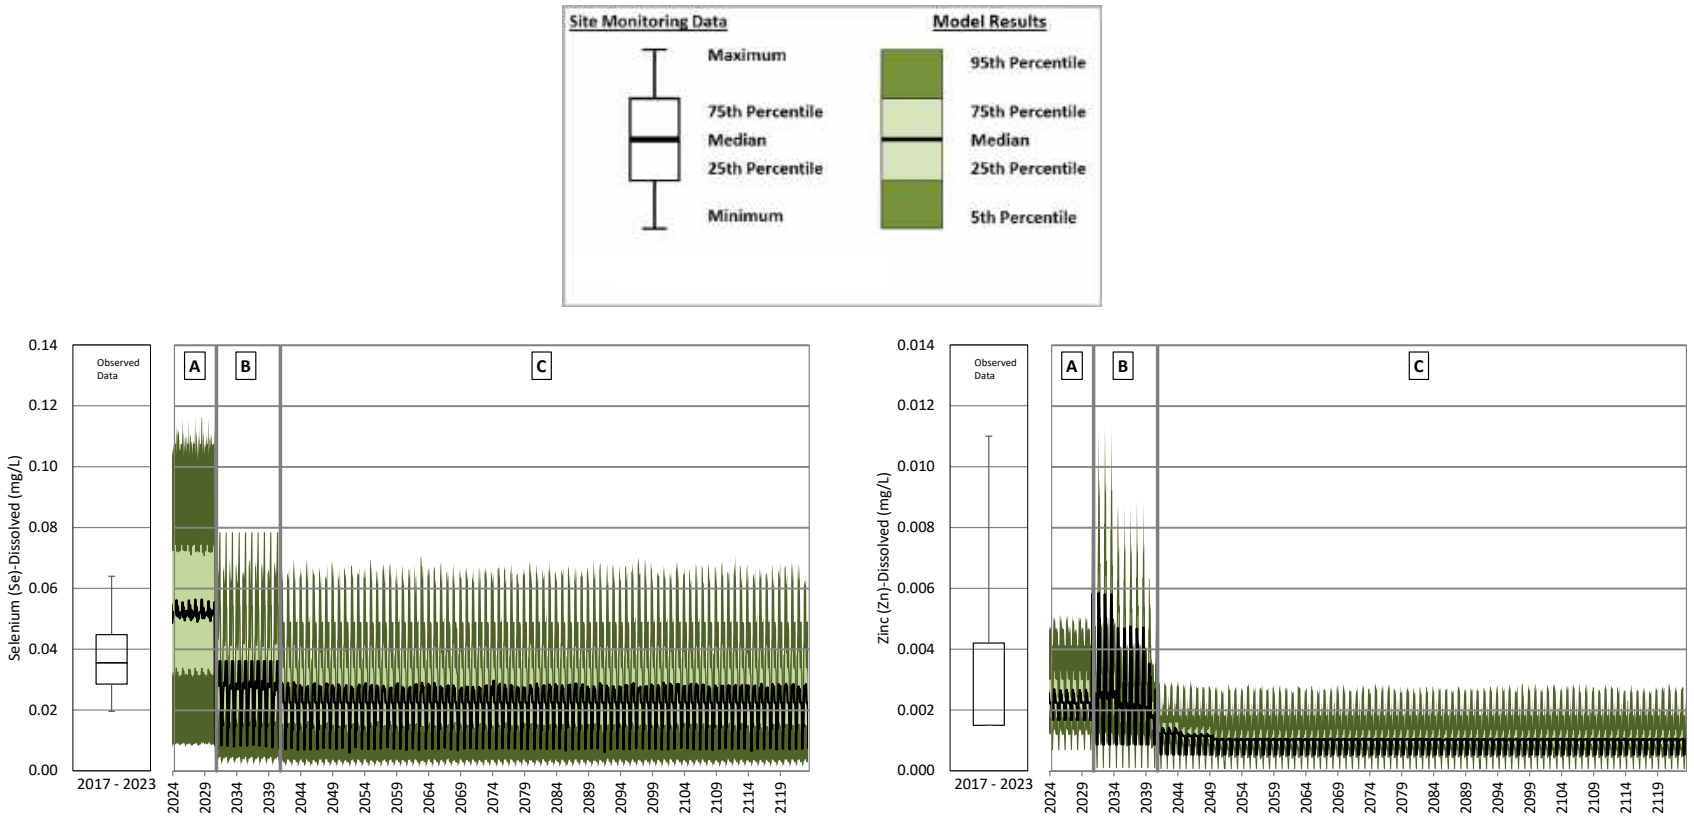

Figure 20: Predicted Dissolved Copper and Dissolved Iron Concentrations in the 9K Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 21: Predicted Dissolved Manganese and Dissolved Molybdenum Concentrations in the 9K Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 22: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in the 9K Sump – Operations, Closure and Post-closure

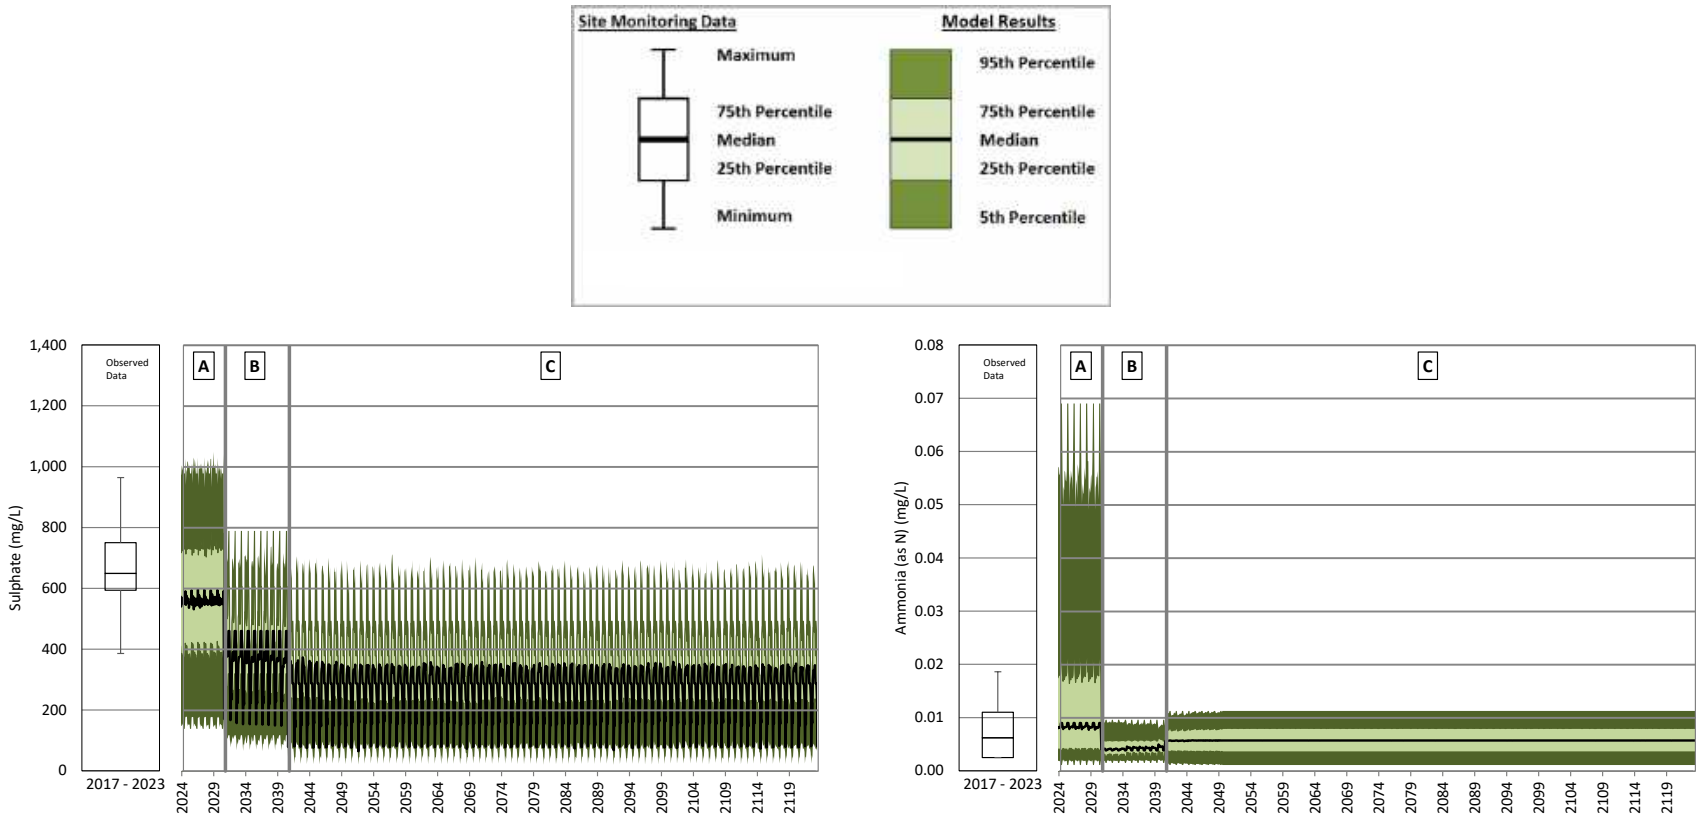

Table 13: Predicted Maximum Concentrations in the Northwest Sump during Operations, Closure and Post-closure

Parameter	Units	Operations Period (January 2024 - March 2031)		Closure (April 2031 - March 2041)		Early Post-Closure (April 2041 - March 2051)		Long Term Post-Closure (April 2051 - April 2131)

a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

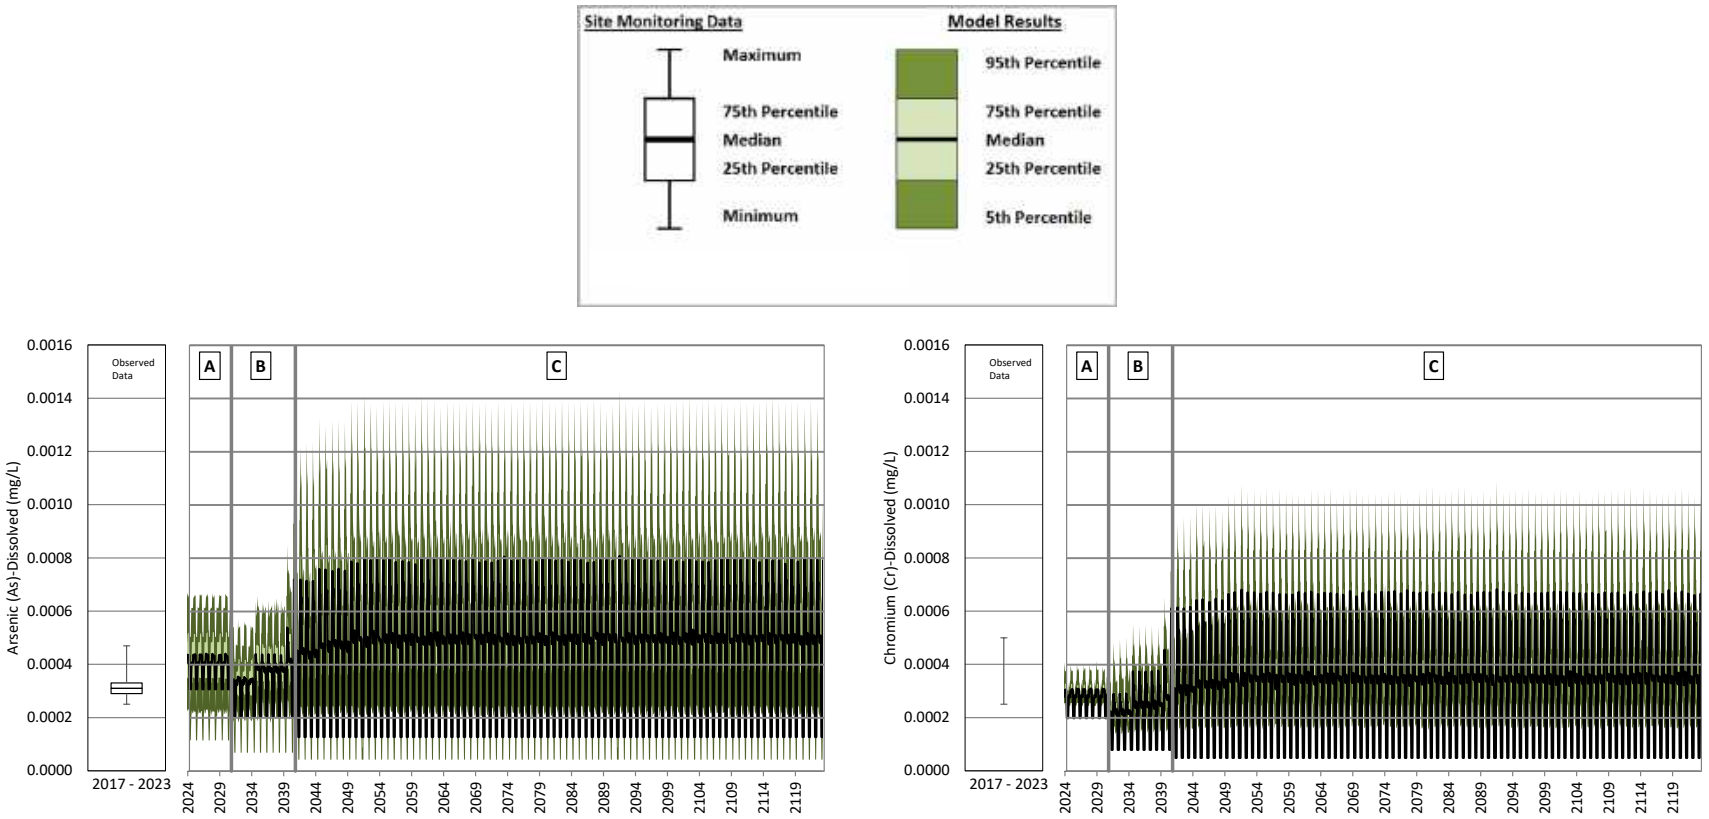

Figure 23: Predicted Sulphate and Total Ammonia Concentrations in the Northwest Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

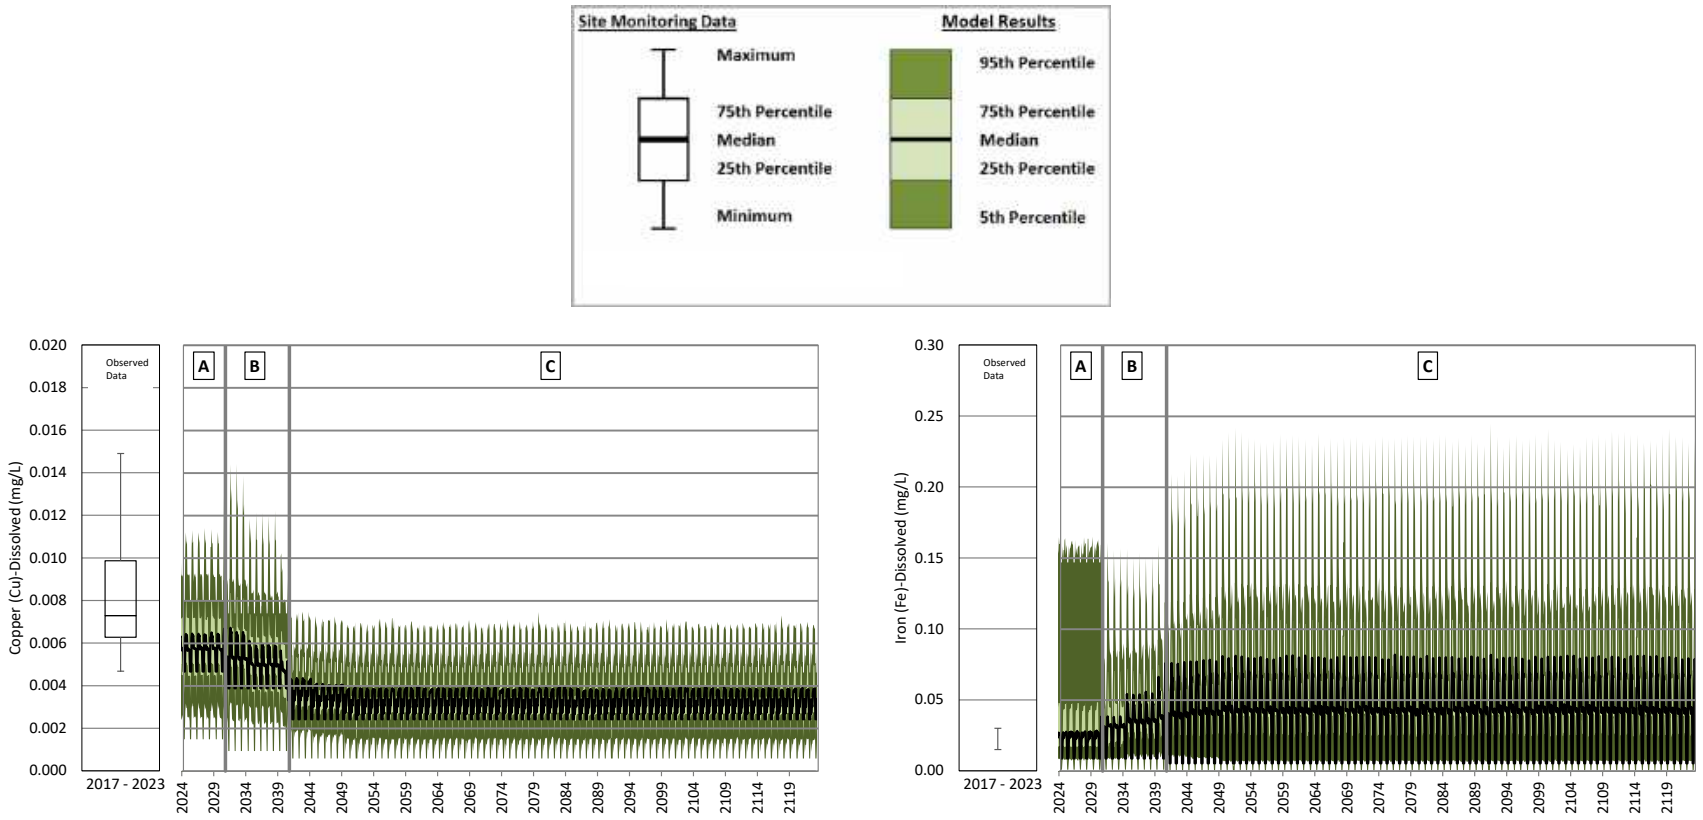

Figure 24: Predicted Nitrate and Total Phosphorus Concentrations in the Northwest Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

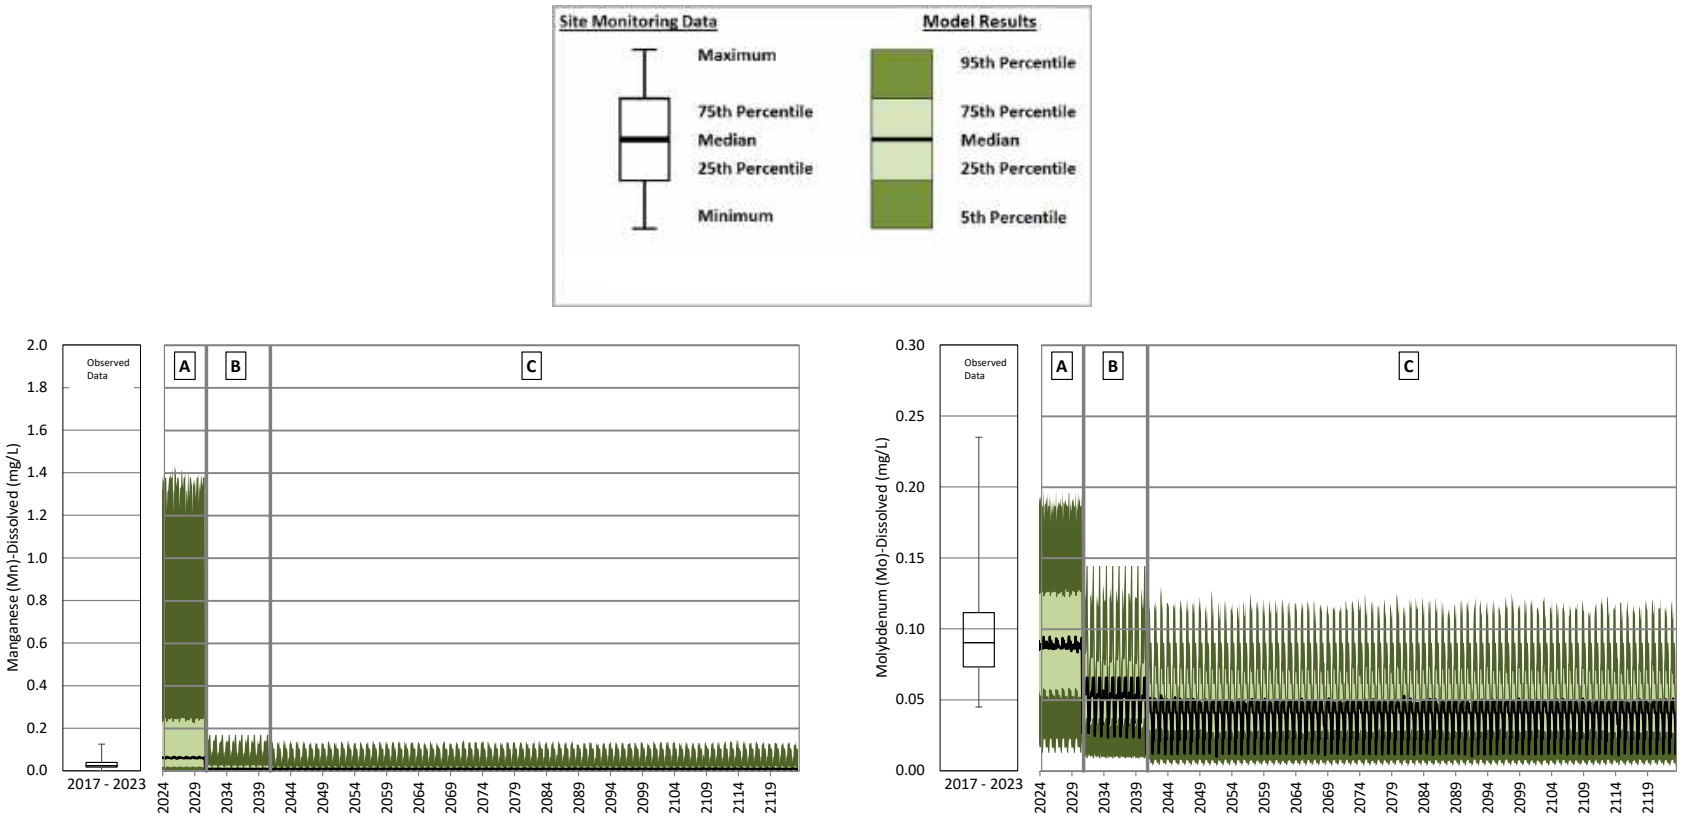

Figure 25: Predicted Total Arsenic and Total Chromium Concentrations in the Northwest Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

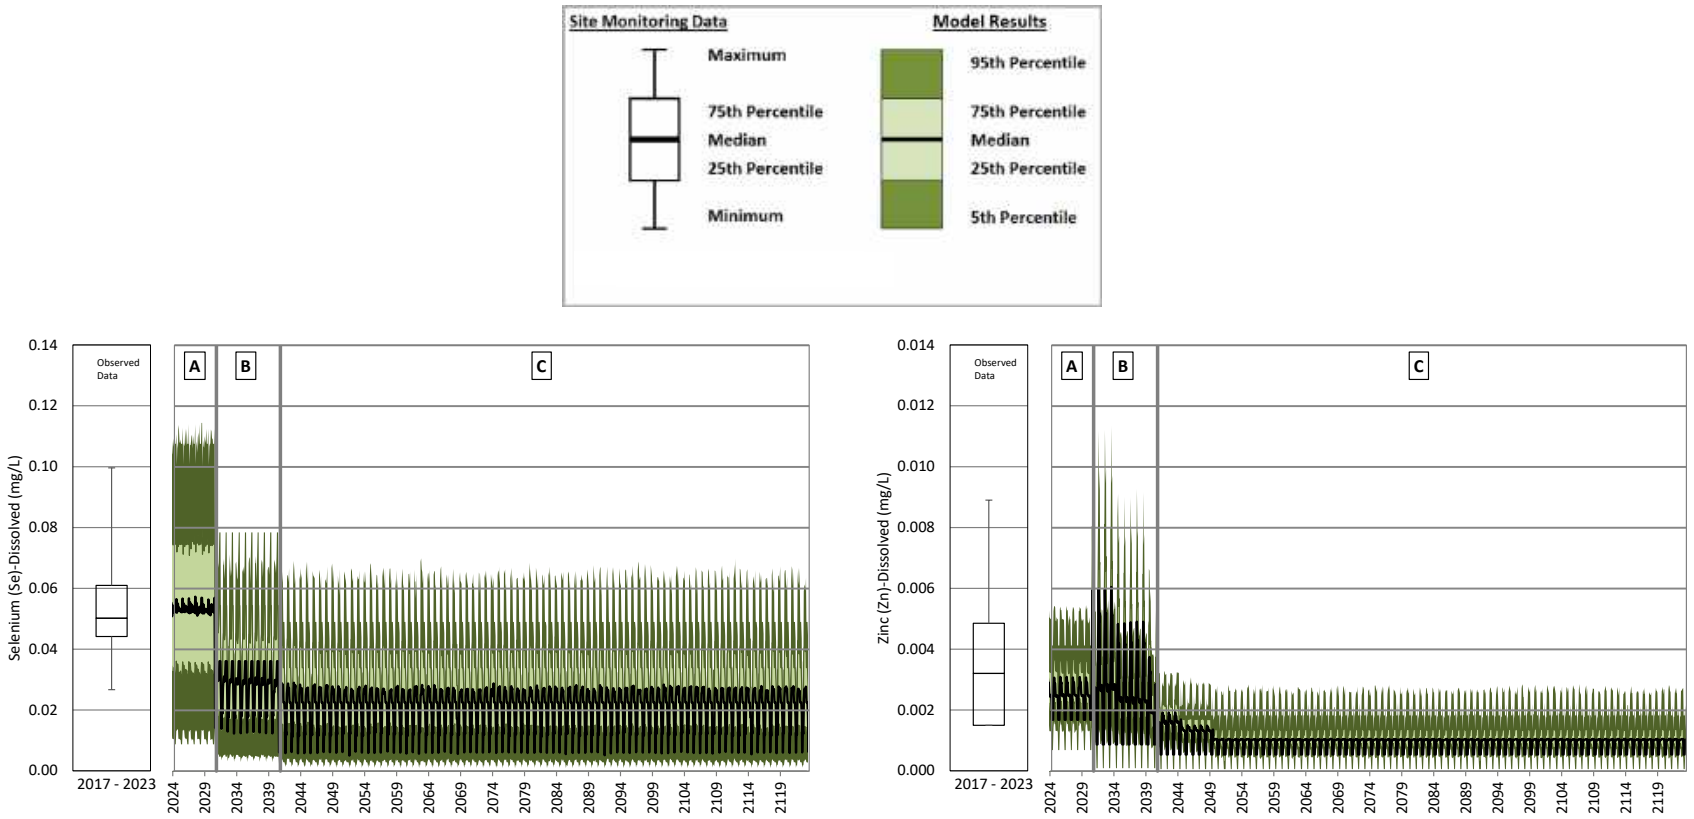

Figure 26: Predicted Total Copper and Total Iron Concentrations in the Northwest Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 27: Predicted Dissolved Manganese and Dissolved Molybdenum Concentrations in the Northwest Sump – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 28: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in the Northwest Sump – Operations, Closure and Post-closure

4.3 Springer-Cariboo Pit

At closure, the PAG material from the Temporary NW PAG Stockpile will be placed in the Springer-Cariboo Pit, and a pit lake will form. The pit will fill passively with groundwater and surface runoff from the pit catchment area. The groundwater inflow to the pit is assumed to flow into the stored PAG material in closure and post-closure. The surface runoff includes runoff and seepage from North Bell RDS, East RDS, and the haul roads. These facilities will be reclaimed during closure. The pit lake is predicted to completely fill between 2059 (99.5th percentile of the 2000 water balance model simulations) and 2063 (mean of the 2000 water balance model simulations), at which point, overflow from the pit will discharge to Bootjack Lake.

Time series plots for key parameters in the Springer-Cariboo Pit for closure and post-closure are shown in Figures 29 to 34. Maximum of median and 95th percentile predictions are presented in Table 14. It is anticipated that particulate metals such as aluminum and copper will be lower in pit lake waters compared to model predictions, as has been observed in operational monitoring (Golder 2016b).

Peak concentrations for most parameters are predicted to occur during the closure period because:

- The PAG material in the Springer-Cariboo Pit contains pore water with a NAG Seep water quality (Table 9).
- The groundwater inflow to the pit, which has a groundwater water quality (Table 9), is assumed to flow into the PAG material and displace the pore water upwards into the forming pit lake.
- The displacement of pore water from the PAG material into the pit lake causes pit lake concentrations to peak in closure.

The only parameters with predicted maximum concentrations greater in post-closure than closure are aluminum, chromium, iron, and lead. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to a greater proportion of the total inflows to the Springer-Cariboo pit.

Figure 34: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in the Springer-Cariboo Pit – Closure and Post-closure

4.4 Mine Drainage Creek Sump

The Mine Drainage Creek Sump receives drainage from undisturbed and disturbed areas, haul roads, and RDSs in its catchment area. Discharge from the Mine Drainage Creek Sump is planned to be directed to Bootjack Lake.

Time series plots for key parameters in the Mine Drainage Creek Sump for closure and post-closure are shown in Figures 35 to 40. Maximum of median and 95th percentile predictions are presented in Table 15.

For most parameters, predicted peak concentrations in the Mine Drainage Creek Sump occur during closure, and then decrease as disturbed areas, haul roads, and RDS areas are reclaimed (Figures 35 to 40). Concentrations are highest during operations for most parameters because RDS and haul road runoff is assigned the NAG water quality input until reclamation, which will occur throughout closure. Water qualities from these facilities are predicted to return to the undisturbed water quality (Table 9). Predicted water quality reaches steady state 10 years after the start of post-closure, after all watershed areas have been reclaimed.

Seasonal peak concentrations during winter are driven by seepage from the East RDS. During winter months, when precipitation occurs as snowfall, East RDS seepage represents a high proportion of the total flow to the Mine Drainage Creek Sump and causes concentrations of parameters to peak.

Some parameters are predicted to have higher concentrations in post-closure than closure. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows to the Mine Drainage Creek Sump, which causes concentrations of parameters, such as aluminum, to increase from closure to post-closure.

a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

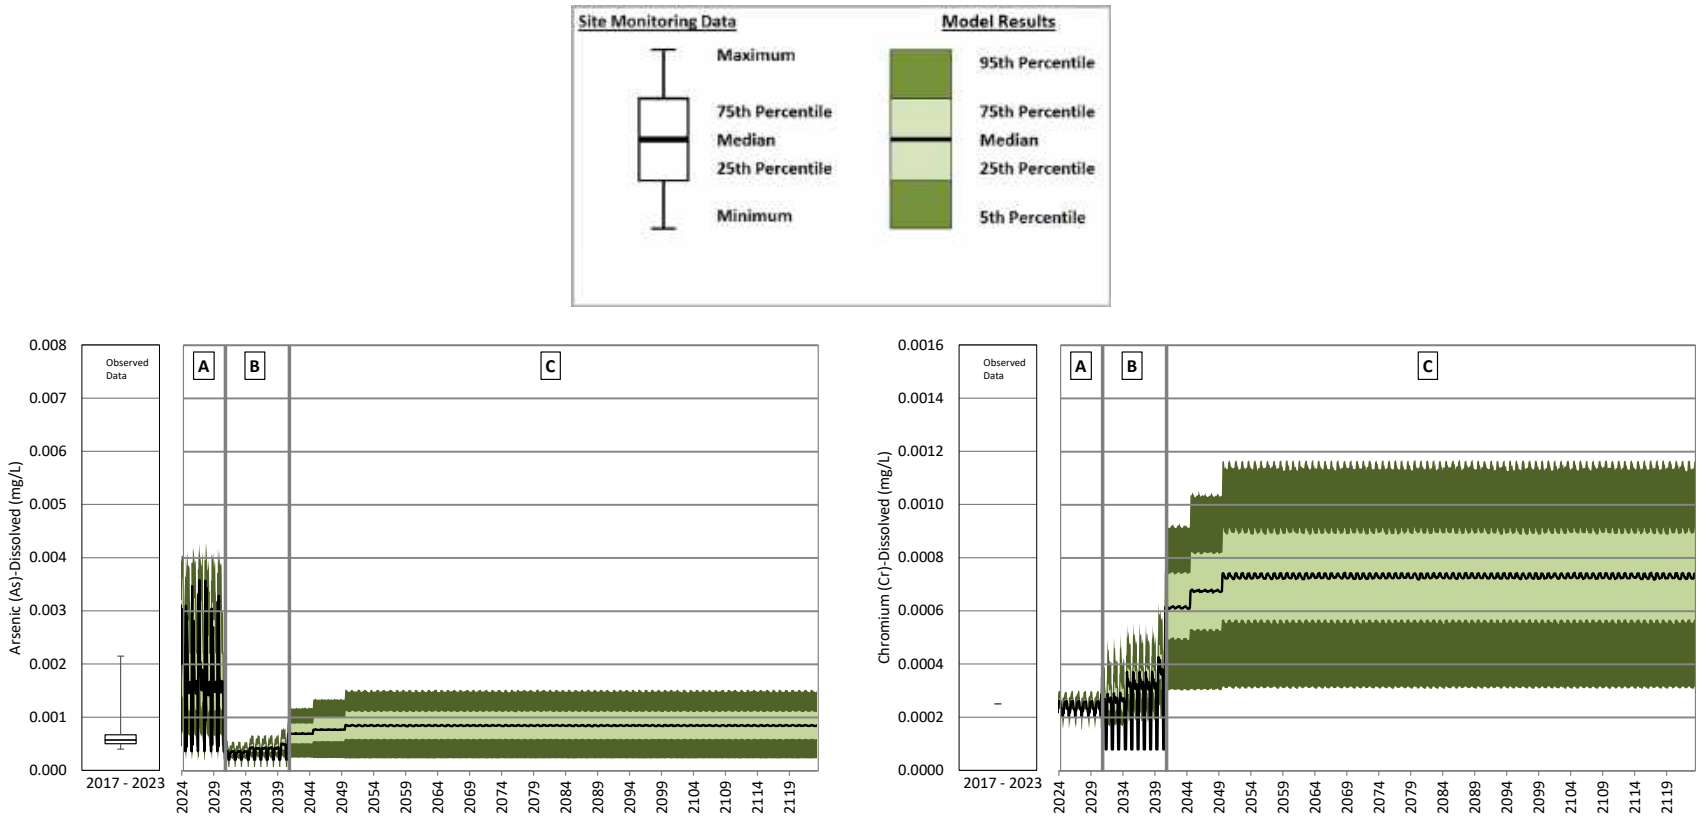

Figure 35: Predicted Sulphate and Total Ammonia Concentrations in the Mine Drainage Creek Sump – Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

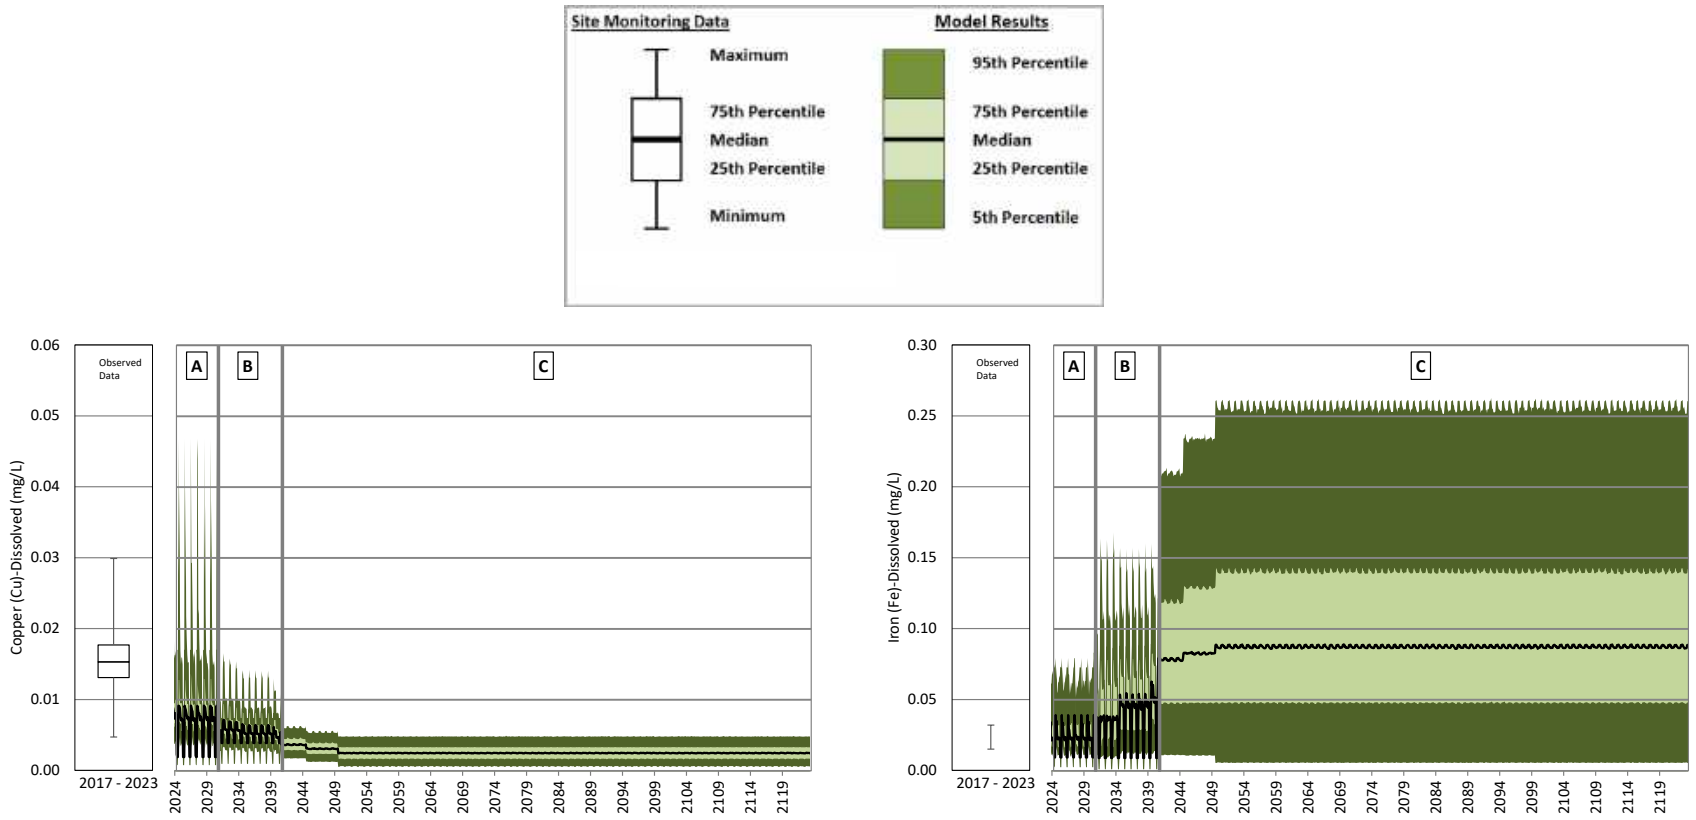

Figure 36: Predicted Nitrate and Total Phosphorus Concentrations in the Mine Drainage Creek Sump – Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

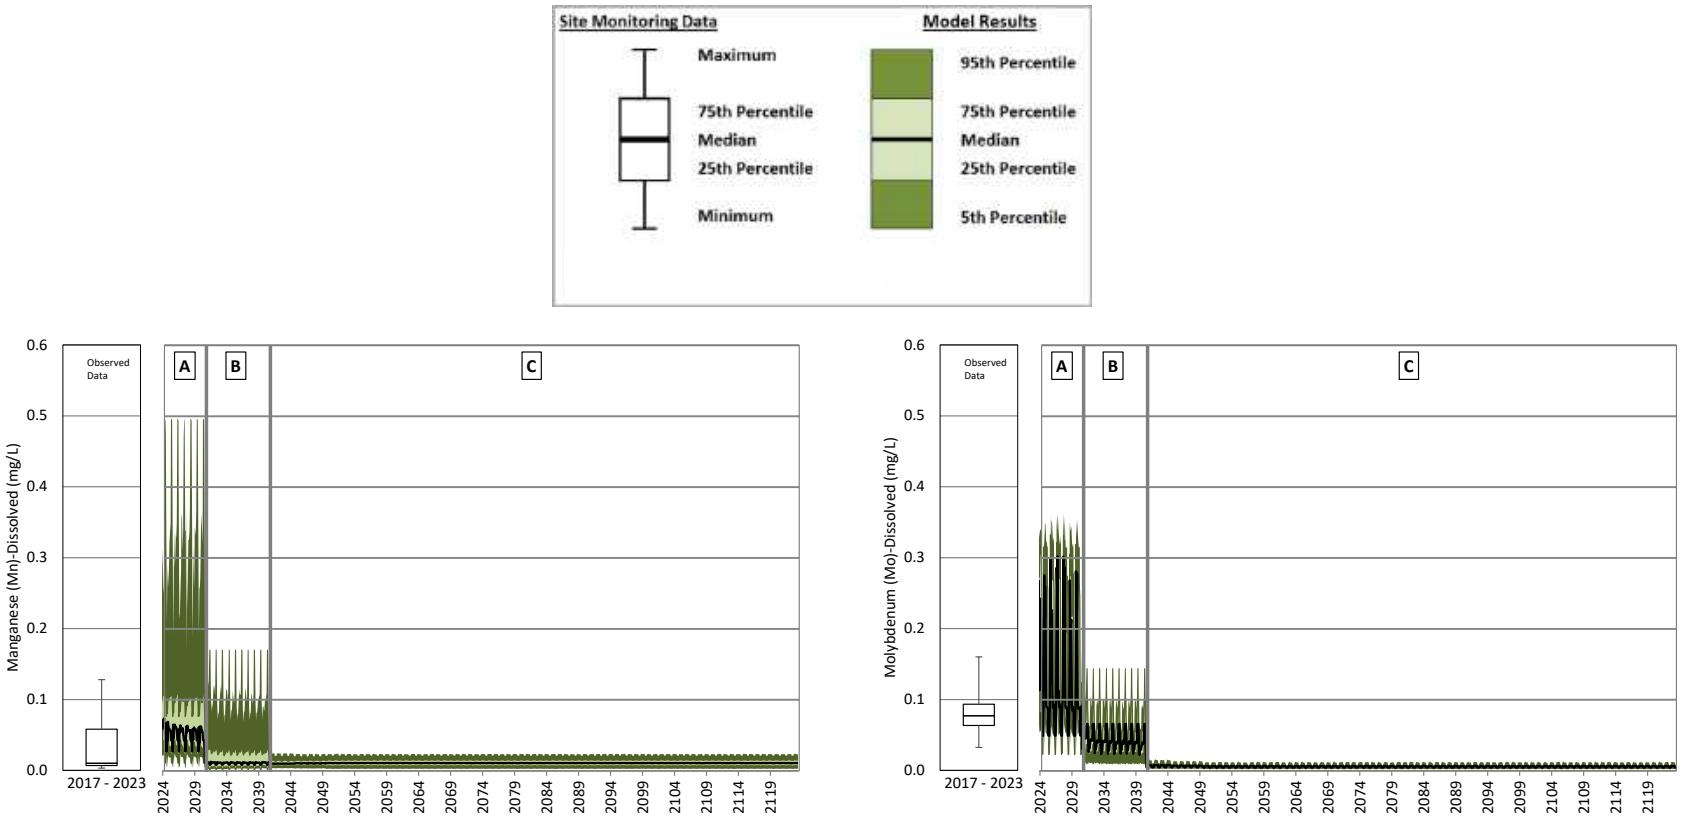

Figure 37: Predicted Dissolved Arsenic and Dissolved Chromium Concentrations in the Mine Drainage Creek Sump – Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

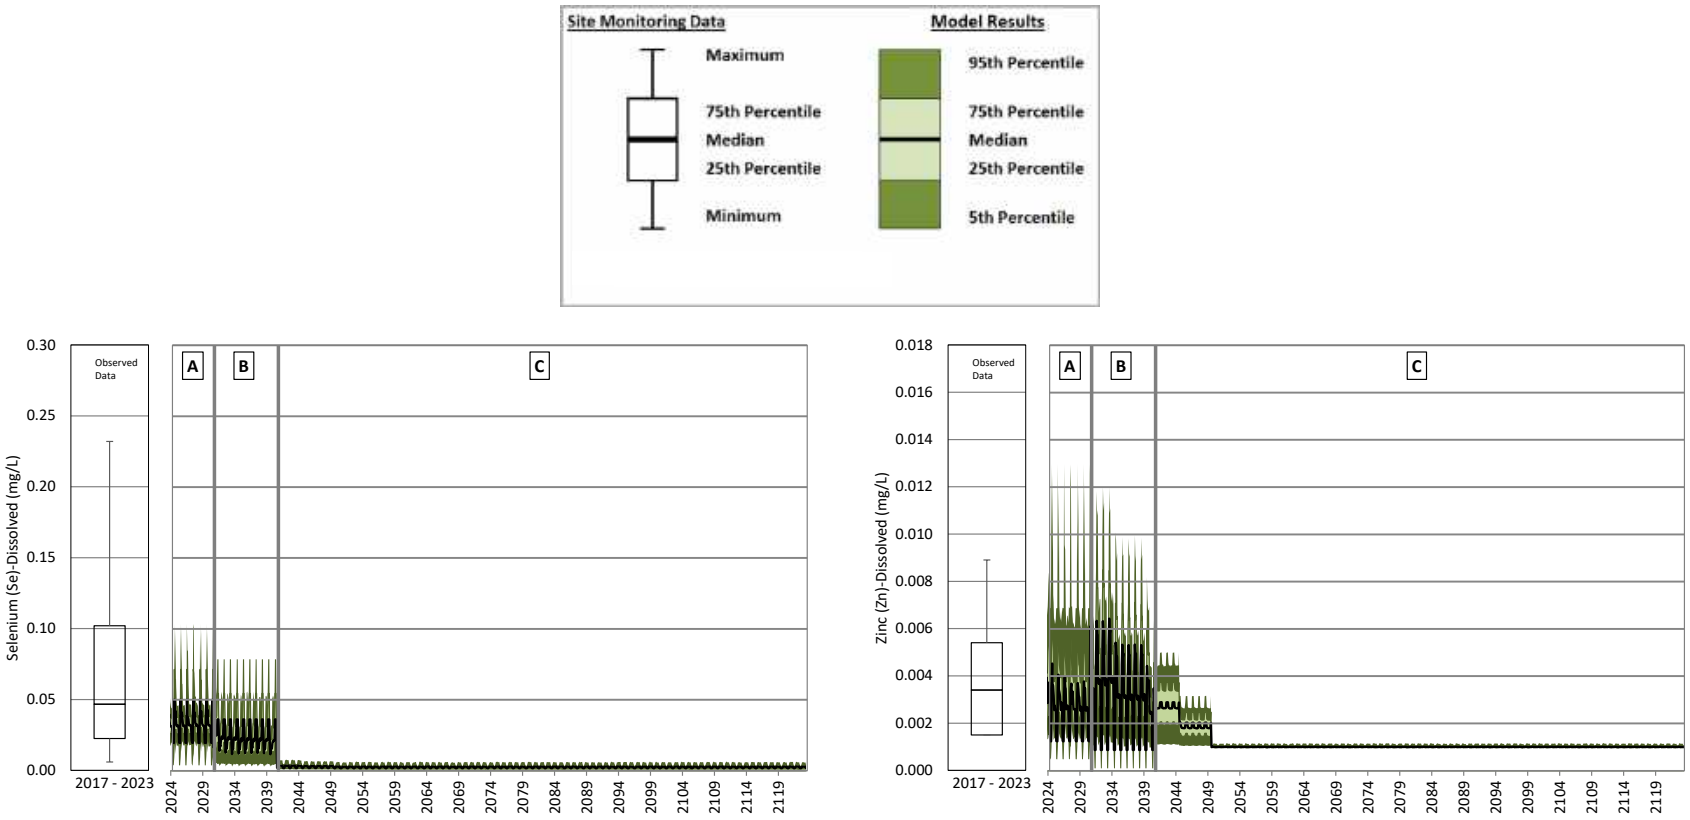

Figure 38: Predicted Dissolved Copper and Dissolved Iron Concentrations in the Mine Drainage Creek Sump – Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 39: Predicted Dissolved Manganese and Dissolved Molybdenum Concentrations in the Mine Drainage Creek Sump – Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 40: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in the Mine Drainage Creek Sump – Closure and Post-closure

4.4.1 Wight Pit

Towards the last year of operation, the TSF pond will be progressively reduced to 0.25 M-m^3 of water. During that time and continuing into closure, the Wight Pit will be used to store excess water. During post-closure, Wight Pit will no longer be used for storage and will be allowed to fill. A pit lake will form in Wight Pit as the mined-out pit refills passively with groundwater, seepage from Boundary Pit, surface runoff from pit walls, disturbed areas, and haul roads in the Wight Pit catchment. Wight Pit is projected to start overflowing in 2048 under the mean results and in 2046 under 99.5th percentile, at which point overflow will be directed to Polley Lake. Reclamation of the disturbed areas and haul roads is assumed to occur during closure (see Section 2.2). Runoff water quality from these facilities is predicted to return to undisturbed water quality as presented in Table 9.

Time series plots for key parameters in Wight Pit for operations, closure and post-closure are shown in Figures 41 to 46. Maximum of median and 95th percentile predictions are presented in Table 16.

Predicted concentrations of key parameters in Wight Pit are generally stable 10 years after the start of post-closure (Figures 41 to 46). Concentrations of key parameters decrease slightly through early post-closure after the pit has filled and is flushed with runoff from reclaimed disturbed areas and haul roads in the Wight Pit catchment area.

Some parameters are predicted to have higher concentrations in post-closure than closure (for example, dissolved copper). The increase in concentration for these parameters is caused by either:

a) Higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows into Wight Pit.

b) Increased proportions of the total inflows to Wight Pit from pit wall runoff that is assigned the Wight Pit wall runoff during post-closure.

Wight Pit has been the subject of some experimental work that looked at Wight Pit as a possible saturated rock fill reactor. Those trials are incomplete, and Wight Pit is currently being used for water storage. This use remains the intended use within the Reclamation and Closure Plan. Should MPMC advance the use of Wight Pit as a saturated rockfill reactor, there will need to be permitting (following a decision) and updates to the Reclamation and Closure Plan.

Table 16: Predicted Maximum Concentrations Wight Pit during Operations, Closure and Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 46: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in Wight Pit – Operations, Closure and Post-closure

4.5 Long Ditch

In closure, the Long Ditch continues to receive flow from the SERDS Ditch and overflow from Bootjack Creek Sump (via SERDS Ditch). Discharge from the Long Ditch will be directed to Polley Lake, subject to water quality meeting requirements. The combined catchment area for the Long Ditch, the SERDS Ditch, and Bootjack Creek includes the SERDS RDS, NEZ RDS, and East RDS along with haul roads, disturbed areas, and undisturbed catchment area. Tailings co-disposal to the SERDS location will include a soil cover during closure that will remediate runoff from the tailings deposition area which runs off into SERDS Ditch. However, seepage water quality from the SERDS tailings is assumed to remain unchanged through closure and post-closure. The proportion of seepage assigned tailings water quality is calculated based on the total proportions of tailings relative to waste rock deposited (3.5% tailings and 96.5% waste rock; MPMC 2022).

Time series plots for key parameters in Long Ditch for closure and post-closure are shown in Figures 46 to 48 for the climate change module results and in Figures 47 to 52. Maximum of median and 95th percentile predictions are presented in Table 17.

Peak concentrations in the Long Ditch are predicted to occur during operations, representing runoff and seepage from un-reclaimed RDS areas within the combined catchment area for the Long Ditch, the SERDS Ditch, and Bootjack Creek (Figures 47 to 52). These facilities are reclaimed throughout closure, at which point runoff is assigned undisturbed water quality (Table 9). Parameter concentrations in the Long Ditch are predicted to decrease through closure, reaching steady state conditions 10 years after the start of post-closure.

Seasonal peak concentrations in winter are driven by seepage from the RDS area within the watershed which is assigned the NAG water quality in perpetuity. During winter months, when precipitation occurs as snowfall, RDS seepage represents a higher proportion of the total flow to the Long Ditch and causes concentrations to peak.

Some parameters are predicted to have higher concentrations in post-closure than closure. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows into Bootjack Creek Sump, SERDS Ditch, and Long Ditch which causes concentrations of some parameters, such as aluminum, to increase.

a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

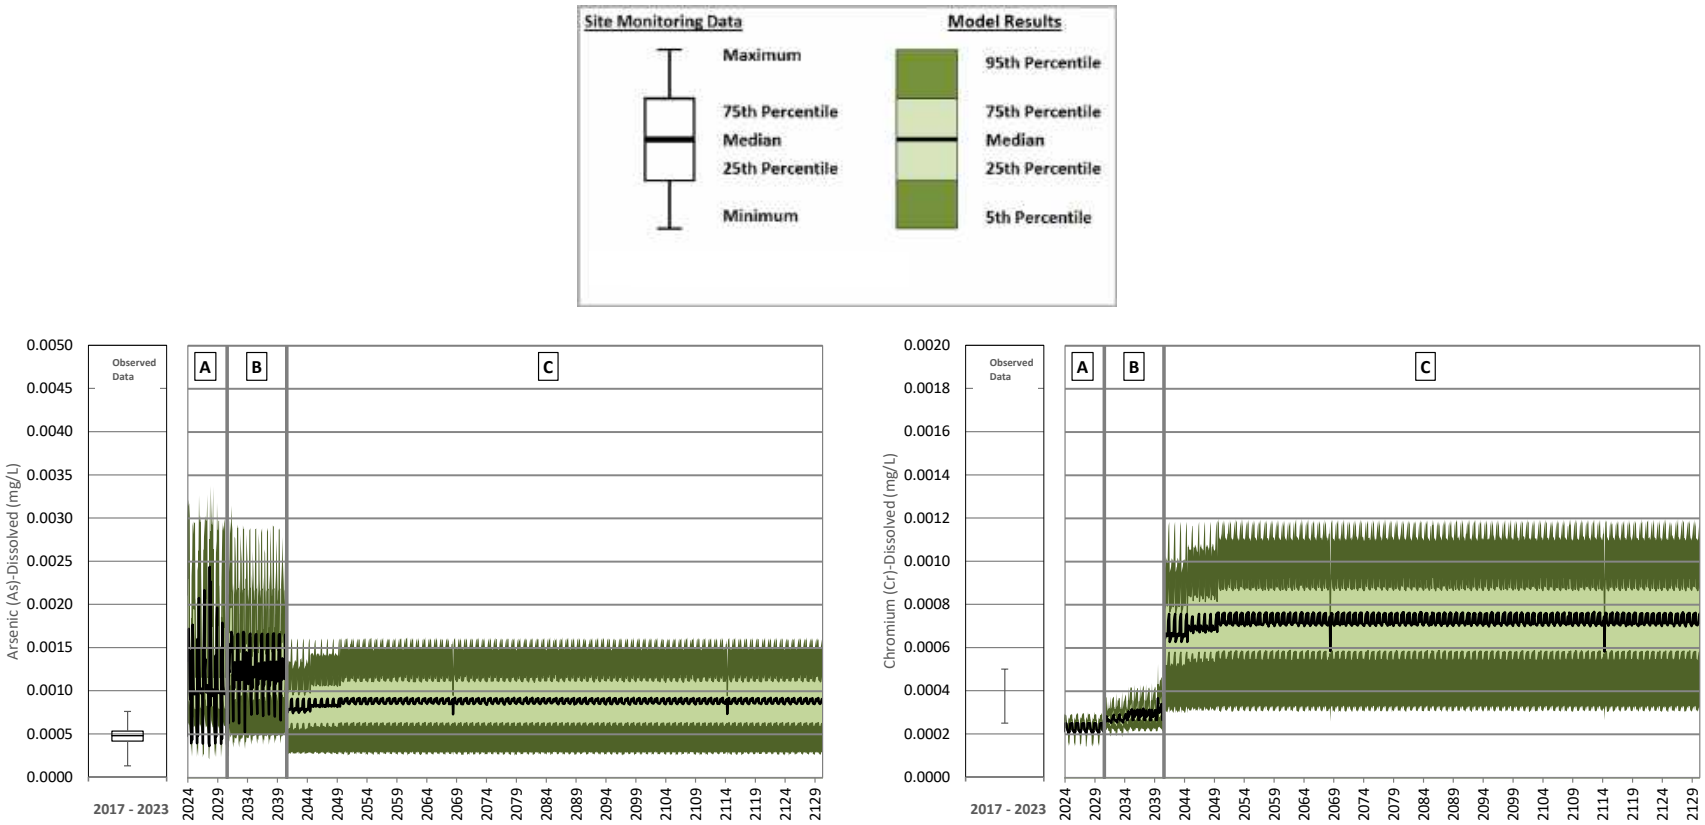

Figure 47: Predicted Sulphate and Total Ammonia Concentrations in Long Ditch – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

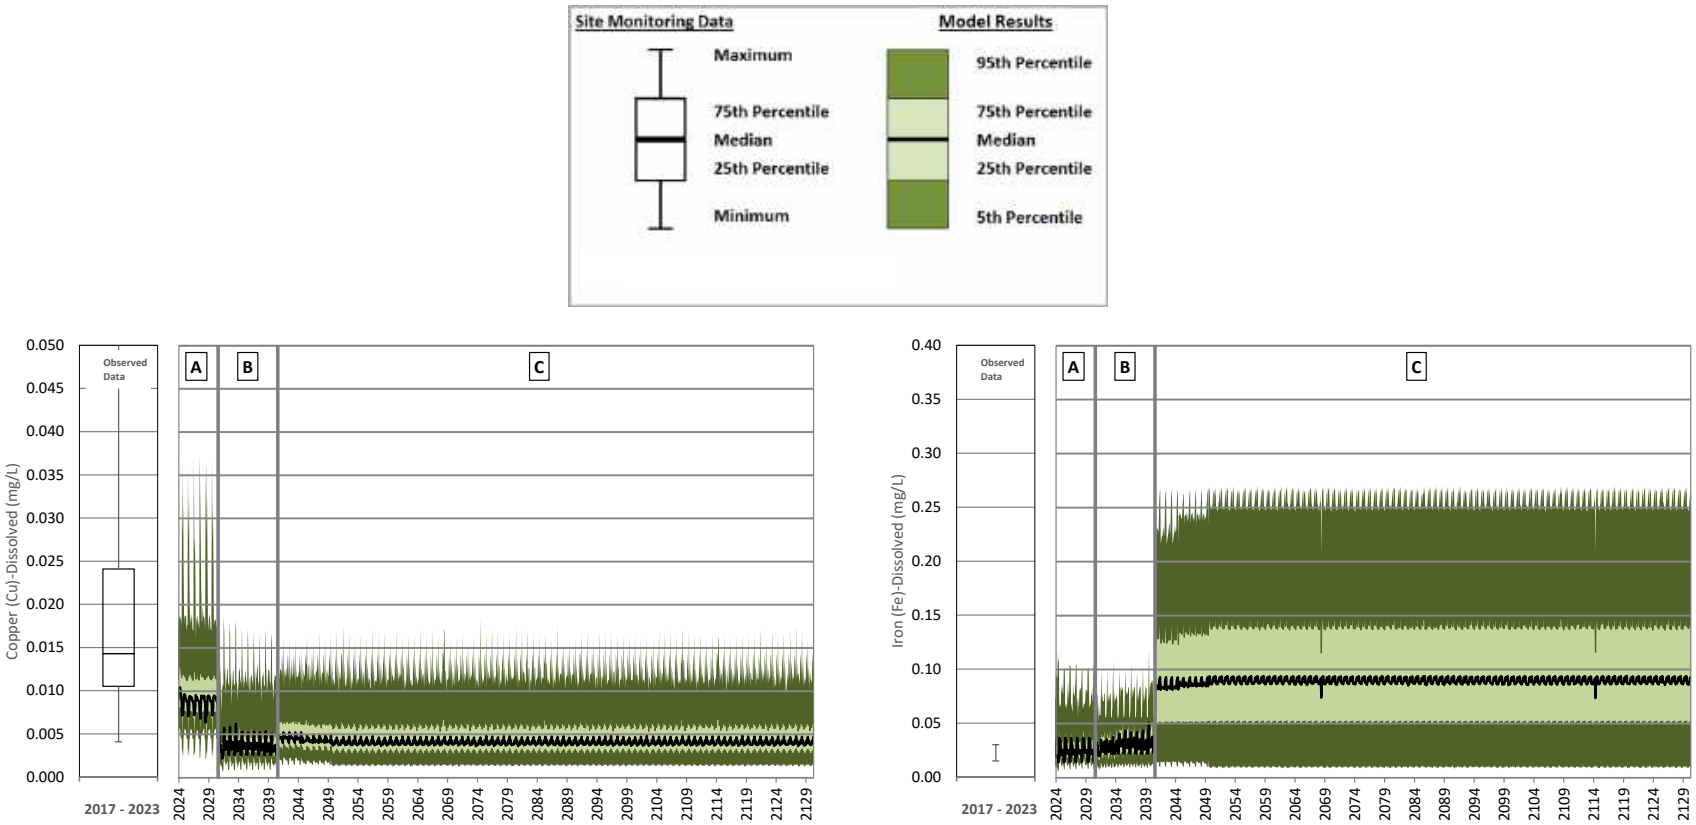

Figure 48: Predicted Nitrate and Total Phosphorus Concentrations in Long Ditch – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

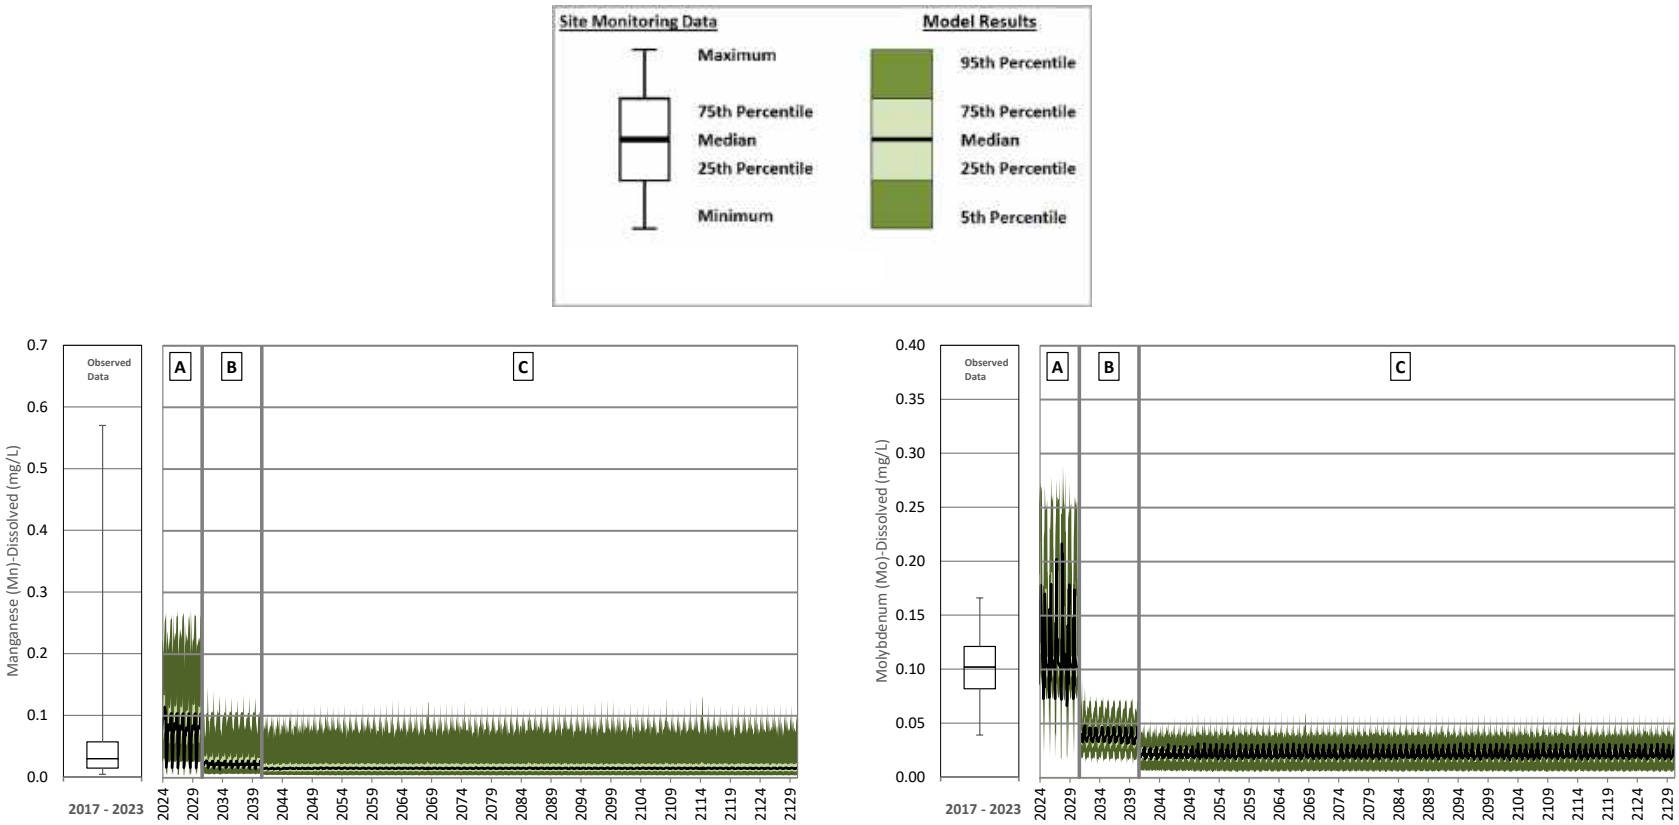

Figure 49: Predicted Dissolved Arsenic and Dissolved Chromium Concentrations in Long Ditch – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

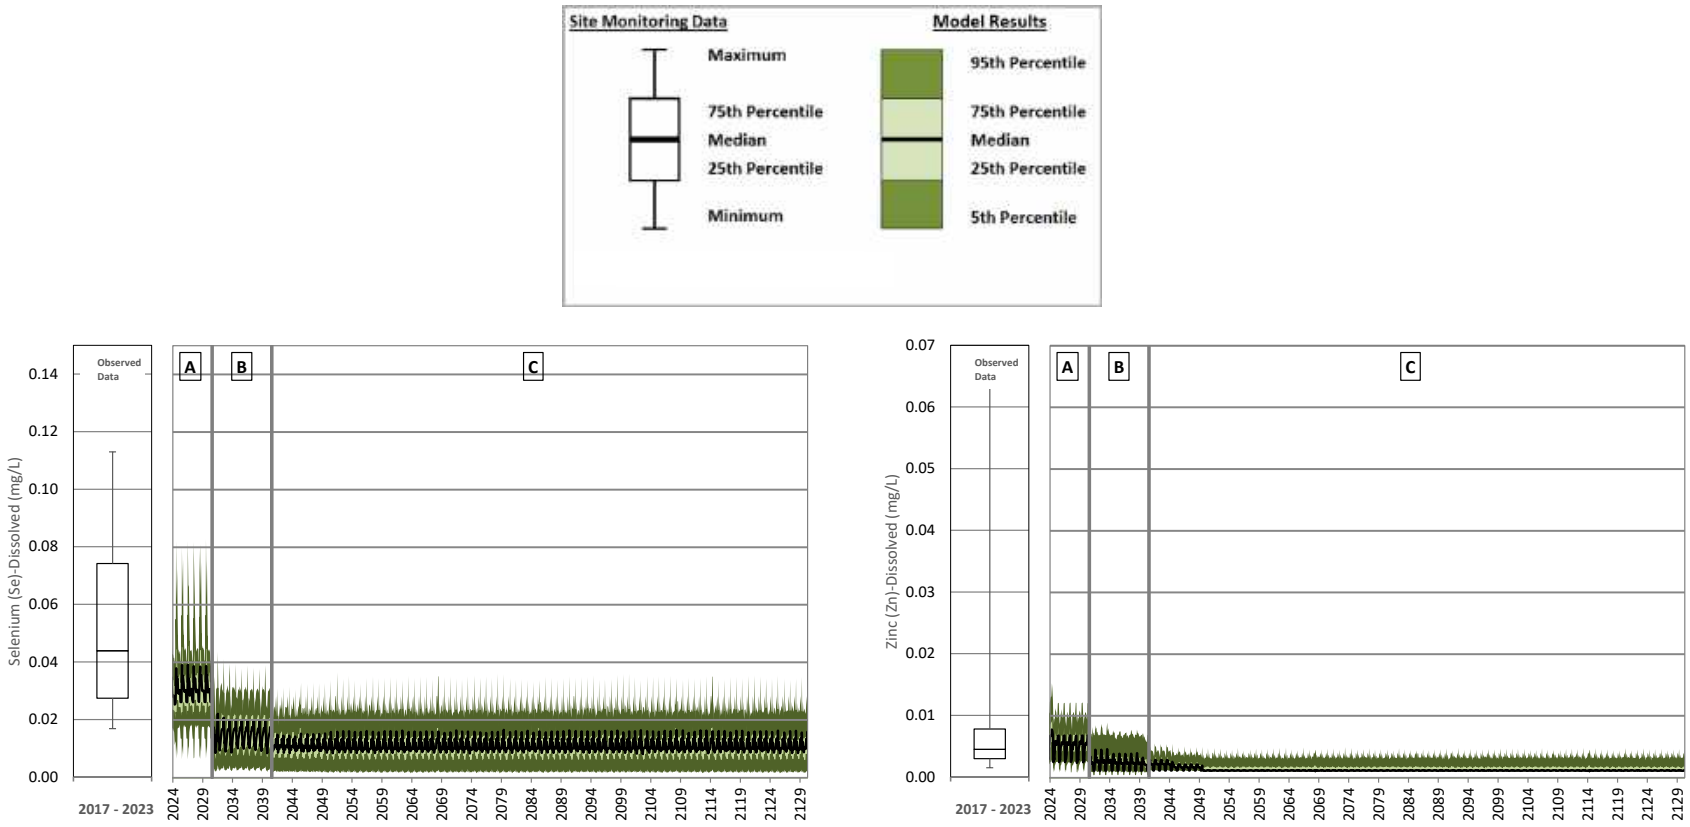

Figure 50: Predicted Dissolved Copper and Dissolved Iron Concentrations in Long Ditch – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 51: Predicted Dissolved Manganese and Dissolved Molybdenum Concentrations in Long Ditch – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure 52: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in Long Ditch – Operations, Closure and Post-closure

4.5.1 South Embankment Seepage Collection Pond

The SWWBM assumes that the SESCP has a small catchment area and receives mostly TSF seepage in closure. Time series plots for key parameters in SESCP for operations, closure and post-closure are shown in Figures 53 to 58. Maximum of median and 95th percentile predictions are presented in Table 18.

For most parameters, the predicted peak concentrations in the SESCP occur during operations, and then decrease as TSF beach and impoundment areas are reclaimed during closure and post-closure. Water quality is predicted to reach steady-state conditions by 2074, after the TSF surface has been reclaimed. Because the saturated TSF seepage is assumed to be the same water quality as the TSF beach, impoundment, and embankment areas, the decrease in SESCP concentrations is coincident with the decrease in parameter concentrations in the TSF beach and impoundment.

The assigned TSF beach, impoundment and embankment water quality changes from the TSF supernatant input to undisturbed water quality during the closure period causing the decrease in concentration in the TSF. As TSF concentrations decrease, concentrations in the SESCP decrease due to saturated seepage from the TSF. The increase in concentrations until 2074 is due to a proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility. While the range in predicted concentrations is considered reasonable, the timing of this transition is uncertain because the amount of time it may take to flush process water from the tailings is unknown.

a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2074 when the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility reaches a steady state.

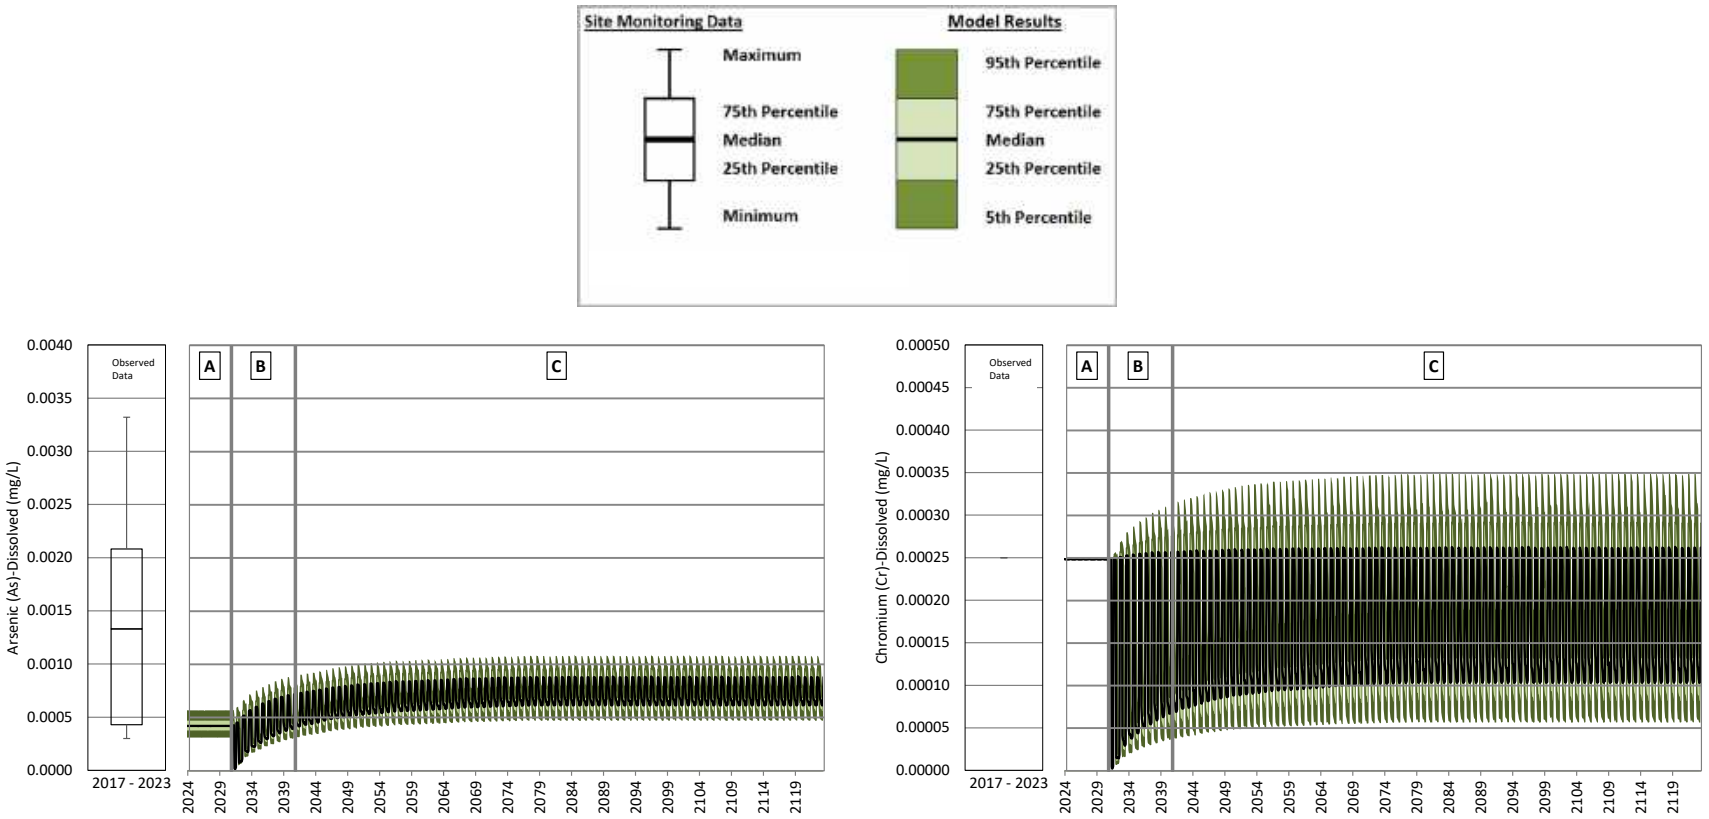

Figure 53: Predicted Sulphate and Total Ammonia Concentrations in the South Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2074 when the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility reaches a steady state.

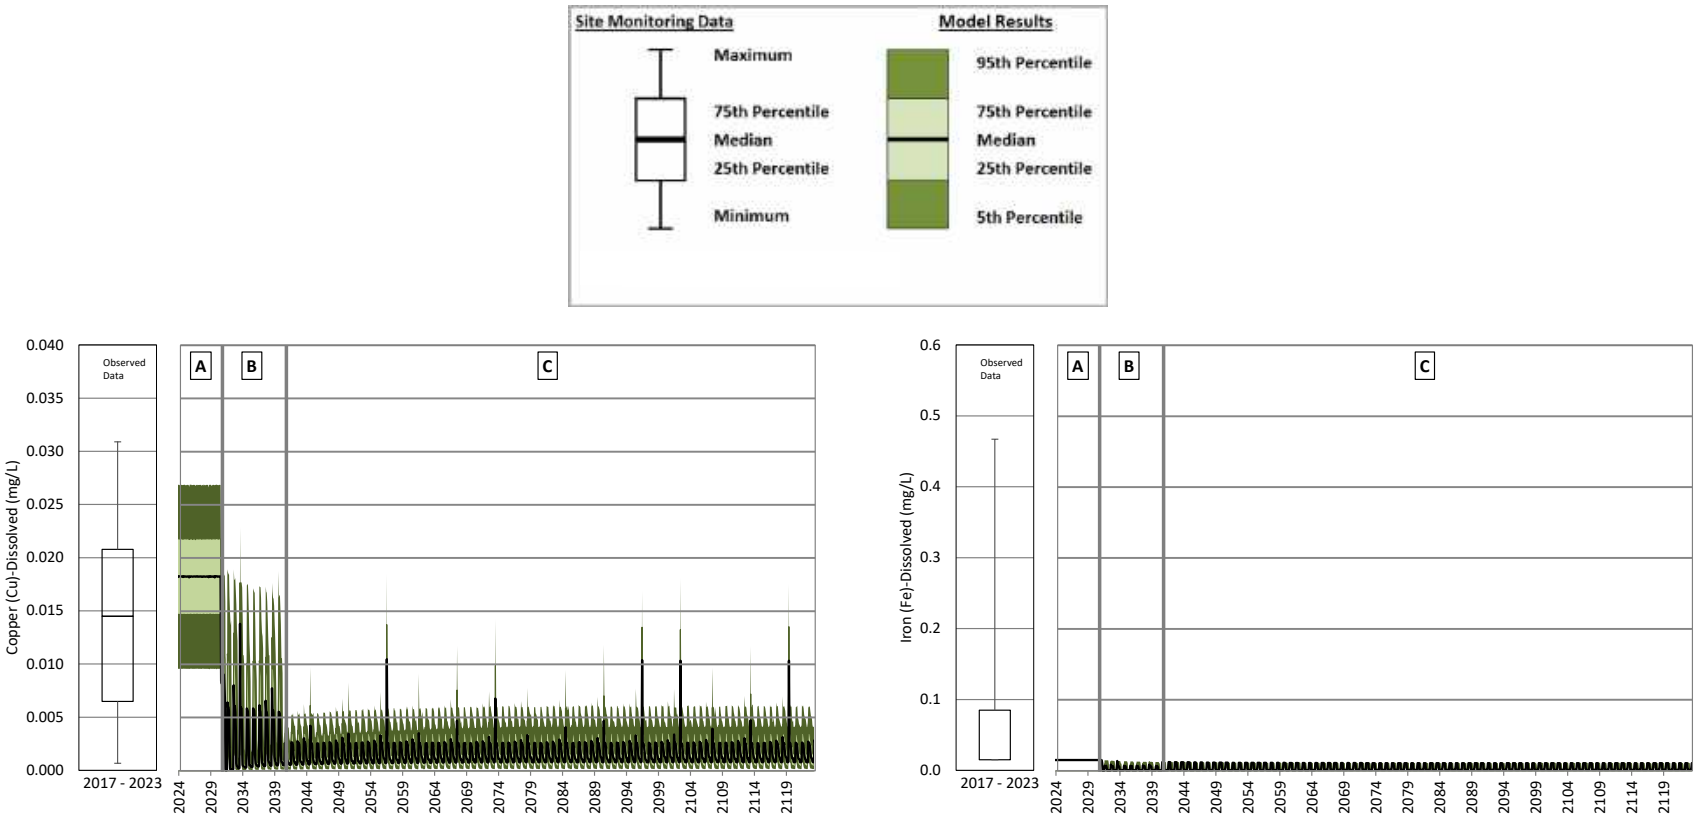

Figure 54: Predicted Nitrate and Total Phosphorus Concentrations in the South Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2074 when the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility reaches a steady state.

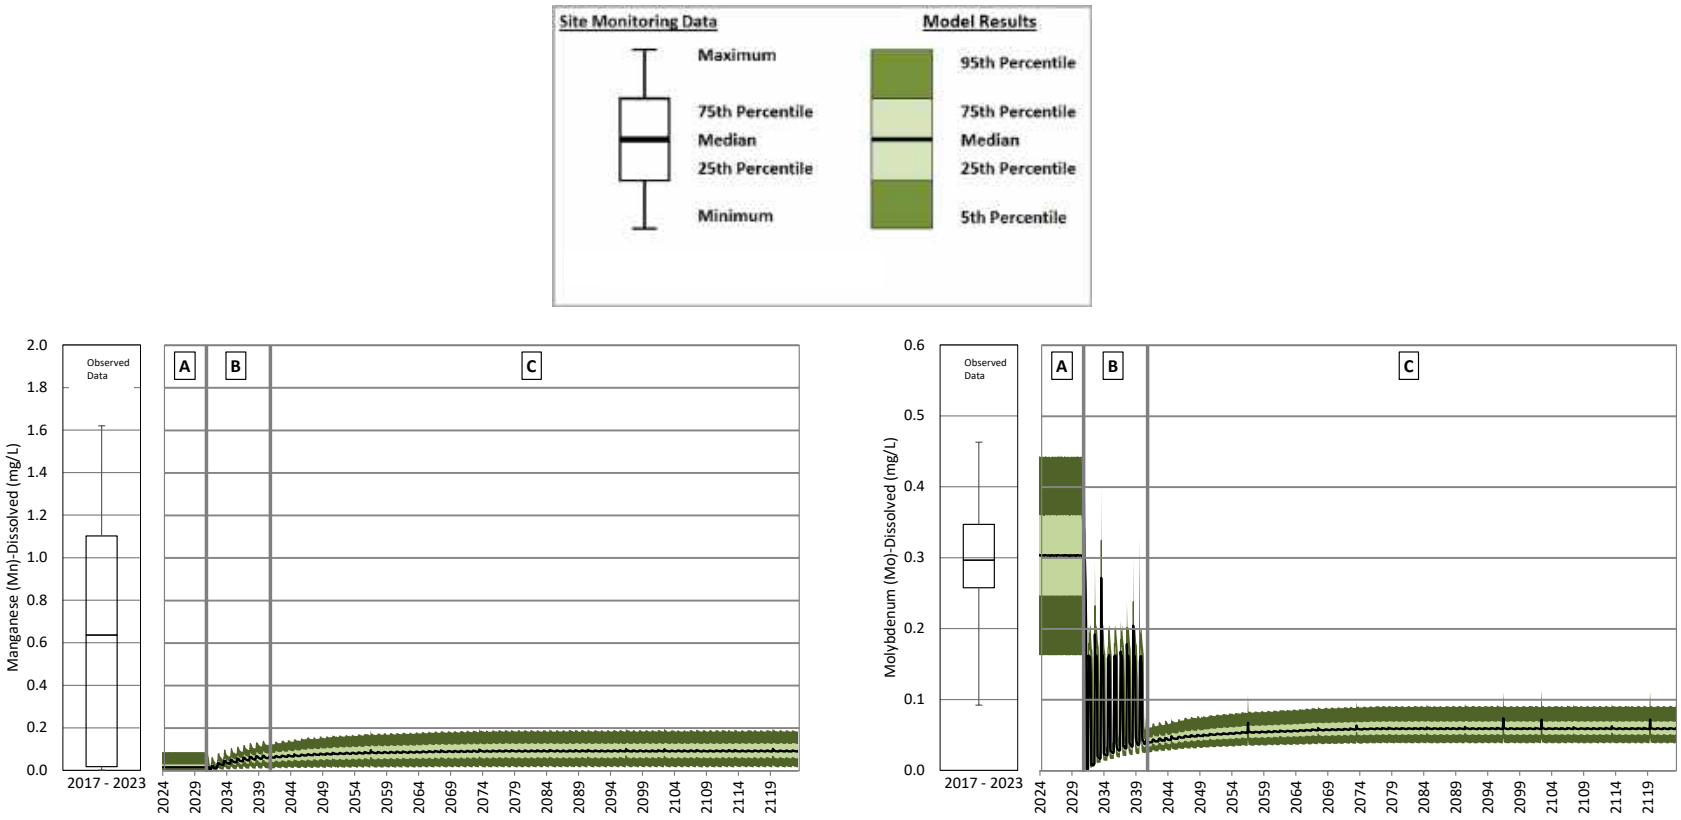

Figure 55: Predicted Dissolved Arsenic and Dissolved Chromium Concentrations in the South Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2074 when the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility reaches a steady state.

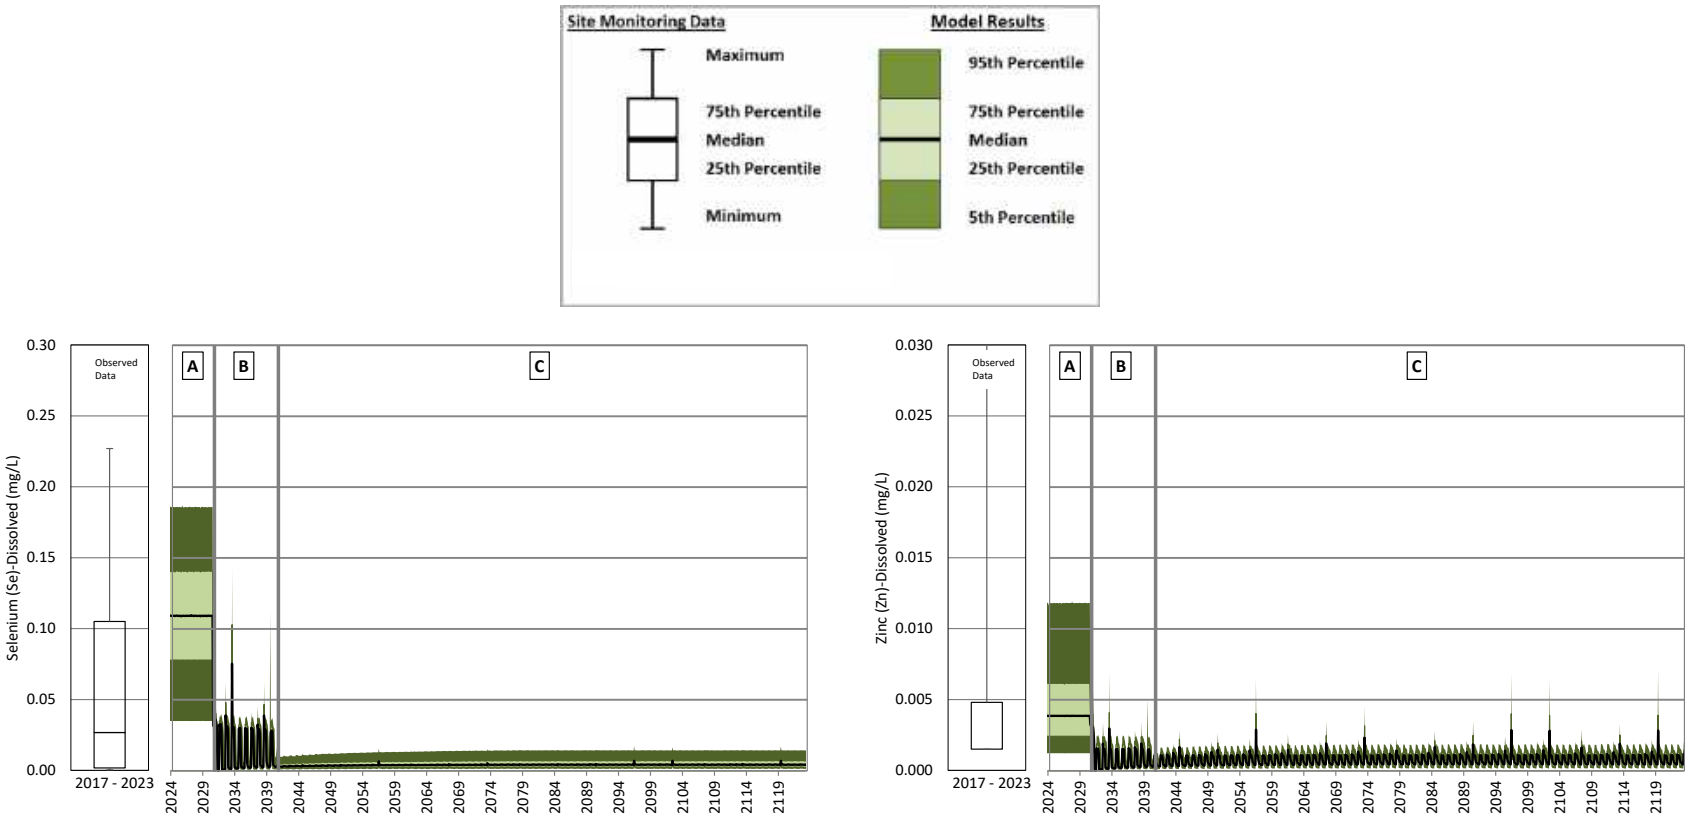

Figure 56: Predicted Dissolved Copper and Dissolved Iron Concentrations in the South Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2074 when the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility reaches a steady state.

Figure 57: Predicted Dissolved Manganese and Dissolved Molybdenum Concentrations in the South Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2074 when the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility reaches a steady state.

Figure 58: Predicted Dissolved Selenium and Dissolved Zinc Concentrations in the South Embankment Seepage Collection Pond – Operations, Closure and Post-closure

4.5.2 Main Embankment Seepage Collection Pond

The SWWBM assumes that the MESCP has minimal surface catchment area from TSF area and undisturbed catchment area and receives mostly TSF seepage in closure. Discharge from the MESCP will be directed to upper Edney Creek. Time series plots for key parameters in MESCP for operations, closure and post-closure are shown in Figures 59 to 64. Maximum of median and 95th percentile predictions are presented in Table 19.

For most parameters, peak concentrations in the MESCP occur during operations, and then are predicted to decrease once mine site areas are reclaimed (Figures 59 to 64). Reclaimed areas of the TSF beach and impoundment are assigned an undisturbed water quality. The increase in concentration until 2051 for most parameters in the MESCP is caused by pumping from the SESCP. Pumping from the SESCP to the MESCP ends in 2051. Similar to the SESCP, the range in predicted concentrations is considered reasonable. However, the timing is uncertain because the amount of time it might take to flush process water from the tailings is unknown.

Table 19: Predicted Maximum Concentrations in the Main Embankment Seepage Collection Pond during Closure and Post-closure

Parameter	Units	Operations Period (January 2024 - March 2031)		Closure (April 2031 - March 2041)		Early Post-Closure (April 2041 - March 2051)		Long Term Post-Closure (April 2051 - April 2131)	
		Maximum of Median Predicted Concentrations	Maximum of 95th Percentile Predicted Concentrations	Maximum of Median Predicted Concentrations	Maximum of 95th Percentile Predicted Concentrations	Maximum of Median Predicted Concentrations	Maximum of 95th Percentile Predicted Concentrations	Maximum of Median Predicted Concentrations	Maximum of 95th Percentile Predicted Concentrations

a) Calculated based on predicted calcium and magnesium concentrations.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2051 when pumping from the SESCP ends.

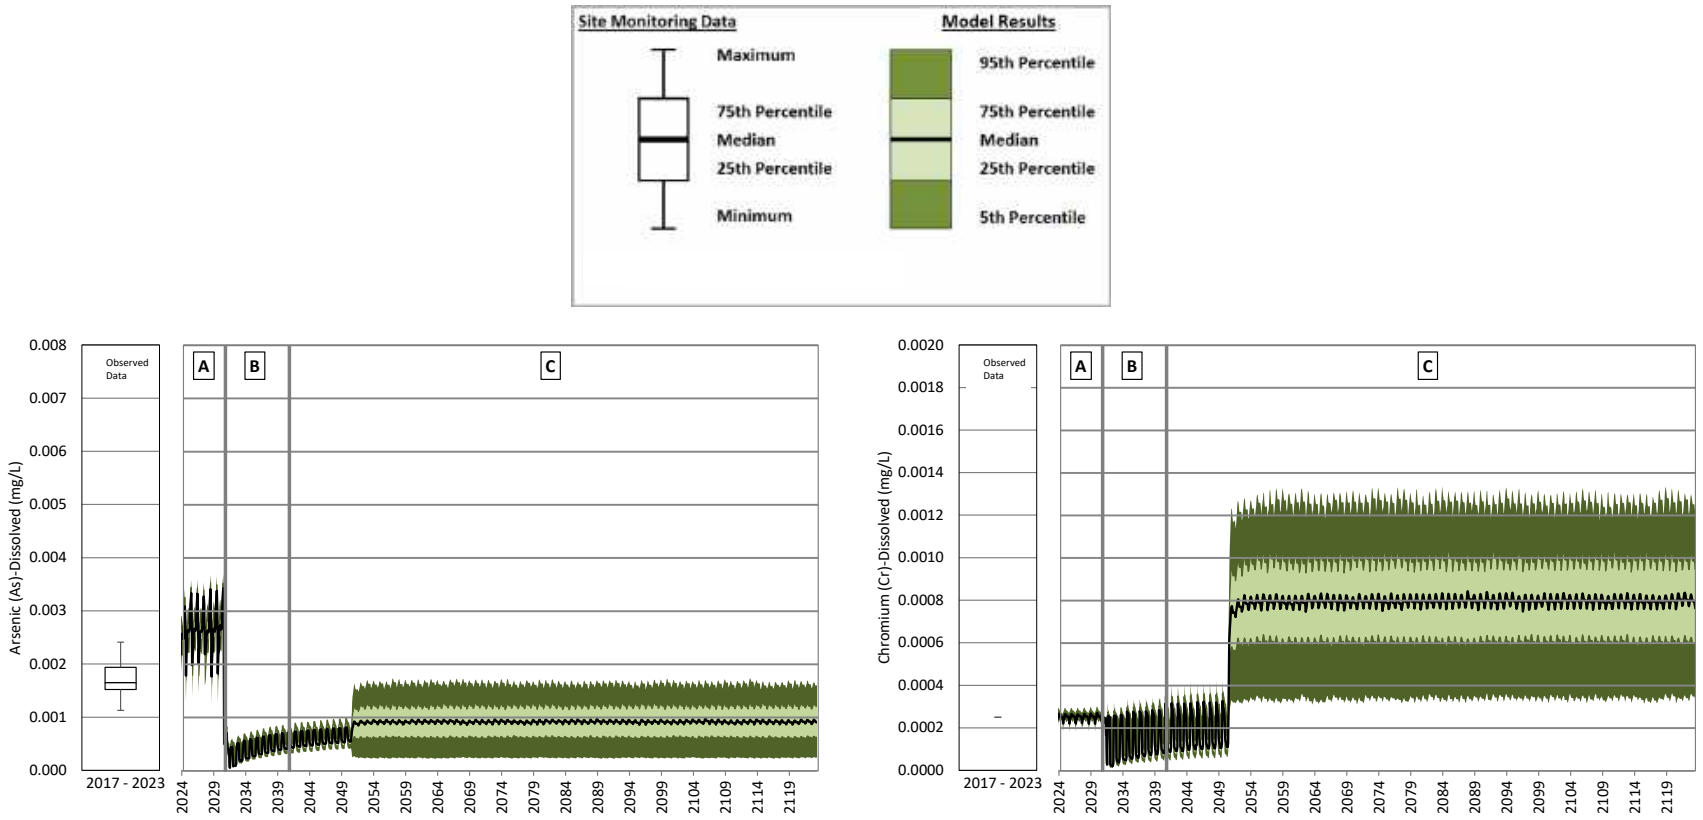

Figure 59: Predicted Sulphate and Total Ammonia Concentrations in the Main Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2051 when pumping from the SESCP ends.

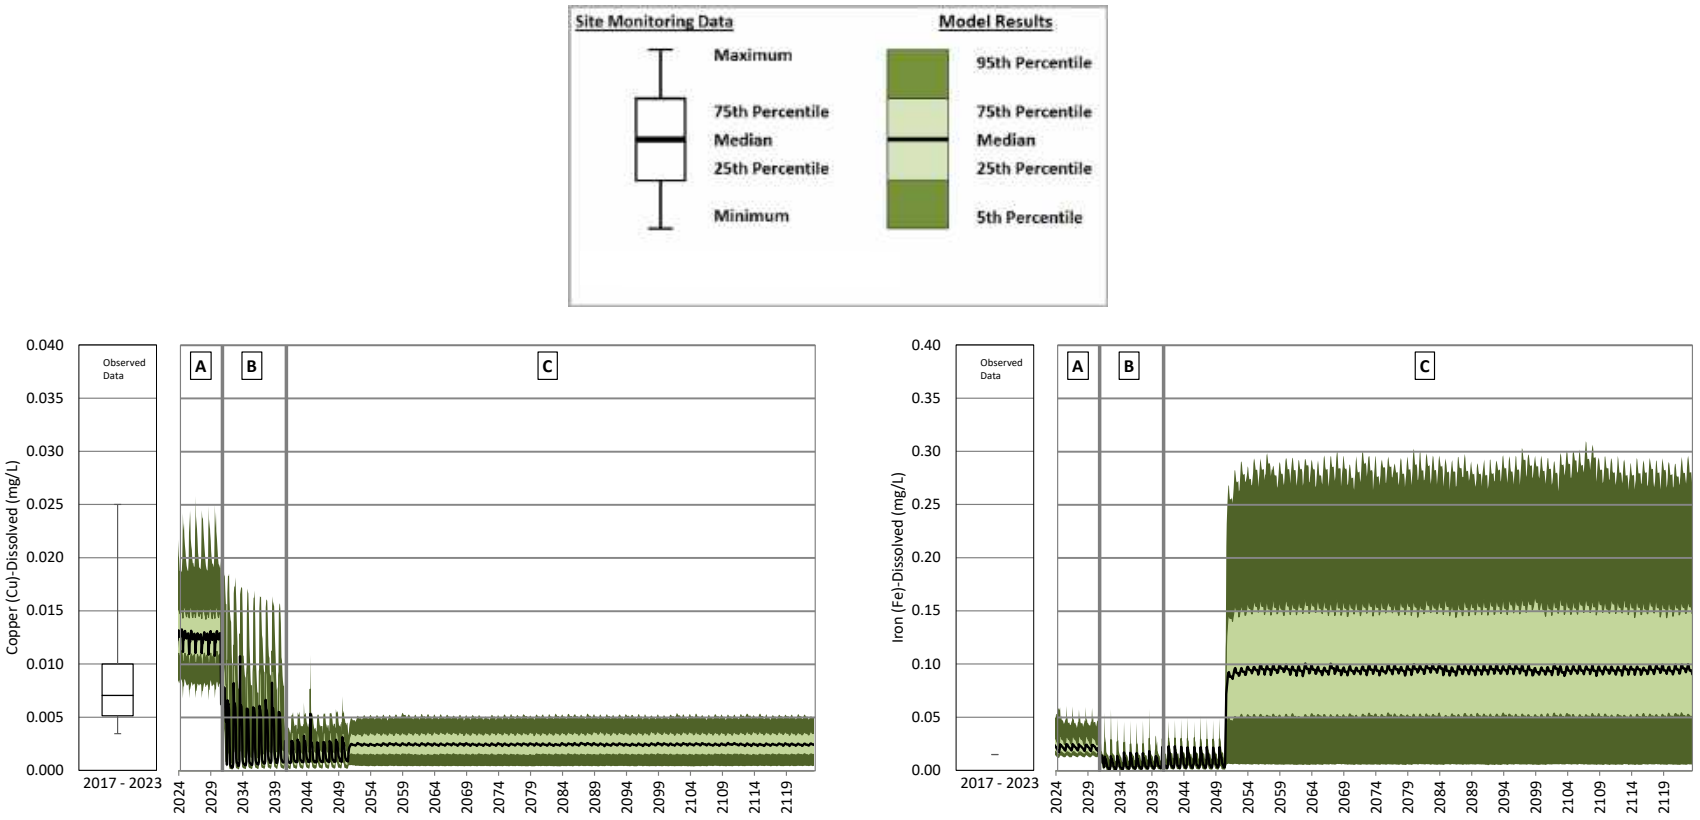

Figure 60: Predicted Nitrate and Total Phosphorus Concentrations in the Main Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2051 when pumping from the SESCP ends.

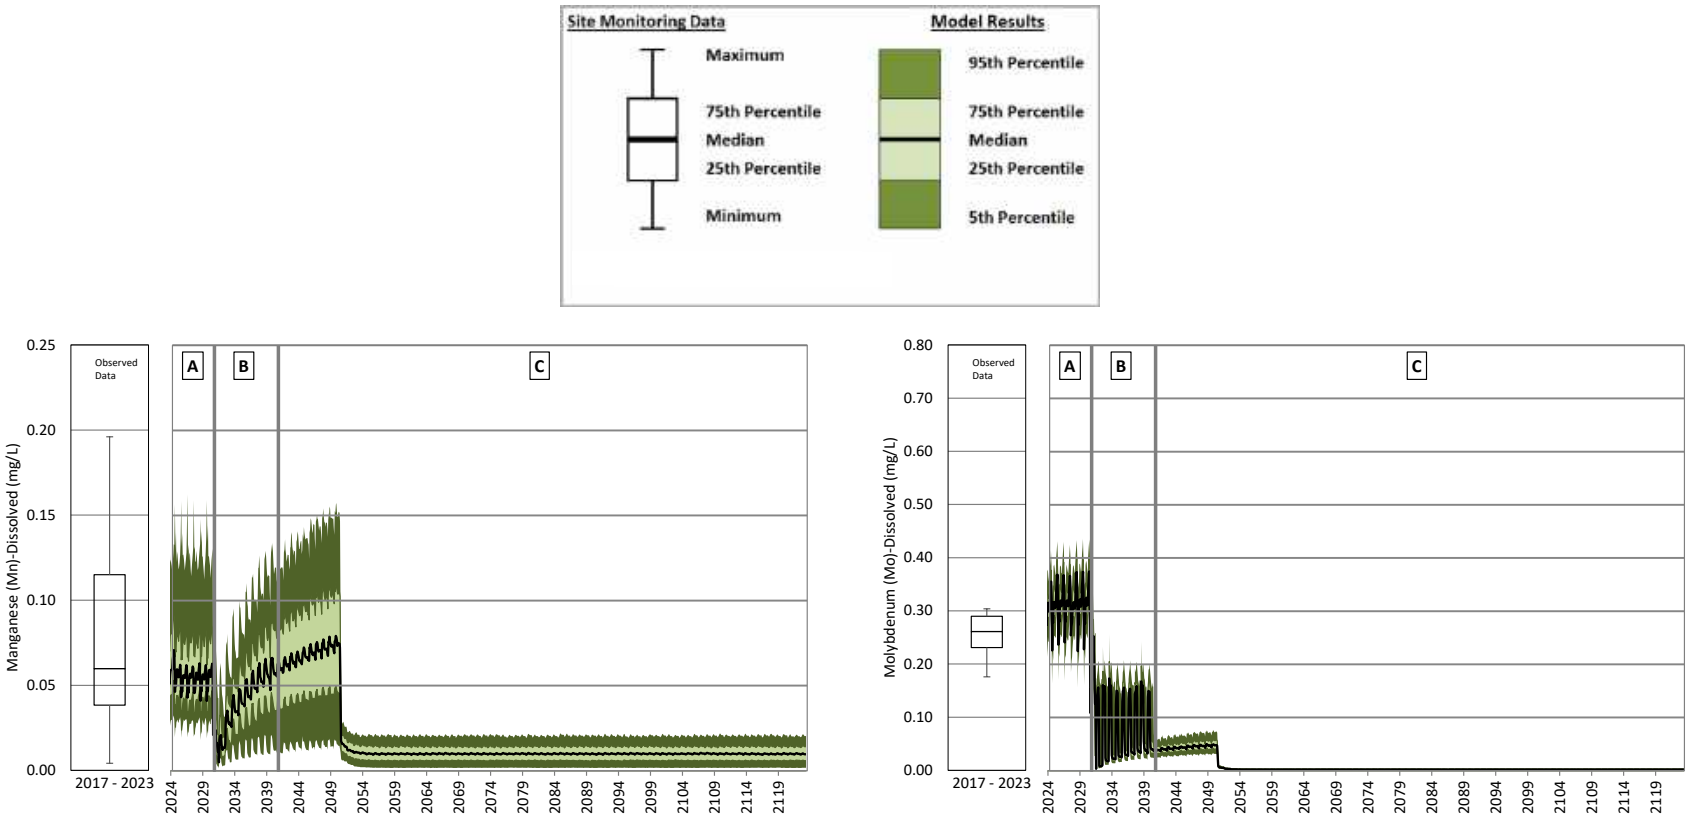

Figure 61: Predicted Dissolved Arsenic and Dissolved Chromium Concentrations in the Main Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2051 when pumping from the SESCP ends.

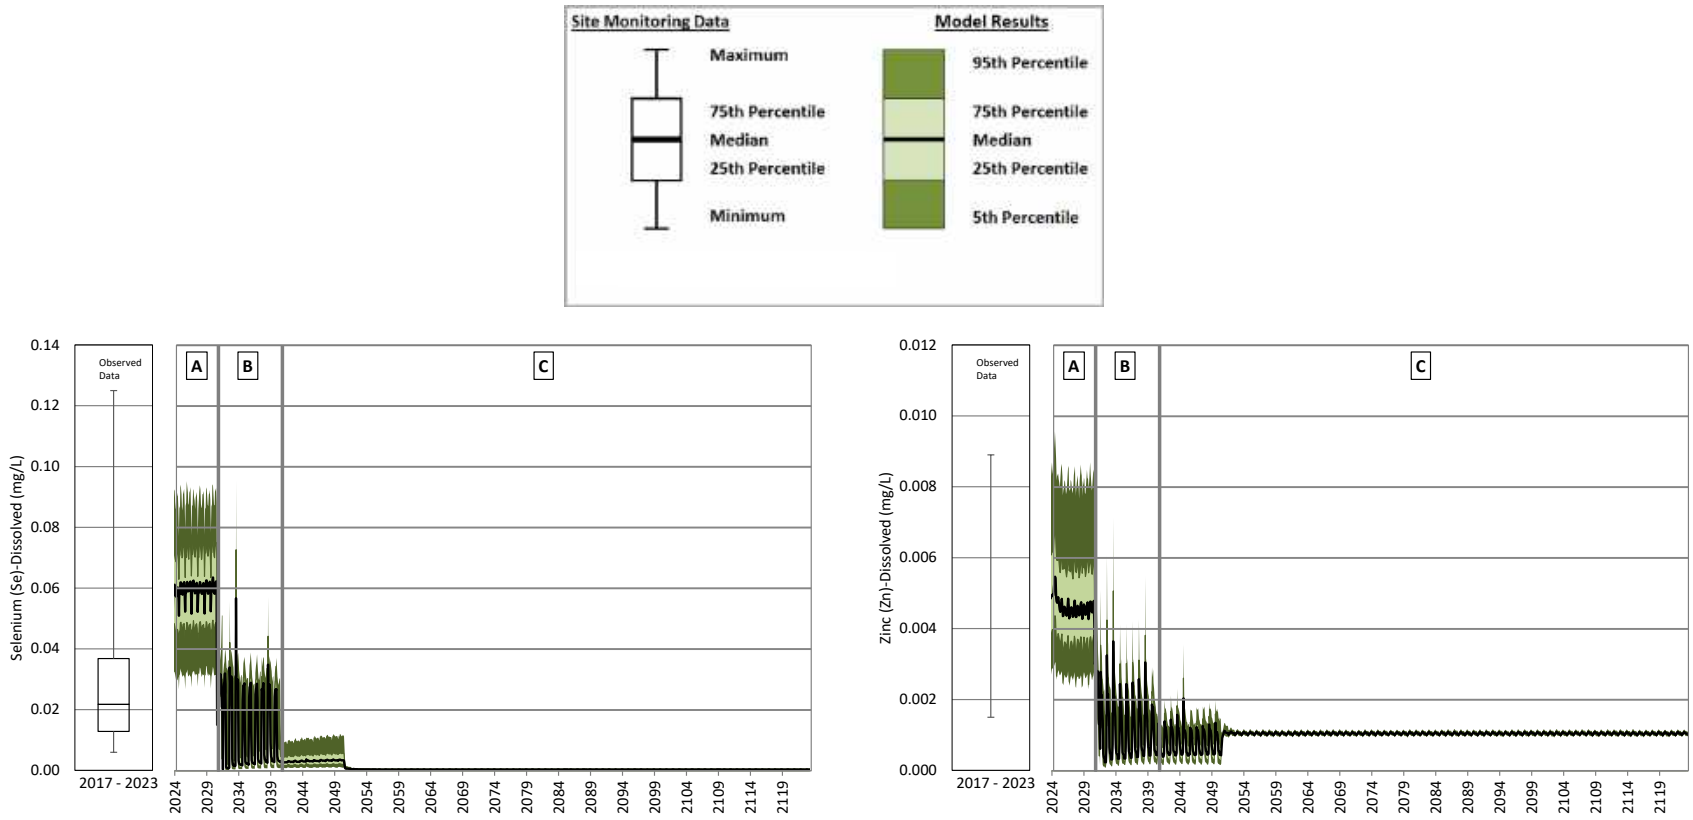

Figure 62: Predicted Dissolved Copper and Dissolved Iron Concentrations in the Main Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2051 when pumping from the SESCP ends.

Figure 63: Predicted Dissolved Manganese and Dissolved Molybdenum Concentrations in the Main Embankment Seepage Collection Pond – Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into post-closure is caused by reclamation of mine site areas that are complete 10 years after the start of post-closure. Predicted concentrations reach a steady state by 2051 when pumping from the SESCP ends.

5.0 SUMMARY

The GoldSim model that was developed for the 2020 WMP to predict discharge water quality at the mine during operations was updated to predict concentrations during operations, closure and post-closure on the mine site under the Springer Expansion mine plan. The model was also updated with additional monitoring data for assigned water quality inputs to refine the distribution inputs into the model. Updated geochemical source terms were also modelled in an alternative scenario (in place of inputs calculated from monitoring data) and were compared to model results that used monitoring data to calculate the water quality inputs. The model results from the scenario that used the geochemical source terms were considered overly conservative and not presented in this report.

The updated model was calibrated against monitoring data from the mine site. During closure and post-closure, discharges from the mine will preferably be returned to their undisturbed watersheds, to the extent possible. Specifically, nine potential mine discharge locations are expected to drain to Polley Lake, Bootjack Lake, Edney Creek, and Hazeltine Creek.

The updated predicted concentrations during operations, closure and post-closure in the mine site are similar to those presented in previous iterations of the water quality model including the 2016 Long Term Water Management Plan (Golder 2016), the 2020 Water Management Plane (Golder 2020) and the 2022 Reclamation and Closure Plan (Golder 2022a). For some parameters, the maximum predicted concentrations of total metals are lower during post-closure in this update of the water quality model. This change in predicted total metal concentrations is due to an adjustment to the particulate addition calculation during post-closure that now assumes a total suspended solids concentration that is representative of a reclaimed water quality input. Changes in concentrations from operations to closure and post-closure are caused by reclamation of mine site areas that are complete during post-closure. Predicted concentrations reach a steady state during post-closure after reclamation of the mine site areas is complete and the Springer Expansion pit is filled. In general, the model predicted higher concentrations in the closure period, relative to the post- closure period for most parameters with the exception of parameters that are predicted to be higher in the assigned undisturbed runoff water quality than in the assigned disturbed, NAG or PAG waste rock water quality. Treatment and mitigation strategies during operations, closure and post-closure are addressed in the treatment section of the WMP (WSP 2023a).

6.0 CLOSURE

This report summarizes the reclamation and closure update of the SWWQM.

We trust this report satisfies your current requirements. Please contact the undersigned should you have any questions.

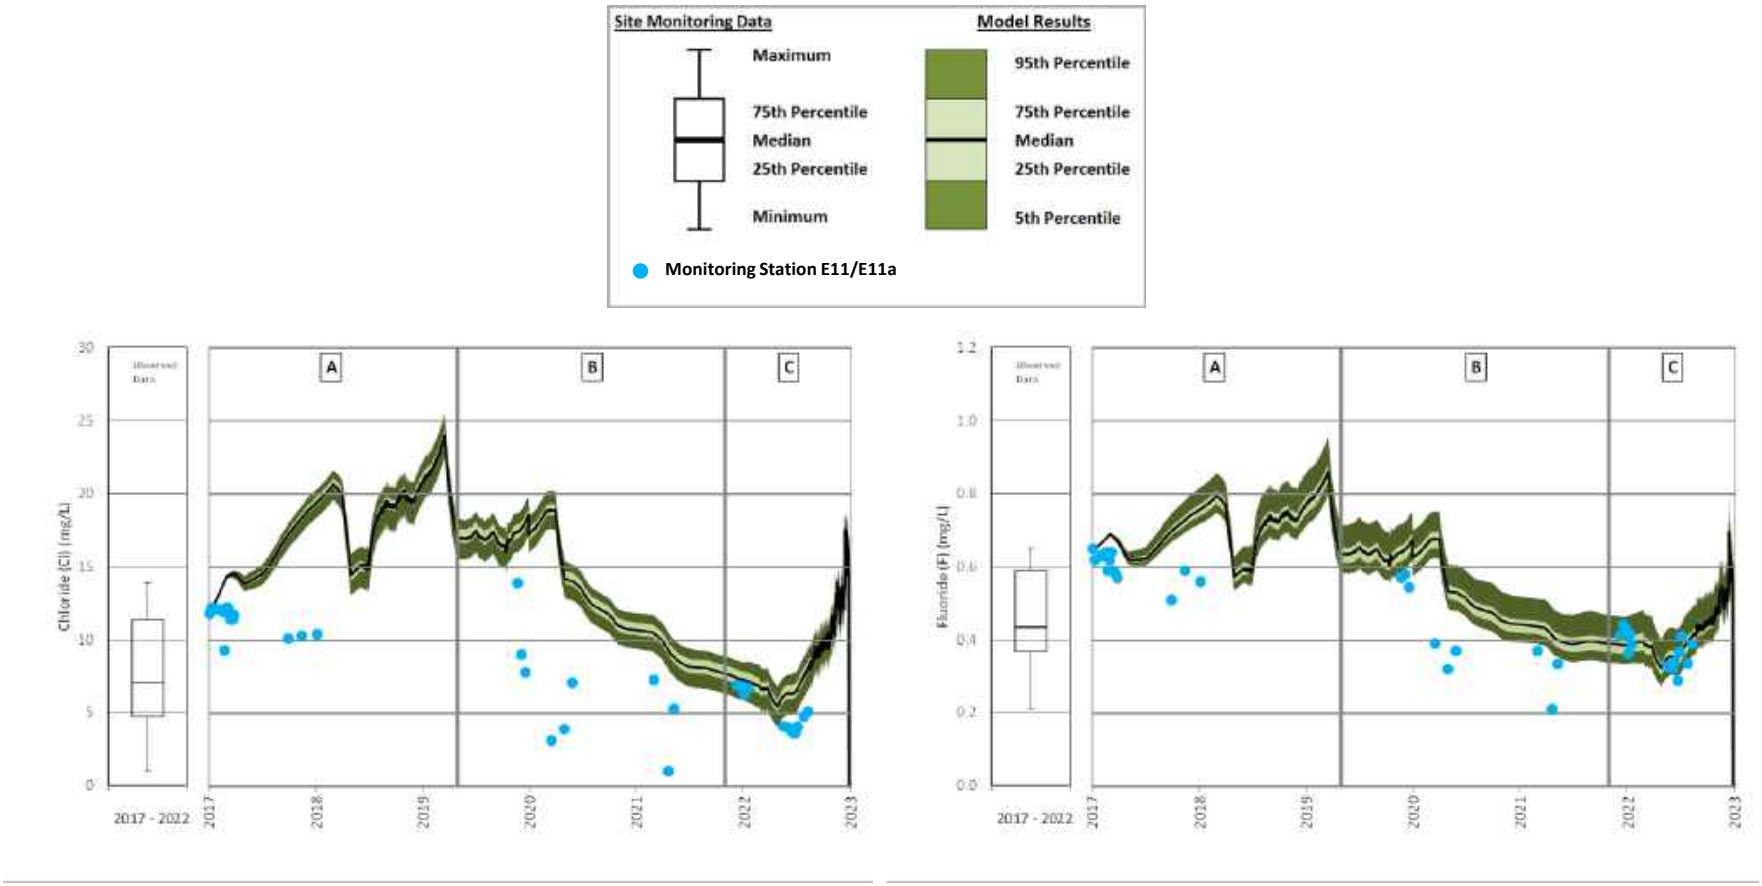
Appendix A – Calibration Figures A 1–A 140



This attachment presents the water quality calibration Figures for Springer Pit, Cariboo Pit, Wight Pit, the Central Collection Sump, the Tailings Storage Facility, the Perimeter Embankment Till Borrow Pond and the Northwest Sump. The calibration period was from January 2017 to January 2023.

Springer Pit Calibration

A = Operations; B = Care and Maintanence; C = Resumed Operations

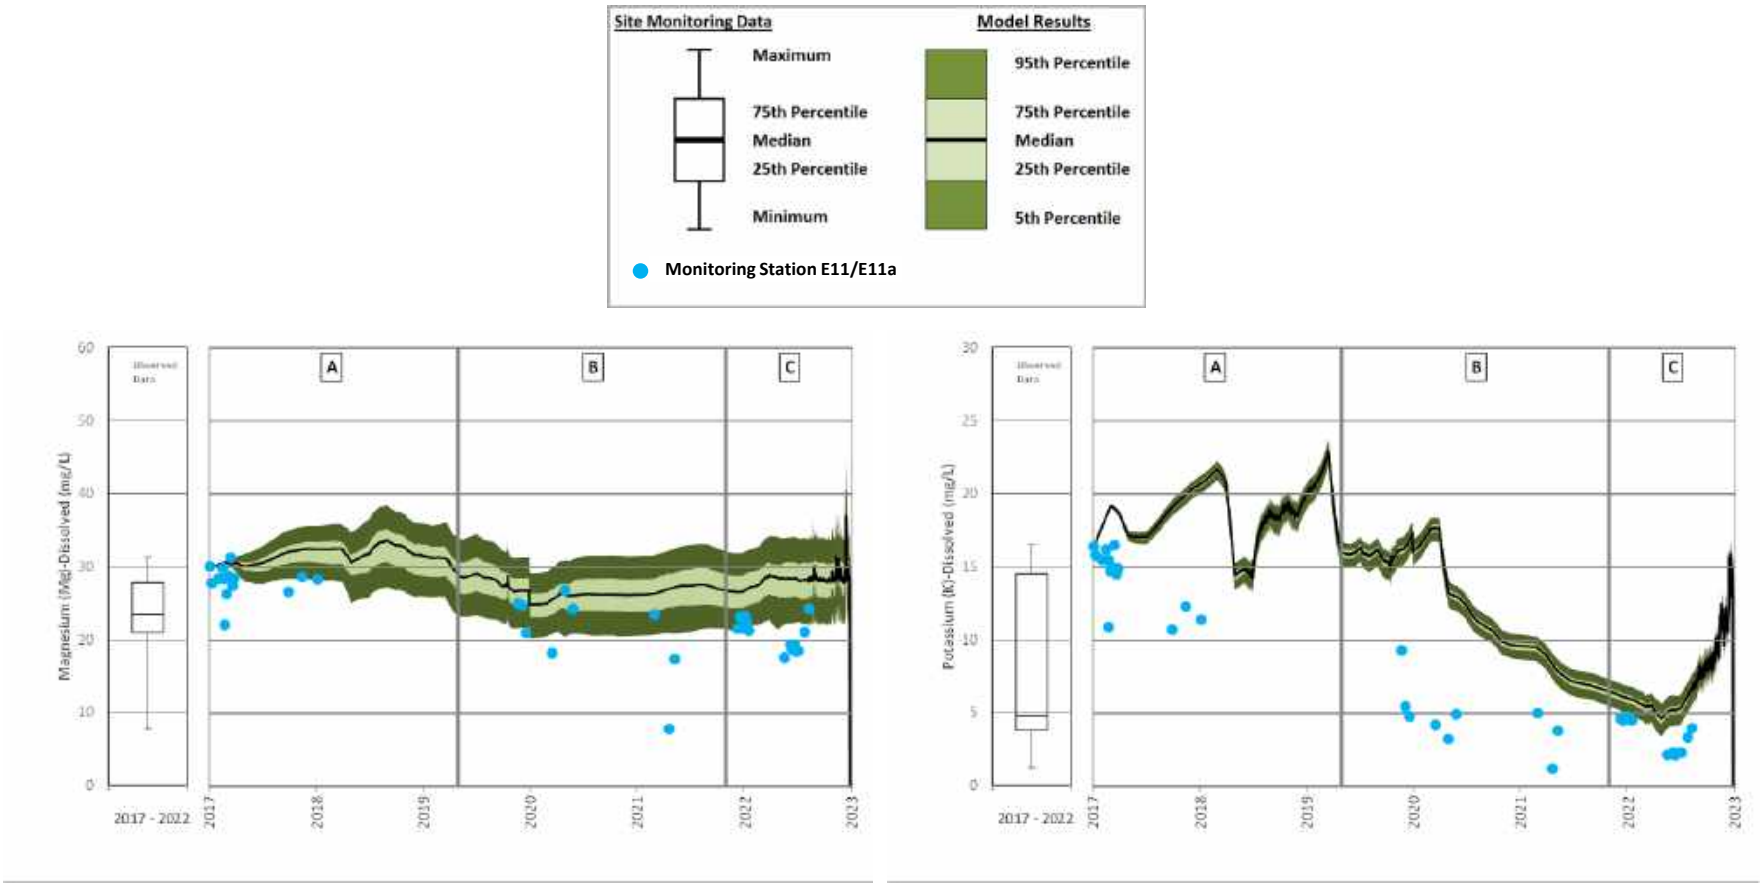


Figure A 1: Springer Pit Calibration – Total Dissolved Solids and Calcium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Chloride and fluoride concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

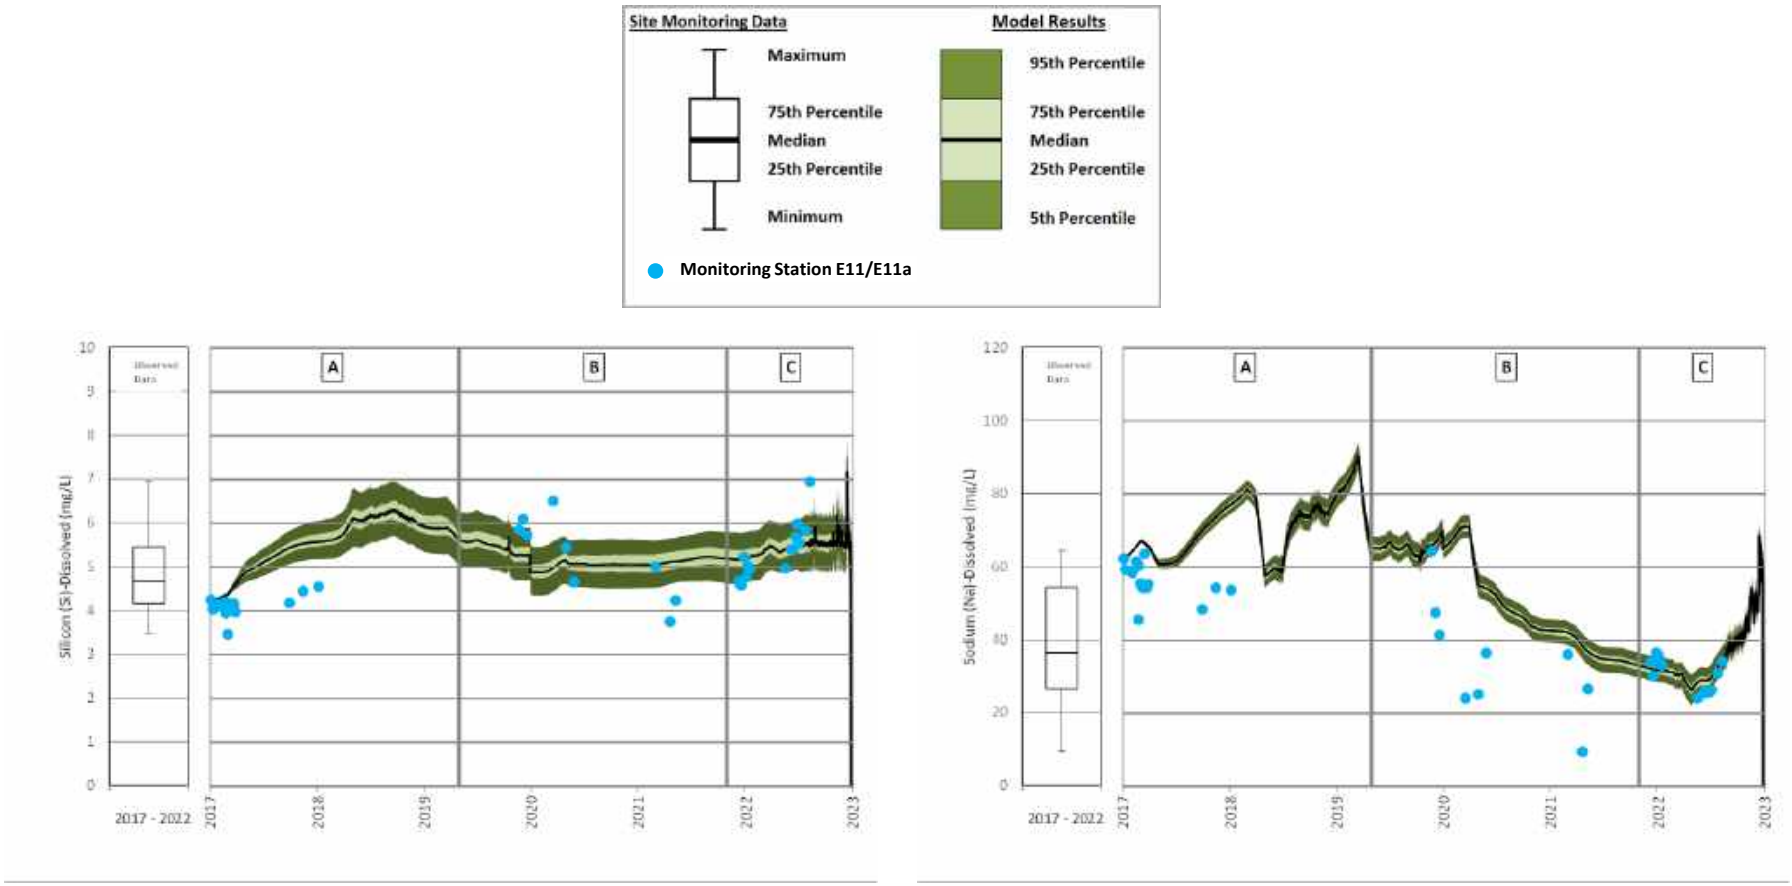

Figure A 2: Springer Pit Calibration – Chloride and Fluoride

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Potassium concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

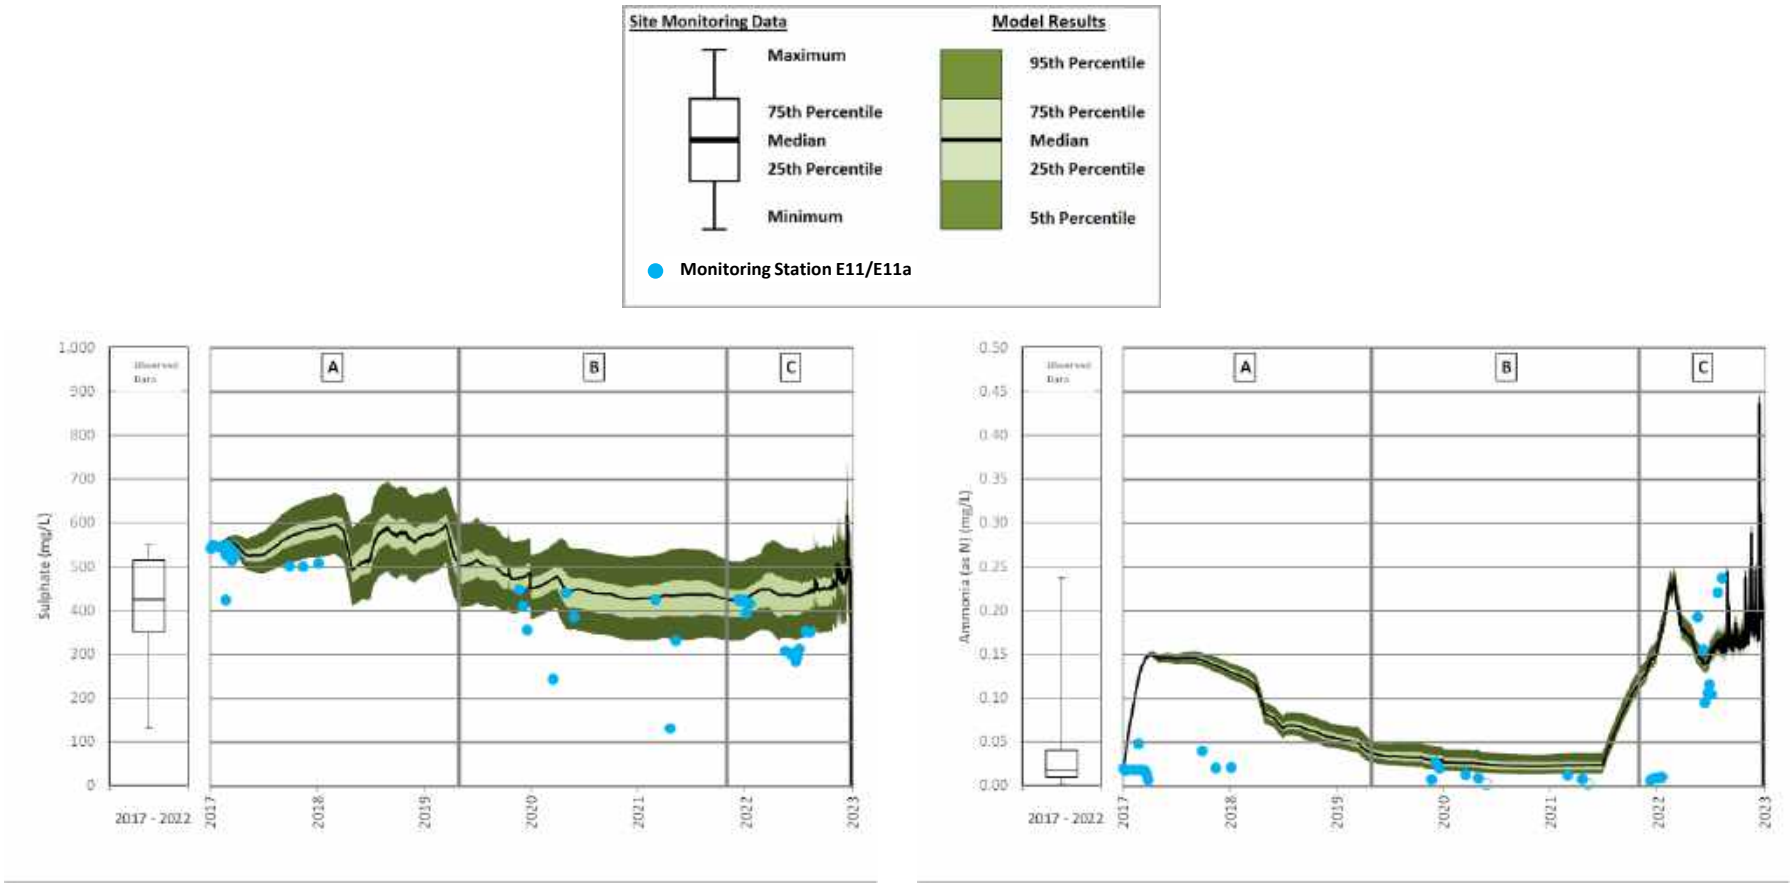

Figure A 3: Springer Pit Calibration – Magnesium and Potassium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Sodium concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in Tailings Storage Facility (TSF) that is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

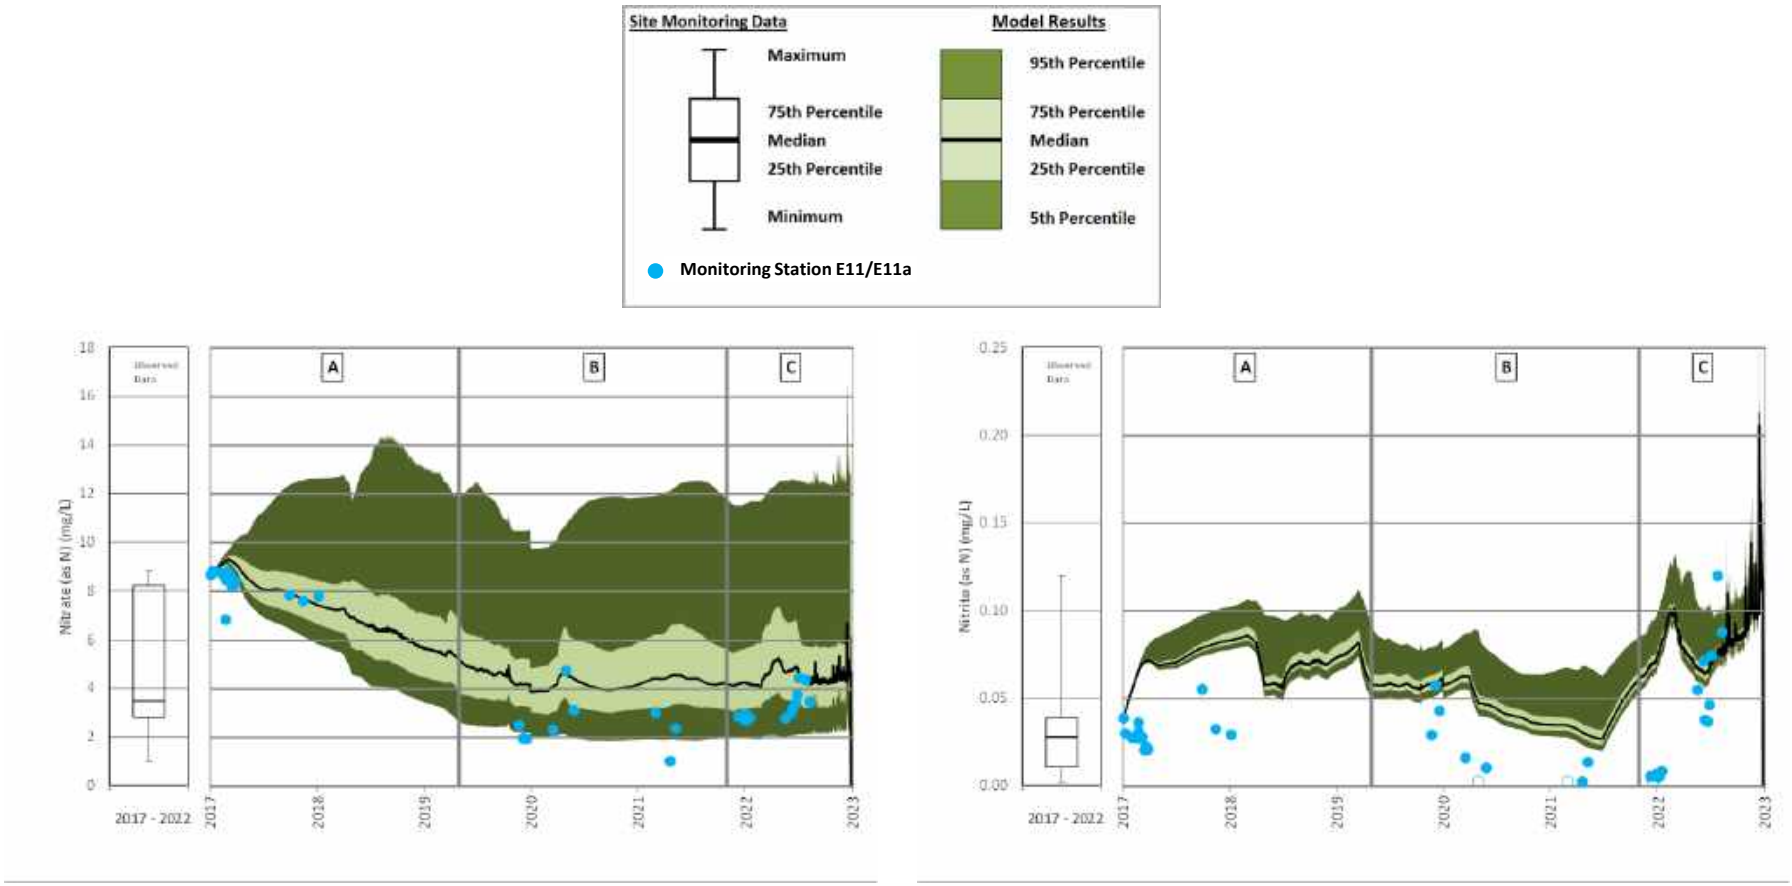

Figure A 4: Springer Pit Calibration – Silicon and Sodium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Total ammonia concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

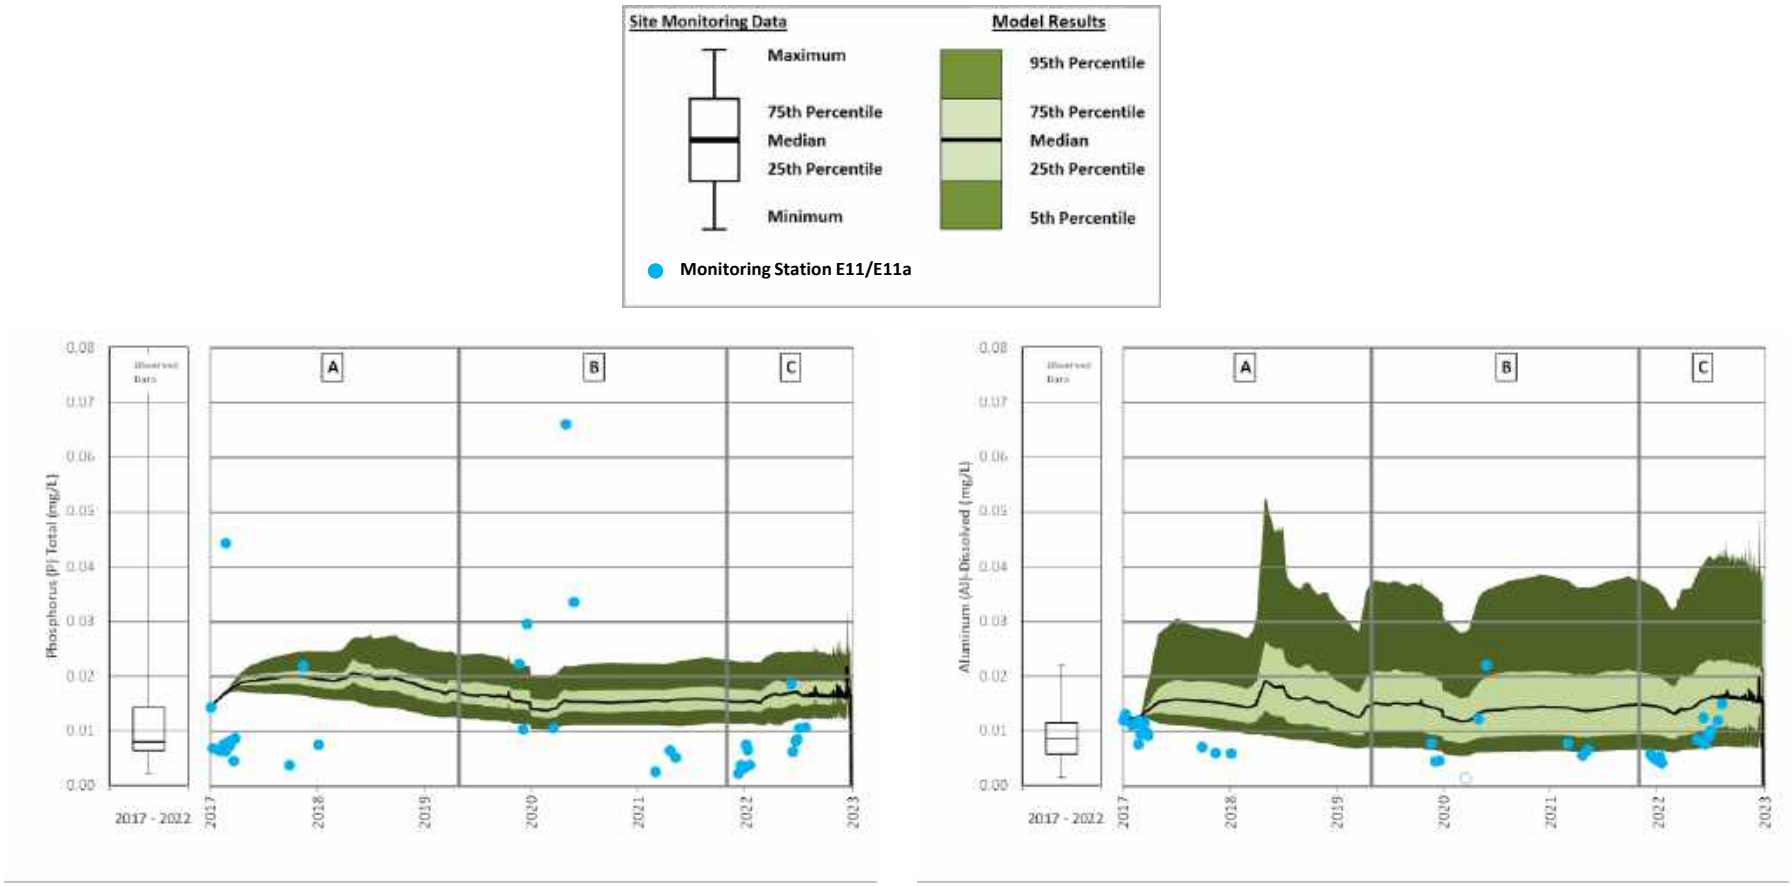

Figure A 5: Springer Pit Calibration – Sulphate and Total Ammonia

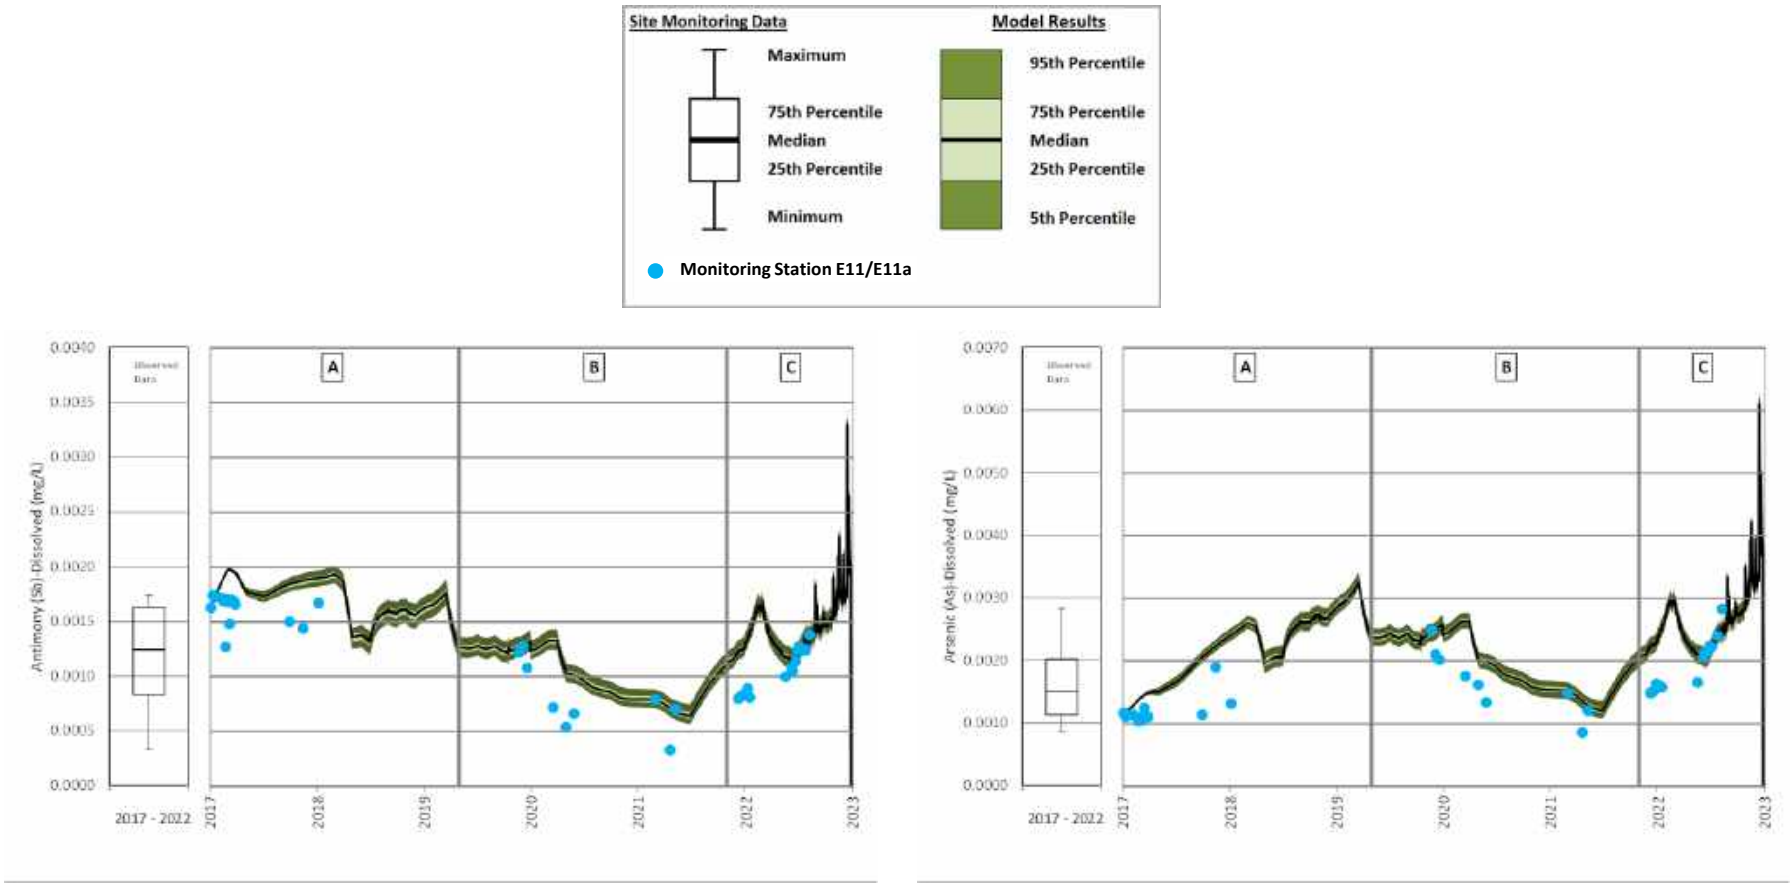
A = Operations; B = Care and Maintanence; C = Resumed Operations



Note: Nitrite concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

Figure A 6: Springer Pit Calibration – Nitrate and Nitrite

A = Operations; B = Care and Maintanence; C = Resumed Operations

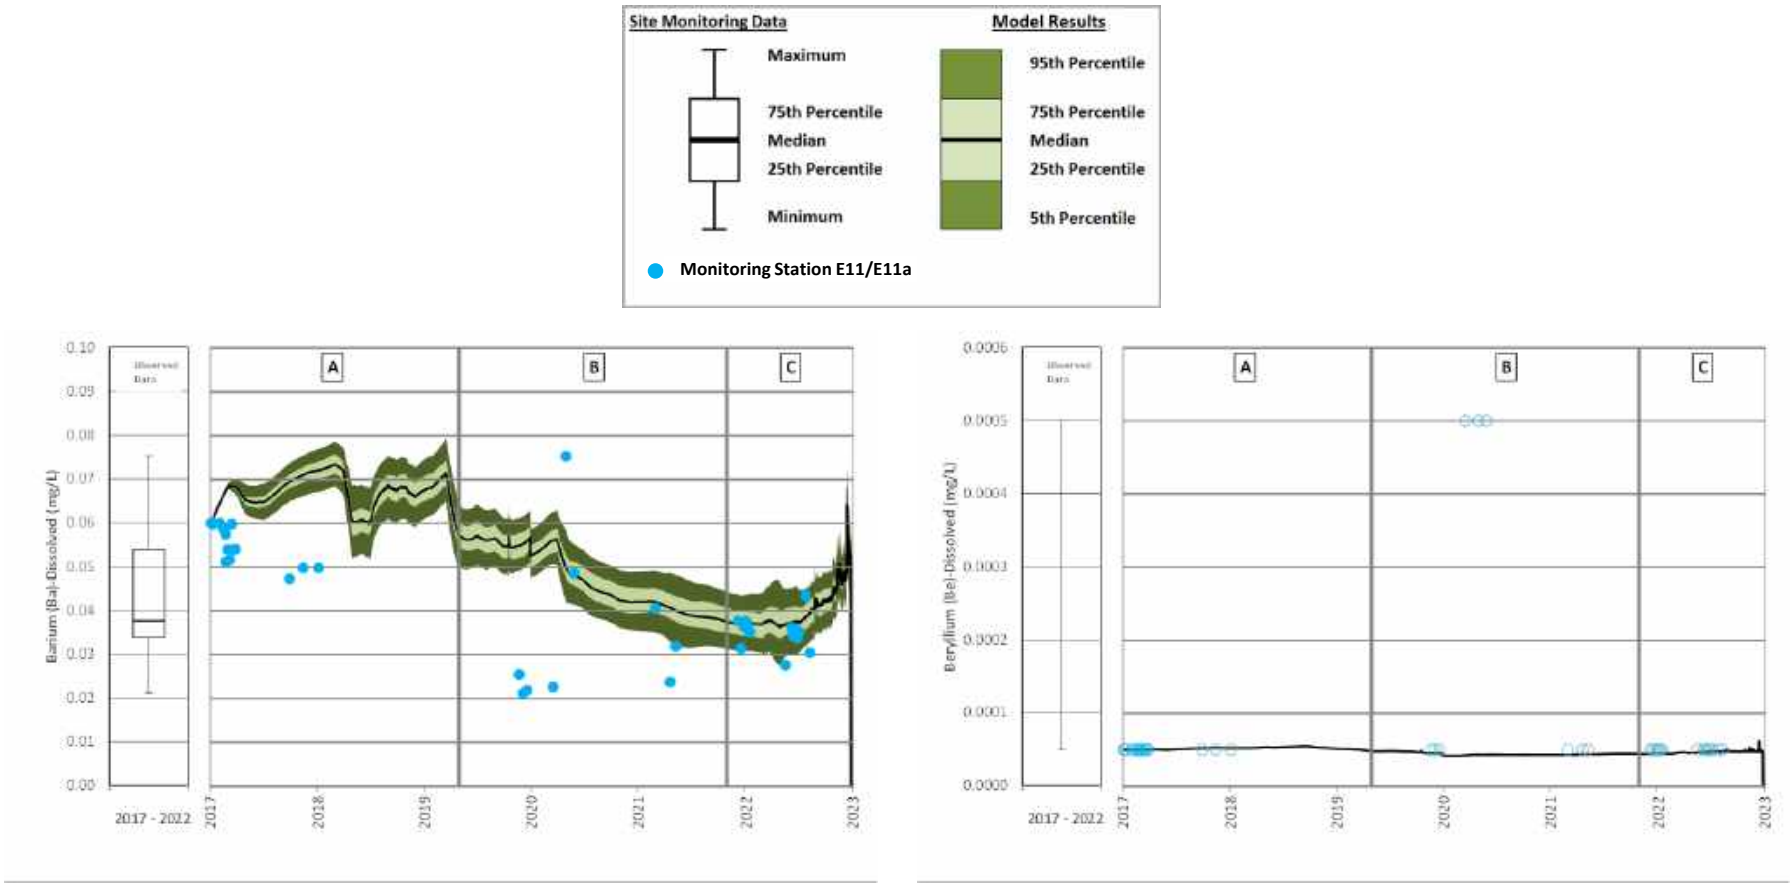


Figure A 7: Springer Pit Calibration – Total Phosphorus and Dissolved Aluminum

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved antimony and dissolved arsenic concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

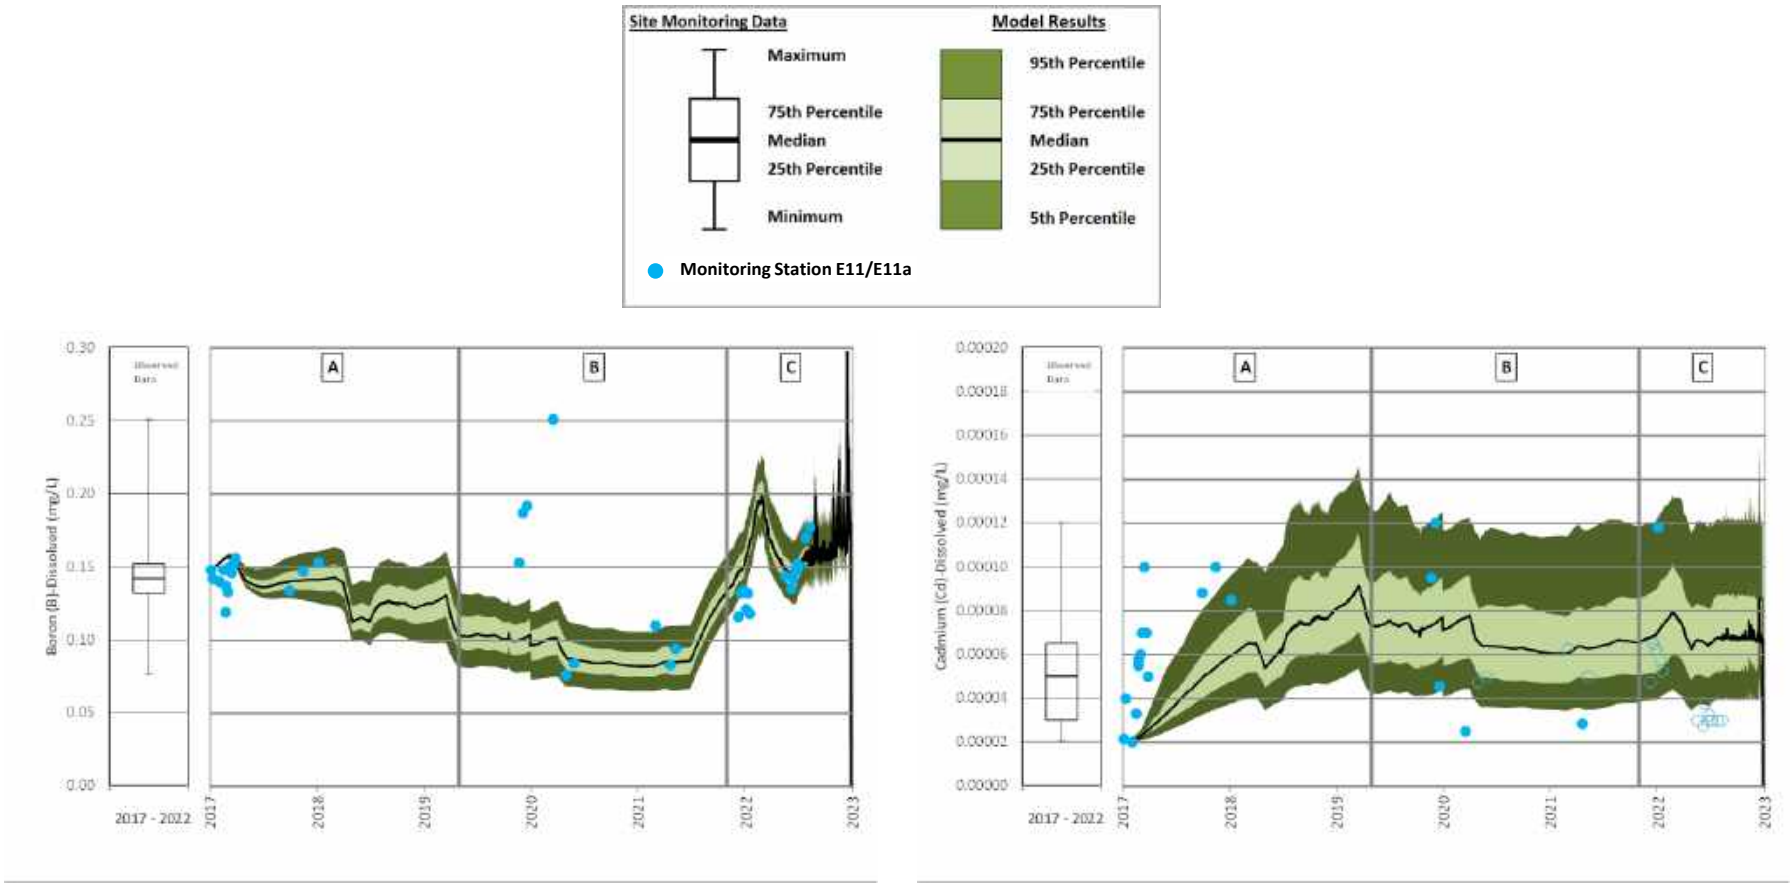

Figure A 8: Springer Pit Calibration – Dissolved Antimony and Dissolved Arsenic

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved barium concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

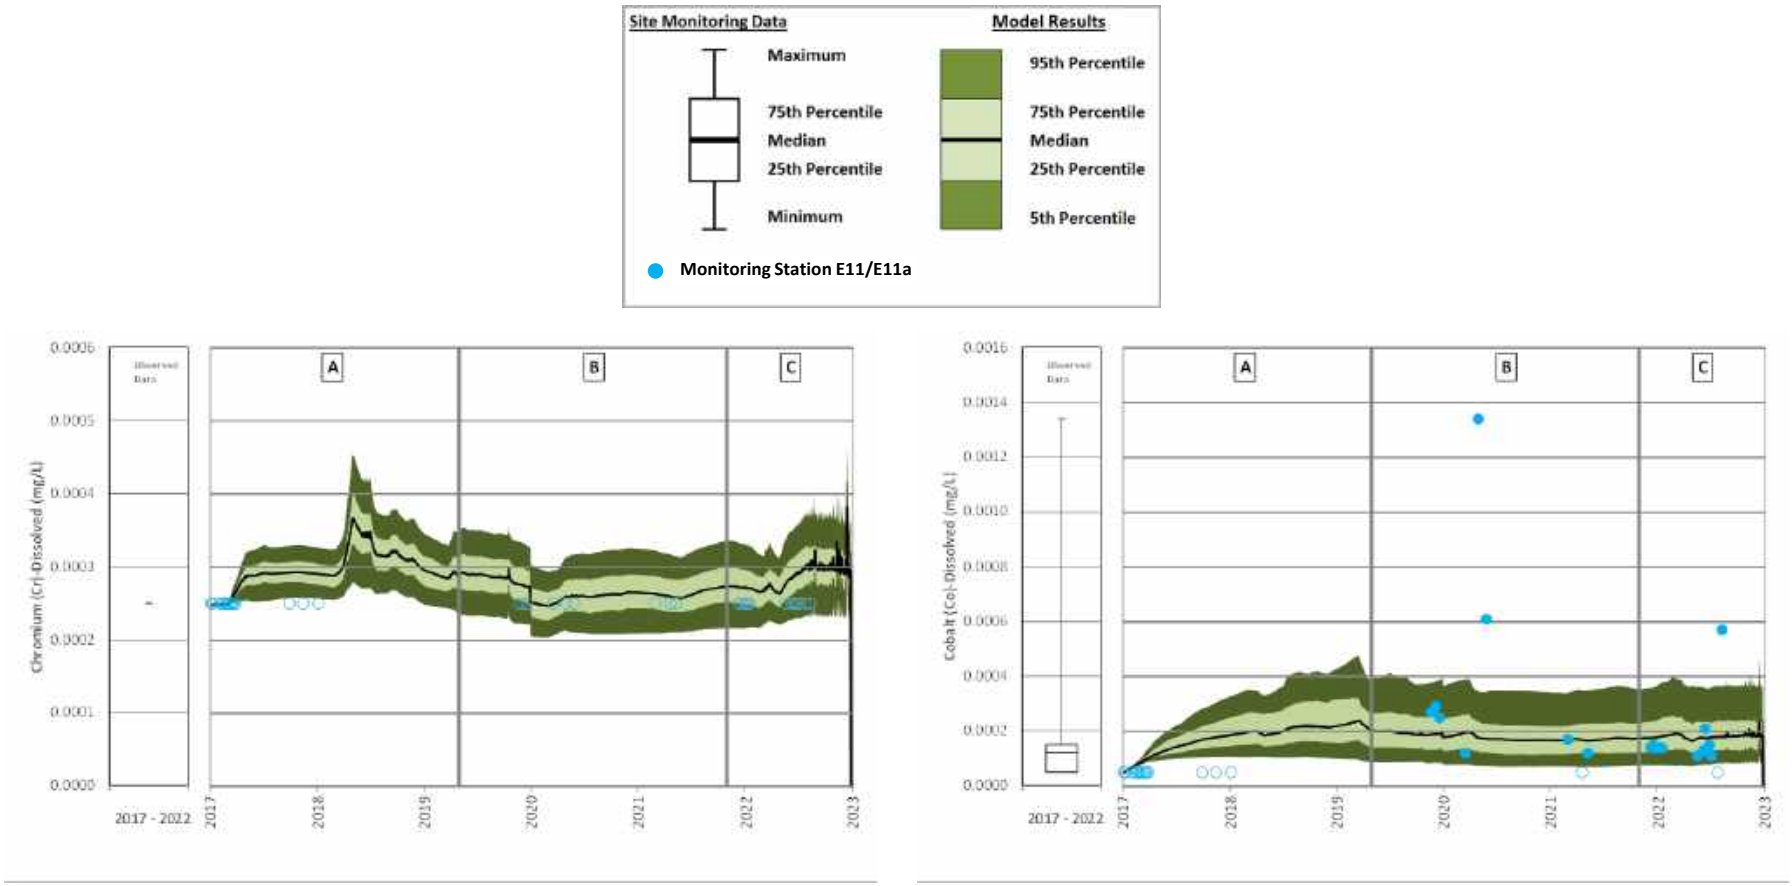

Figure A 9: Springer Pit Calibration – Dissolved Barium and Dissolved Beryllium

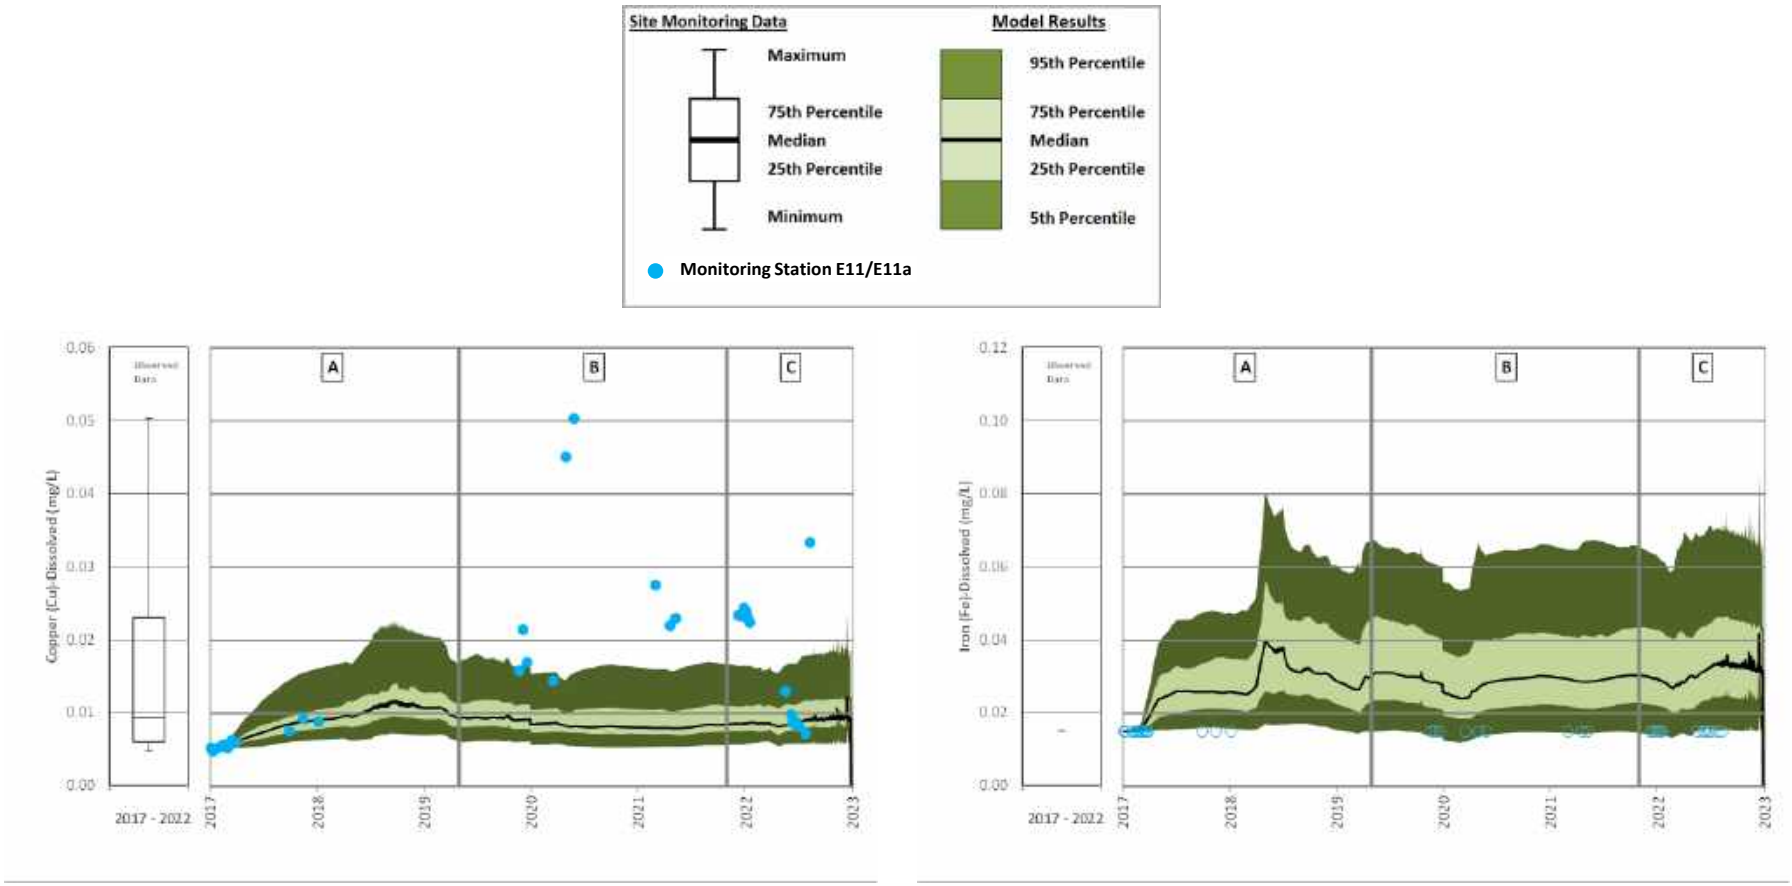
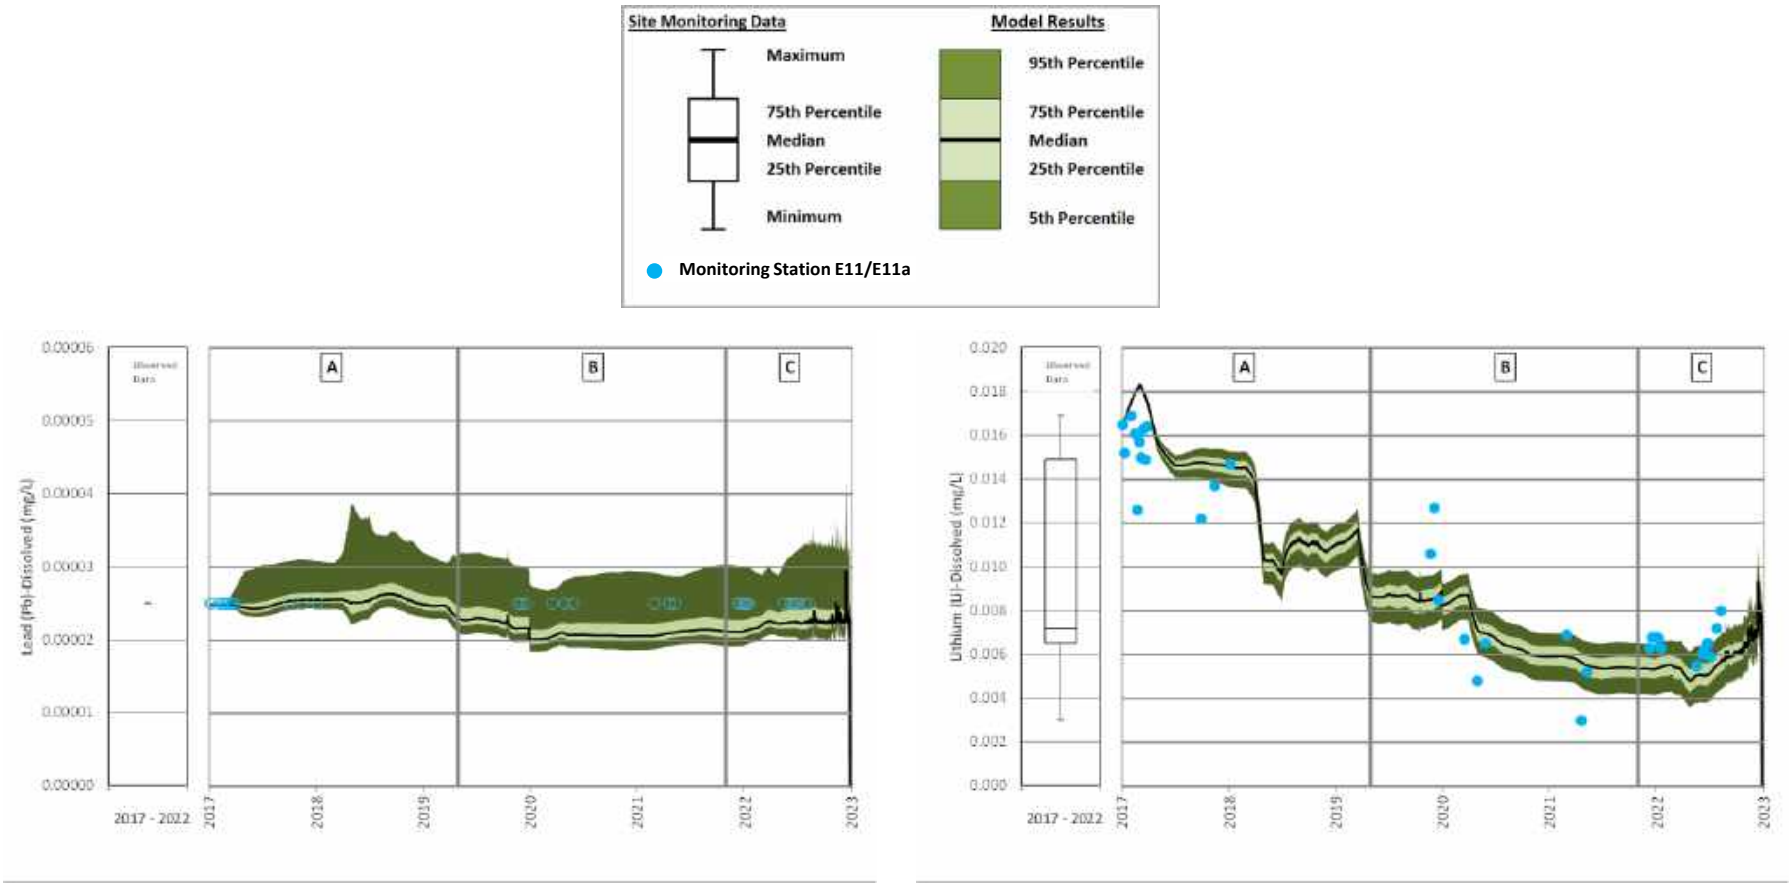
A = Operations; B = Care and Maintanence; C = Resumed Operations



Note: Dissolved boron concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

Figure A 10: Springer Pit Calibration – Dissolved Boron and Dissolved Cadmium



A = Operations; B = Care and Maintanence; C = Resumed Operations

Figure A 11: Springer Pit Calibration – Dissolved Chromium and Dissolved Cobalt

A = Operations; B = Care and Maintanence; C = Resumed Operations

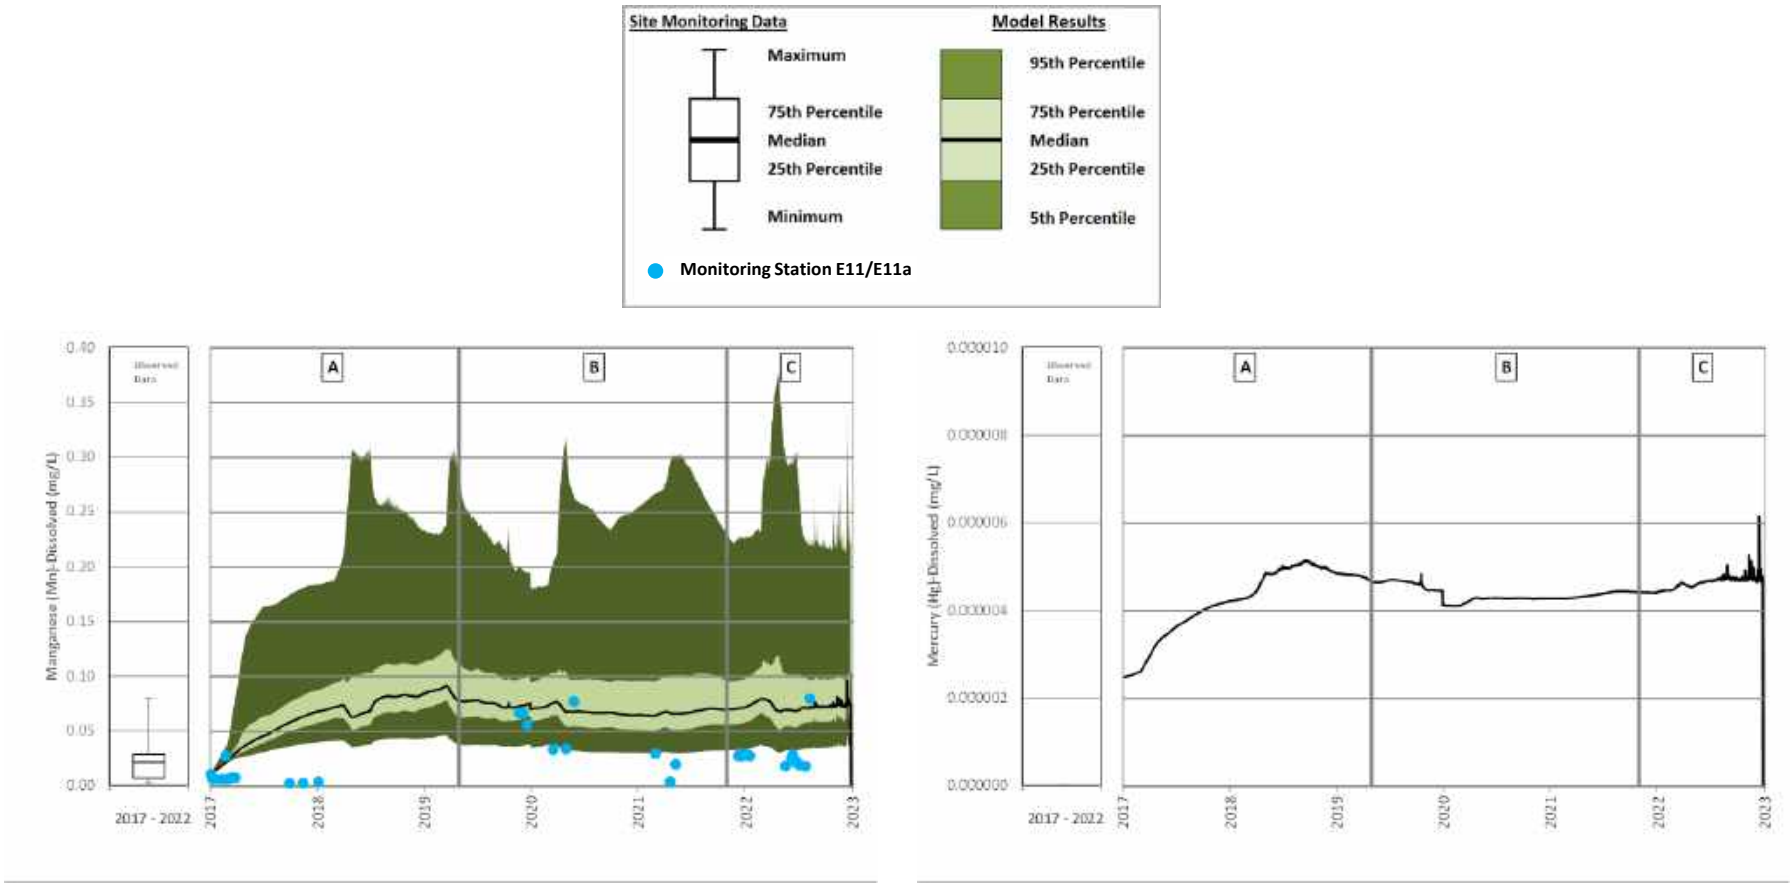


Figure A 12: Springer Pit Calibration – Dissolved Copper and Dissolved Iron

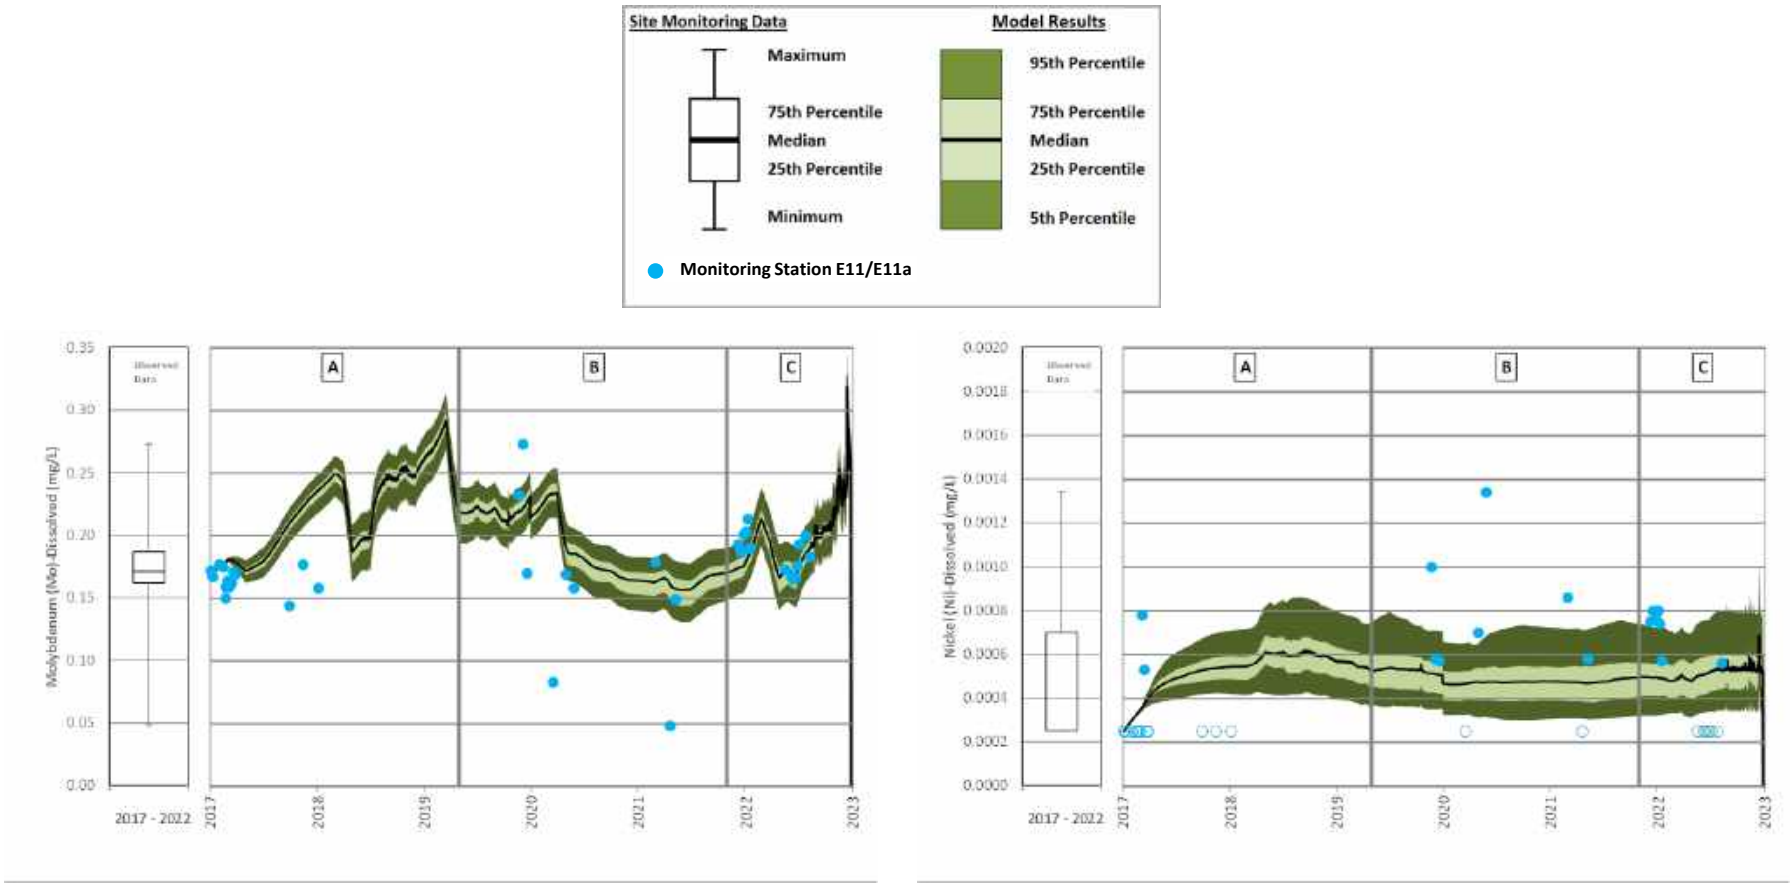
A = Operations; B = Care and Maintanence; C = Resumed Operations



Note: Dissolved lithium concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

Figure A 13: Springer Pit Calibration – Dissolved Lead and Dissolved Lithium

A = Operations; B = Care and Maintanence; C = Resumed Operations

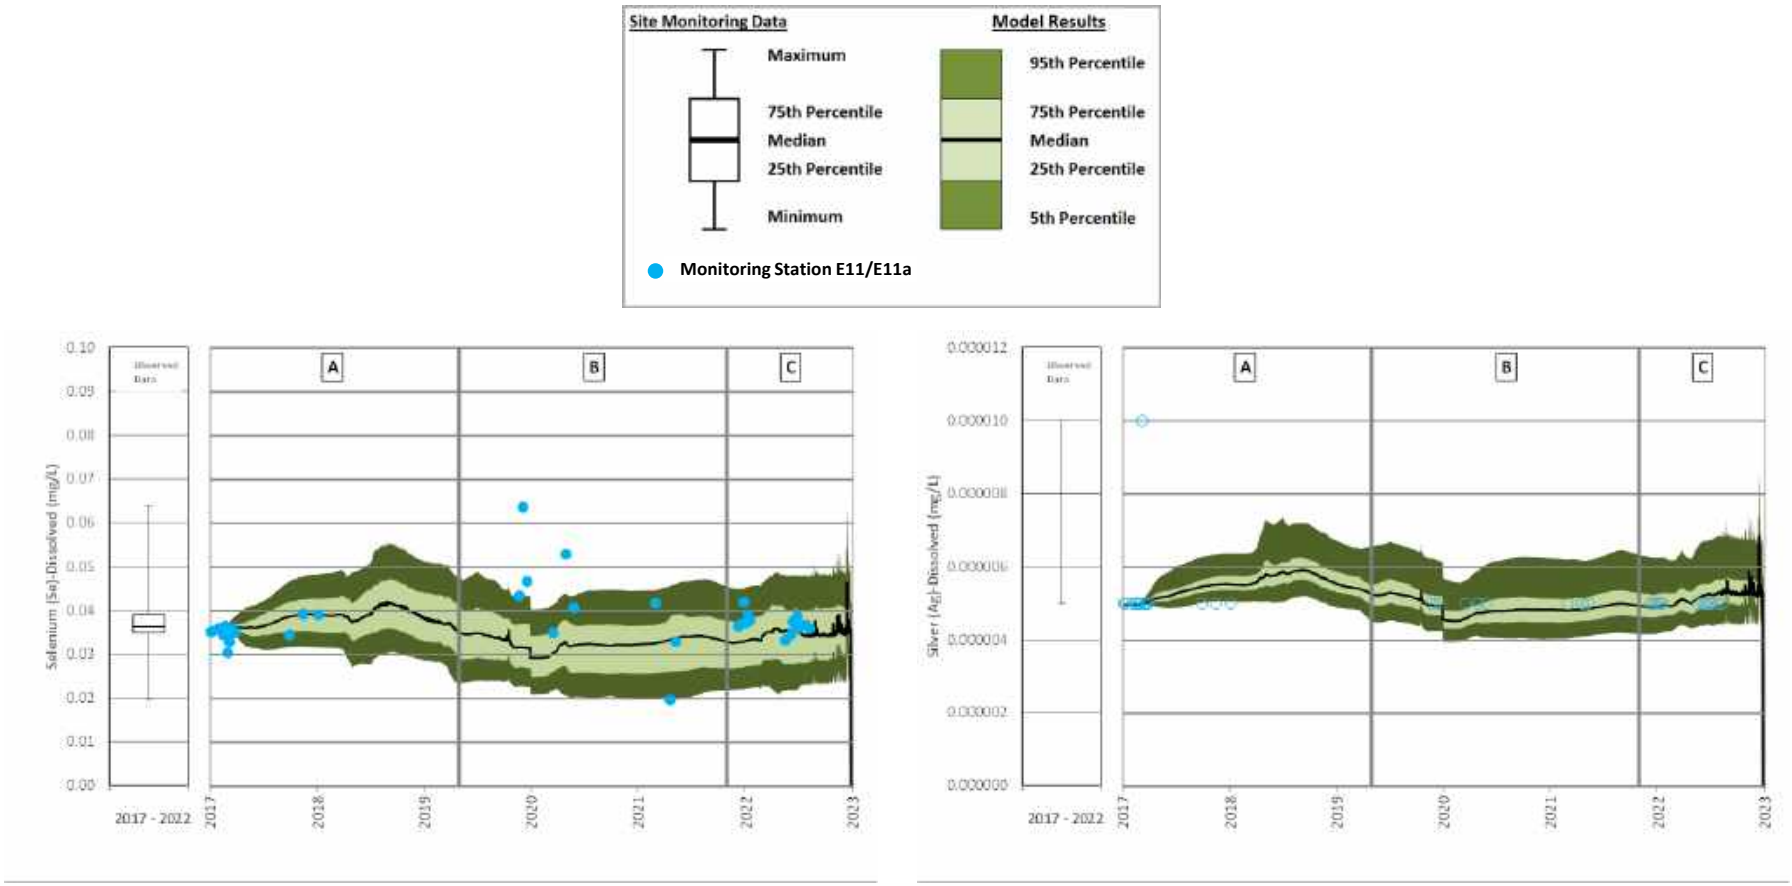


Figure A 14: Springer Pit Calibration – Dissolved Manganese and Dissolved Mercury

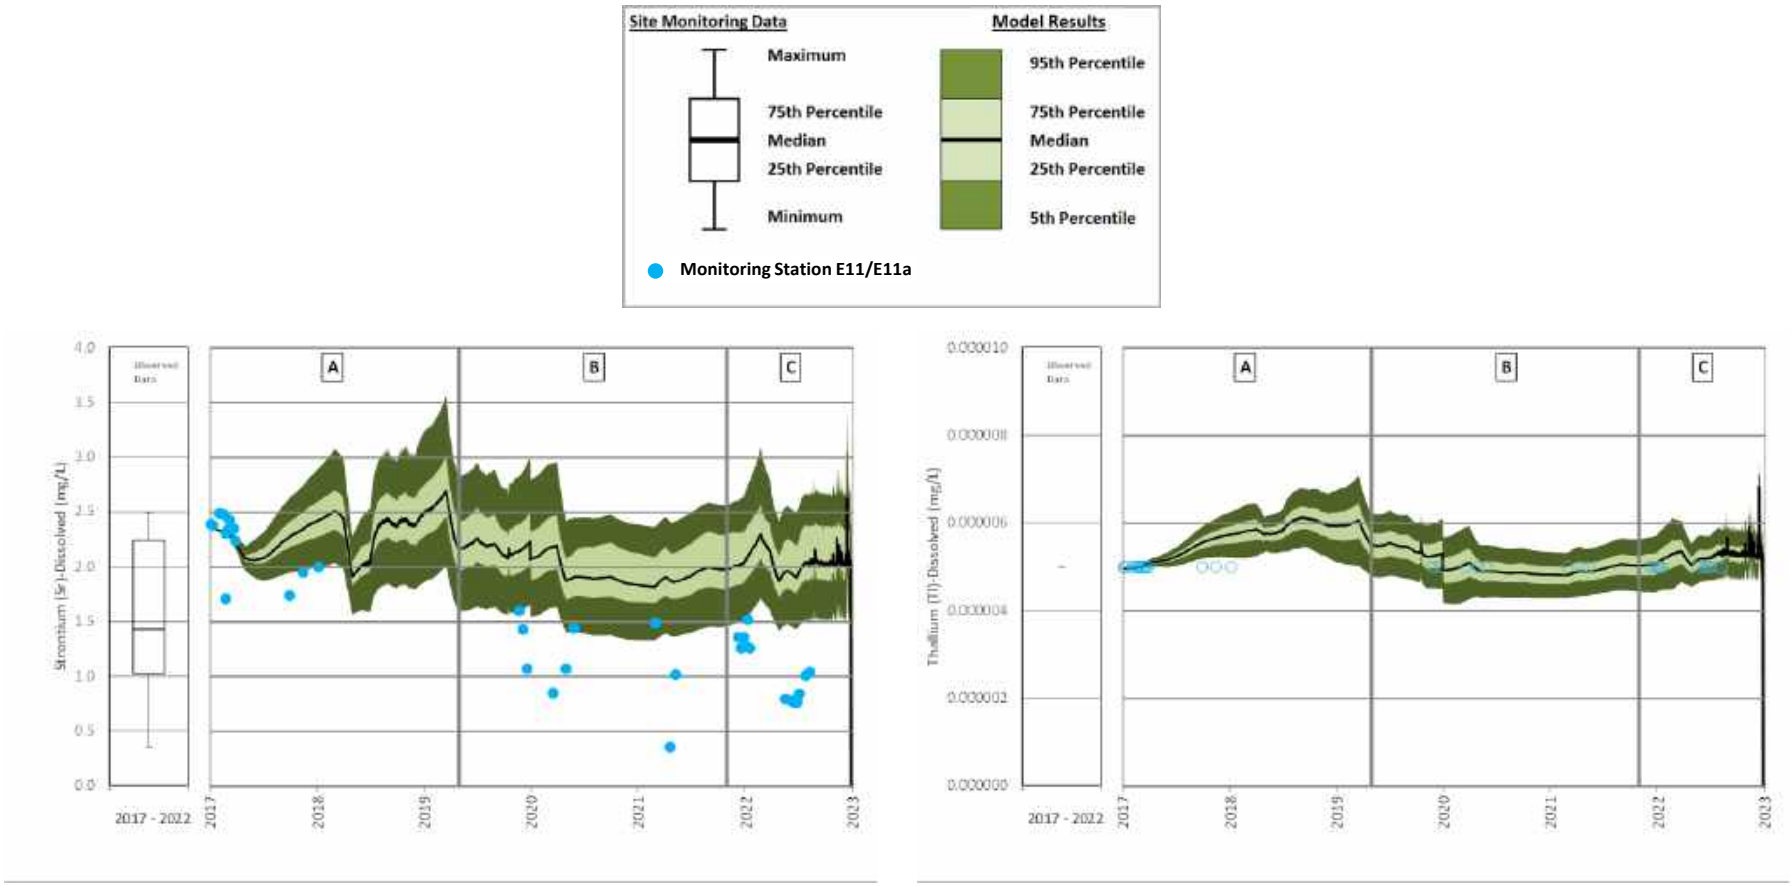
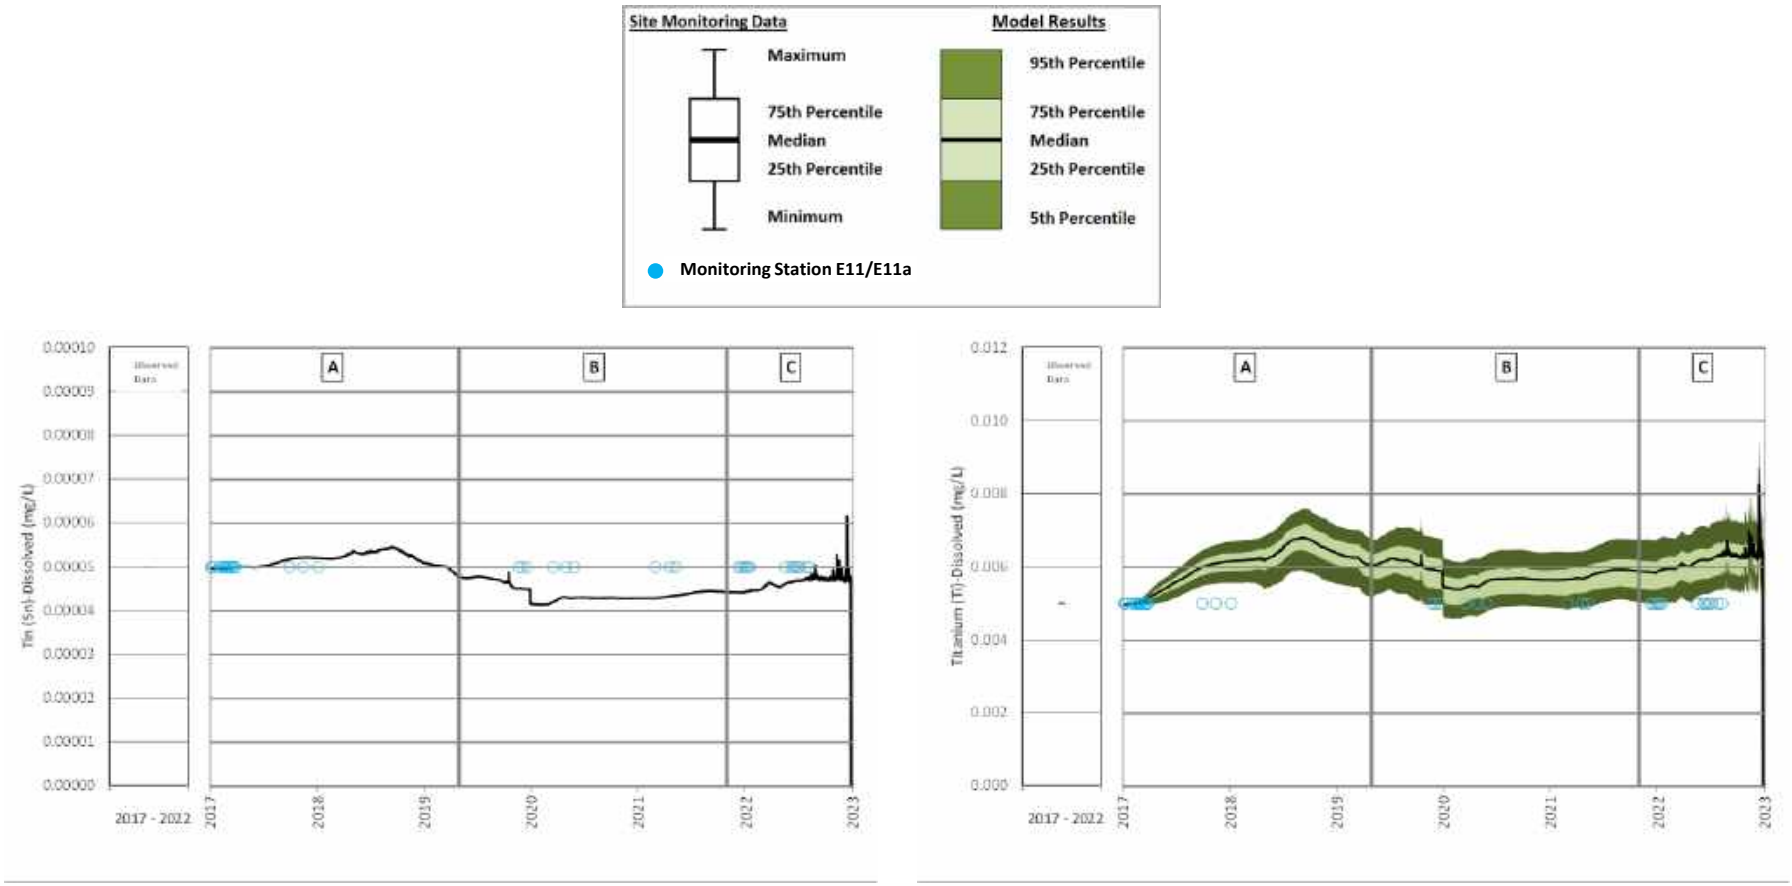
A = Operations; B = Care and Maintanence; C = Resumed Operations



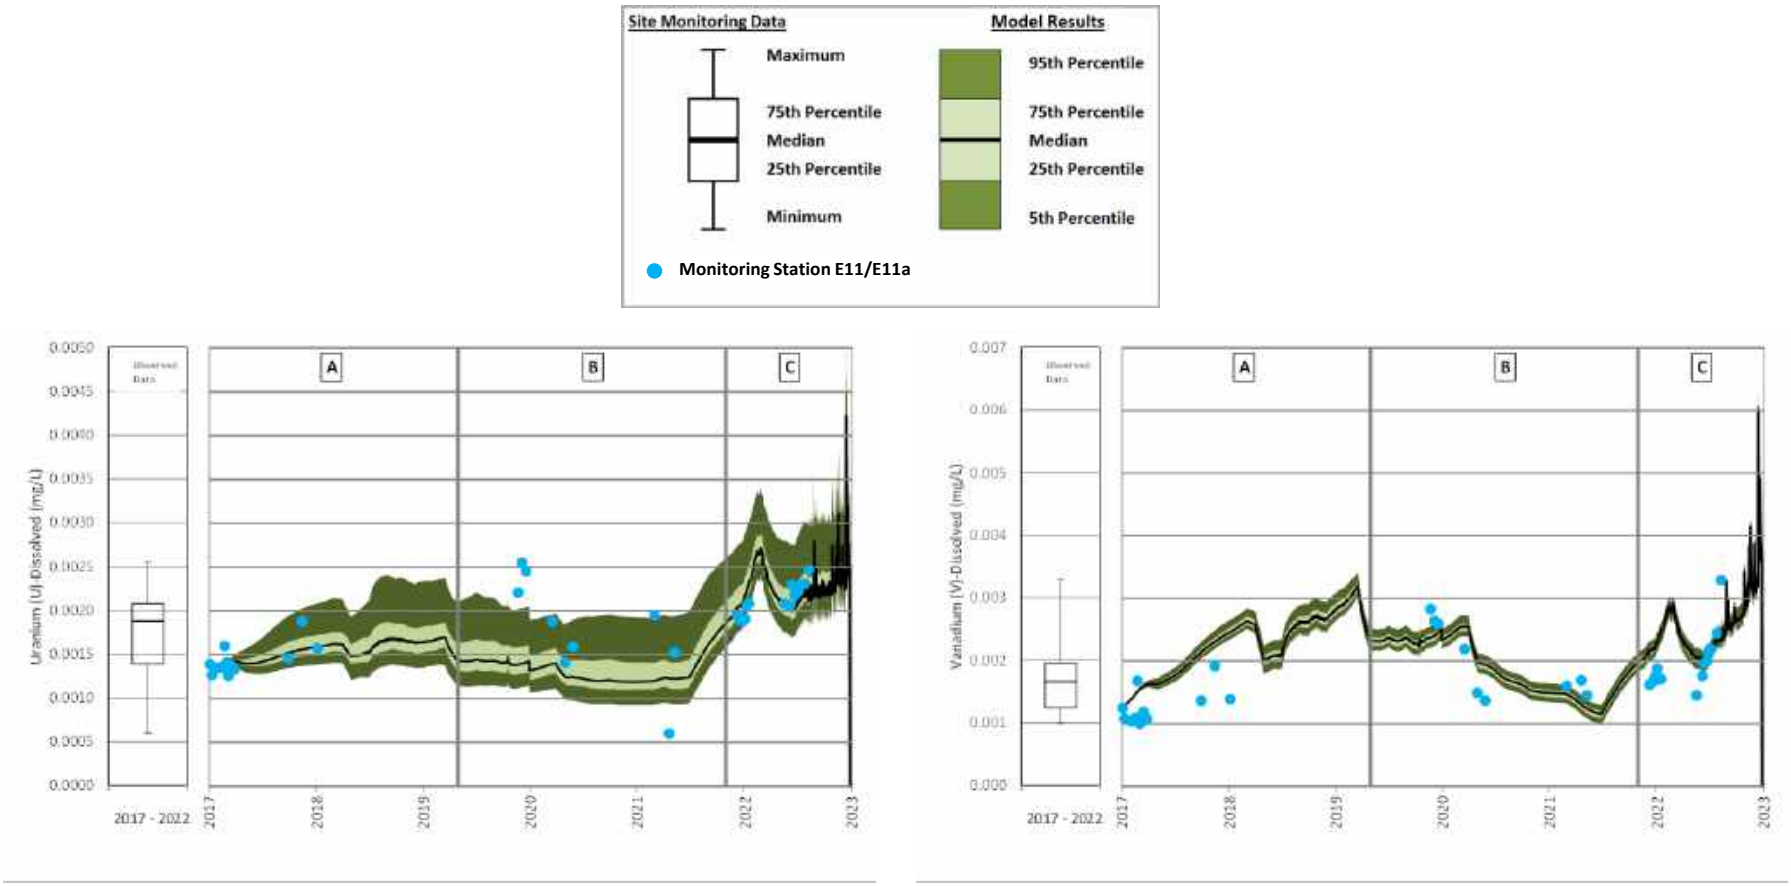
Note: Dissolved molybdenum concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

Figure A 15: Springer Pit Calibration – Dissolved Molybdenum and Dissolved Nickel



A = Operations; B = Care and Maintanence; C = Resumed Operations

Figure A 16: Springer Pit Calibration – Dissolved Selenium and Dissolved Silver



A = Operations; B = Care and Maintanence; C = Resumed Operations

Figure A 17: Springer Pit Calibration – Dissolved Strontium and Dissolved Thallium

A = Operations; B = Care and Maintanence; C = Resumed Operations

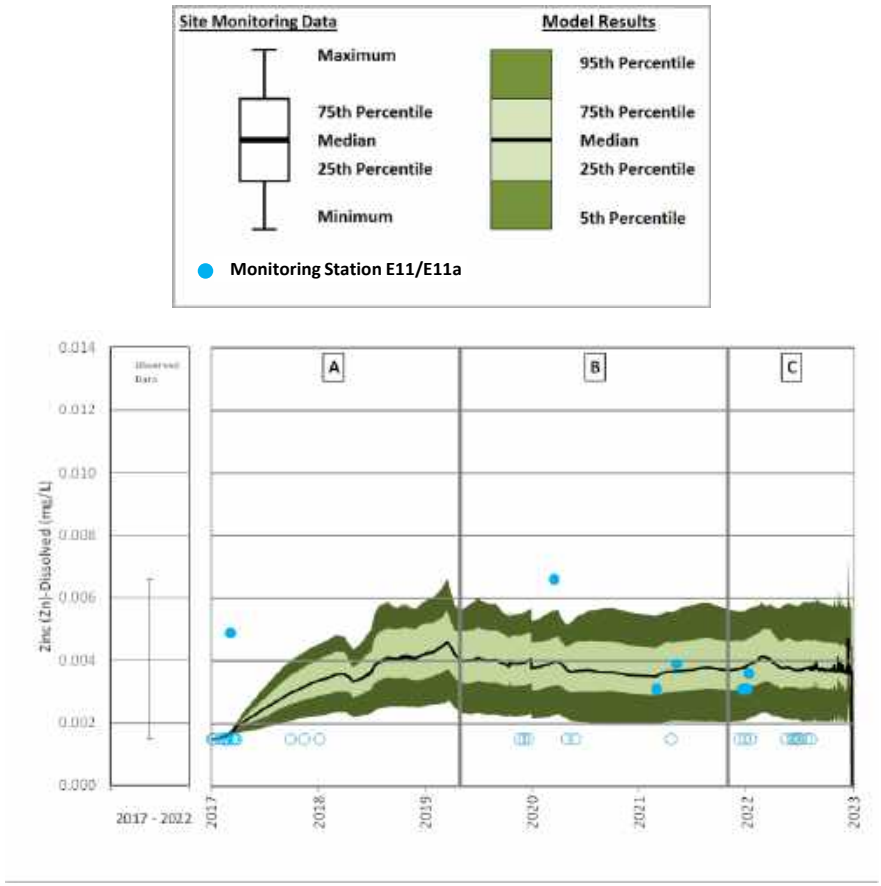


Figure A 18: Springer Pit Calibration – Dissolved Tin and Dissolved Titanium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved uranium and vanadium concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

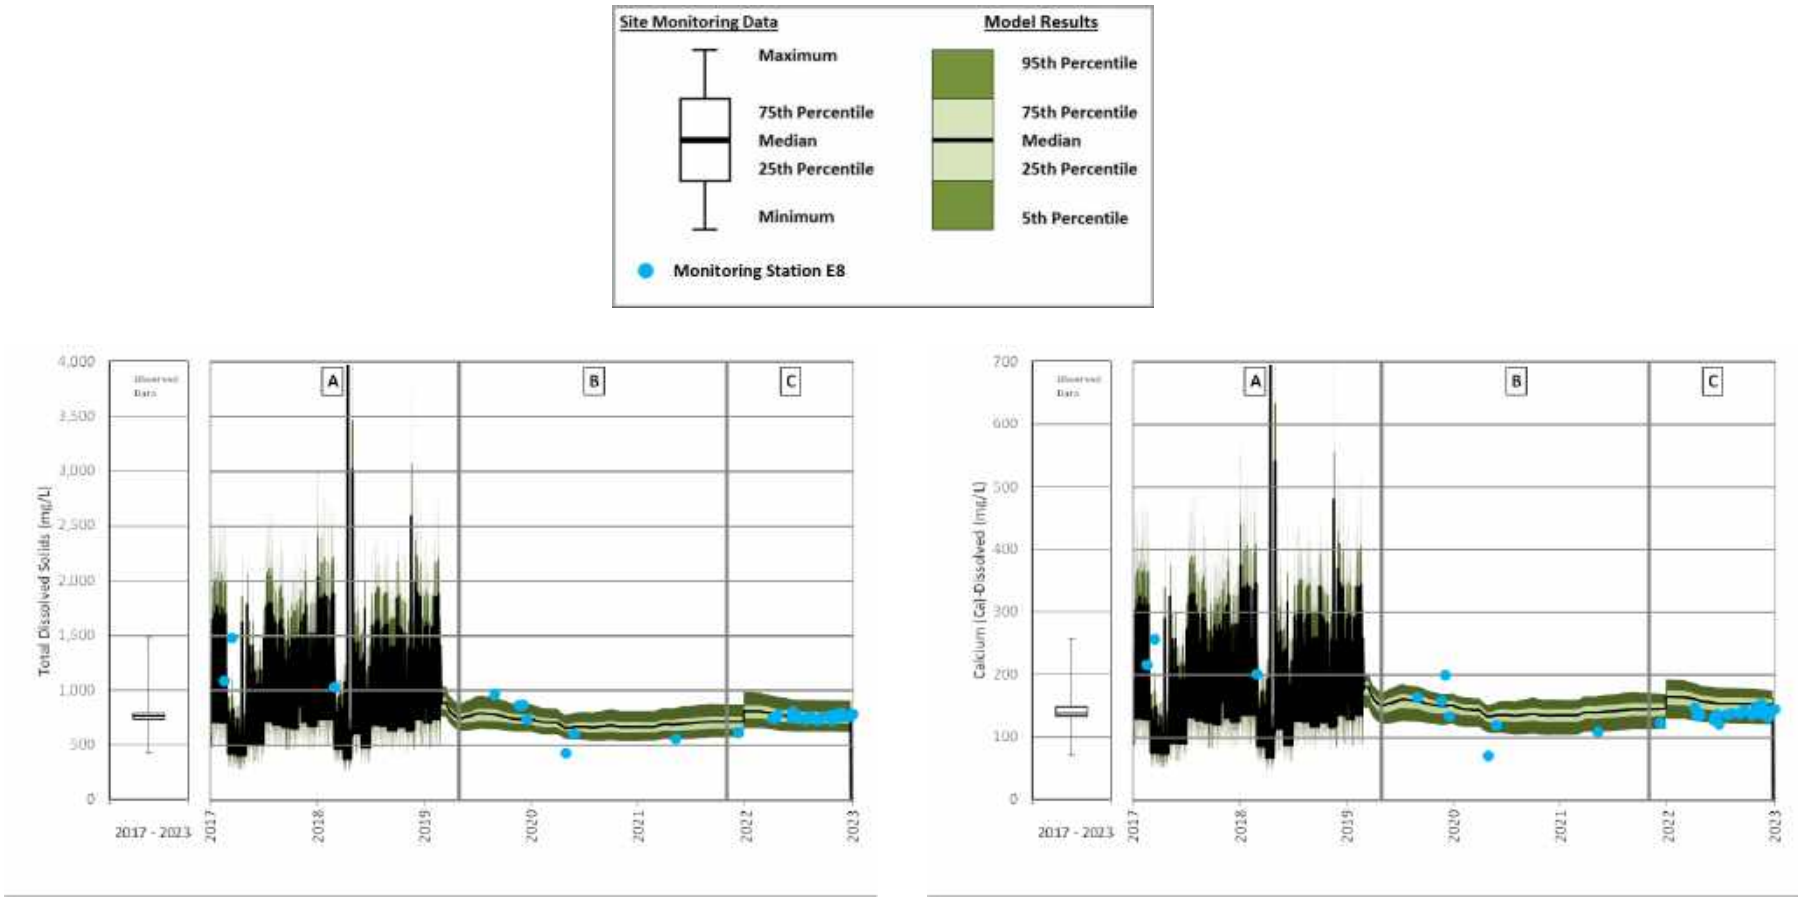

Figure A 19: Springer Pit Calibration – Dissolved Uranium and Dissolved Vanadium

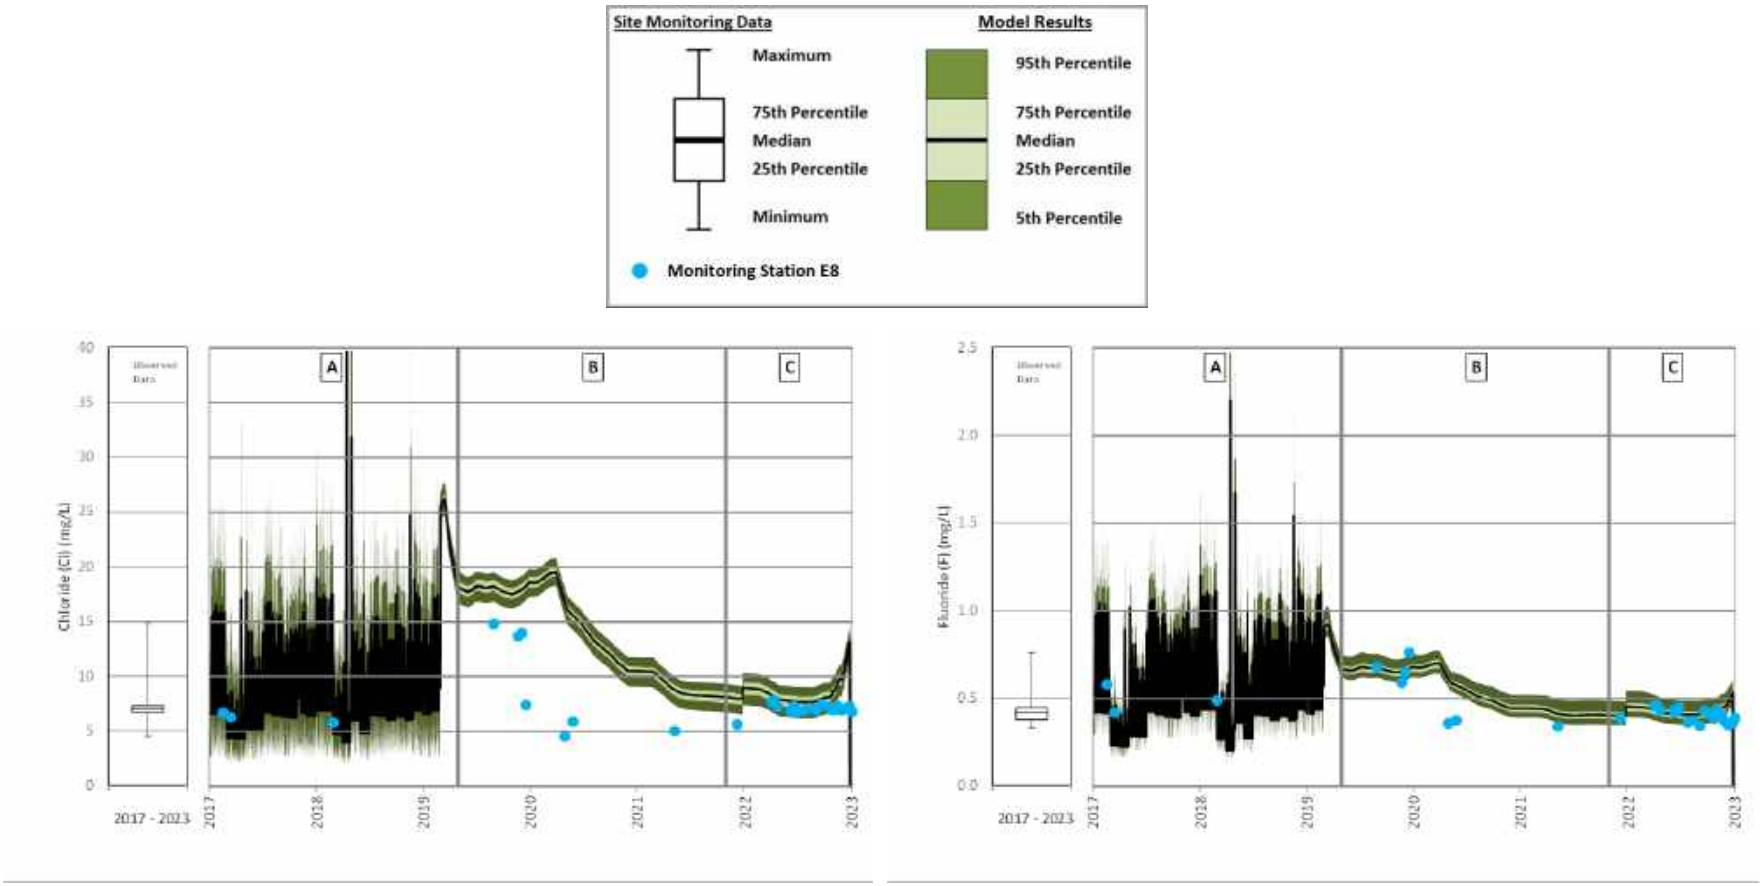
A = Operations; B = Care and Maintanence; C = Resumed Operations

Figure A 20: Springer Pit Calibration – Dissolved Zinc



Cariboo Pit Calibration

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Total dissolved solids and calcium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

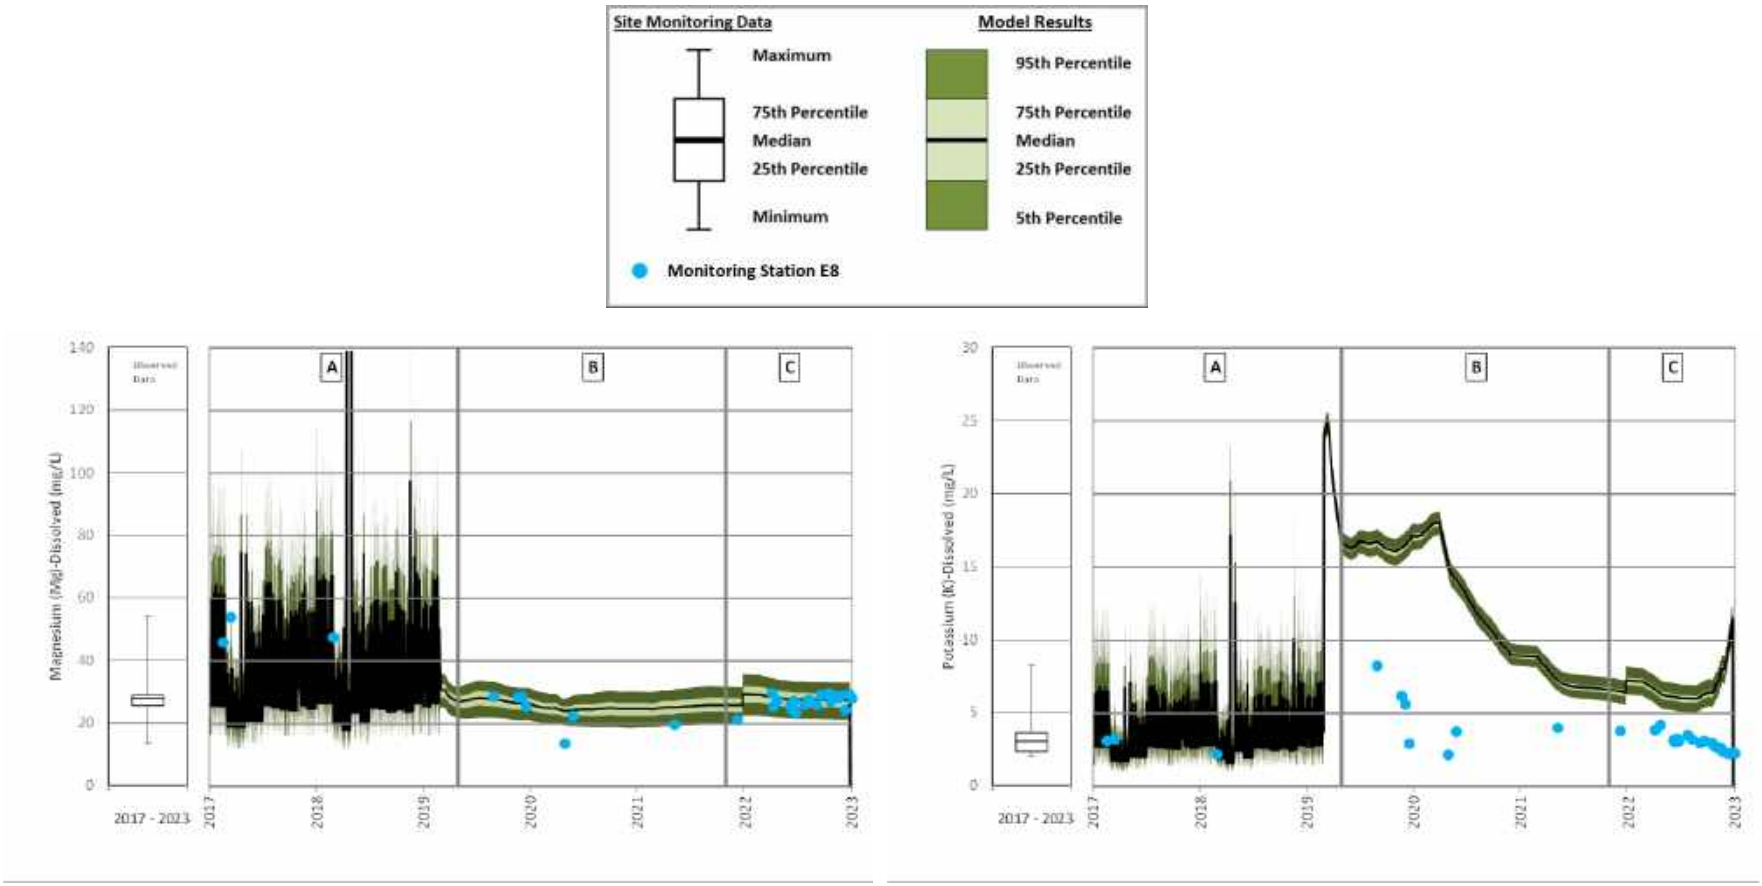


Figure A 21: Cariboo Pit Calibration – Total Dissolved Solids and Calcium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Chloride and fluoride concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

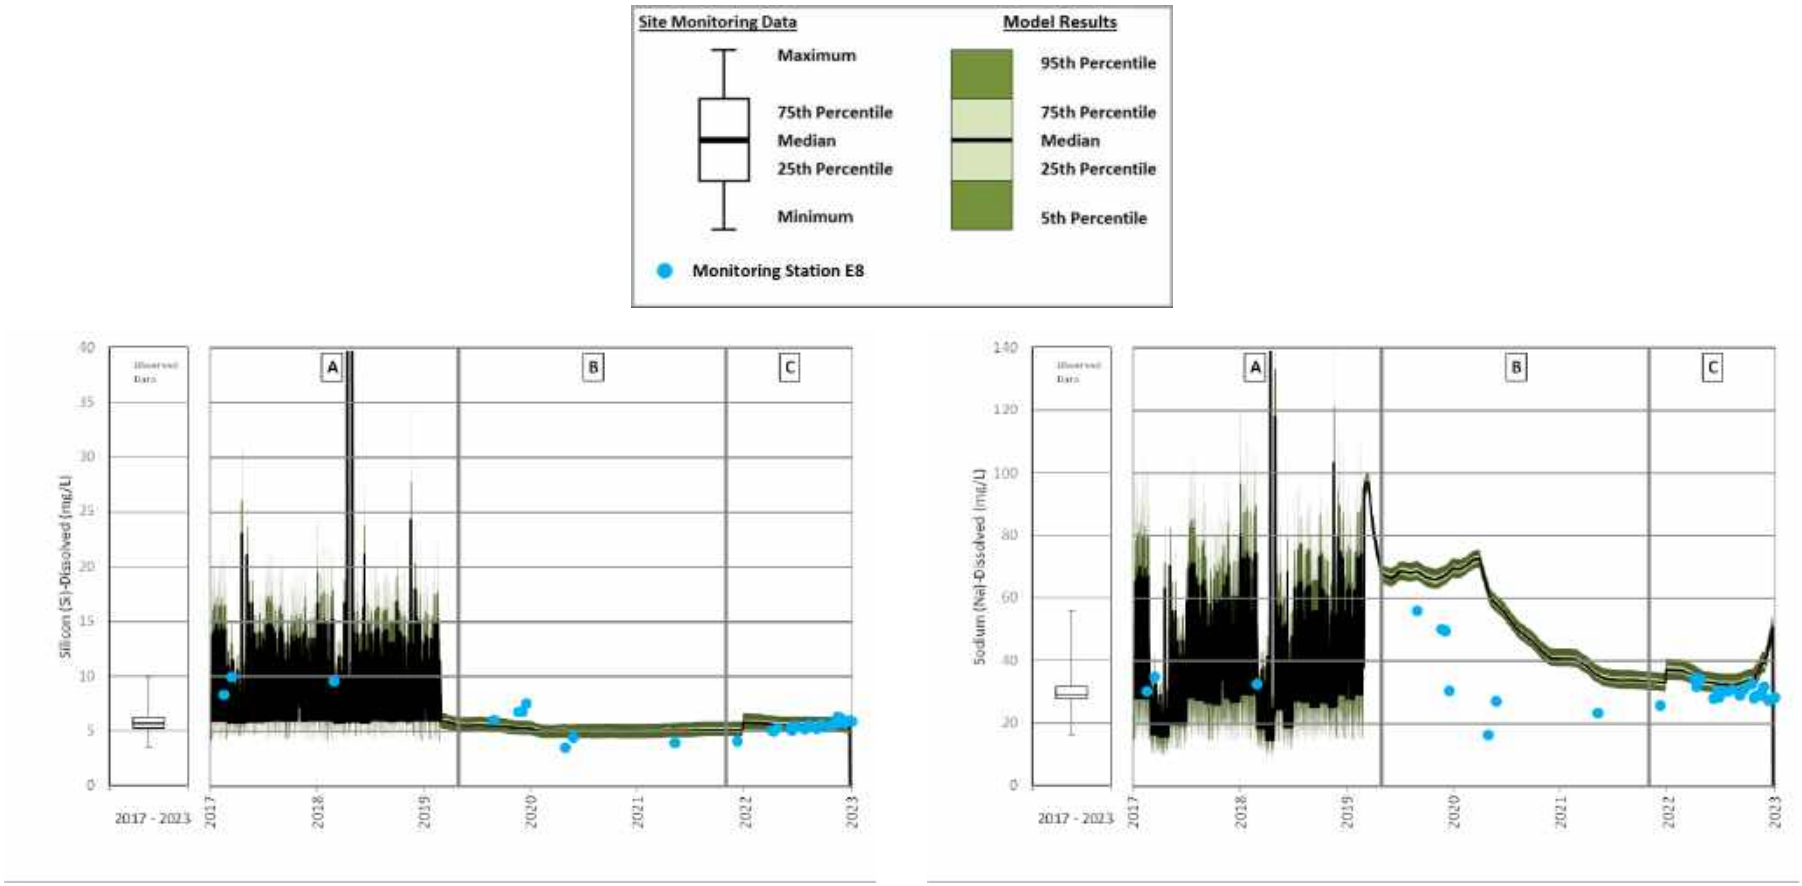

Figure A 22: Cariboo Pit Calibration – Chloride and Fluoride

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Magnesium and potassium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit..

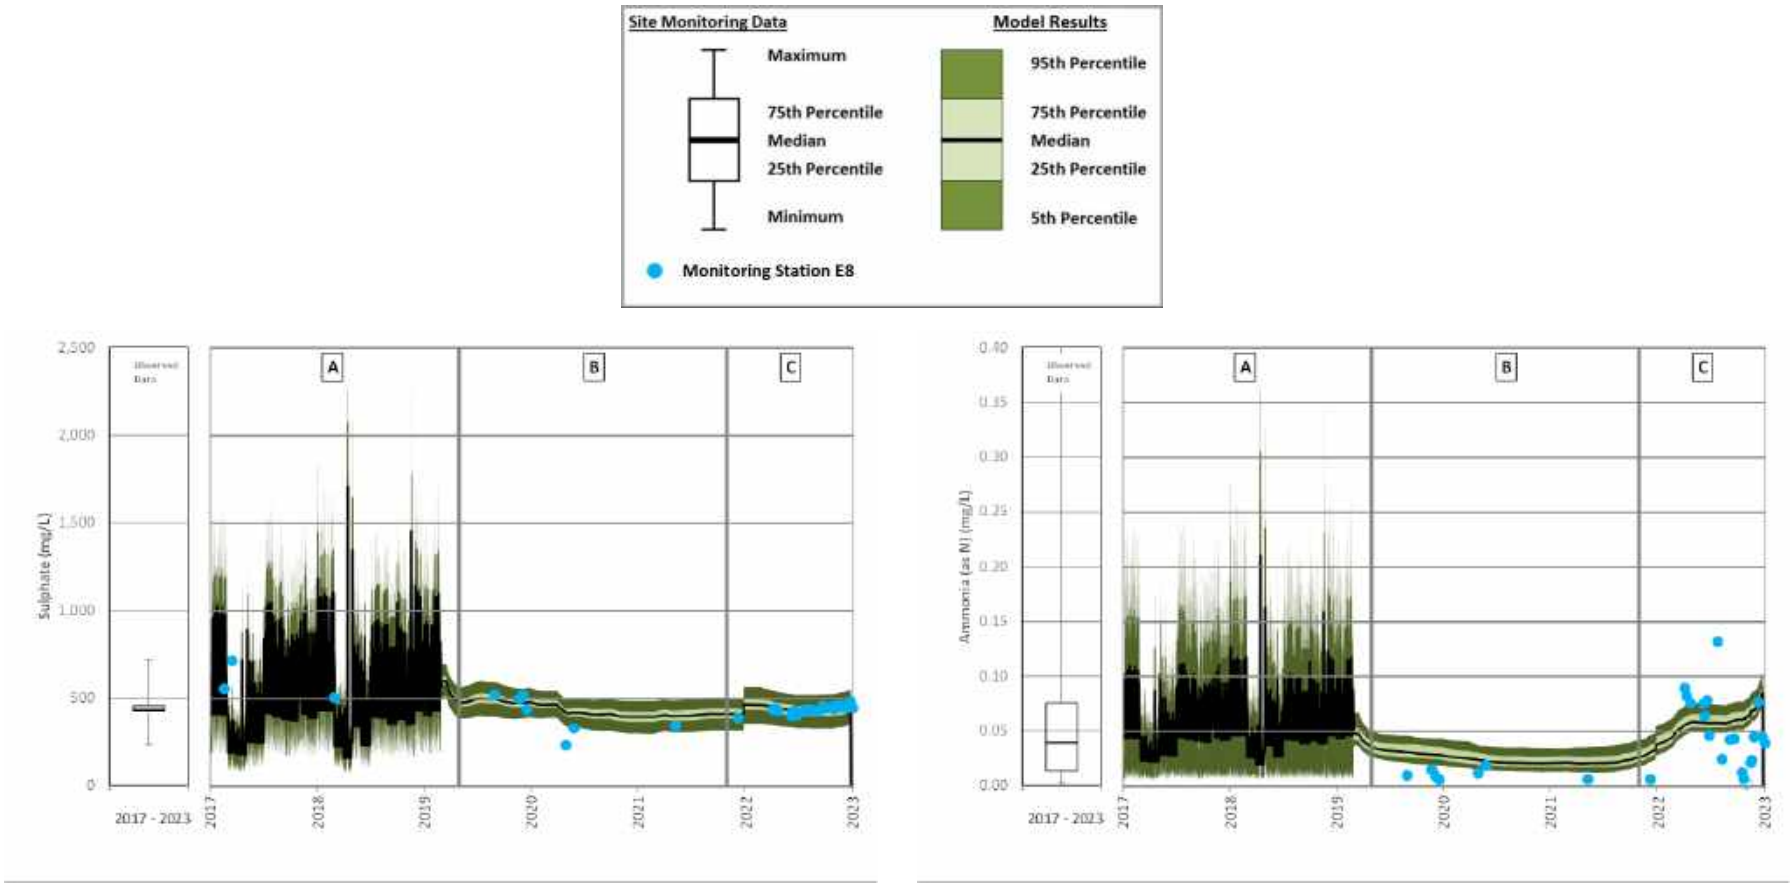

Figure A 23: Cariboo Pit Calibration – Magnesium and Potassium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Silicon and sodium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

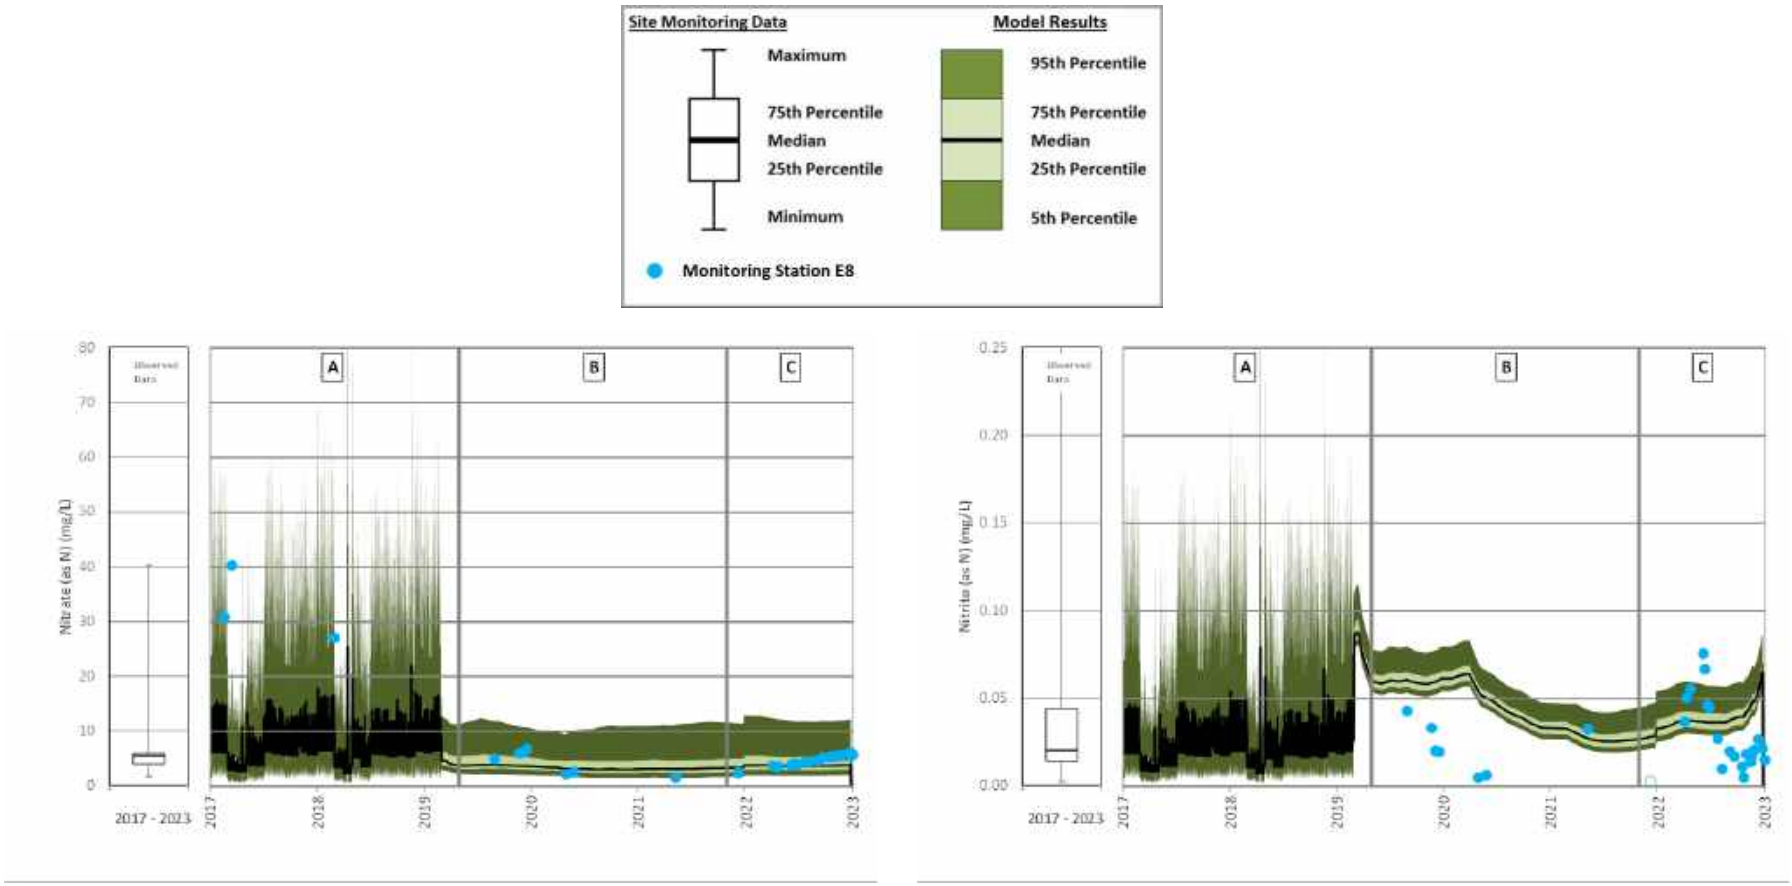

Figure A 24: Cariboo Pit Calibration – Silicon and Sodium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Sulphate and total ammonia concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

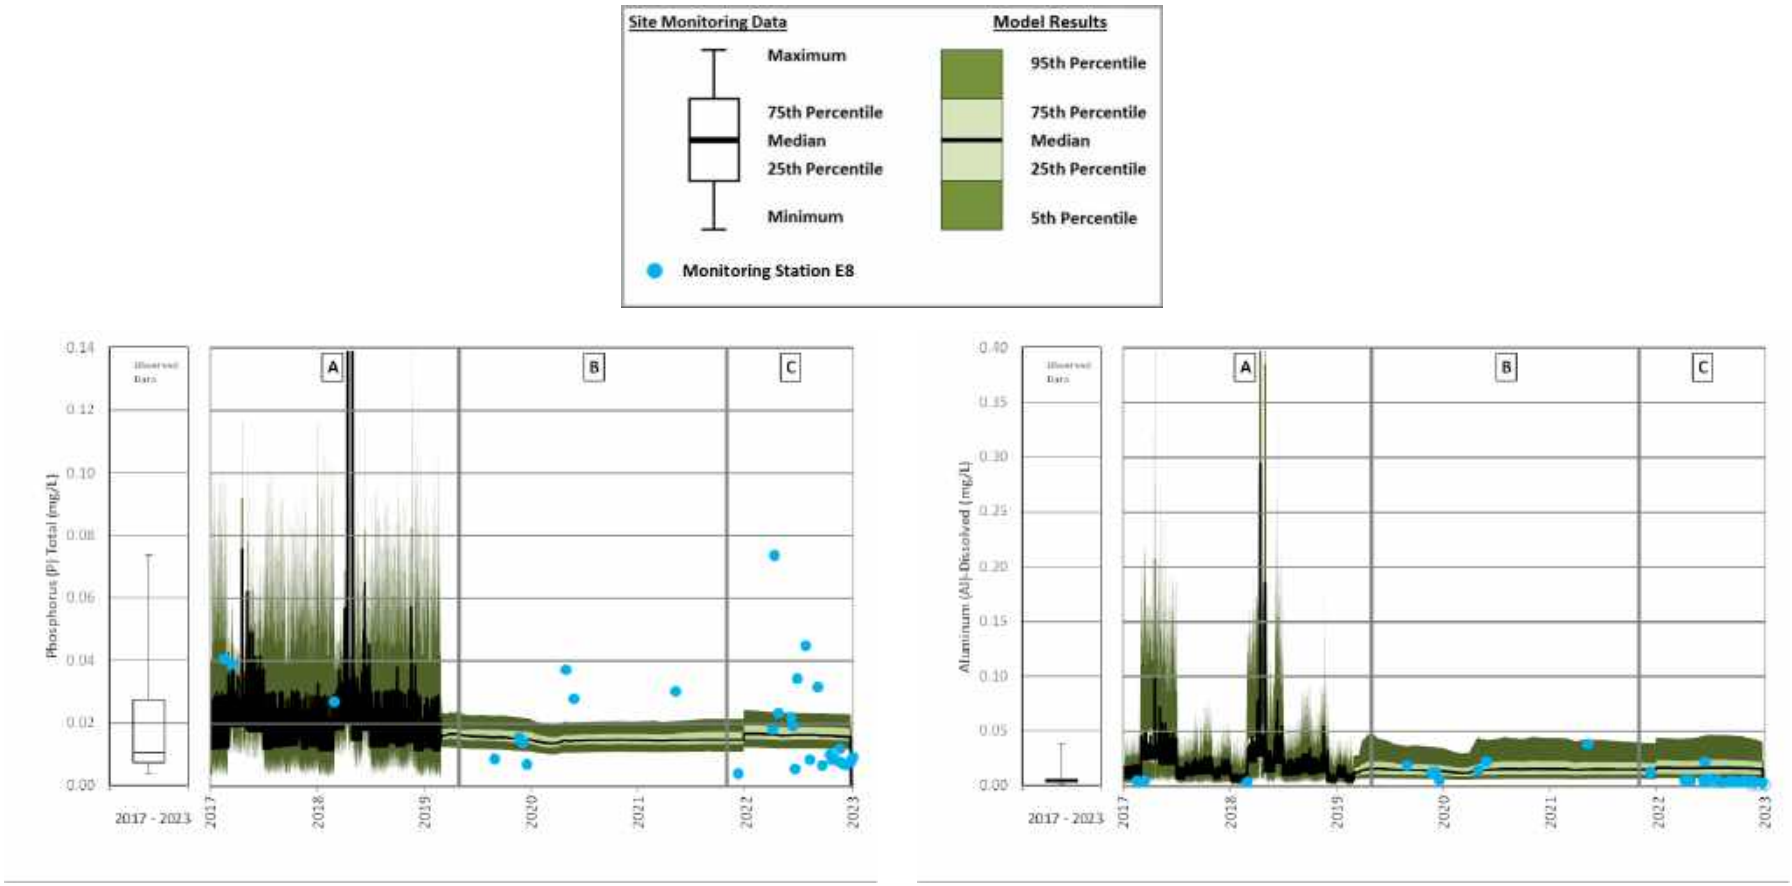

Figure A 25: Cariboo Pit Calibration – Sulphate and Total Ammonia

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Nitrate and nitrite concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

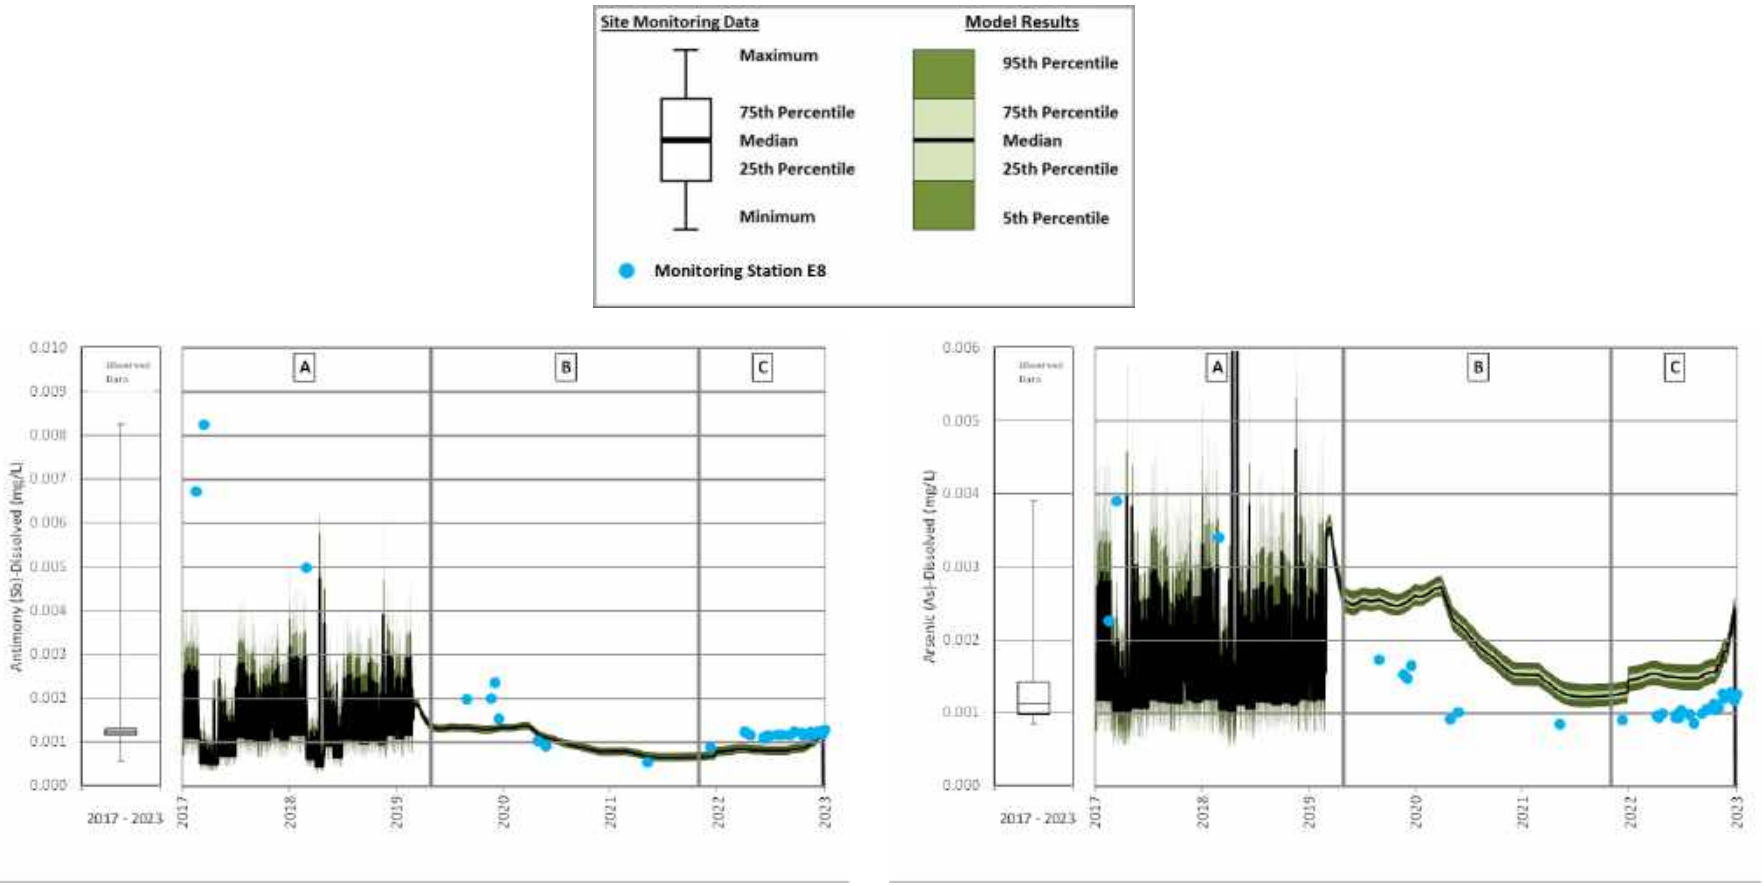

Figure A 26: Cariboo Pit Calibration – Nitrate and Nitrite

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Total phosphorus and dissolved aluminum concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

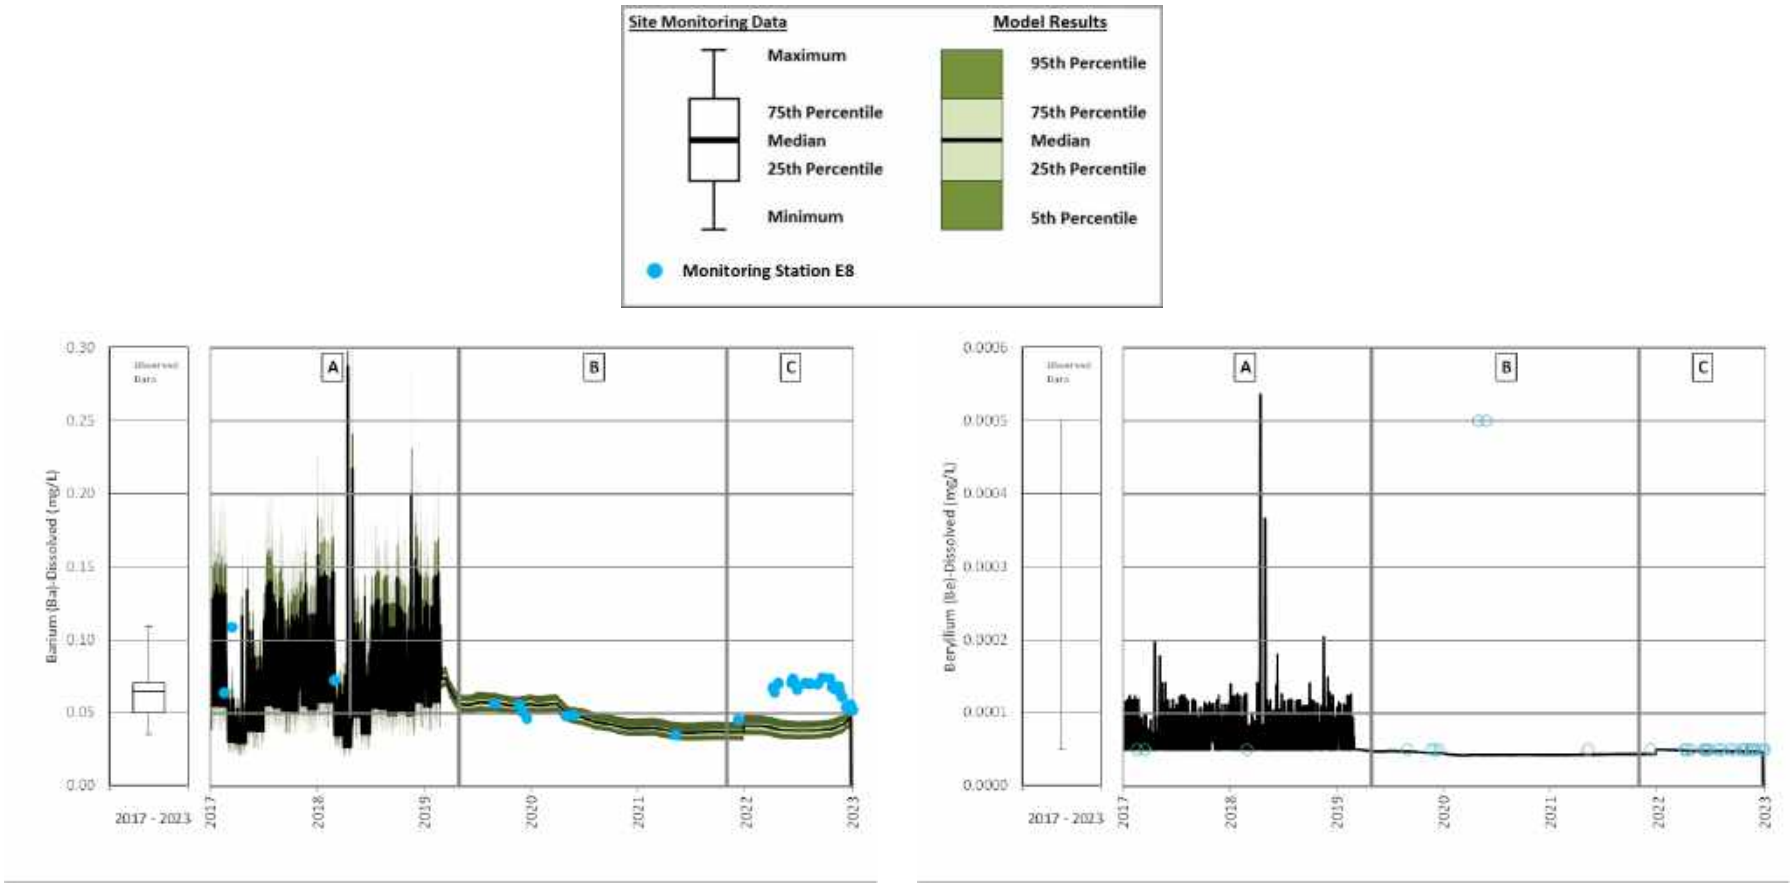

Figure A 27: Cariboo Pit Calibration – Total Phosphorus and Dissolved Aluminum

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved antimony and dissolved arsenic concentrations increase in Springer Pit at the start of resumed operations because of higher concentrations in the Tailings Storage Facility (TSF) which is pumped to Springer Pit. The increased concentrations in the TSF are caused by tailings deposition when operations resumed.

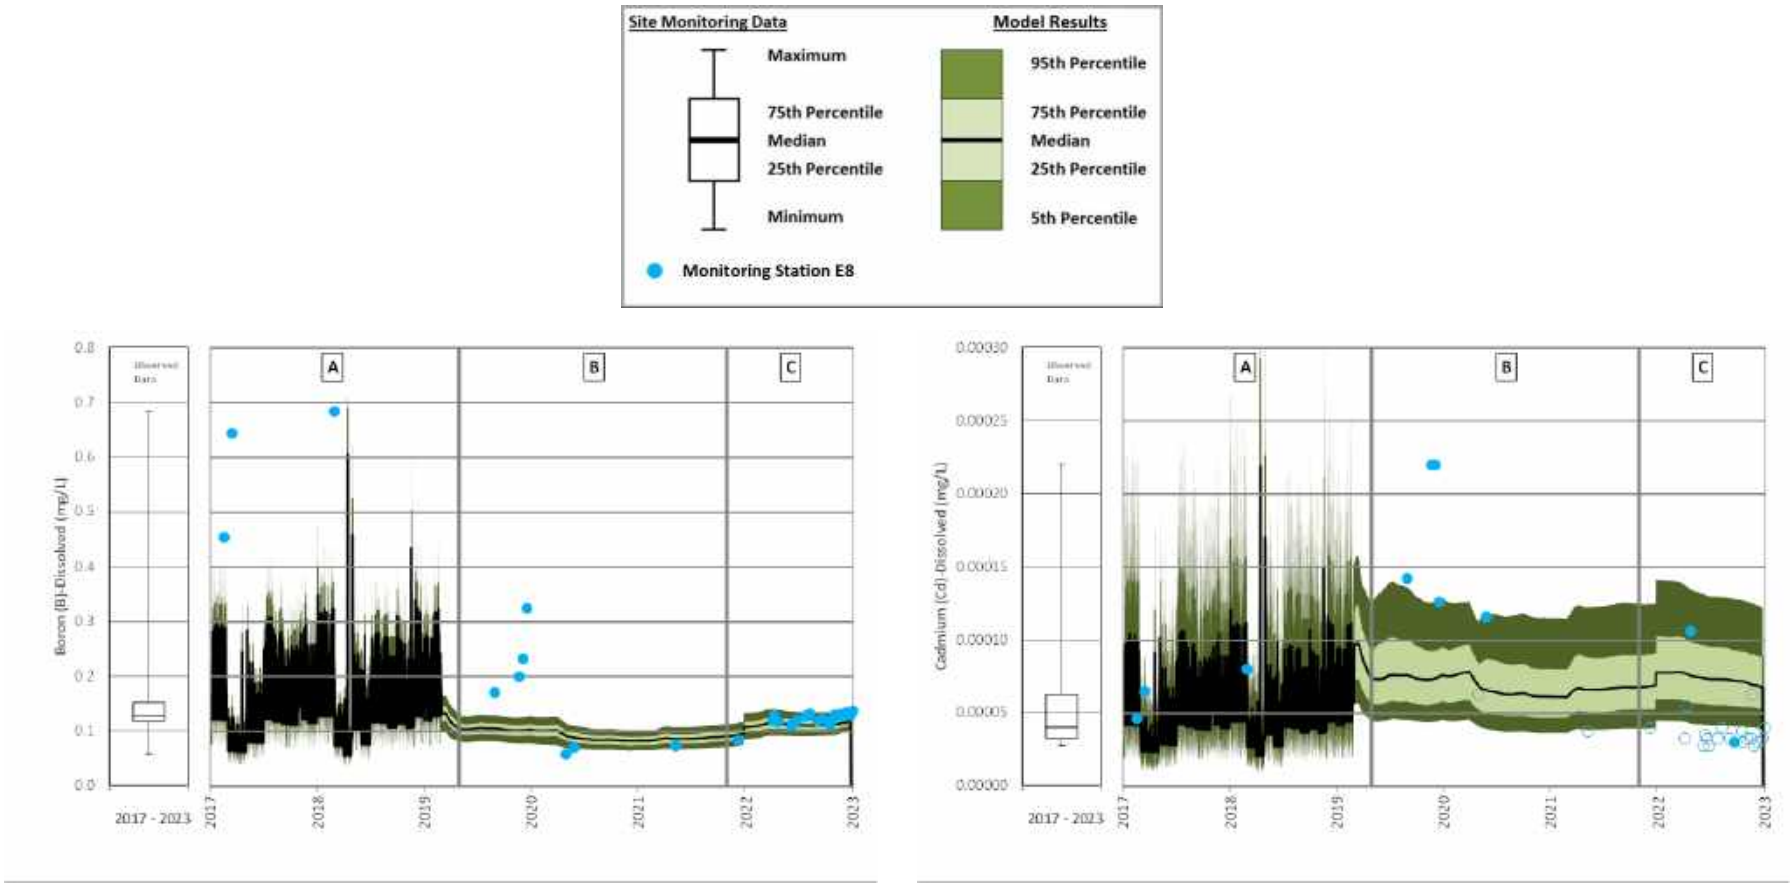

Figure A 28: Cariboo Pit Calibration – Dissolved Antimony and Dissolved Arsenic

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved barium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

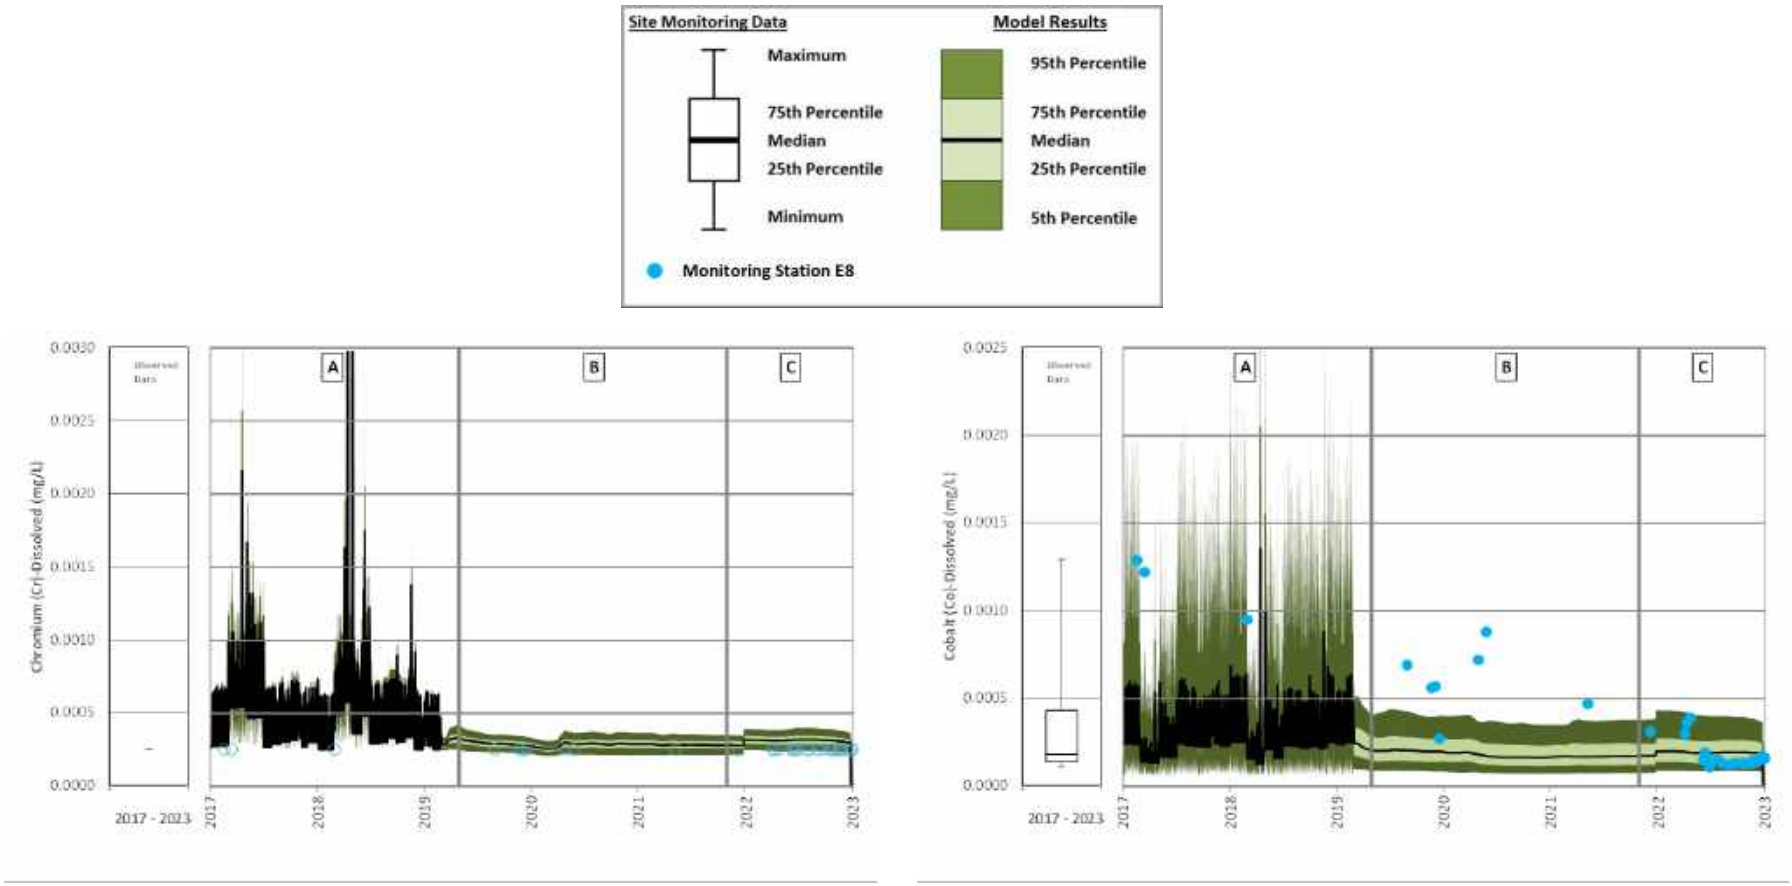

Figure A 29: Cariboo Pit Calibration – Dissolved Barium and Dissolved Beryllium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved boron and dissolved cadmium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

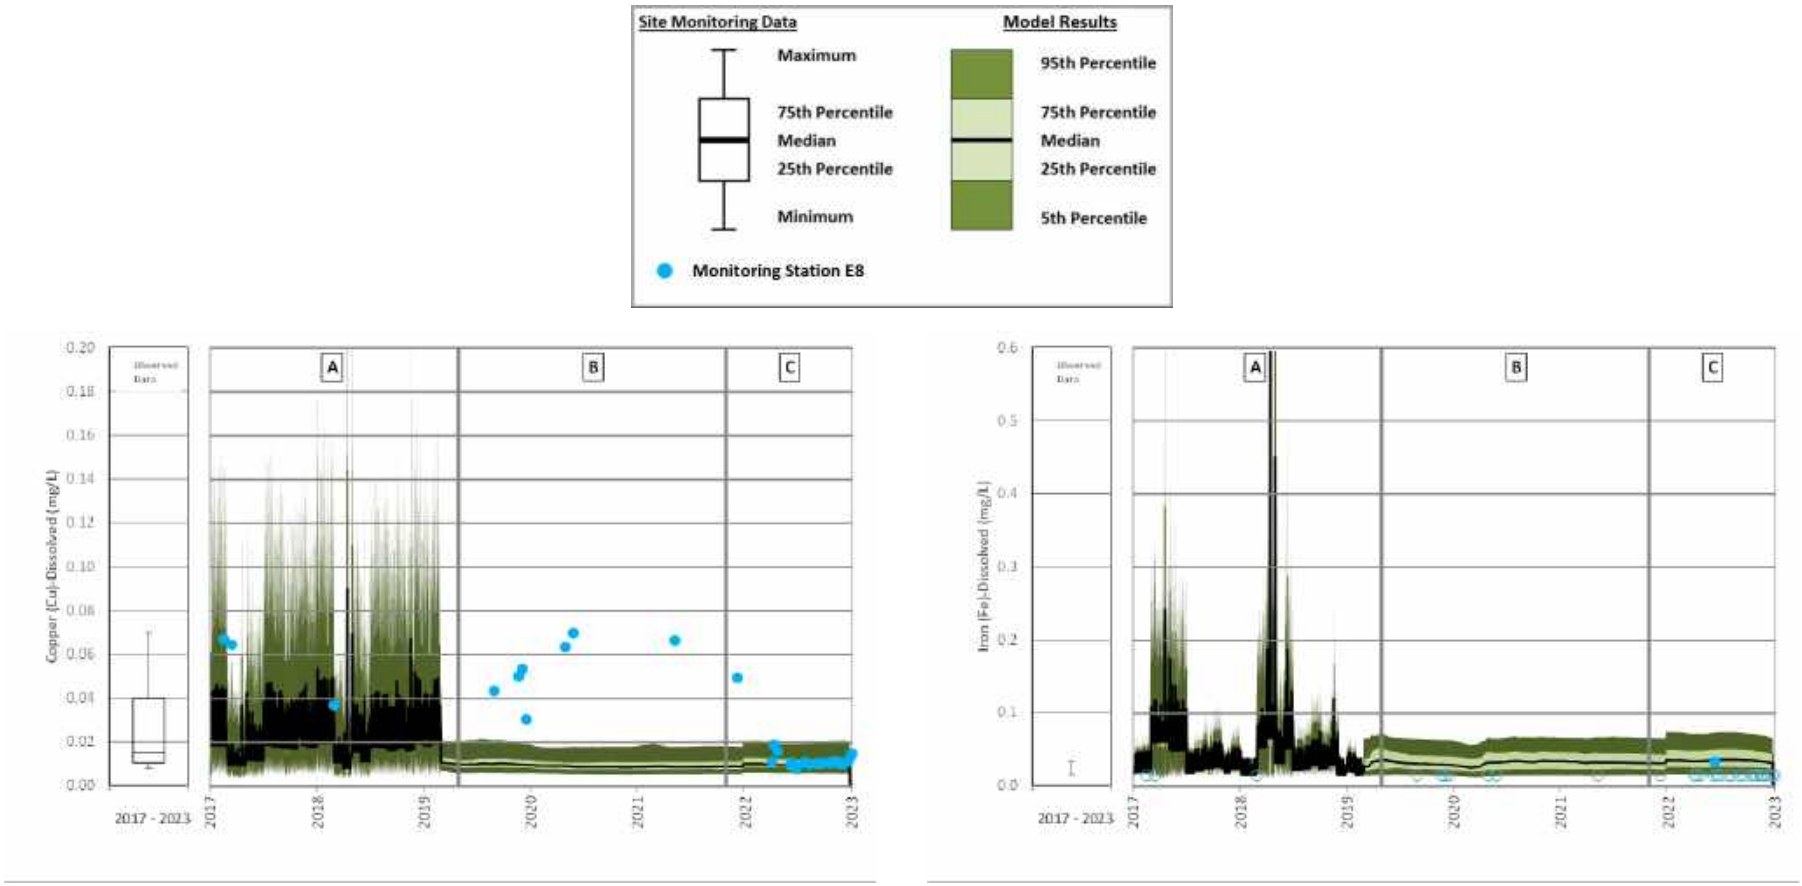

Figure A 30: Cariboo Pit Calibration – Dissolved Boron and Dissolved Cadmium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved chromium and dissolved cobalt concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

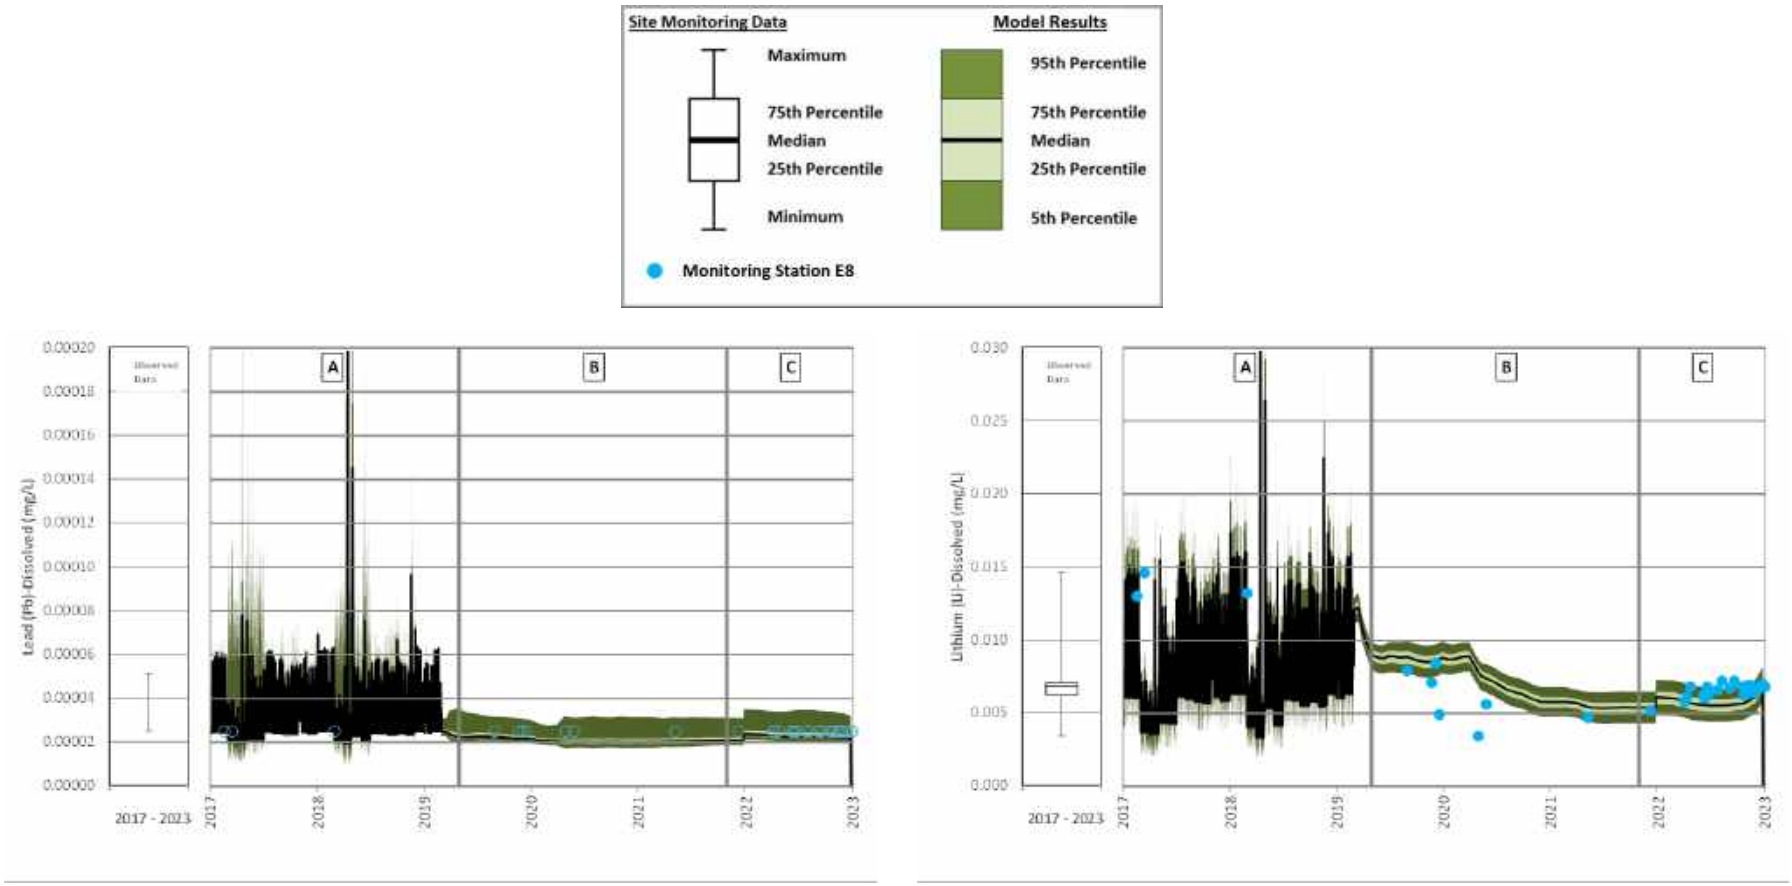

Figure A 31: Cariboo Pit Calibration – Dissolved Chromium and Dissolved Cobalt

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved copper and dissolved iron concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

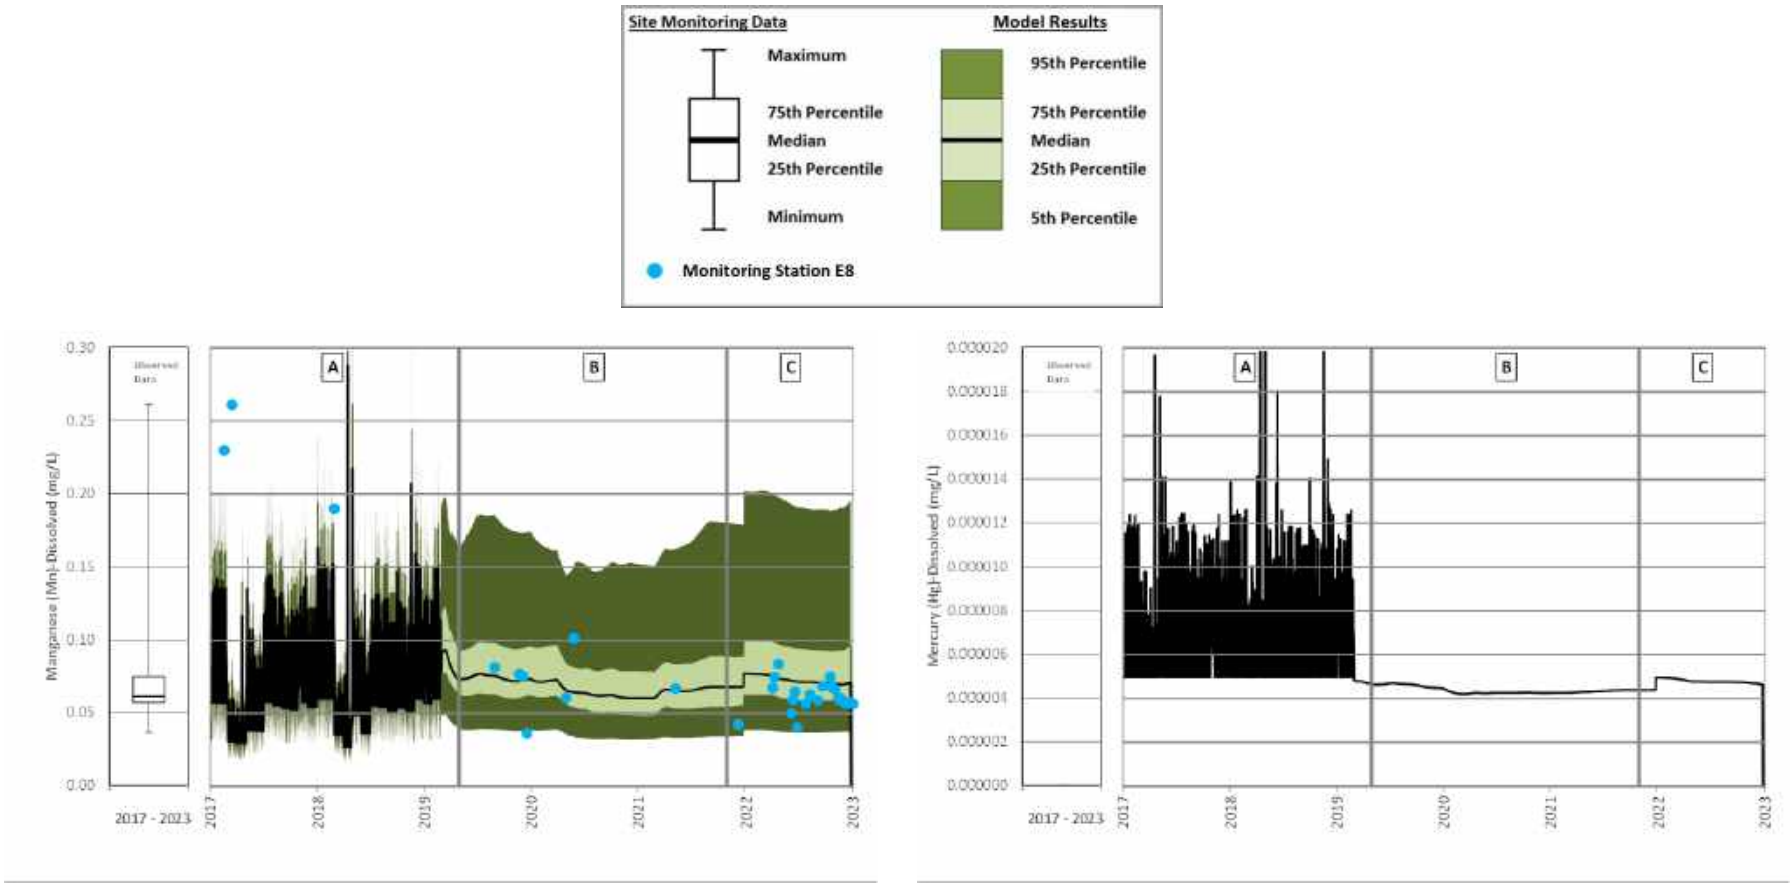

Figure A 32: Cariboo Pit Calibration – Dissolved Copper and Dissolved Iron

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved lead and dissolved lithium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

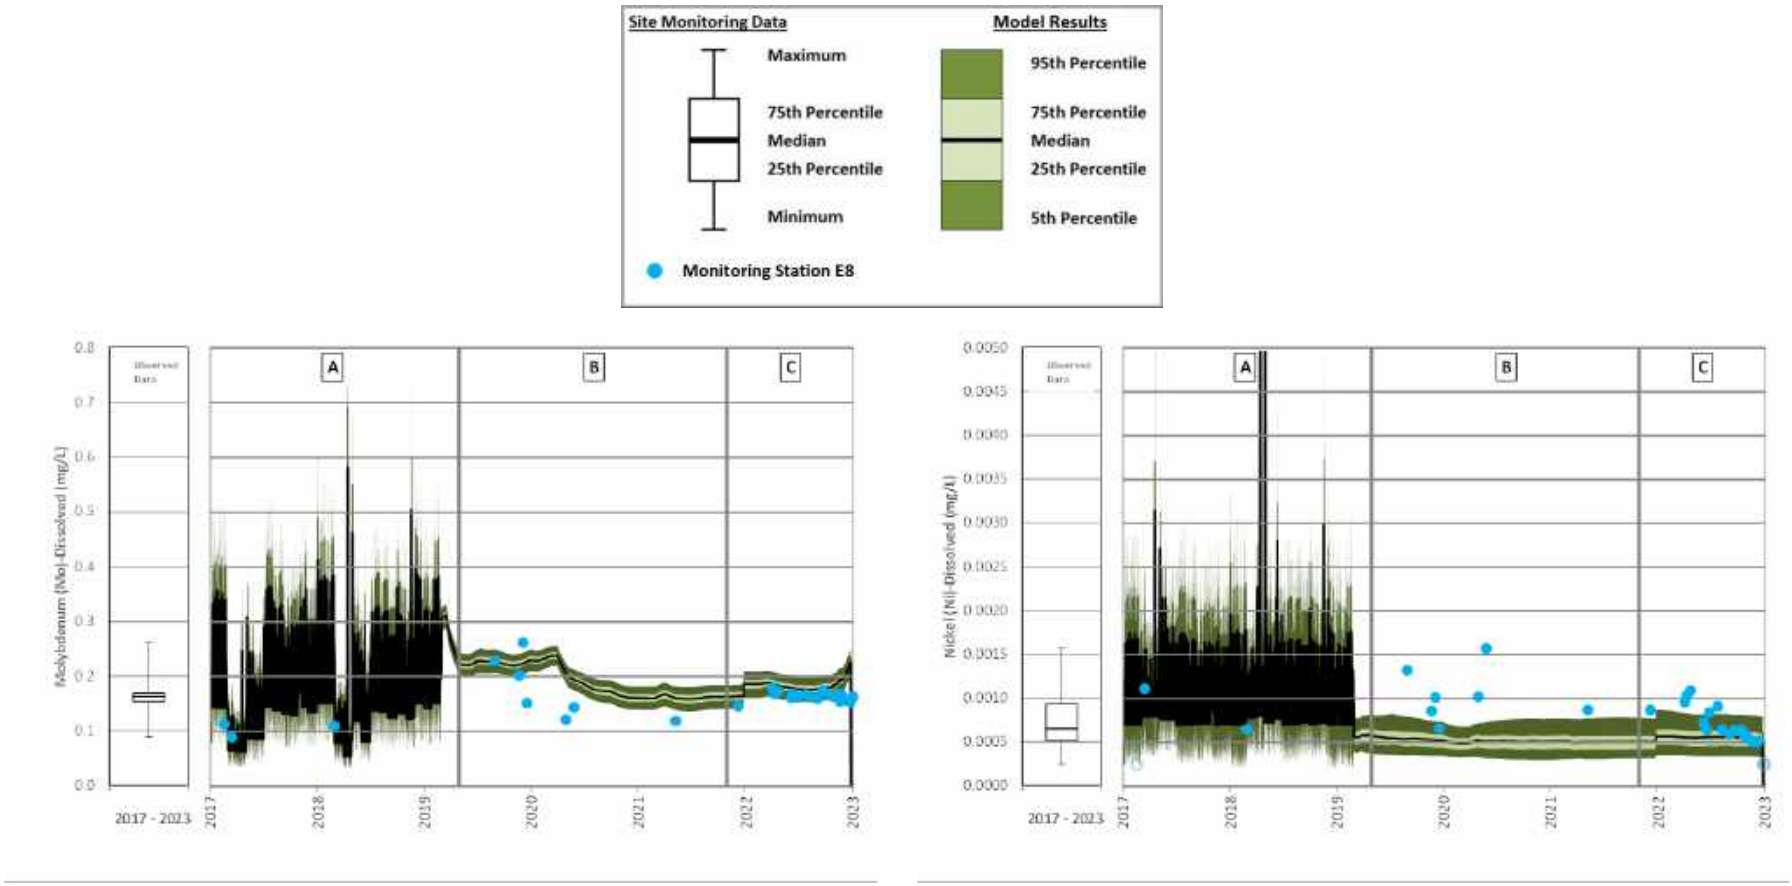

Figure A 33: Cariboo Pit Calibration – Dissolved Lead and Dissolved Lithium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved manganese concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

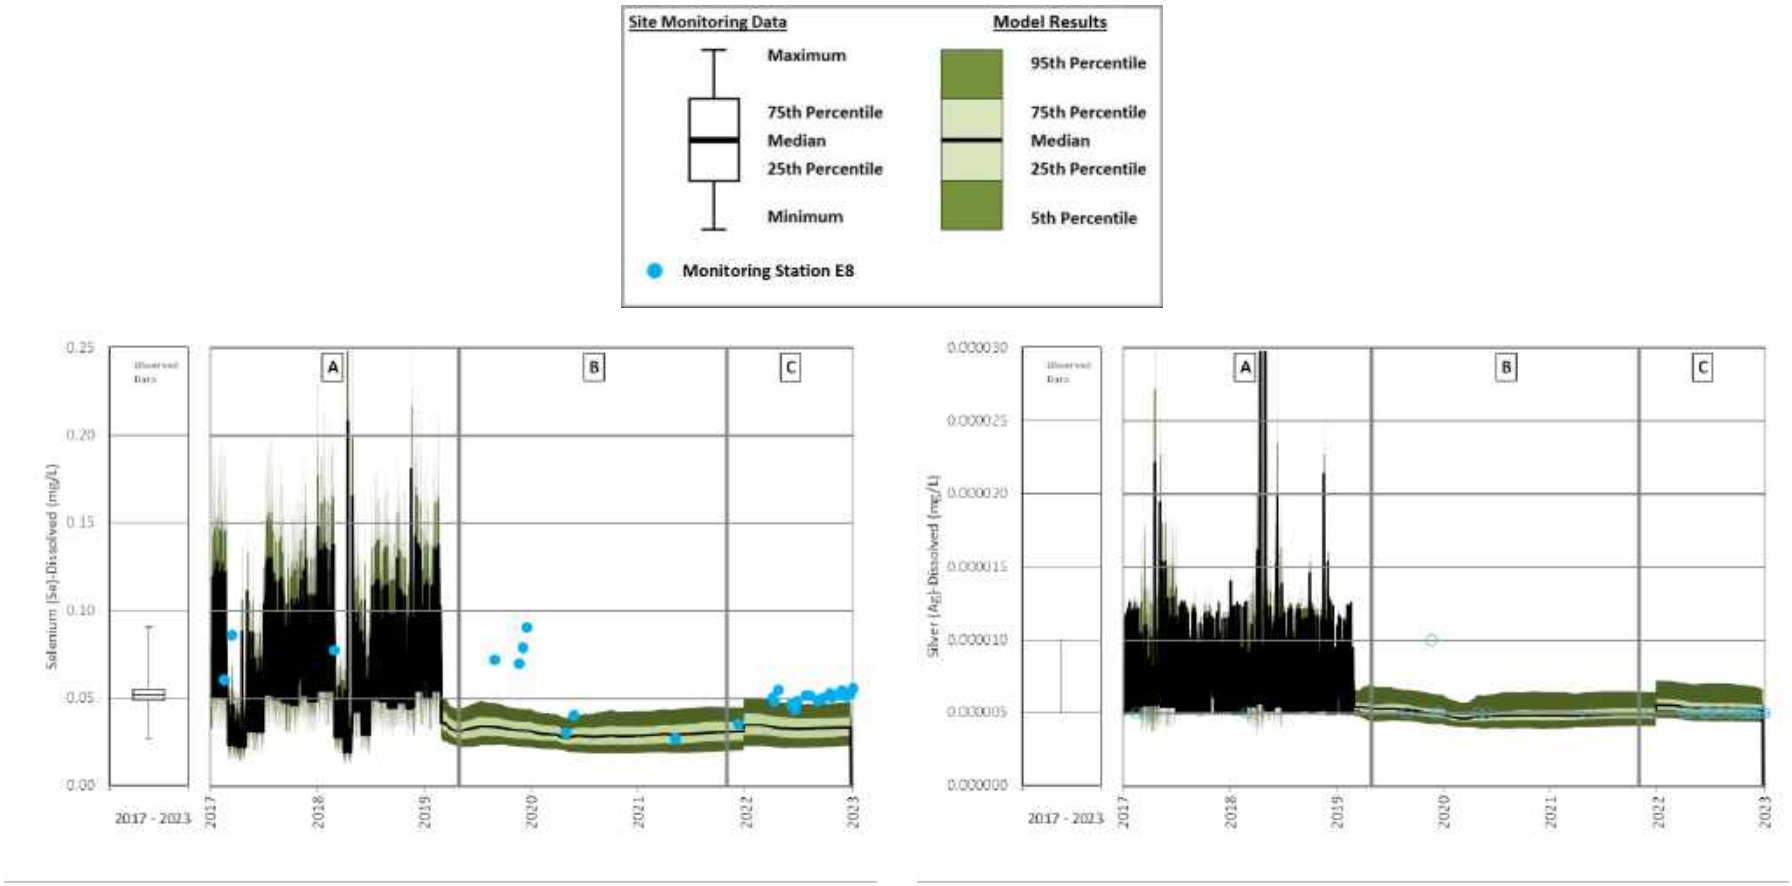

Figure A 34: Cariboo Pit Calibration – Dissolved Manganese and Dissolved Mercury

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved molybdenum and dissolved nickel concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

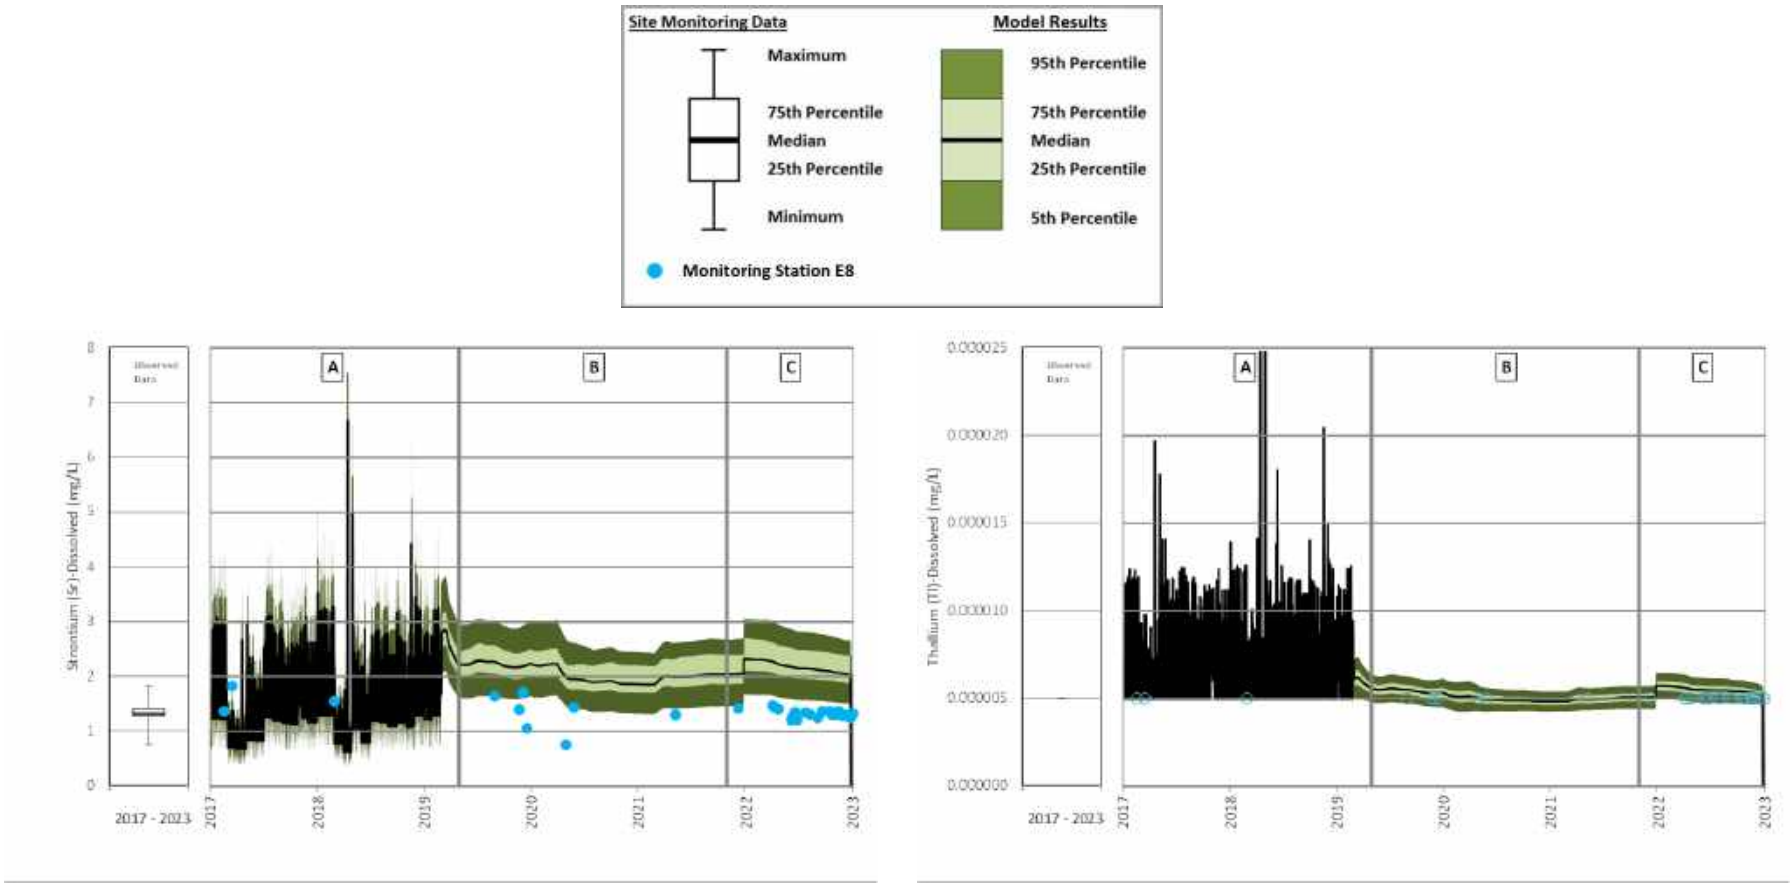

Figure A 35: Cariboo Pit Calibration – Dissolved Molybdenum and Dissolved Nickel

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved selenium and dissolved silver concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

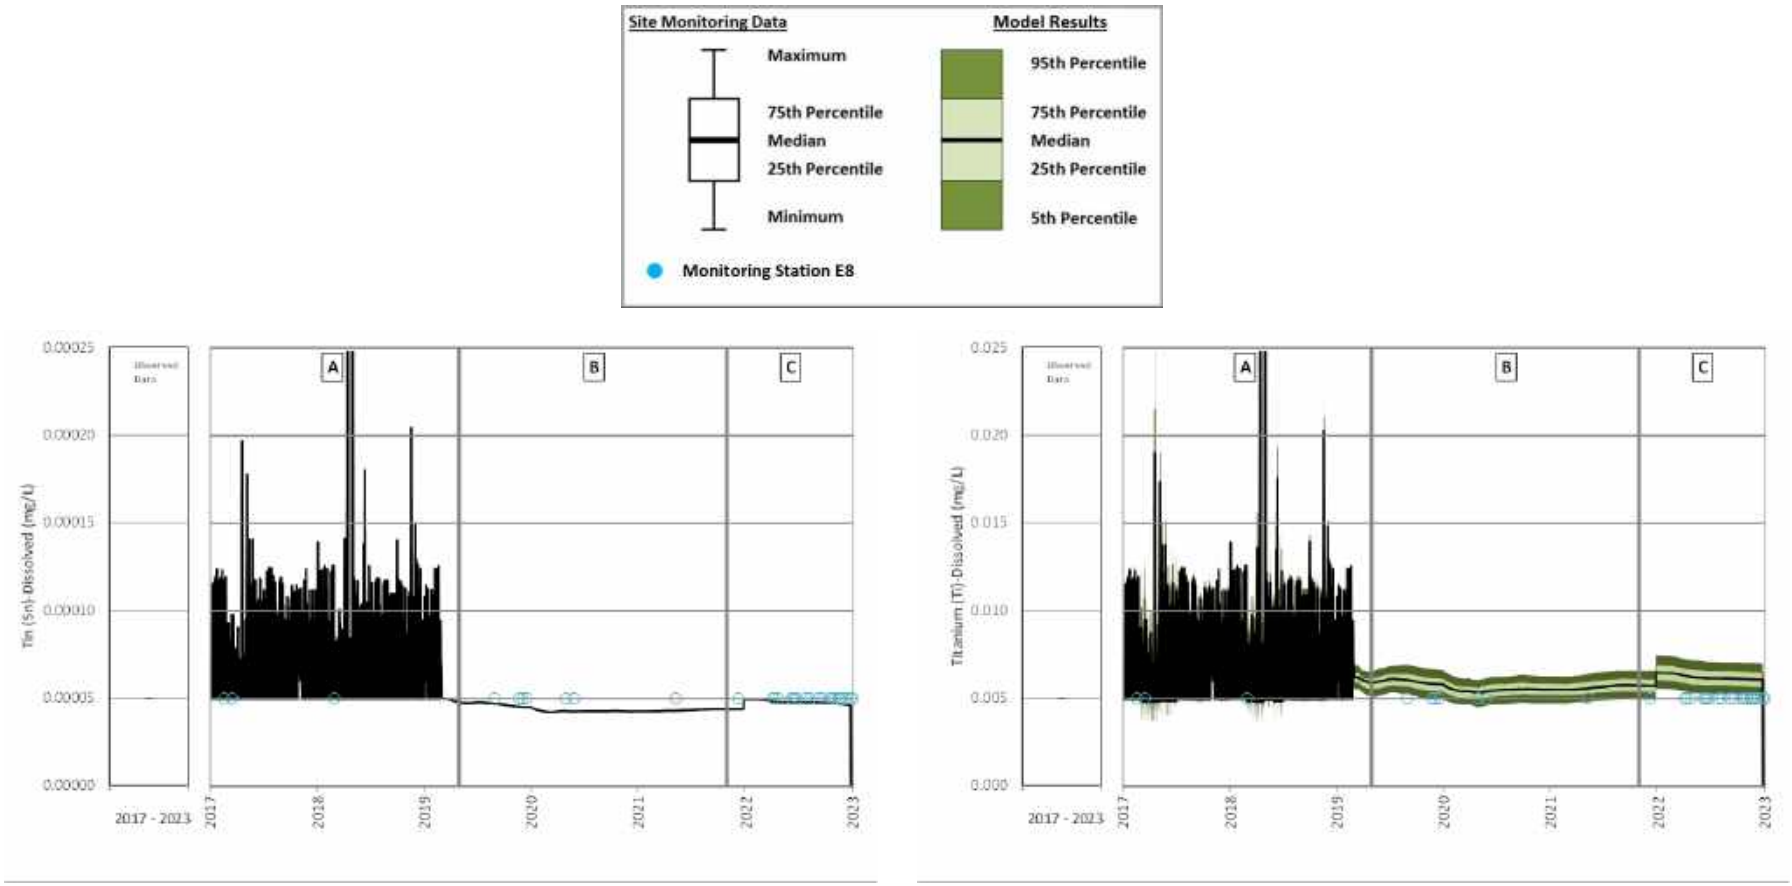

Figure A 36: Cariboo Pit Calibration – Dissolved Selenium and Dissolved Silver

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved strontium and dissolved thallium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

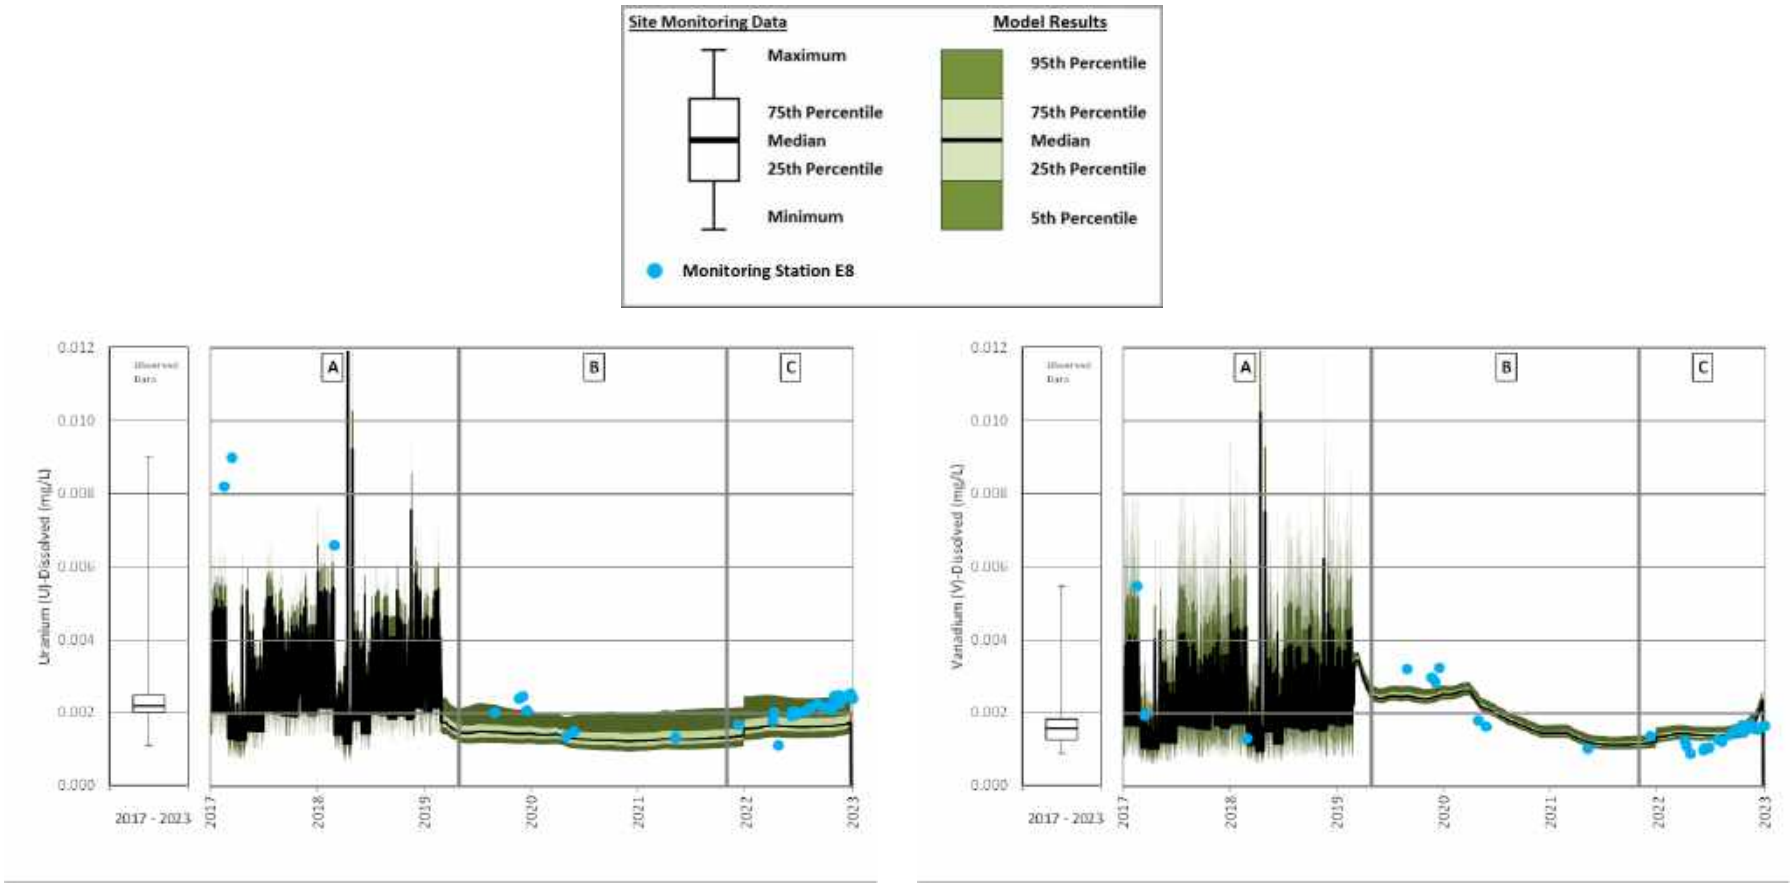

Figure A 37: Cariboo Pit Calibration – Dissolved Strontium and Dissolved Thallium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved titanium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

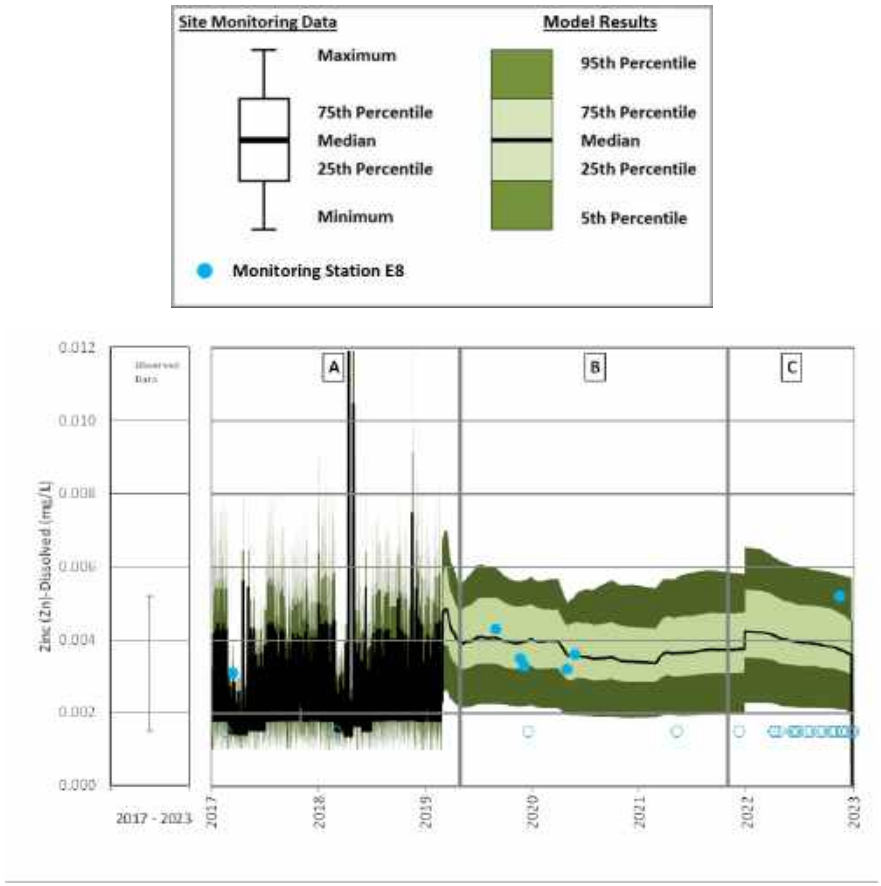

Figure A 38: Cariboo Pit Calibration – Dissolved Tin and Dissolved Titanium

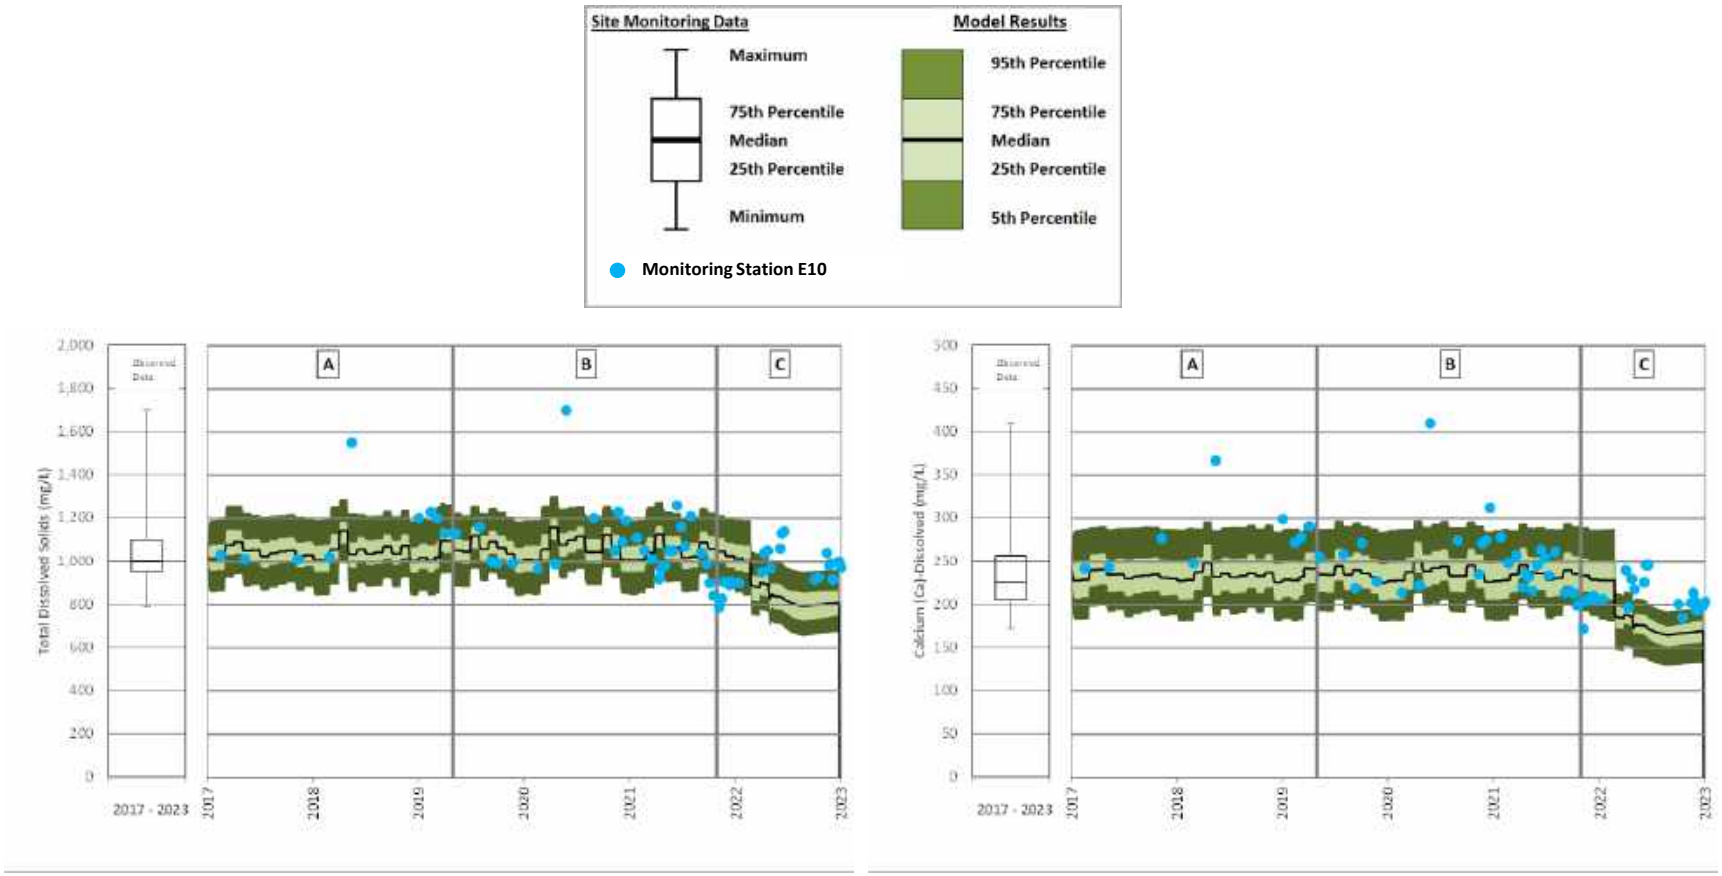
A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved uranium and dissolved vanadium concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

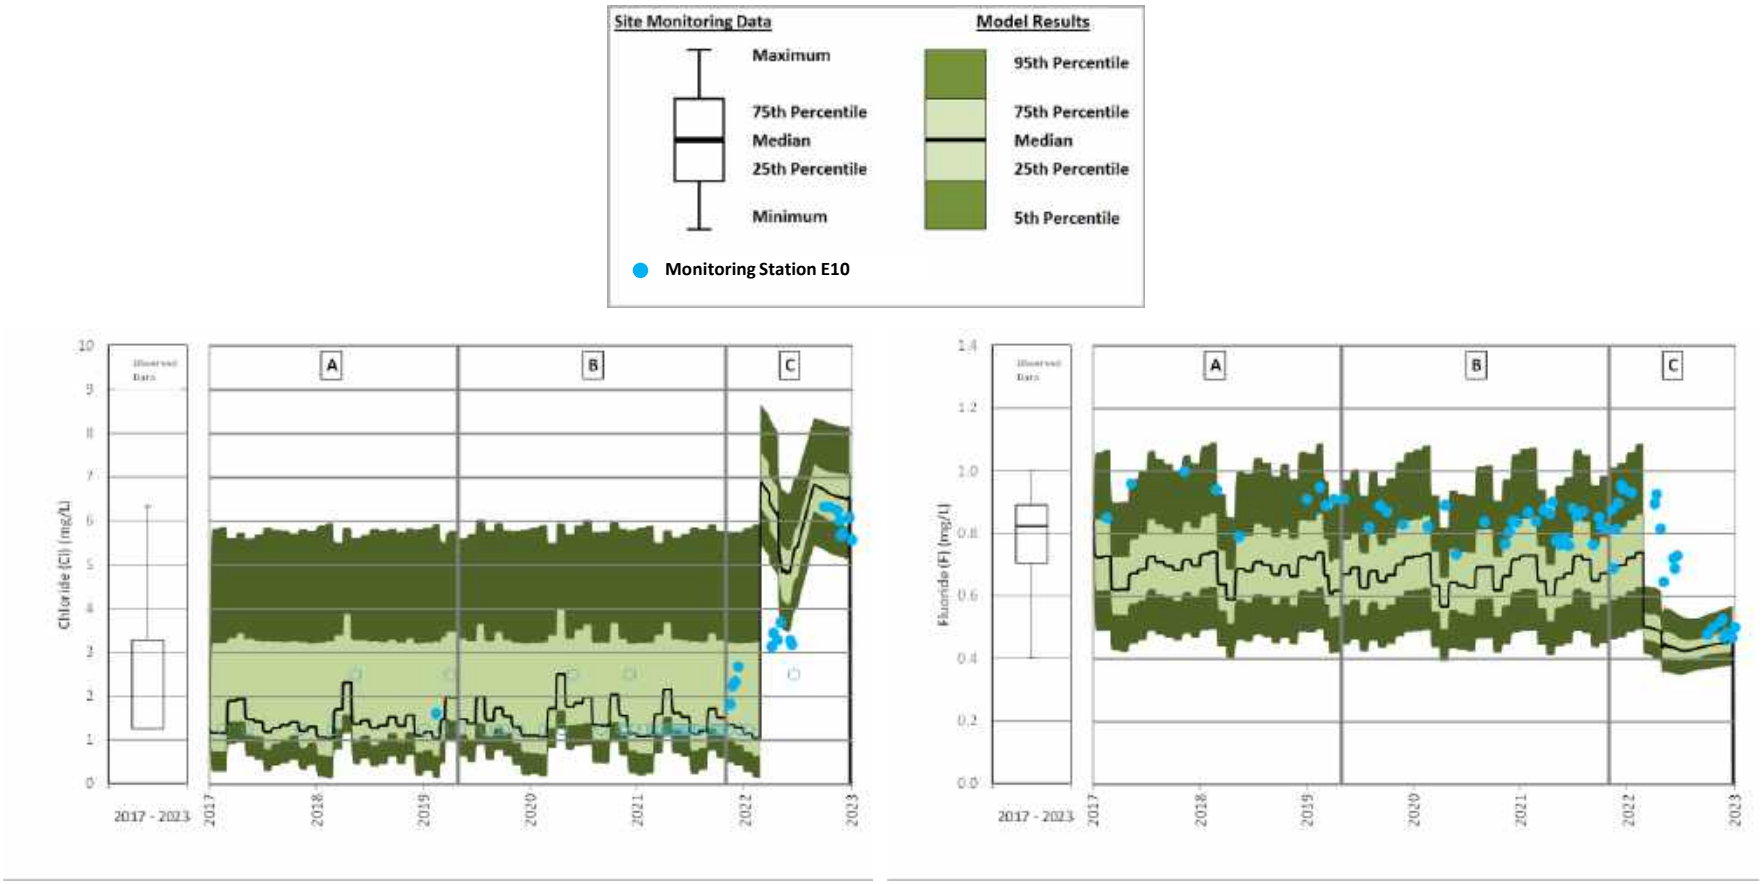
Figure A 39: Cariboo Pit Calibration – Dissolved Uranium and Dissolved Vanadium



A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Cariboo Pit is a flow-through system until March 2019 when the Tailings Storage Facility (TSF) is pumped to Cariboo Pit. Dissolved zinc concentrations increase in 2022 because of pumping from Springer Pit to Cariboo Pit.

Figure A 40: Cariboo Pit Calibration – Dissolved Zinc



Wight Pit Calibration

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Total dissolved solids and calcium decrease in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

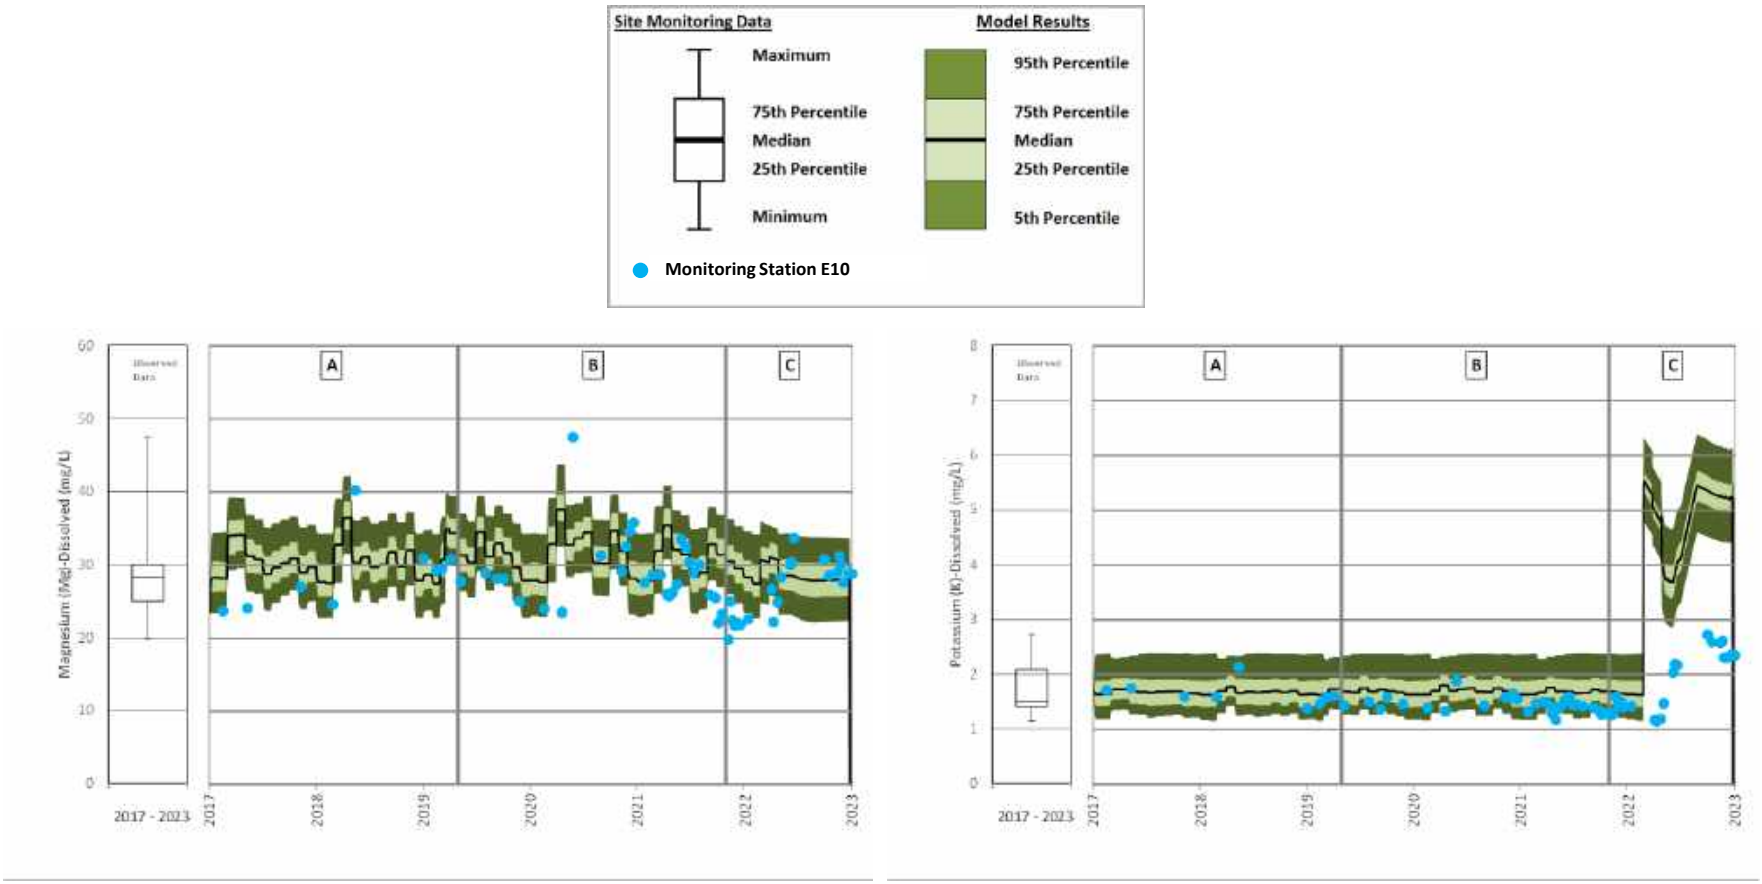


Figure A 41: Wight Pit Calibration – Total Dissolved Solids and Calcium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Chloride concentrations increase in Wight Pit and fluoride concentrations decrease in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

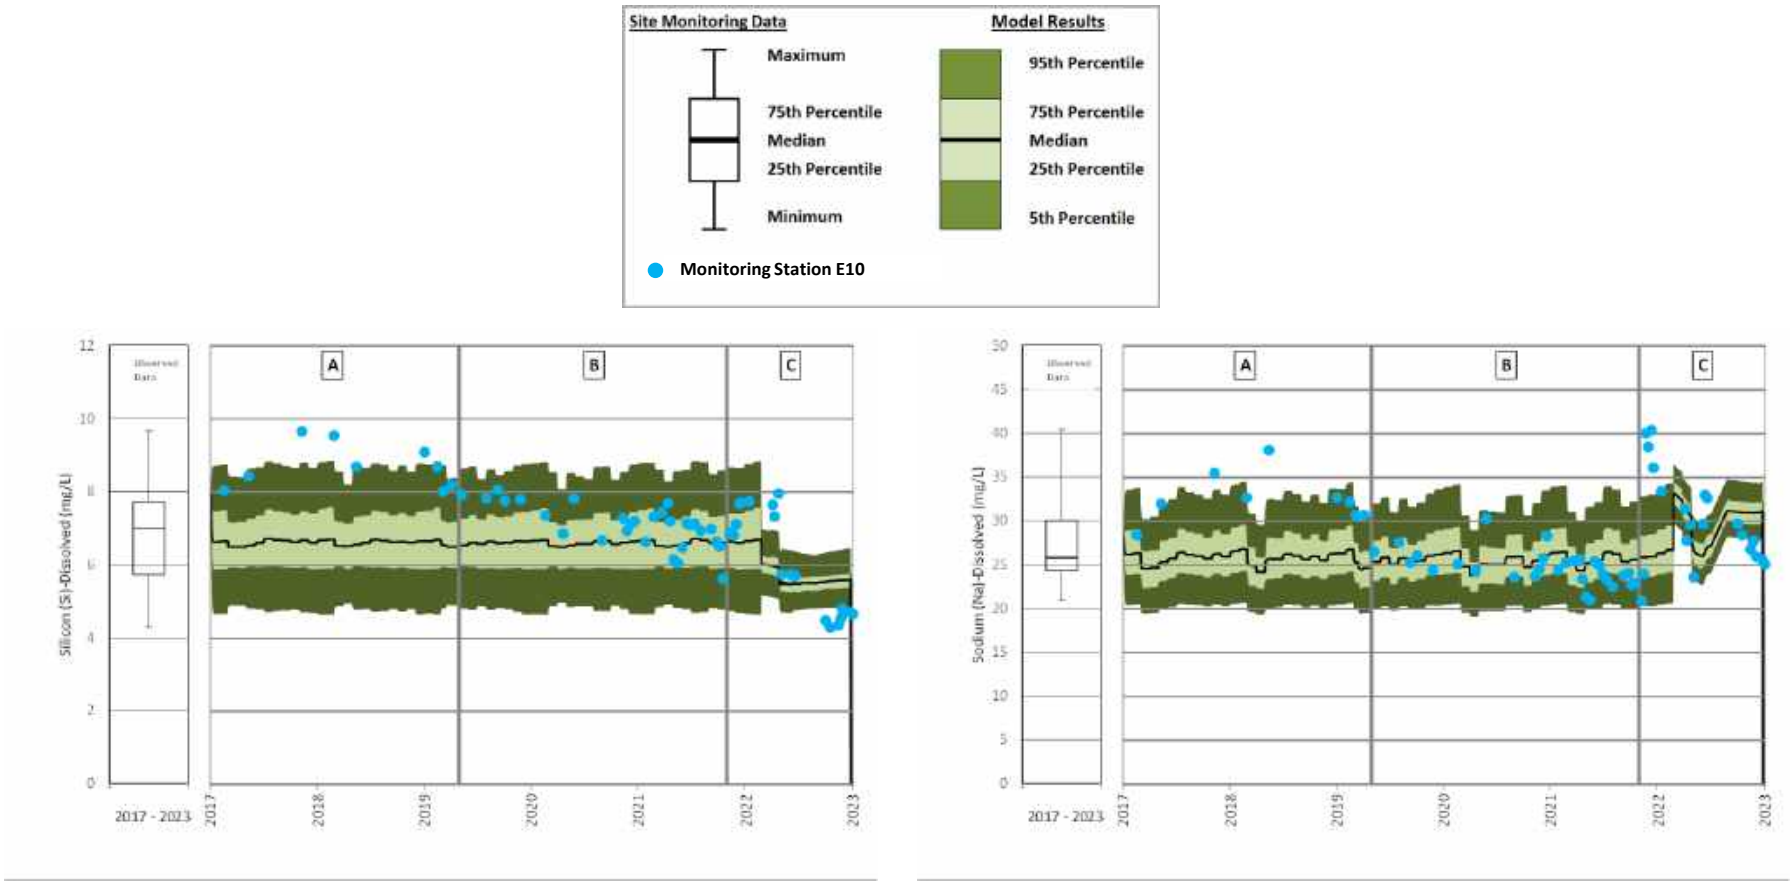

Figure A 42: Wight Pit Calibration – Chloride and Fluoride

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Potassium concentrations increase in Wight Pit decrease in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

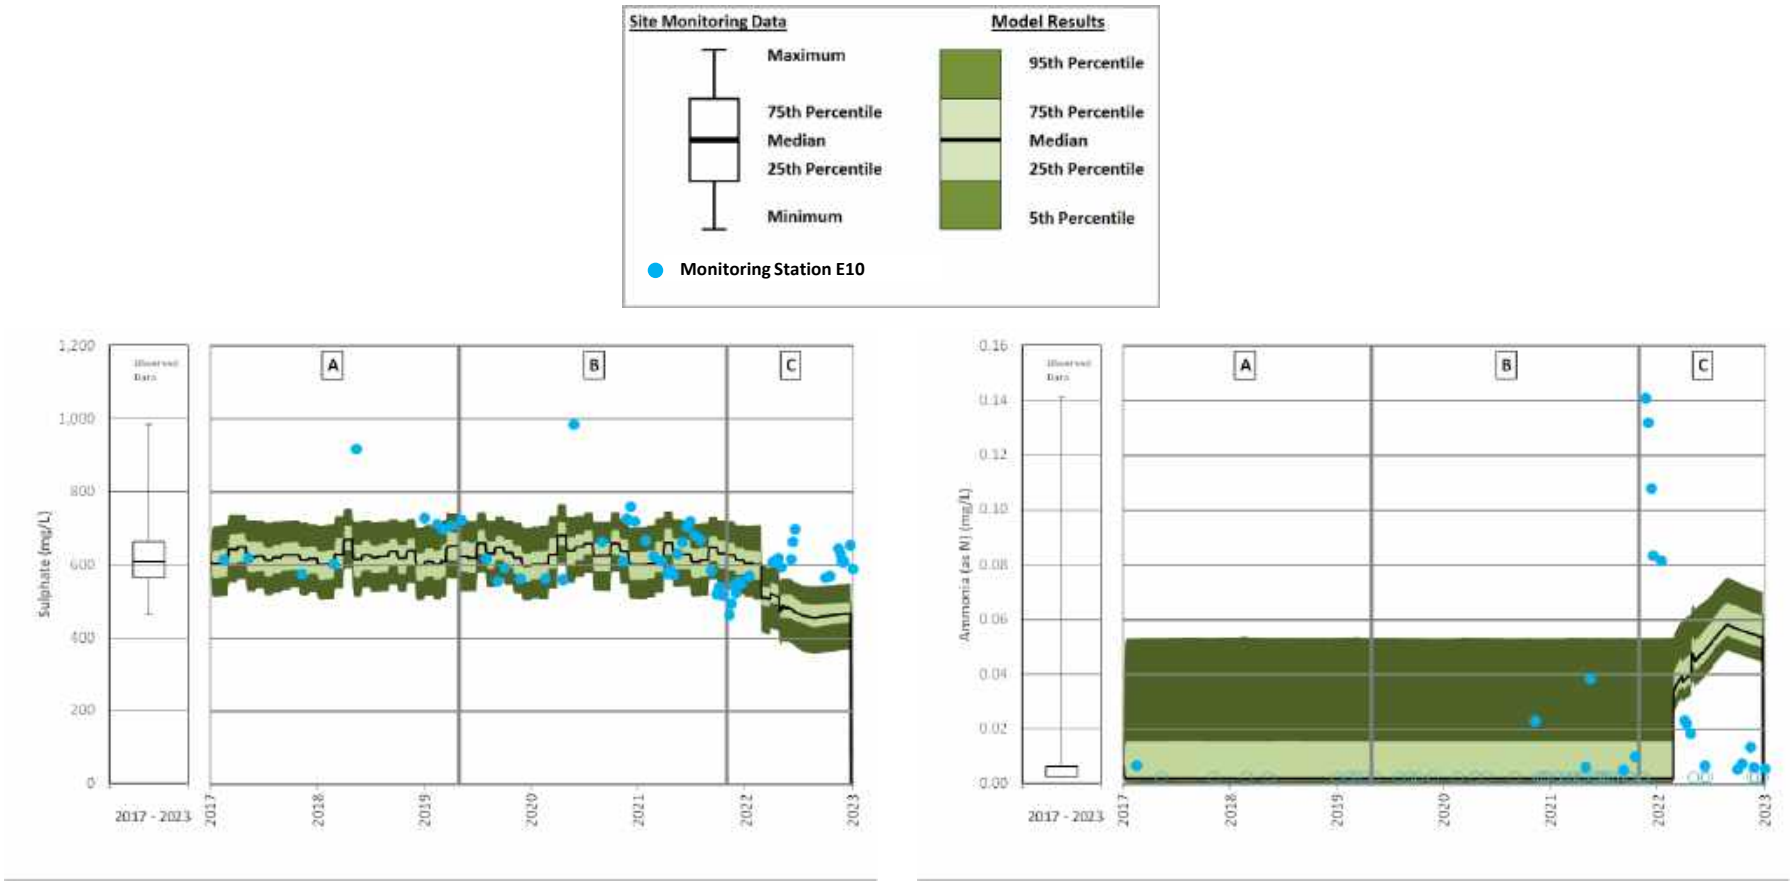

Figure A 43: Wight Pit Calibration – Magnesium and Potassium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Silicon concentrations decrease in Wight Pit and sodium concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

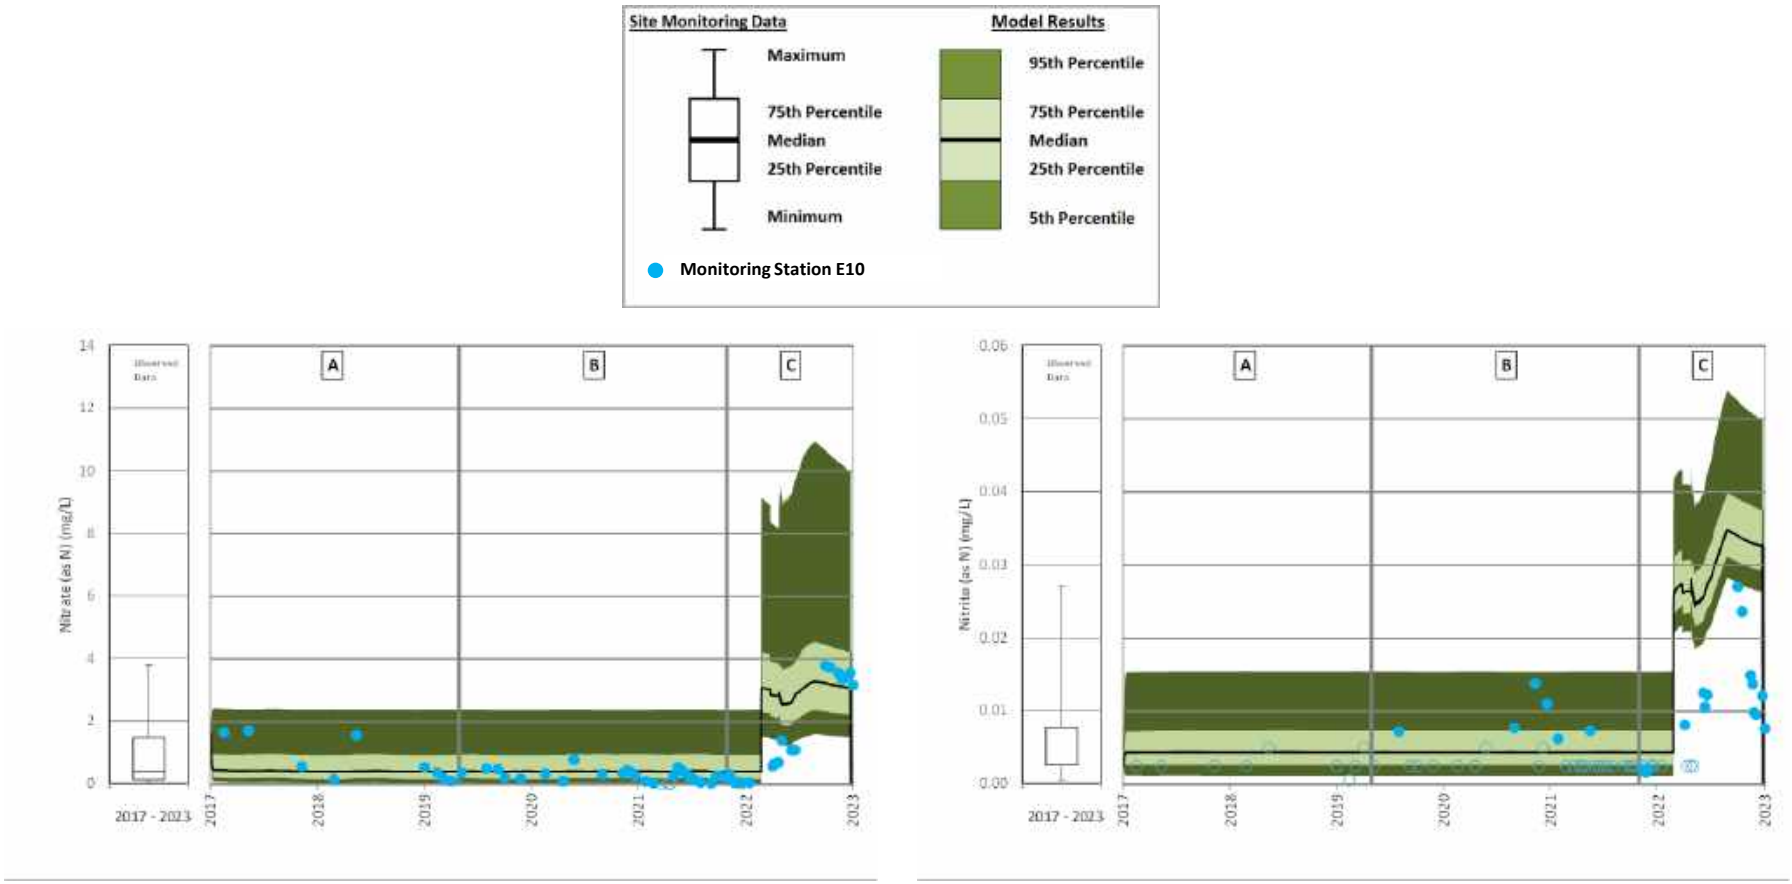

Figure A 44: Wight Pit Calibration – Silicon and Sodium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Sulphate concentrations decrease in Wight Pit and total ammonia concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

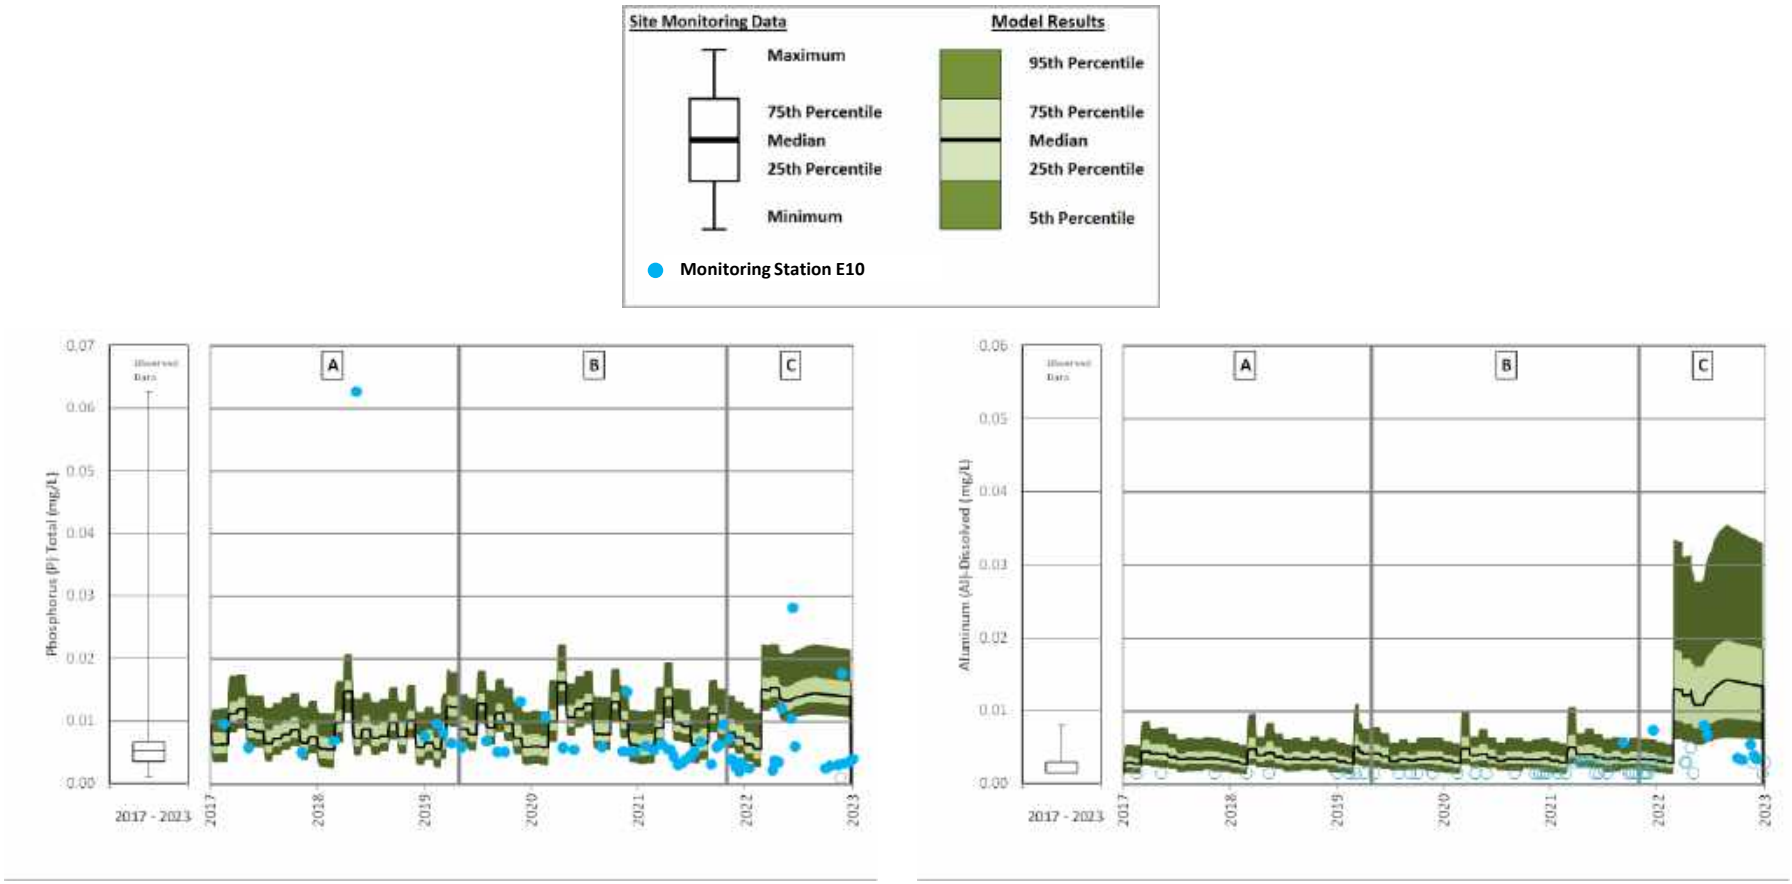

Figure A 45: Wight Pit Calibration – Sulphate and Total Ammonia

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Nitrate and nitrite concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

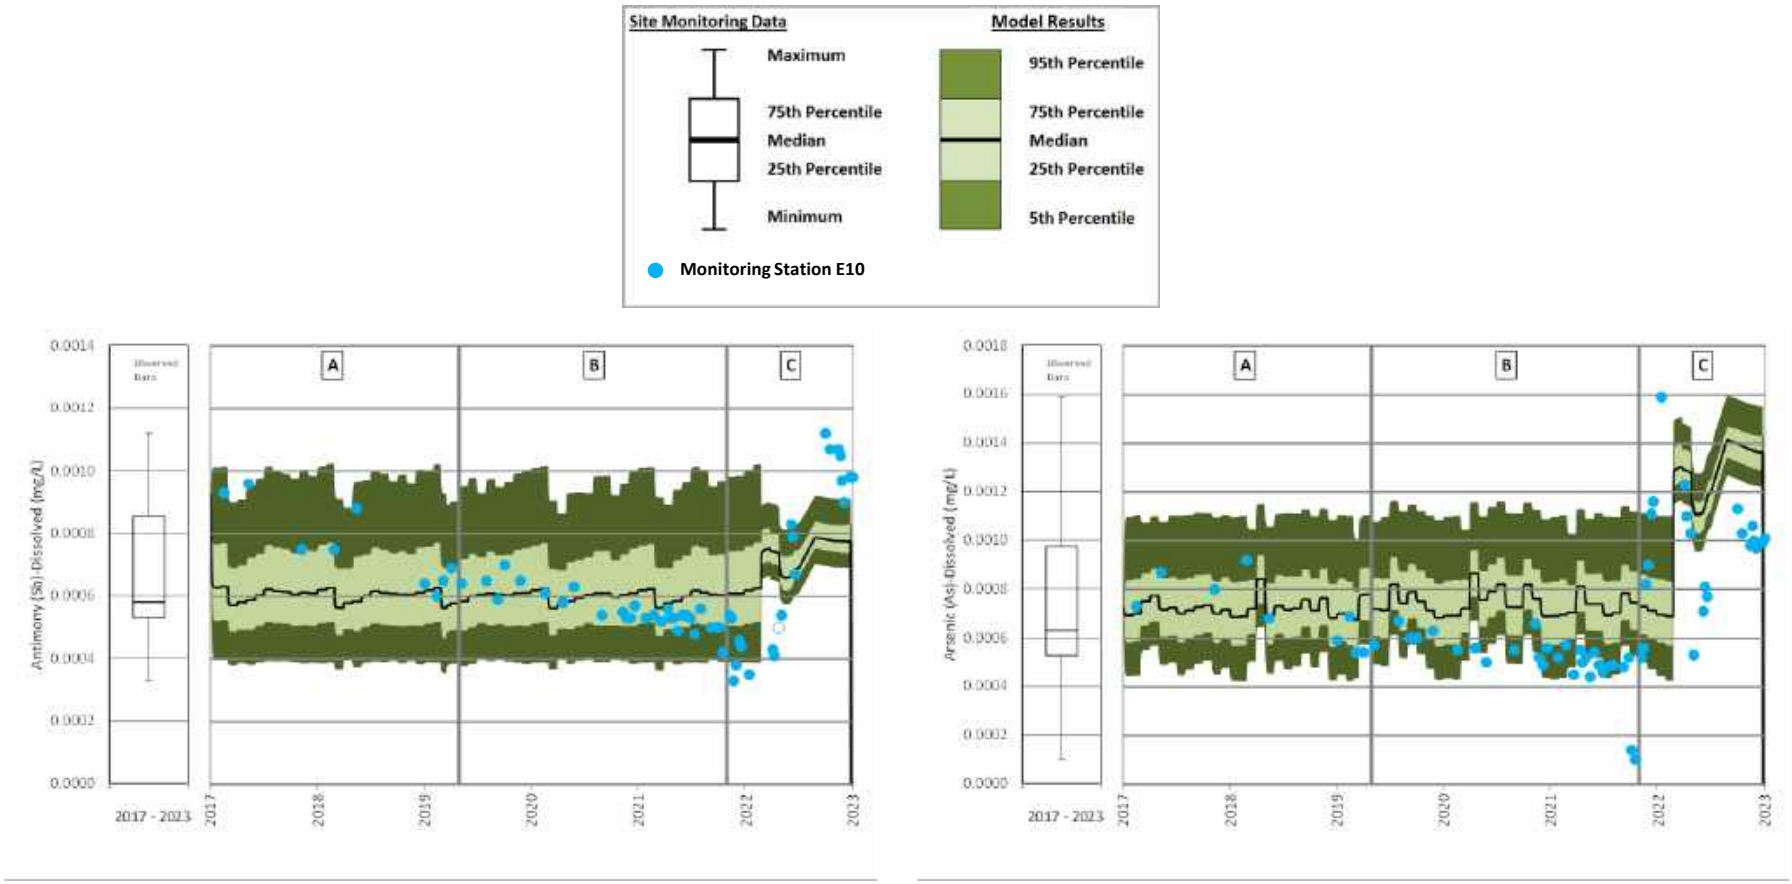

Figure A 46: Wight Pit Calibration – Nitrate and Nitrite

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Total phosphorus and dissolved aluminum concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

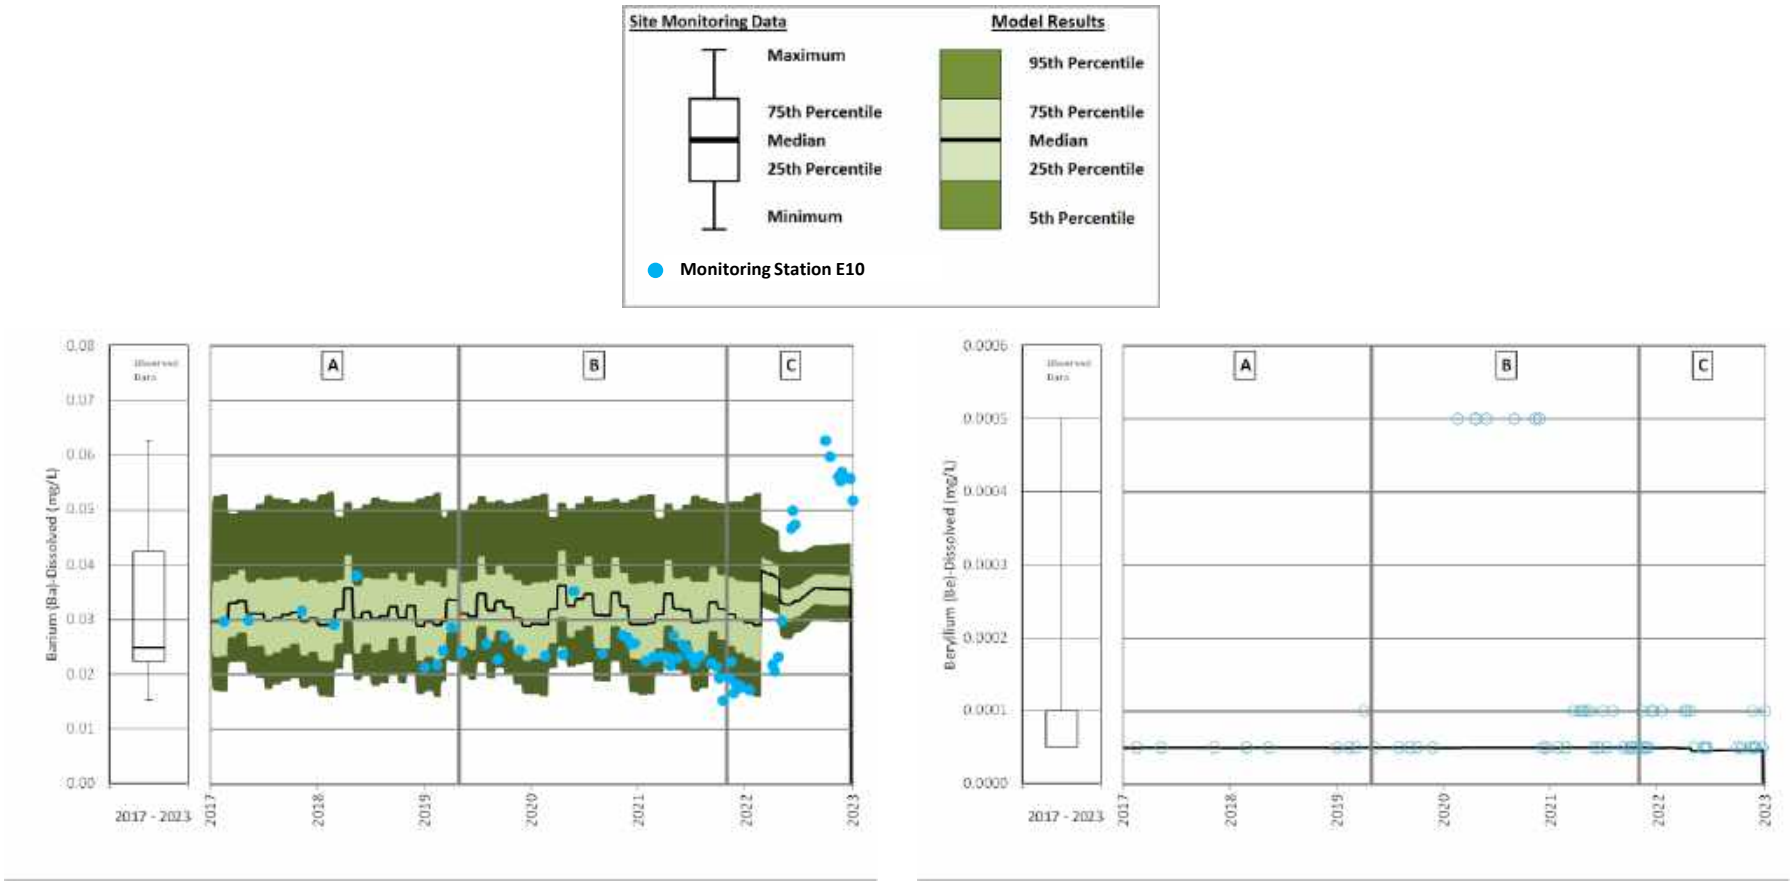

Figure A 47: Wight Pit Calibration – Total Phosphorus and Dissolved Aluminum

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved antimony and dissolved arsenic concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

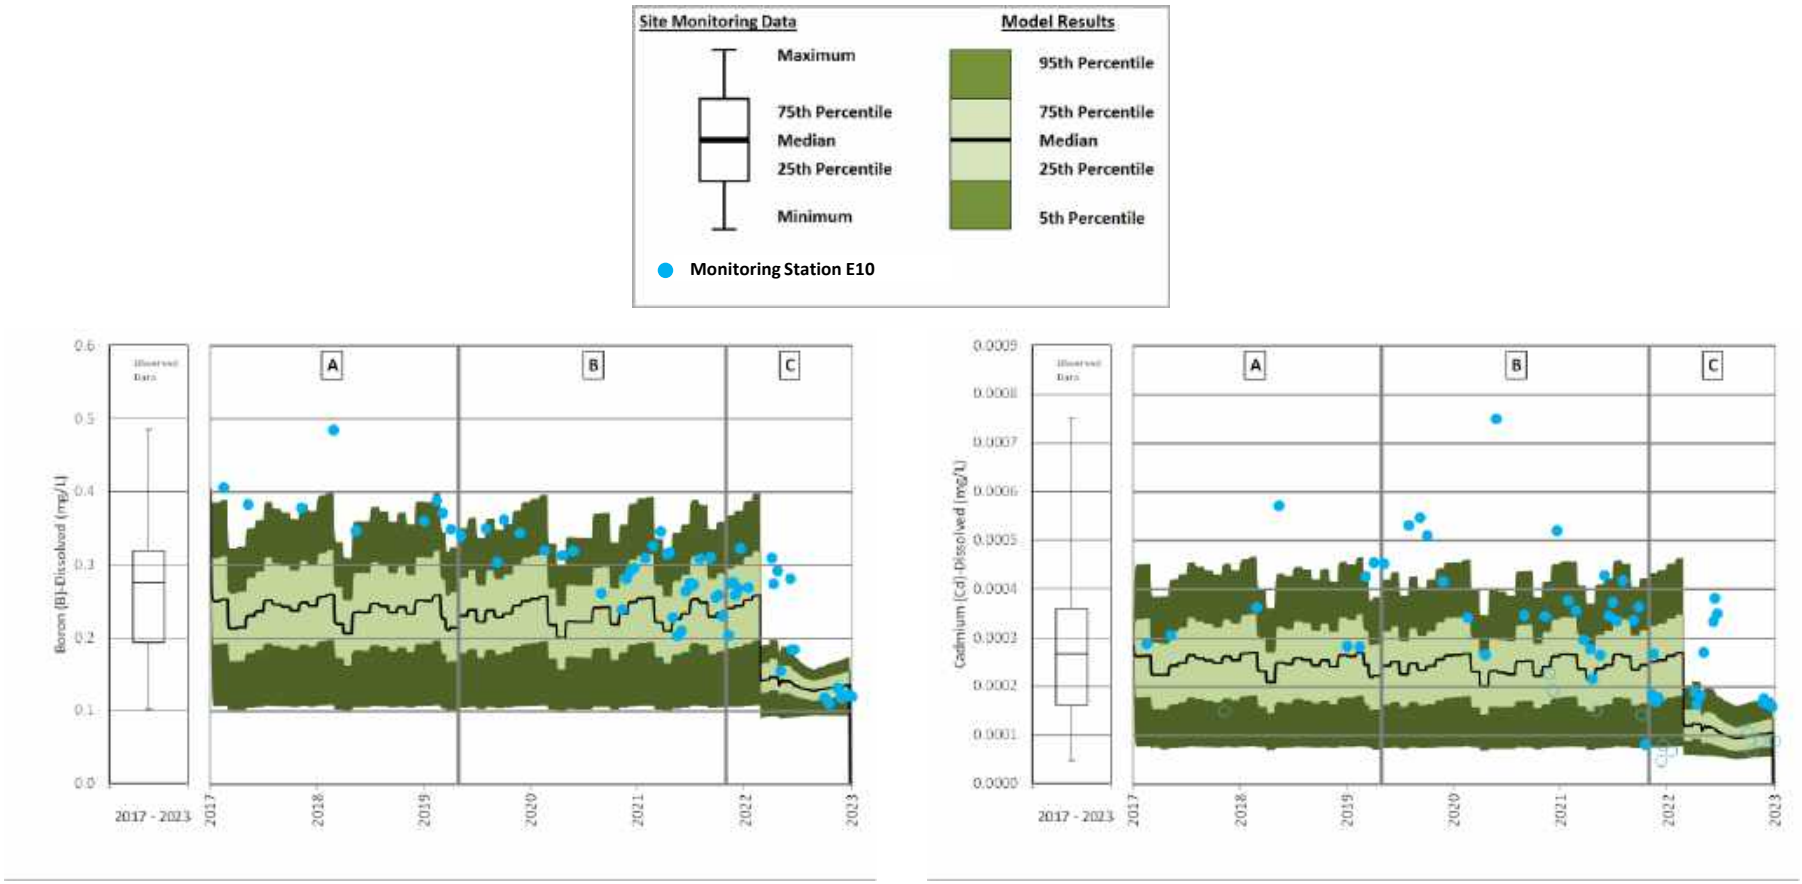

Figure A 48: Wight Pit Calibration – Dissolved Antimony and Dissolved Arsenic

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved barium concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

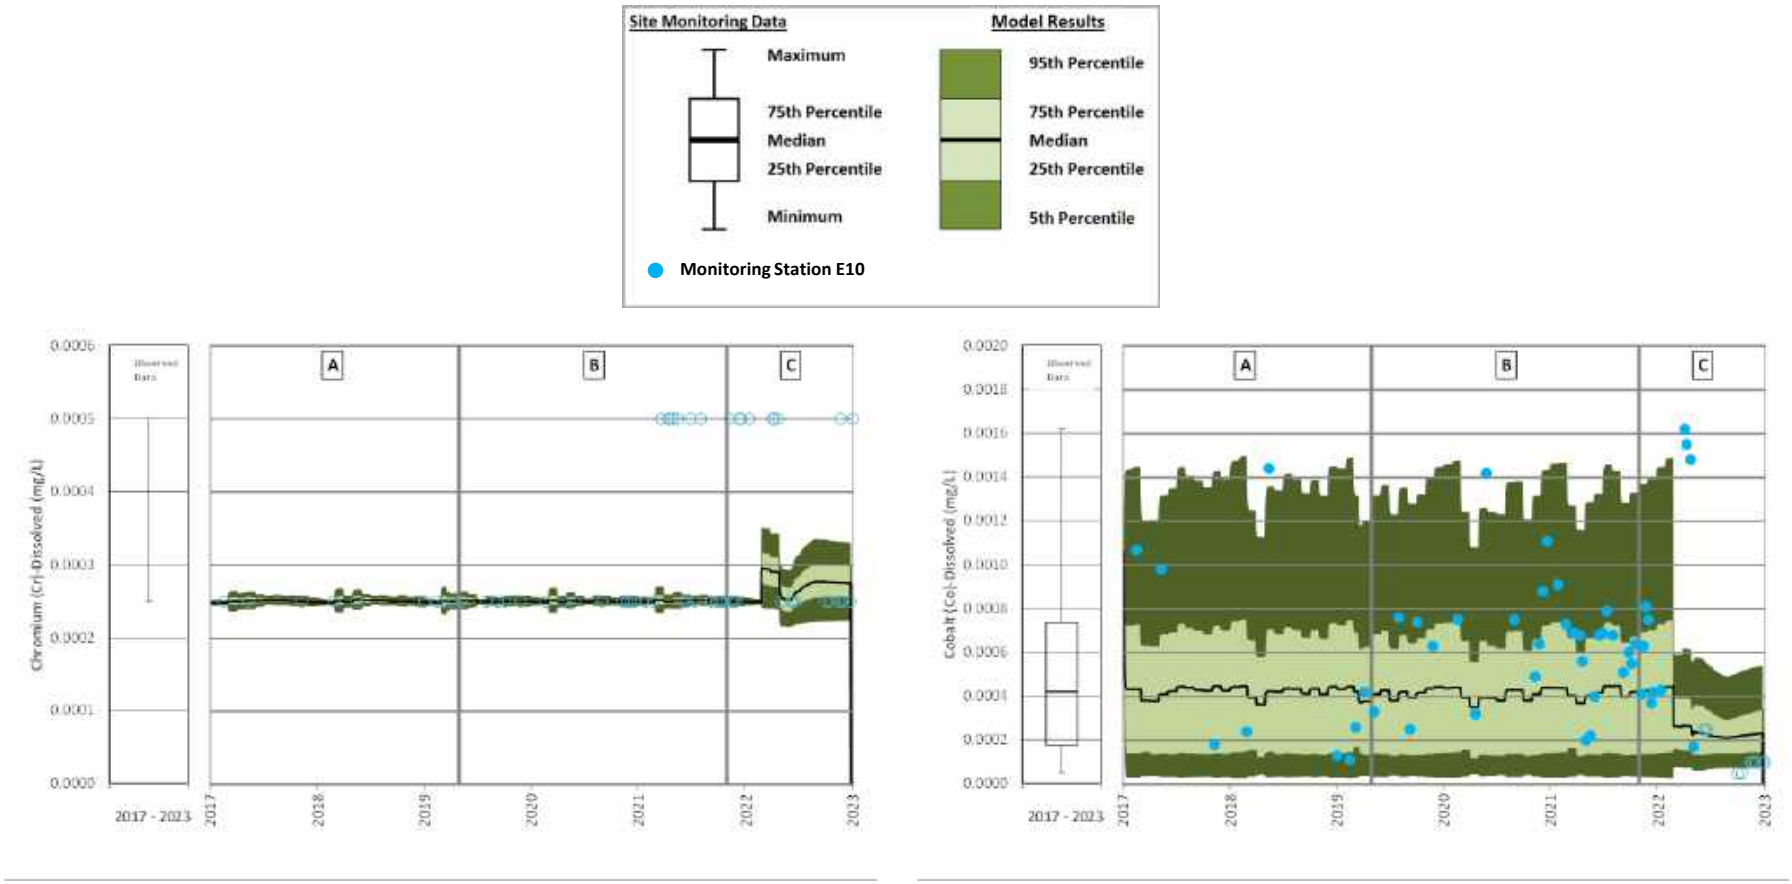

Figure A 49: Wight Pit Calibration – Dissolved Barium and Dissolved Beryllium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved boron and dissolved cadmium concentrations decrease in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

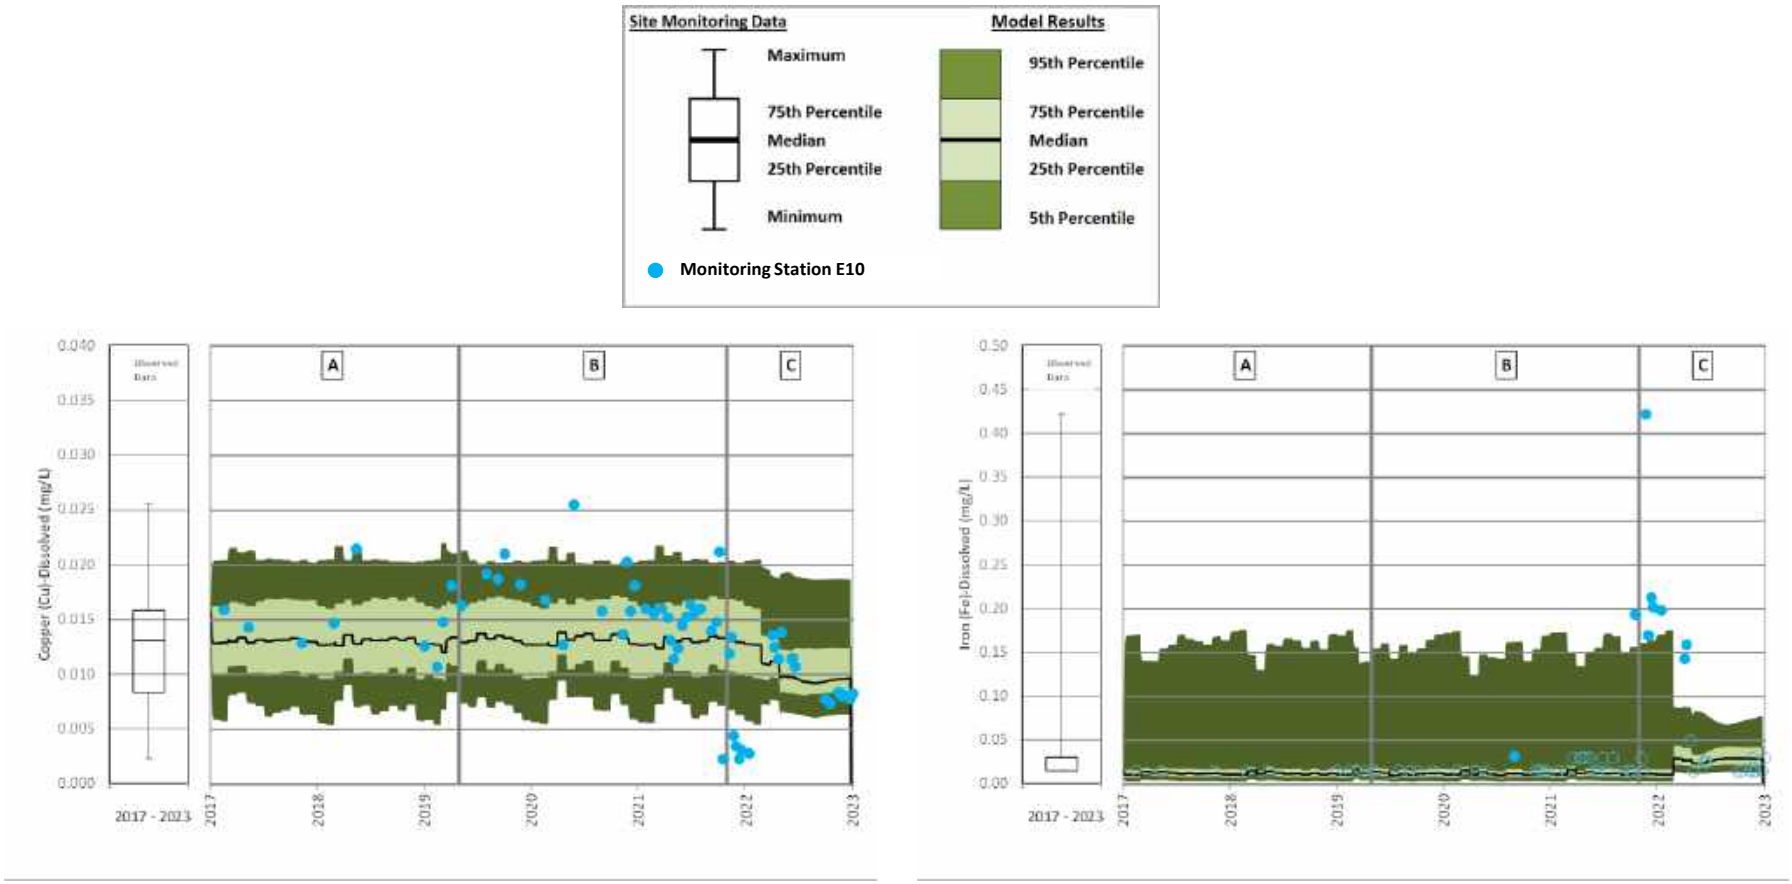

Figure A 50: Wight Pit Calibration – Dissolved Boron and Dissolved Cadmium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved chromium concentrations increase in Wight Pit and dissolved cobalt concentrations decrease at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

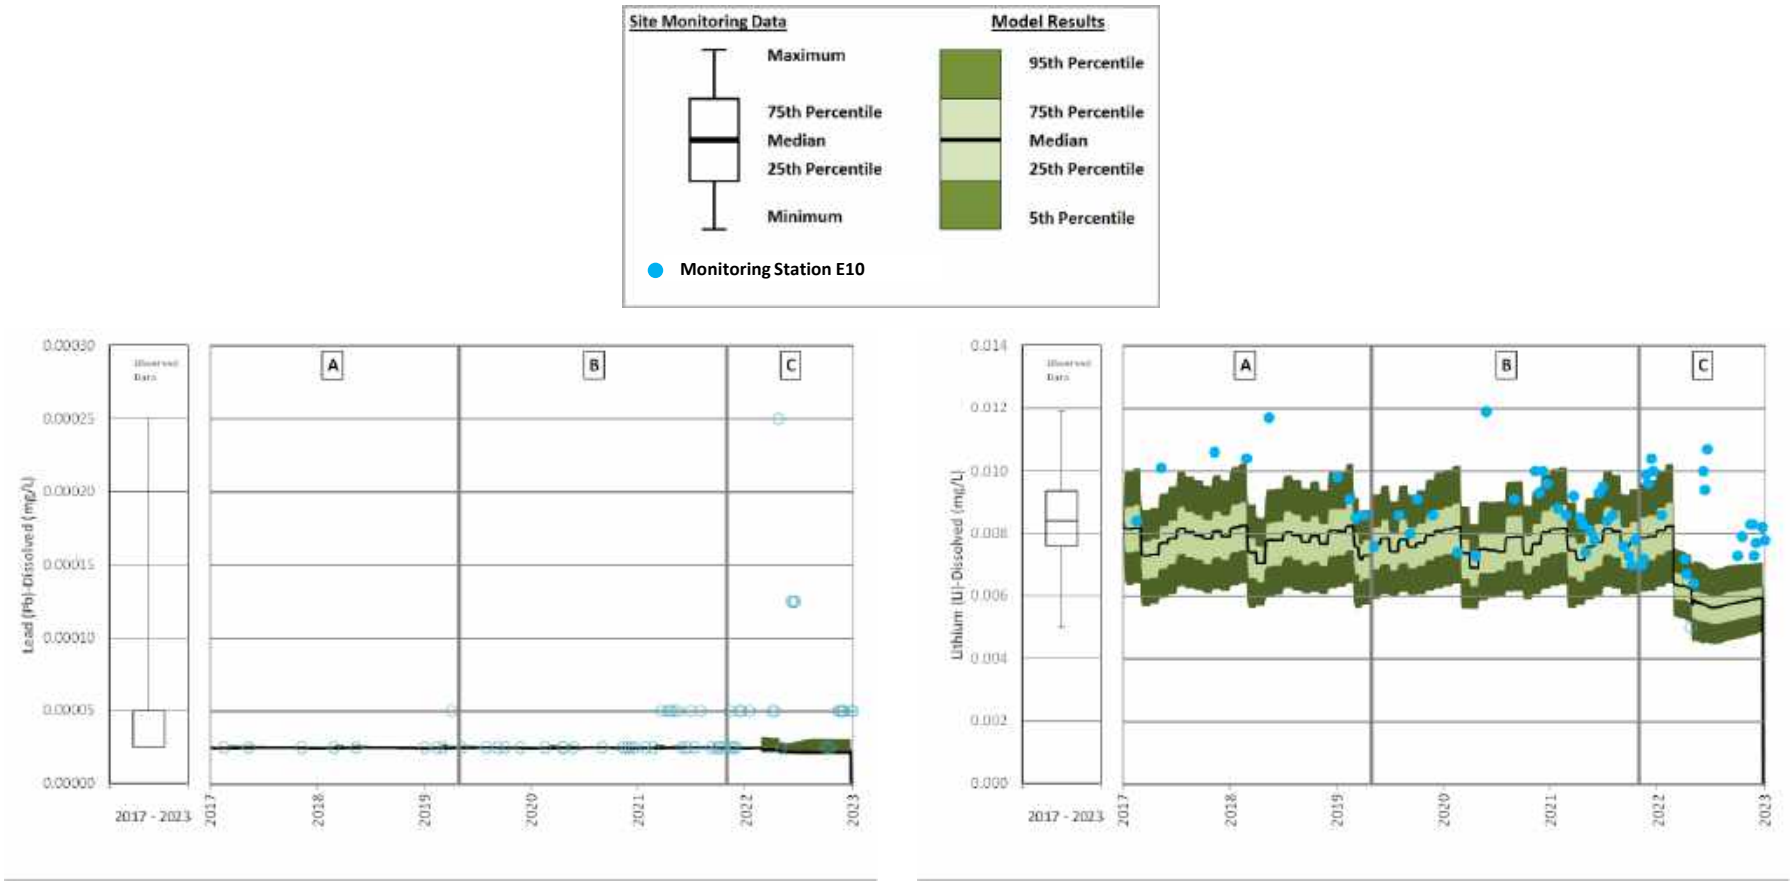

Figure A 51: Wight Pit Calibration – Dissolved Chromium and Dissolved Cobalt

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved copper concentrations increase in Wight Pit and dissolved iron concentrations decrease at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

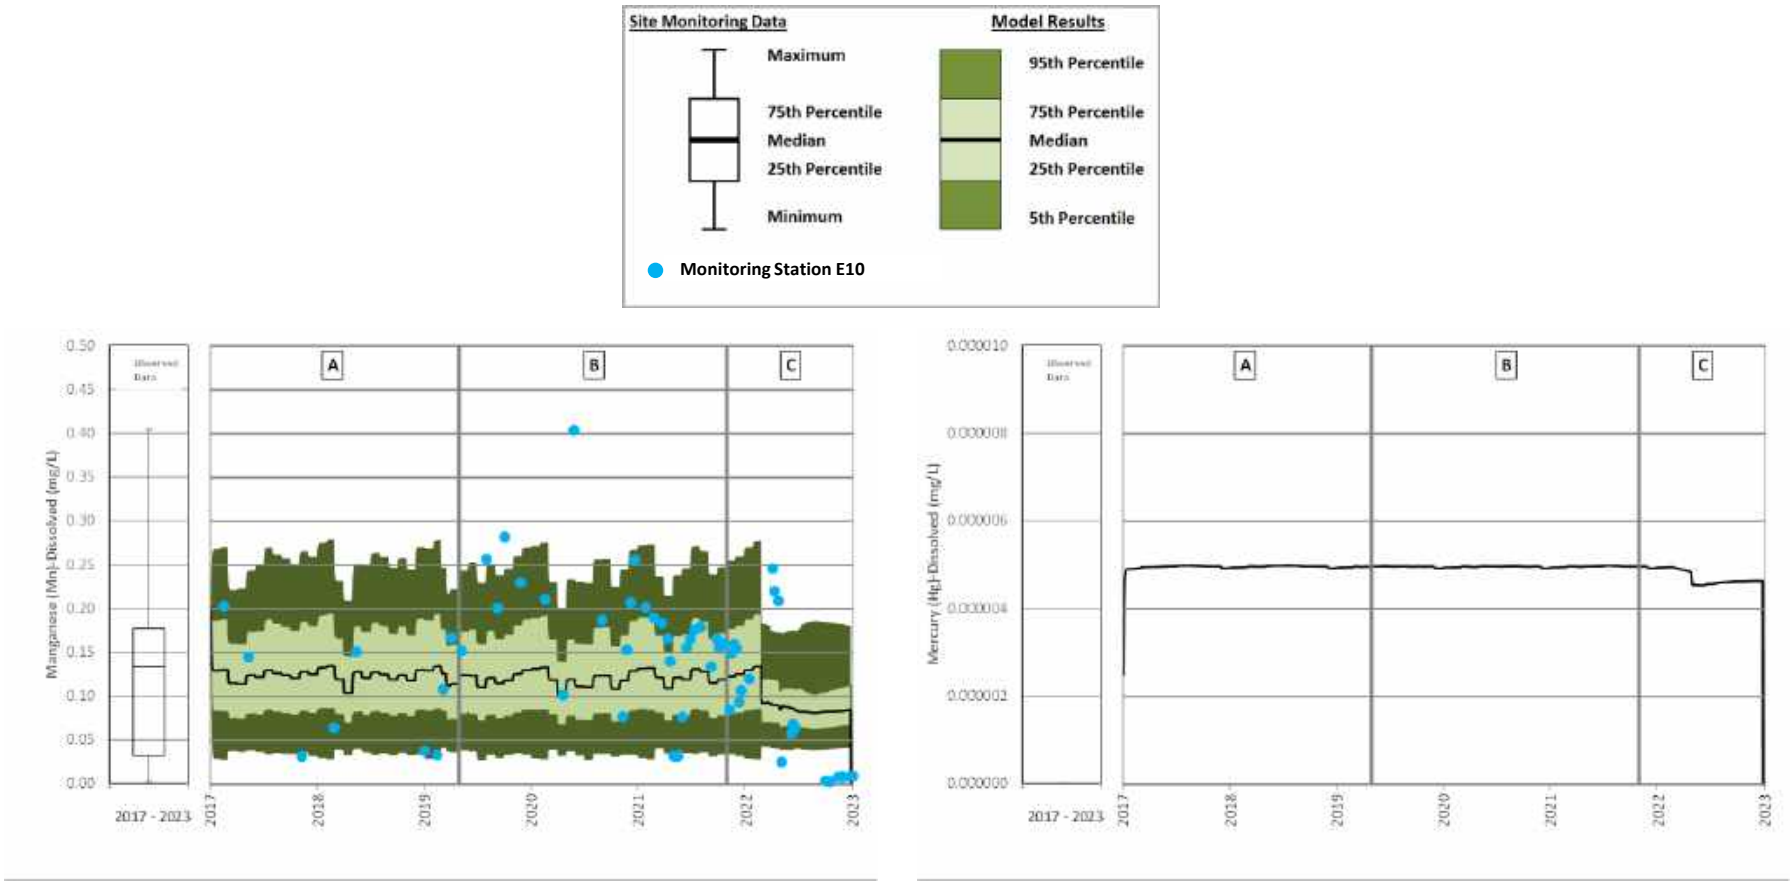

Figure A 52: Wight Pit Calibration – Dissolved Copper and Dissolved Iron

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved lithium concentrations decrease in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

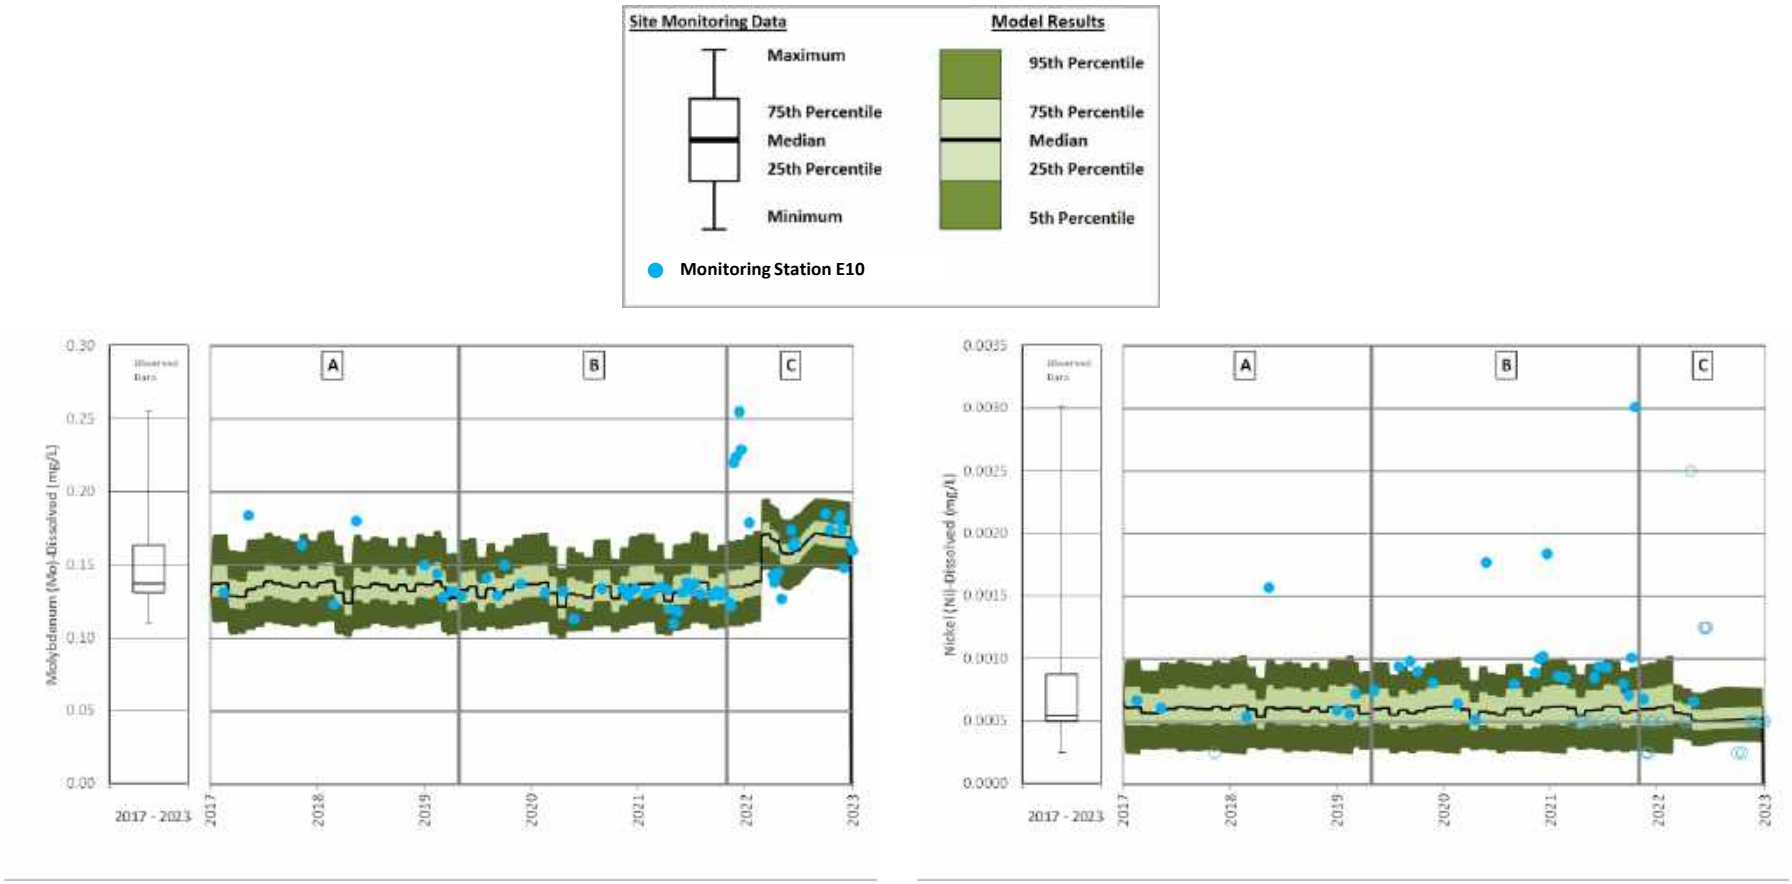

Figure A 53: Wight Pit Calibration – Dissolved Lead and Dissolved Lithium

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved manganese concentrations decrease in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

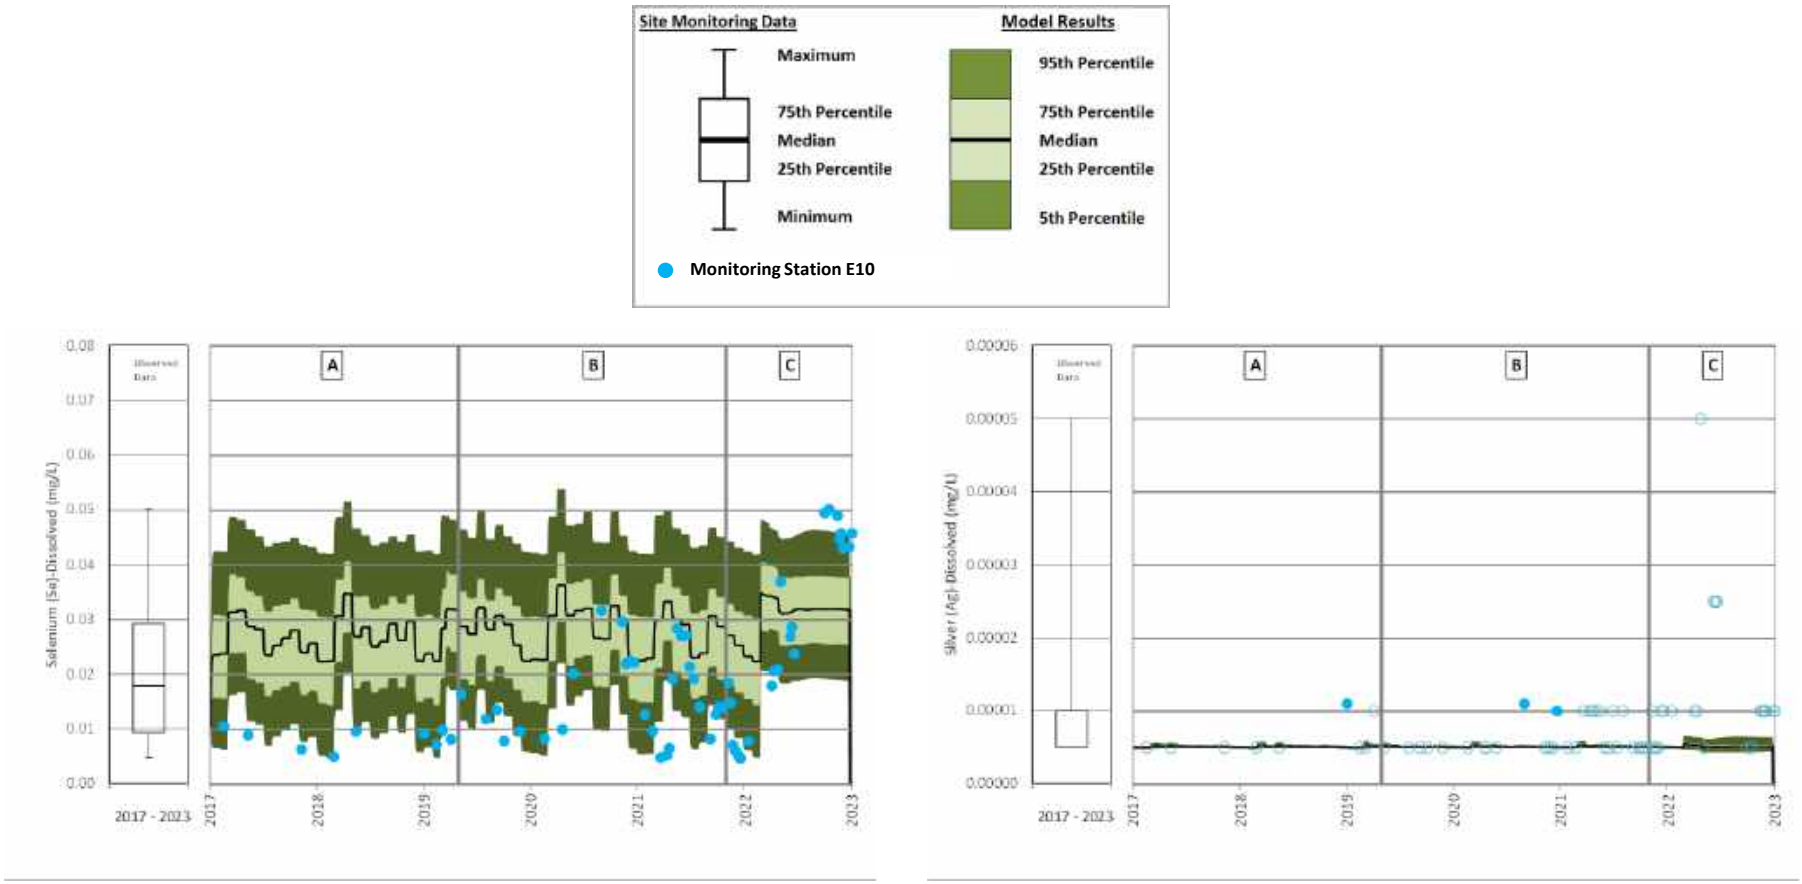

Figure A 54: Wight Pit Calibration – Dissolved Manganese and Dissolved Mercury

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved molybdenum concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

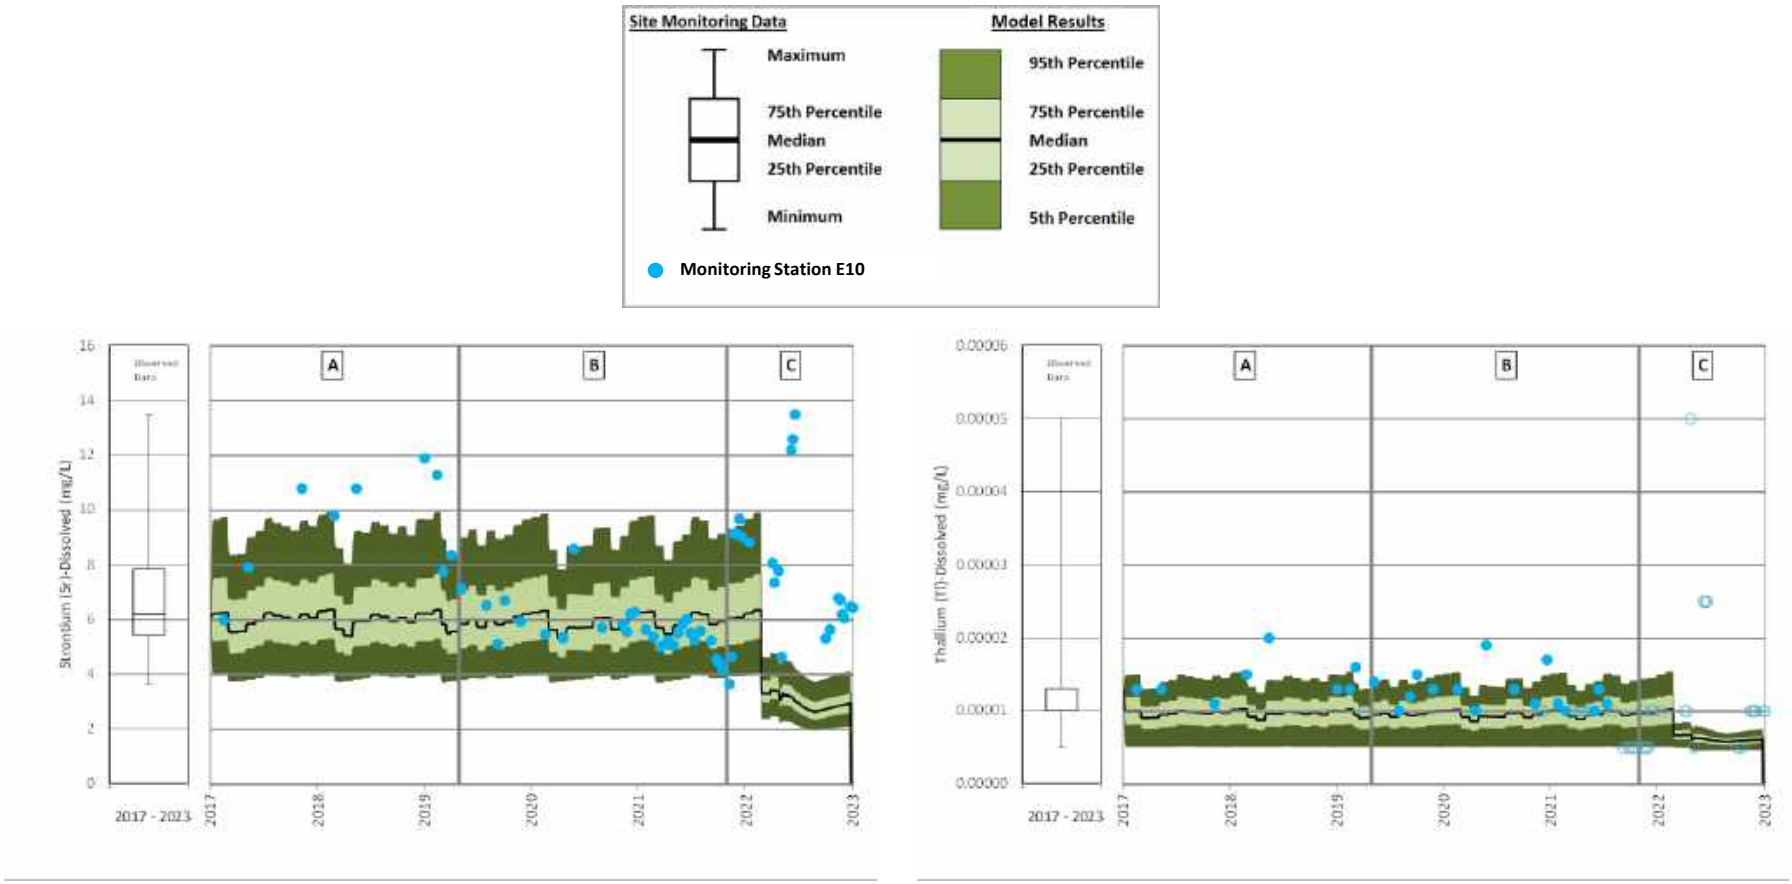

Figure A 55: Wight Pit Calibration – Dissolved Molybdenum and Dissolved Nickel

A = Operations; B = Care and Maintanence; C = Resumed Operations

Note: Dissolved selenium concentrations increase in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

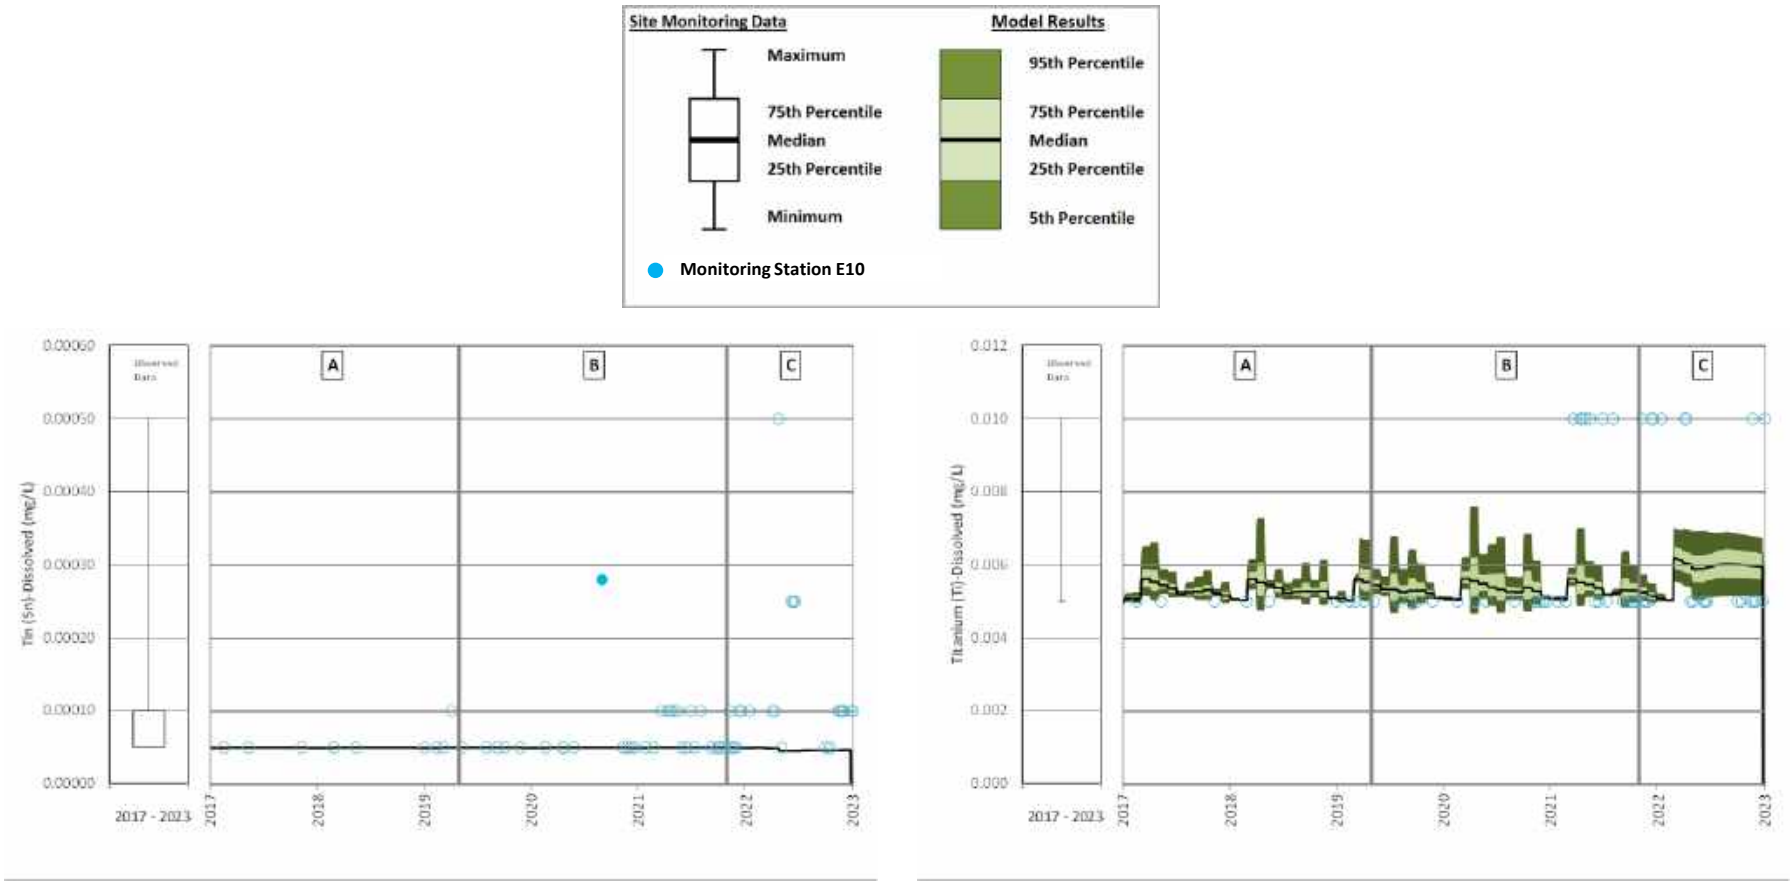

Figure A 56: Wight Pit Calibration – Dissolved Selenium and Dissolved Silver

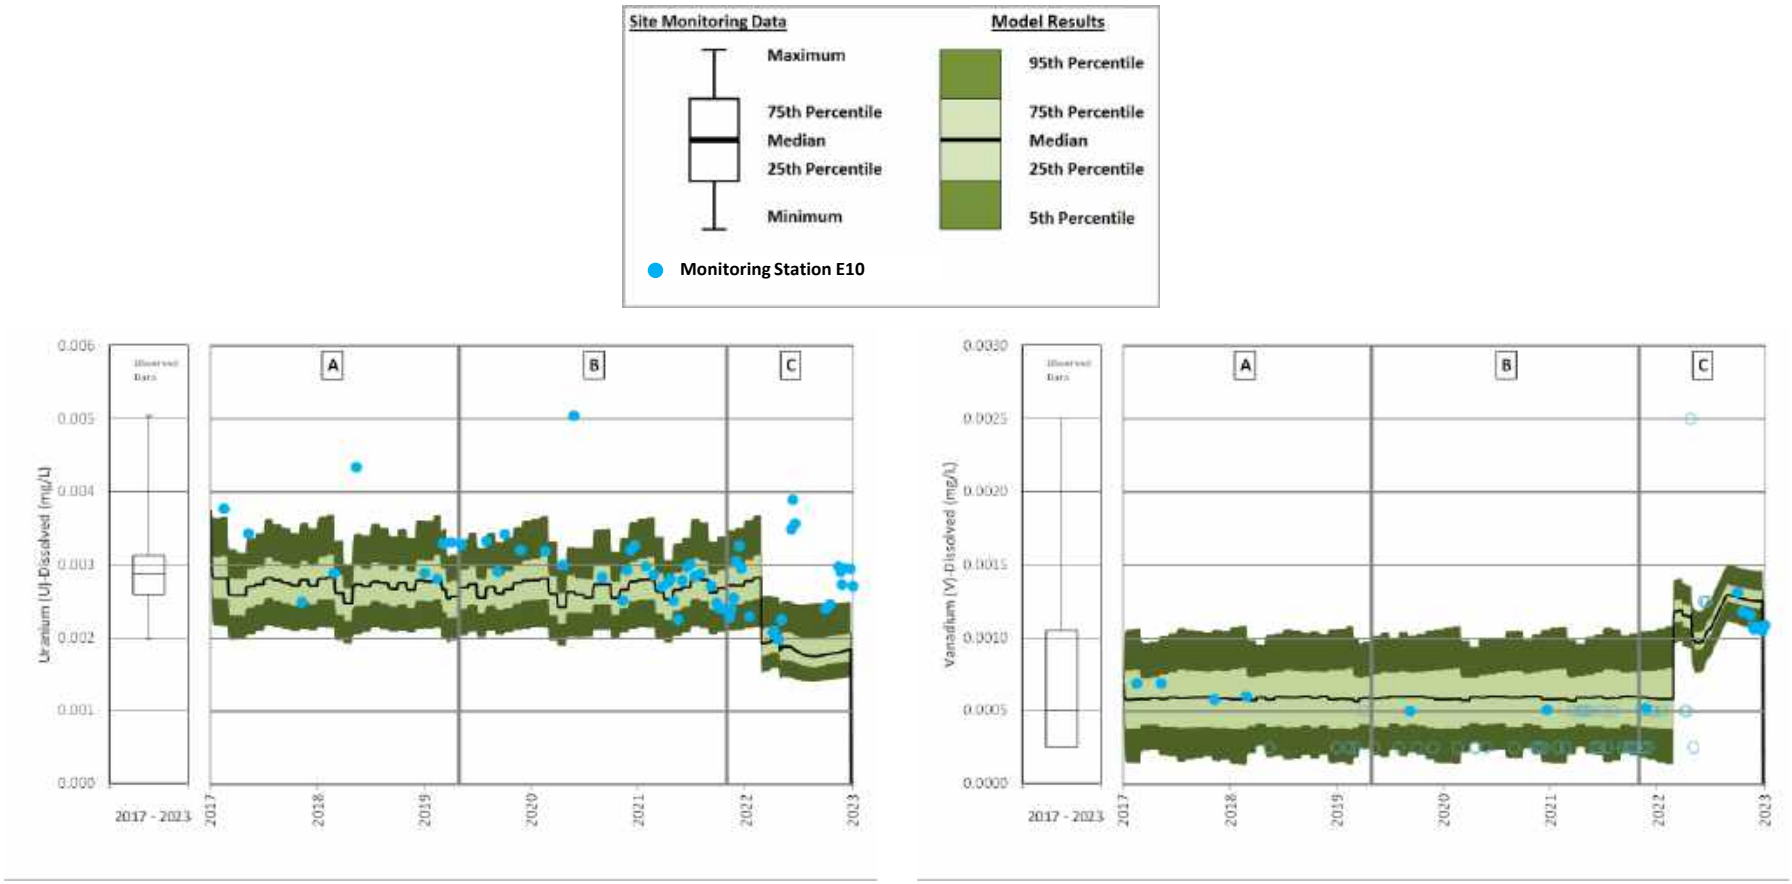
A = Operations; B = Care and Maintanence; C = Resumed Operations



Note: Dissolved strontium and dissolved thallium concentrations decrease in Wight Pit at the start of resumed operations because of pumping from the Tailings Storage Facility and from Cariboo Pit.

Appendix B – Water Quality Figures B 1–B 260

This attachment presents the water quality results Figures for Springer Pit, Cariboo Pit, Springer-Cariboo Pit, Wight Pit, the Central Collection Sump, the Tailings Storage Facility, the Perimeter Embankment Till Borrow Pond the 9K Sump, the Northwest Sump and Long Ditch. The operations period is from January 2024 to December 2024. The closure period is from January 2035 to December 2045. The post-closure period is from January 2045 to January 2135.

Model Results for Springer Pit and Cariboo Pit are only presented for the operations period. The model results for the combined Springer-Cariboo Pit are presented for closure and post-closure.

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

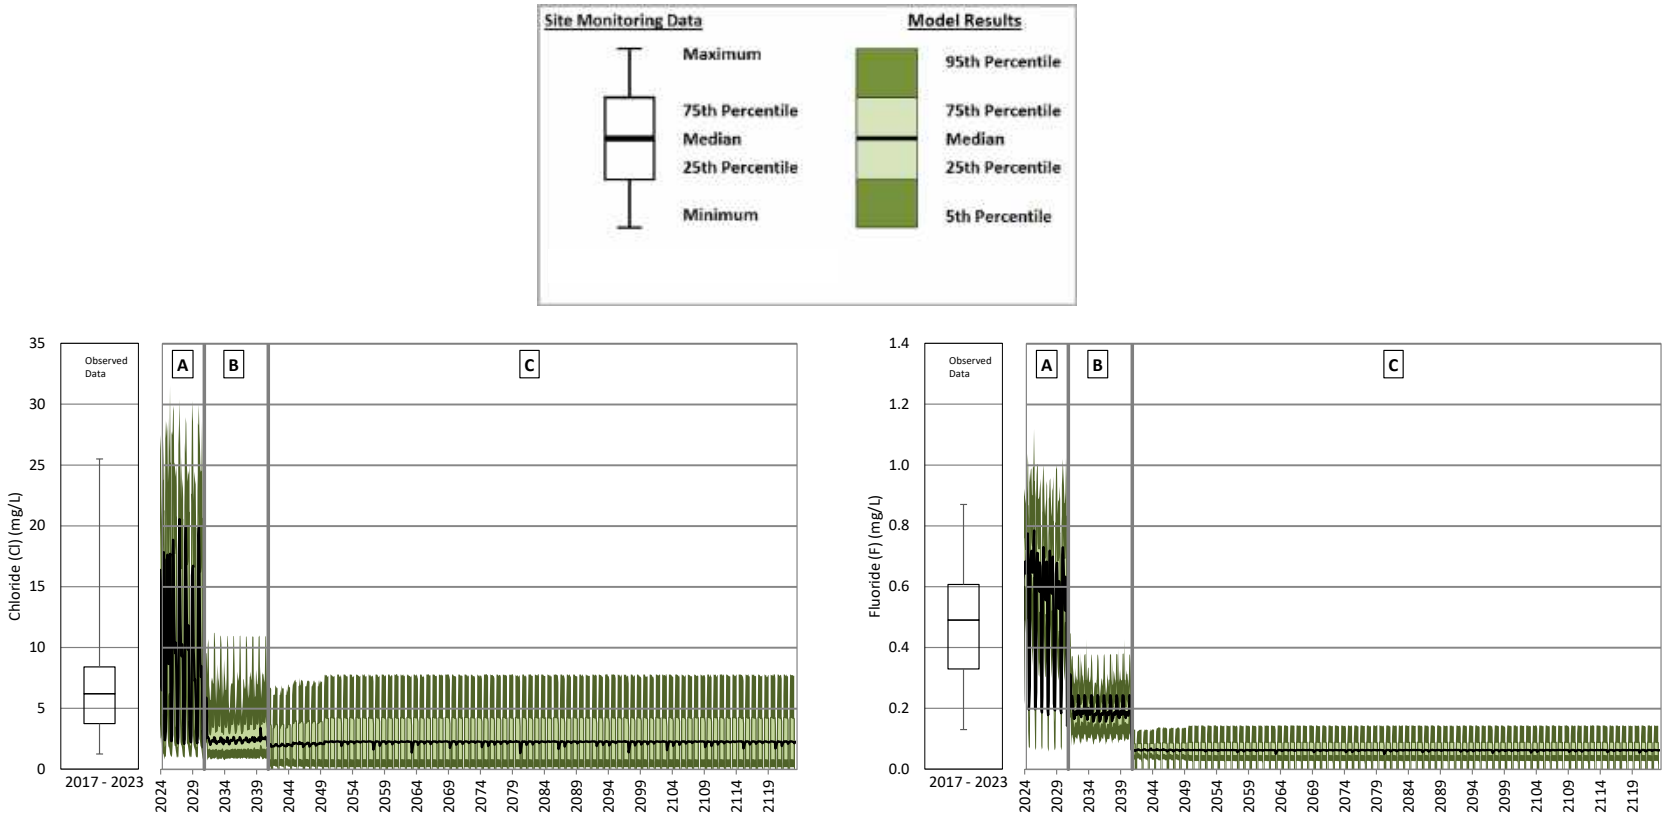
Figure B **80: Wight Pit Operations, Closure and Post-closure – Dissolved Zinc**



Central Collection Sump Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

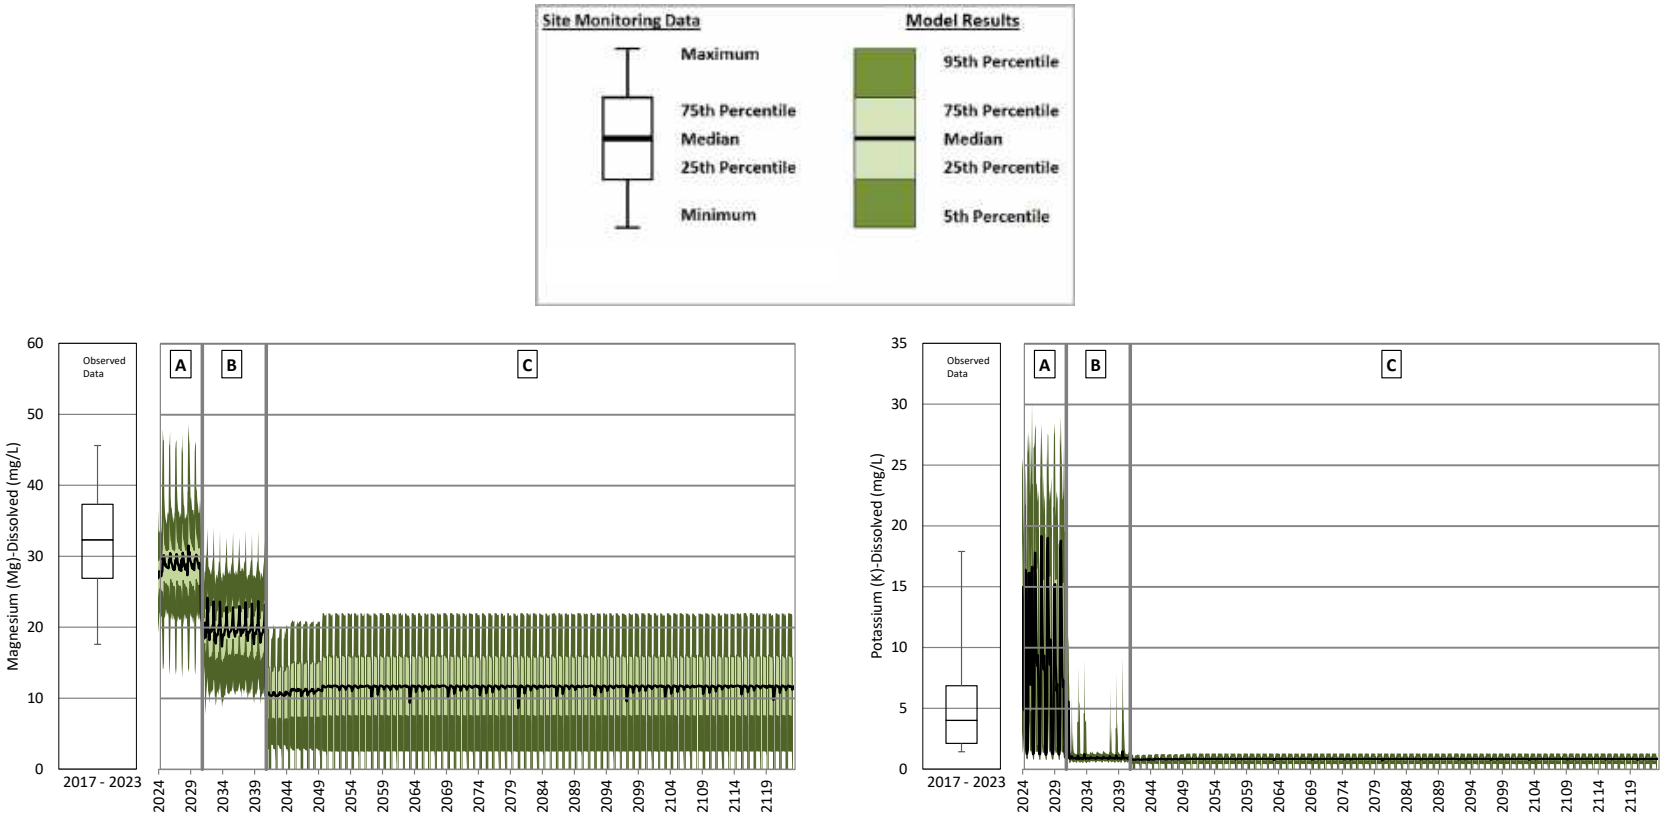


Figure B **81: Central Collection Sump Operations, Closure and Post-closure – Total Dissolved Solids and Calcium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

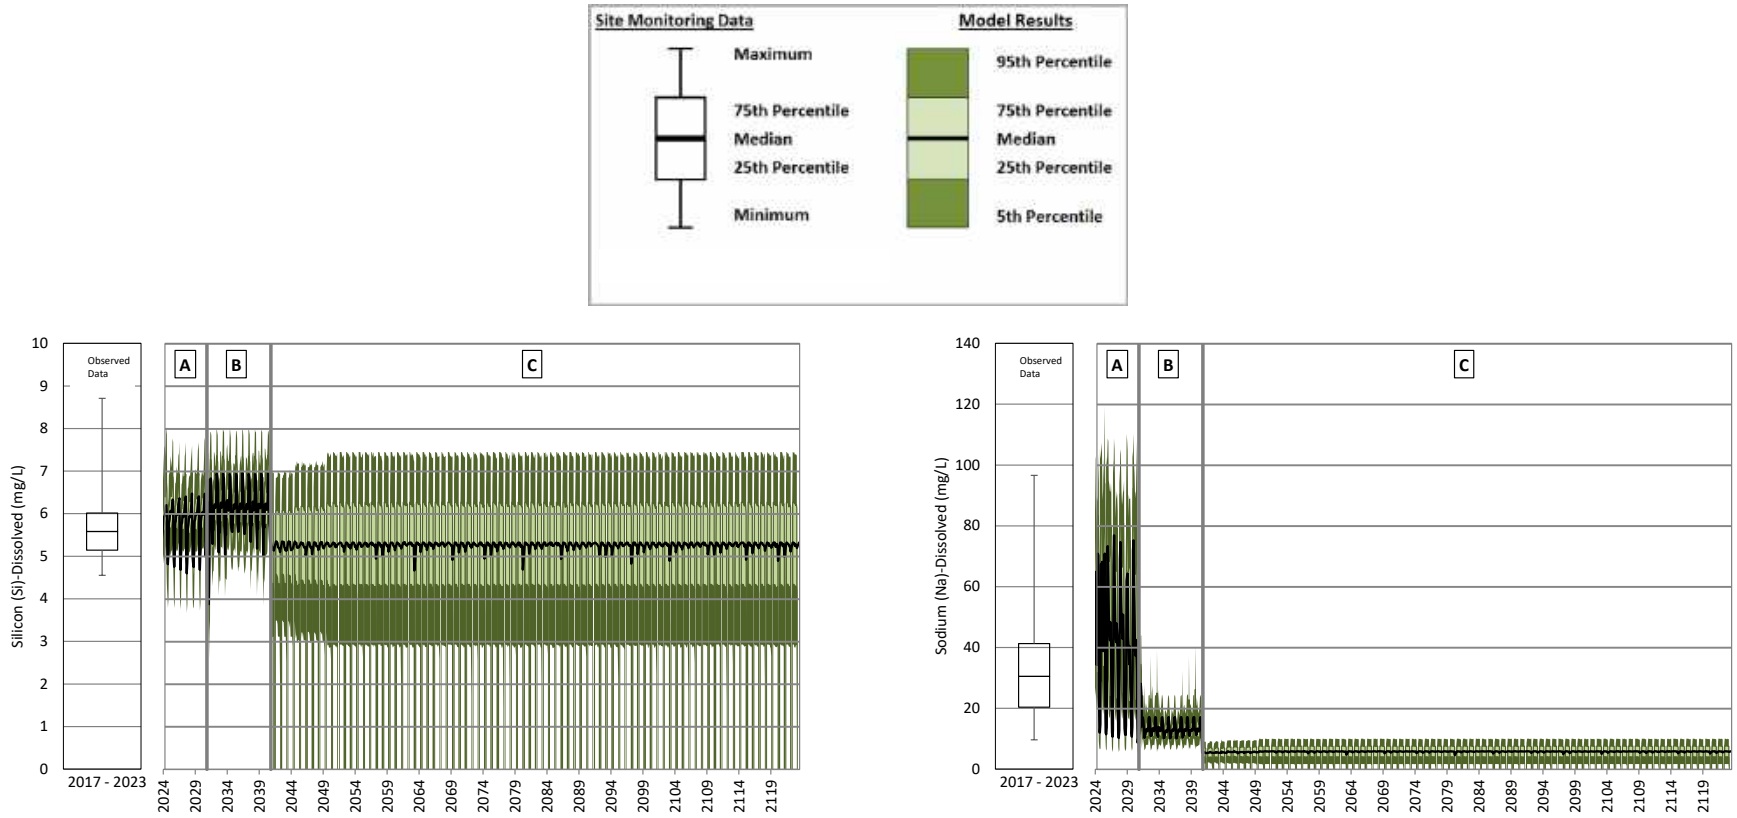

Figure B **82: Central Collection Sump Operations, Closure and Post-closure – Chloride and Fluoride**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

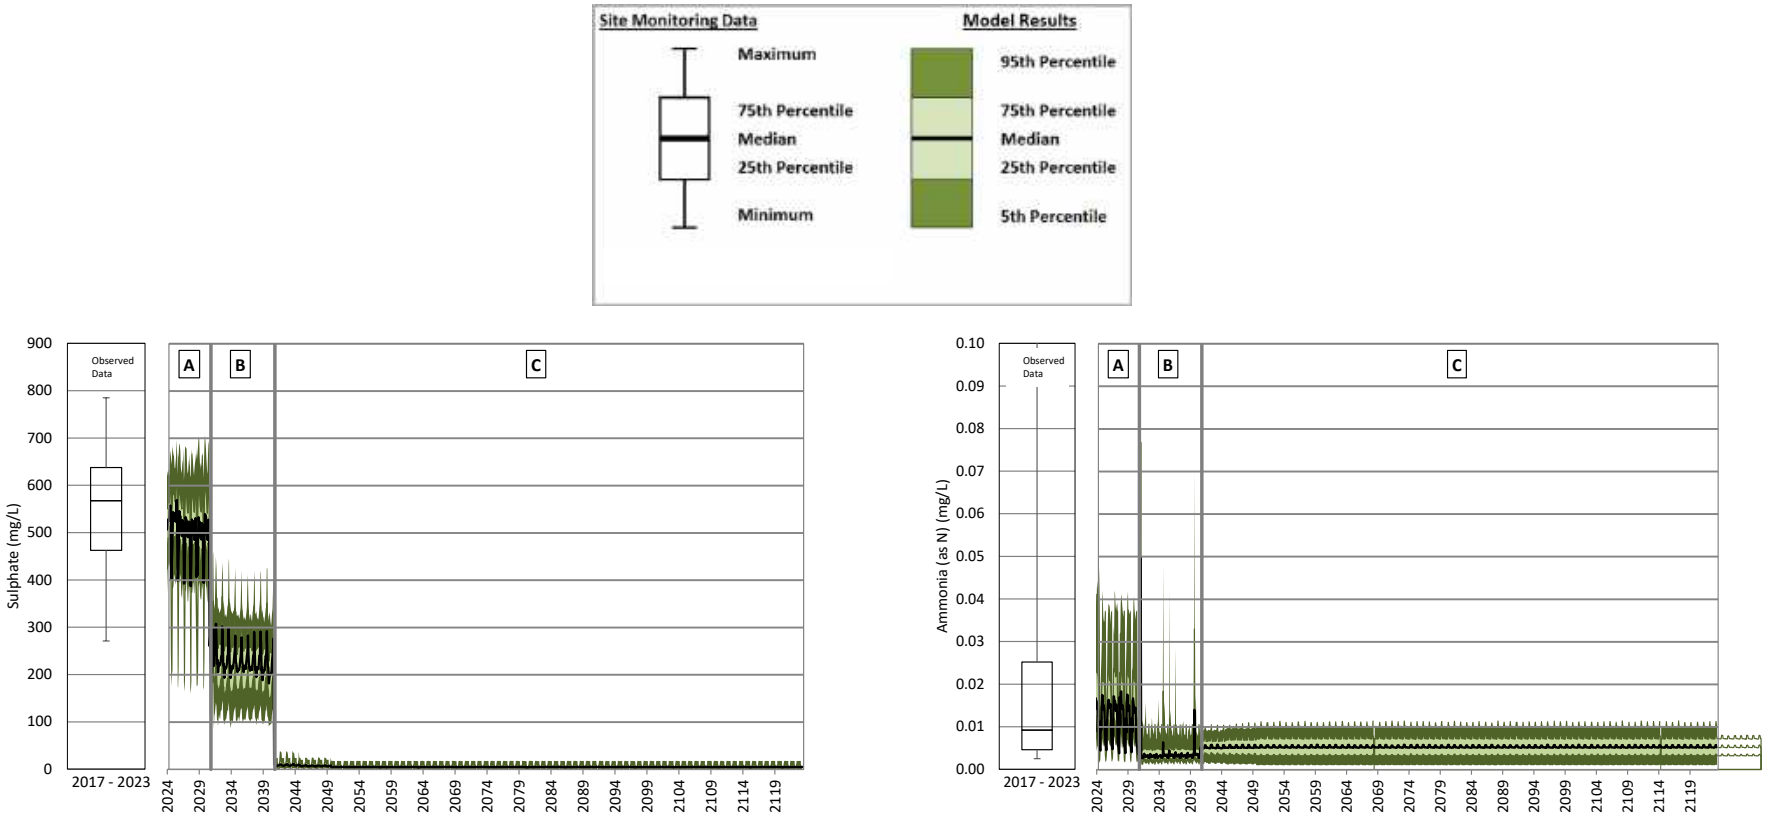

Figure B **83: Central Collection Sump Operations, Closure and Post-closure – Magnesium and Potassium**

A = Operations; B = Closure; C = Post-closure

Note: The increase in silicon concentrations from operations to closure and post-closure is caused by runoff from areas that were assigned the disturbed water quality input being reclaimed and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher maximum silicon concentrations than the disturbed water quality input. Sodium concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

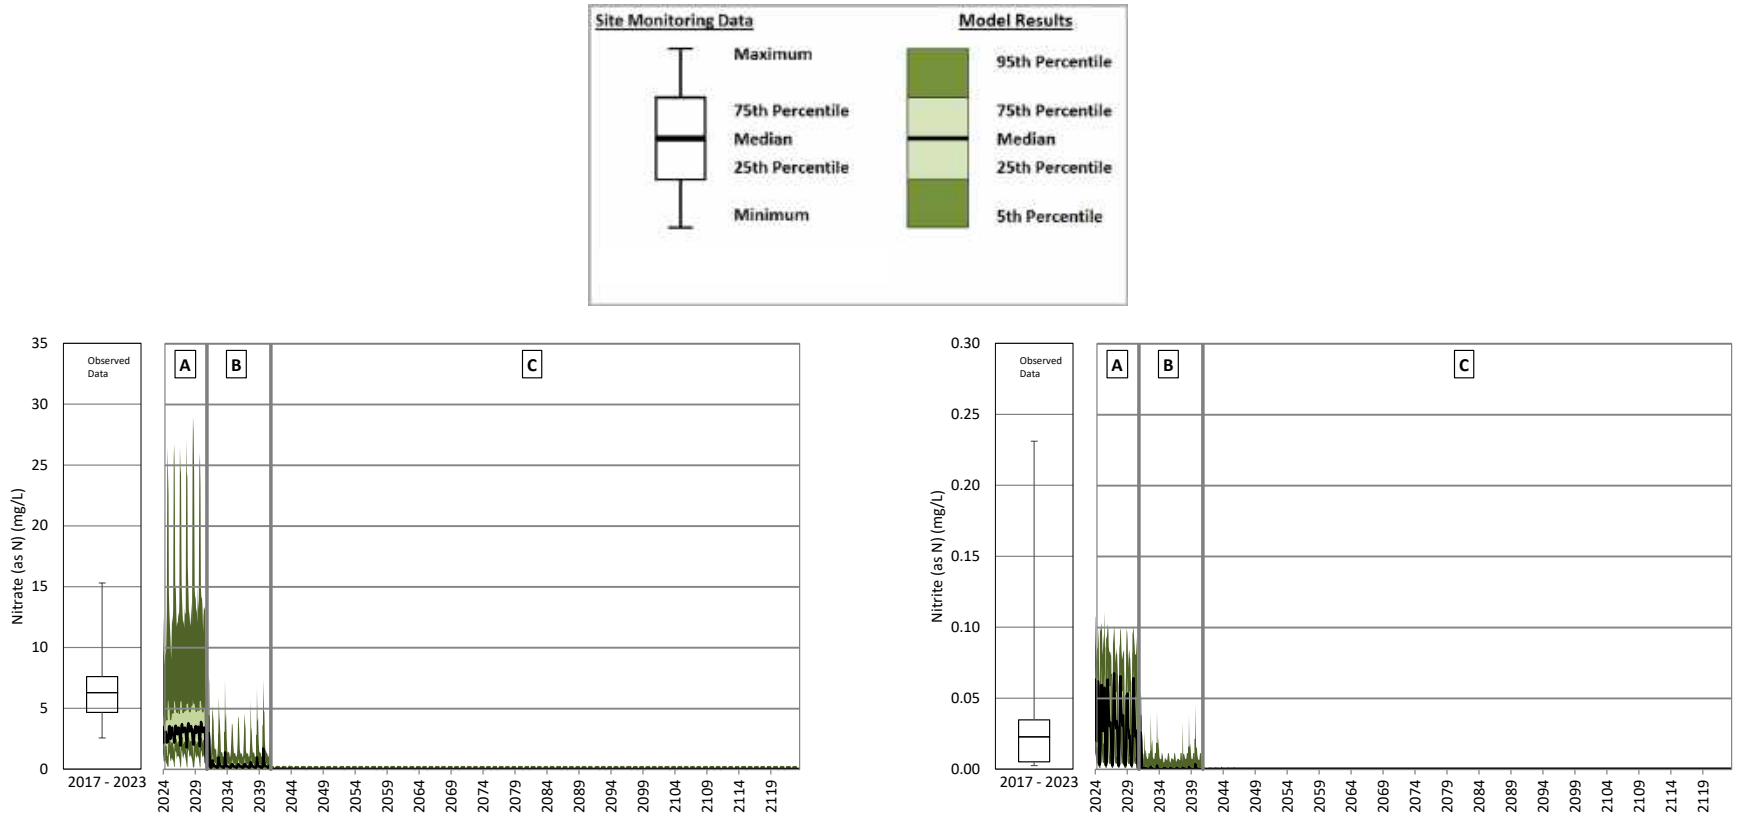

Figure B **84: Central Collection Sump Operations, Closure and Post-closure – Silicon and Sodium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

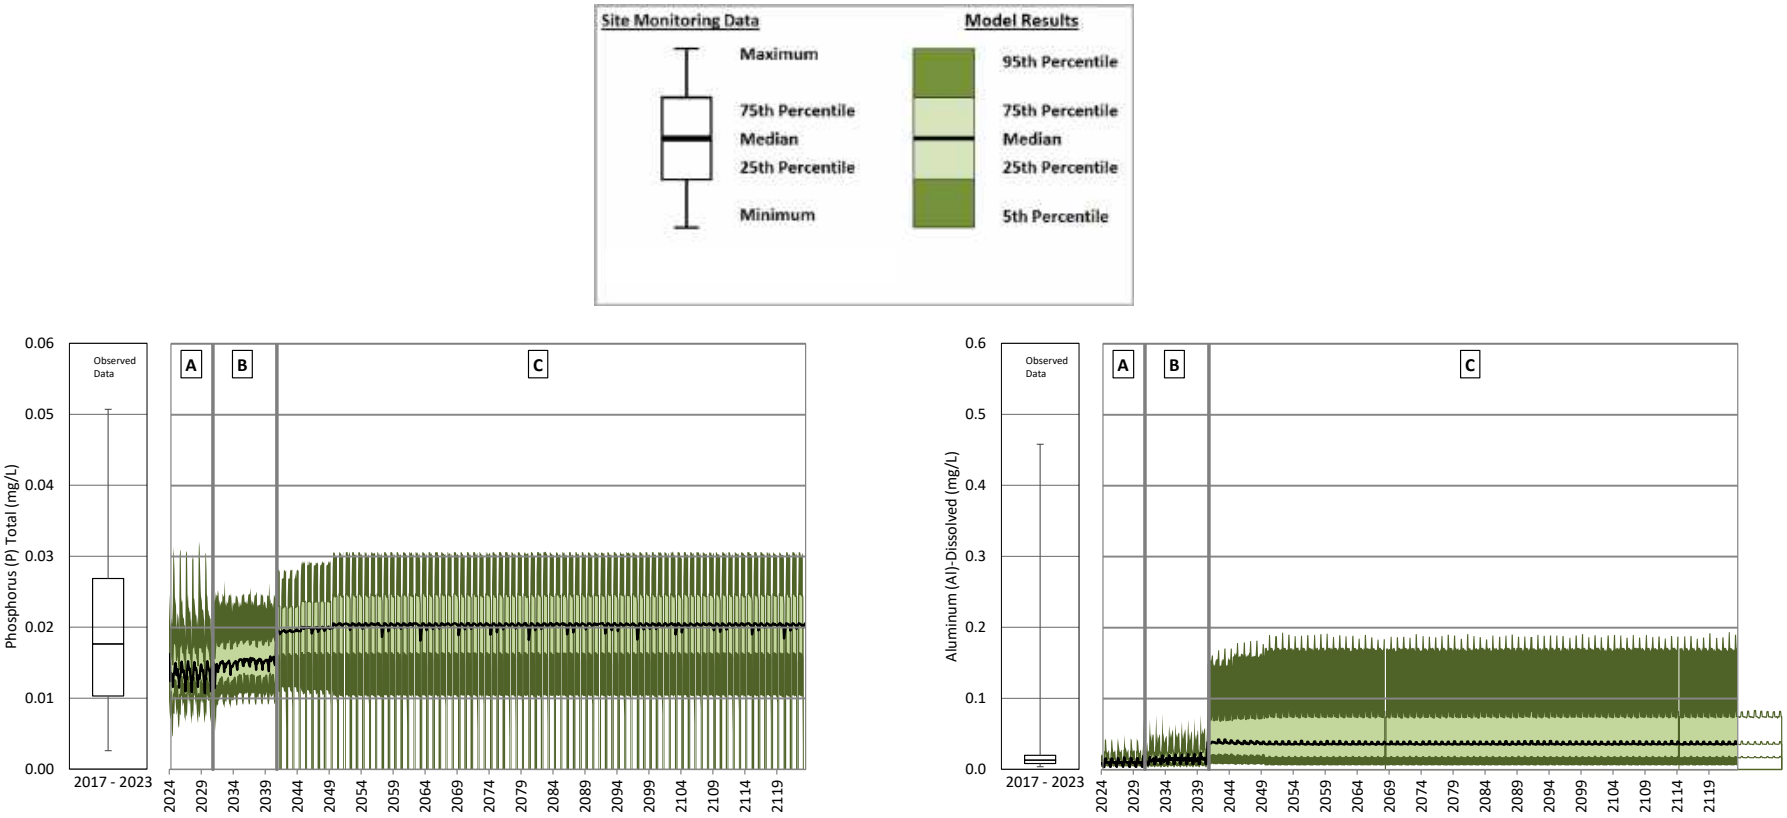

Figure B **85: Central Collection Sump Operations, Closure and Post-closure – Sulphate and Total Ammonia**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

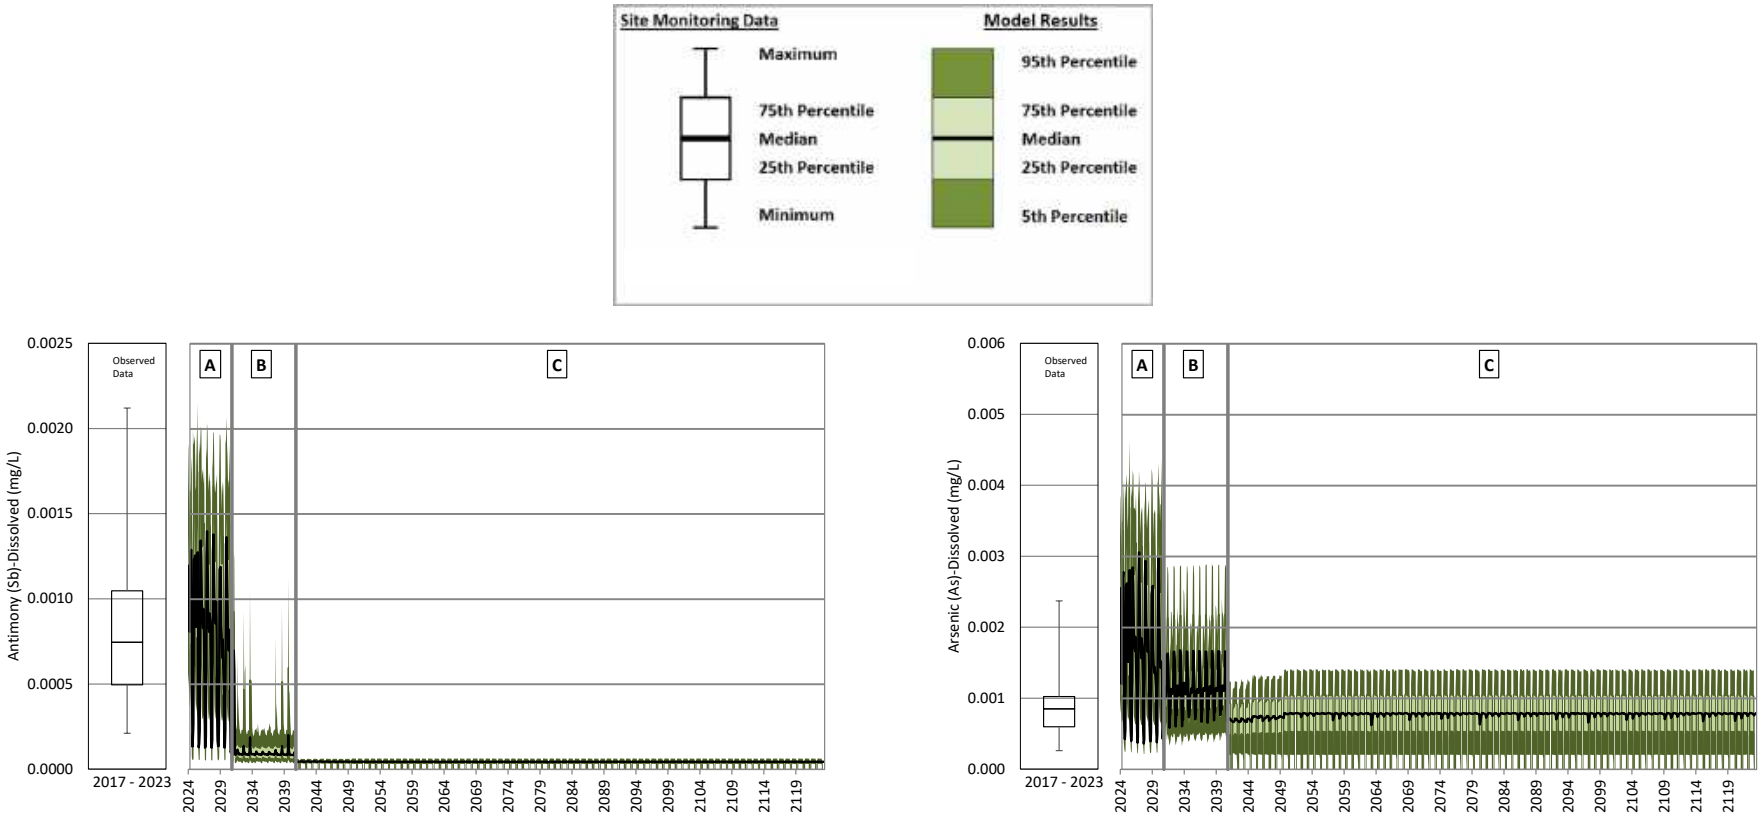

Figure B **86: Central Collection Sump Operations, Closure and Post-closure – Nitrate and Nitrite**

A = Operations; B = Closure; C = Post-closure

Note: Total phosphorus and dissolved aluminum concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for total phosphorus and dissolved aluminum than the NAG waste rock and disturbed runoff water quality inputs.

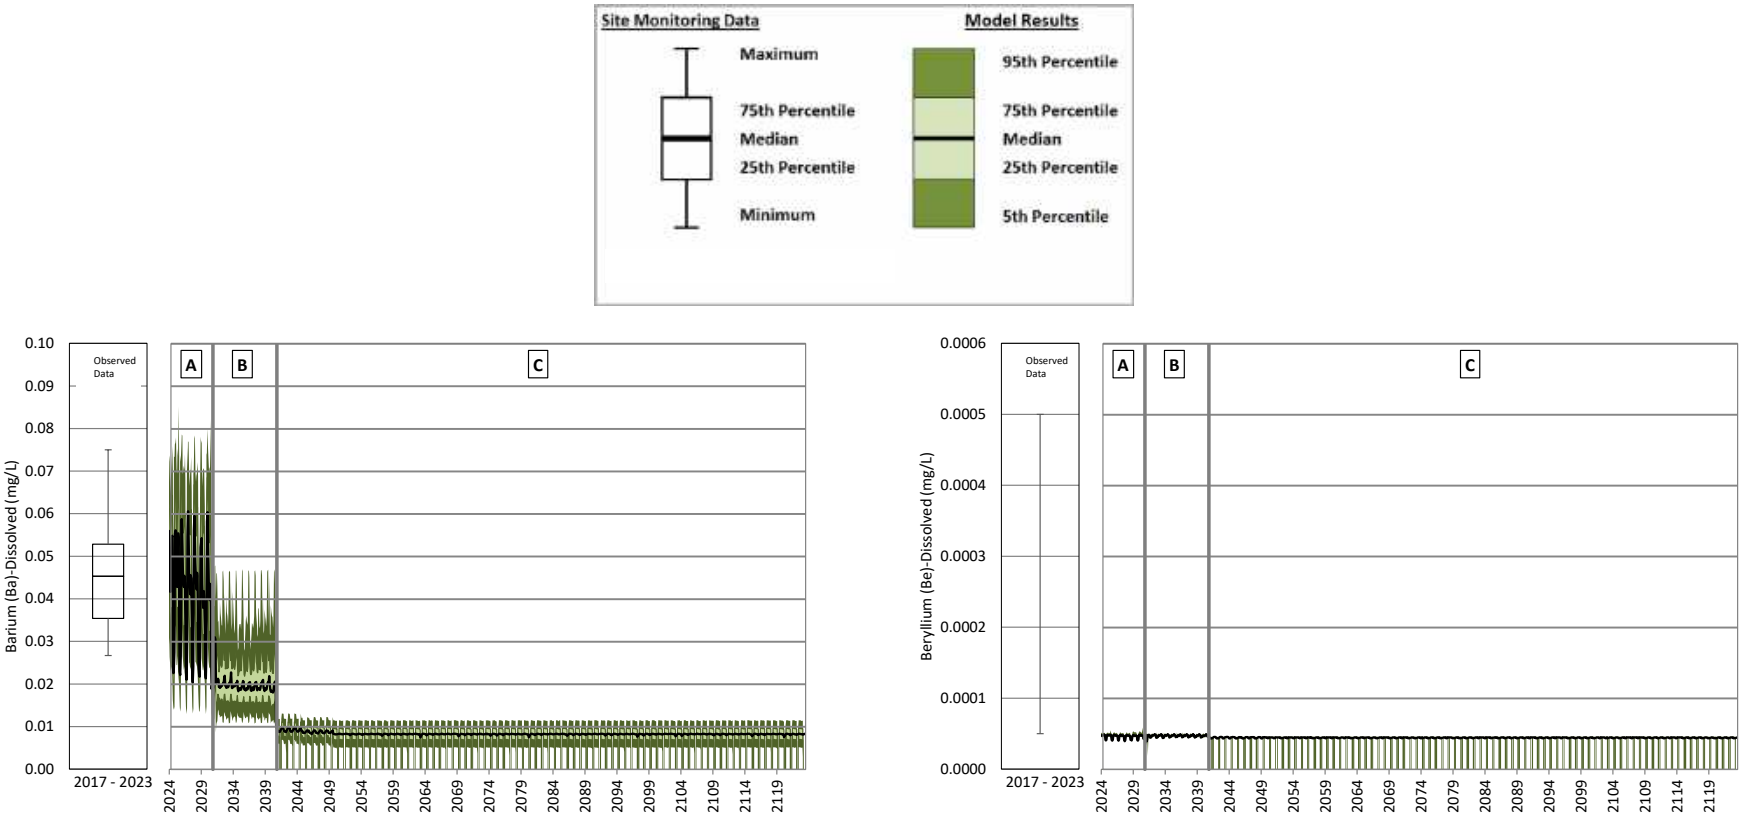

Figure B **87: Central Collection Sump Operations, Closure and Post-closure – Total Phosphorus and Dissolved Aluminum**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

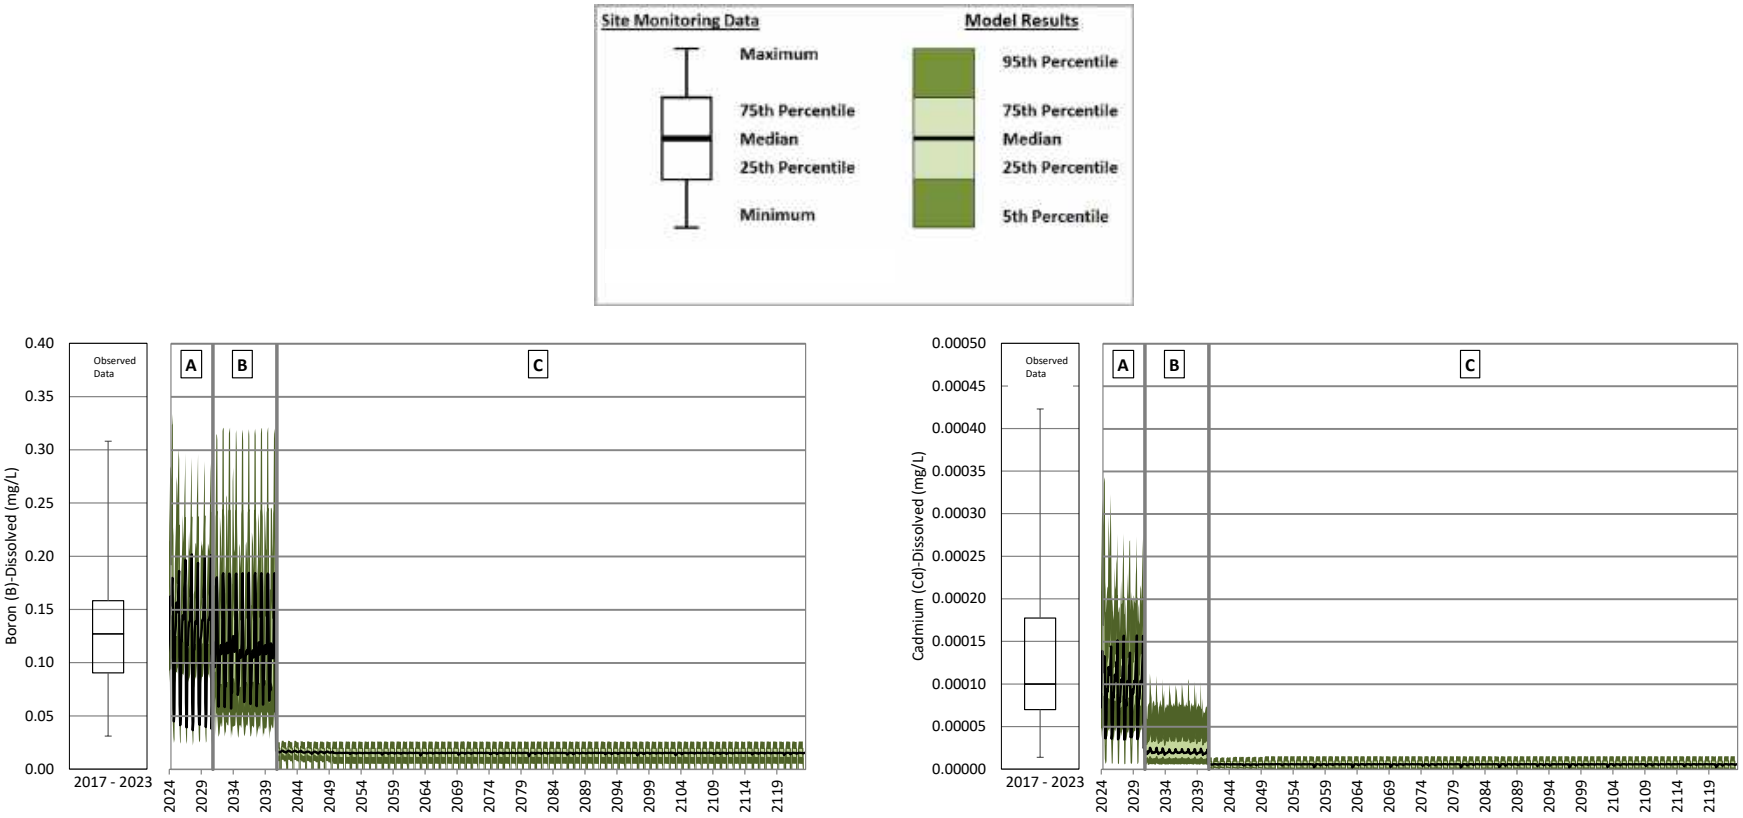

Figure B **88: Central Collection Sump Operations, Closure and Post-closure – Dissolved Antimony and Dissolved Arsenic**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

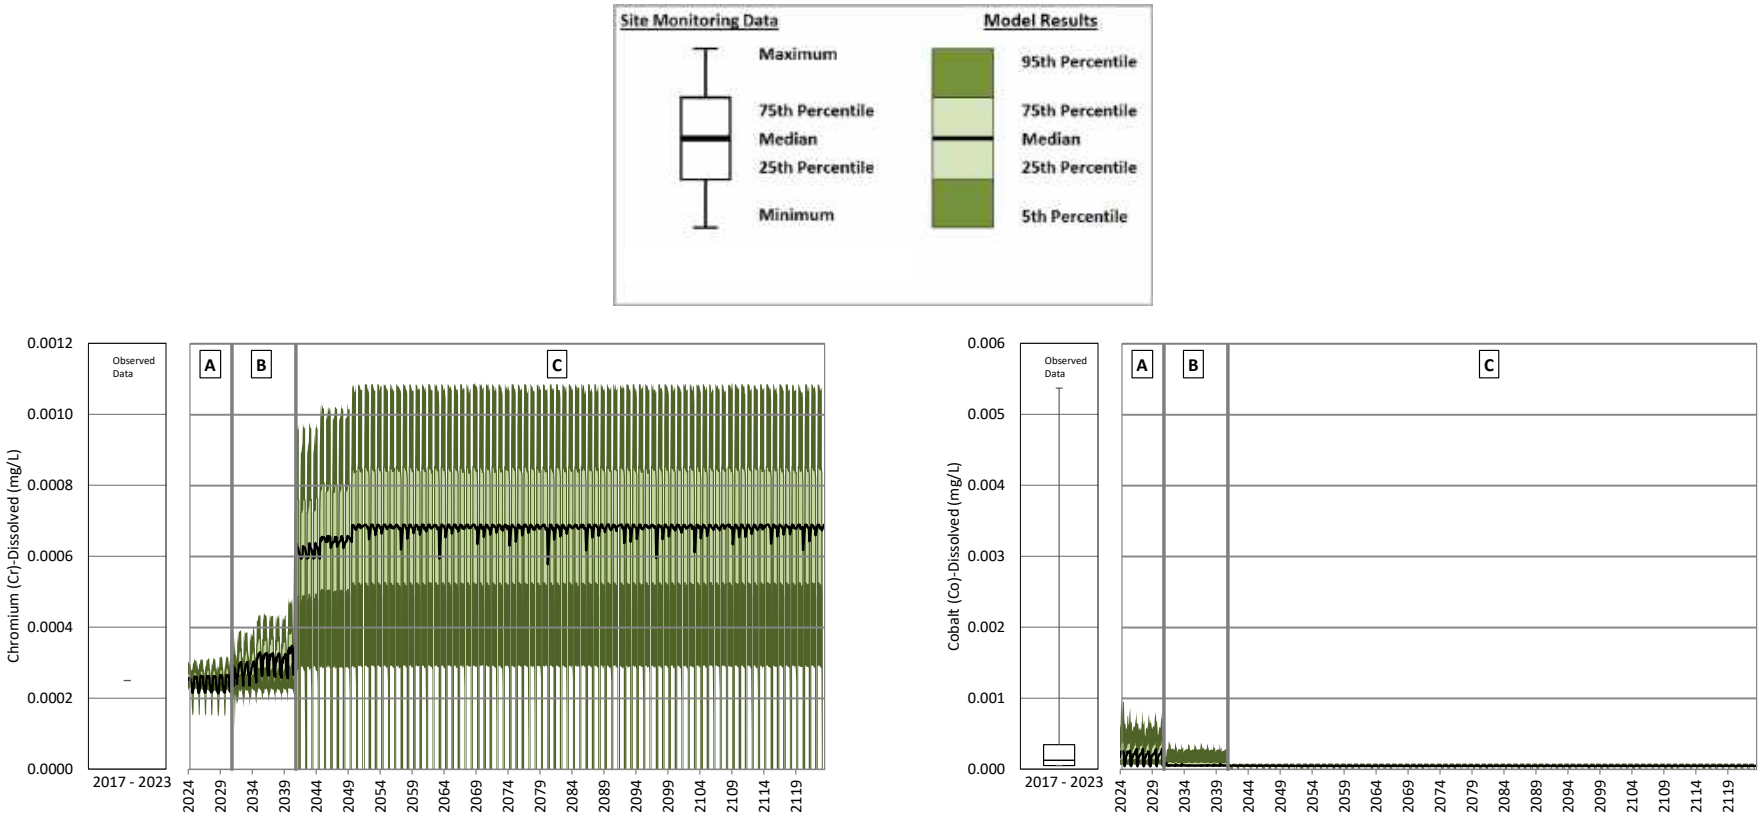

Figure B **89: Central Collection Sump Operations, Closure and Post-closure – Dissolved Barium and Dissolved Beryllium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

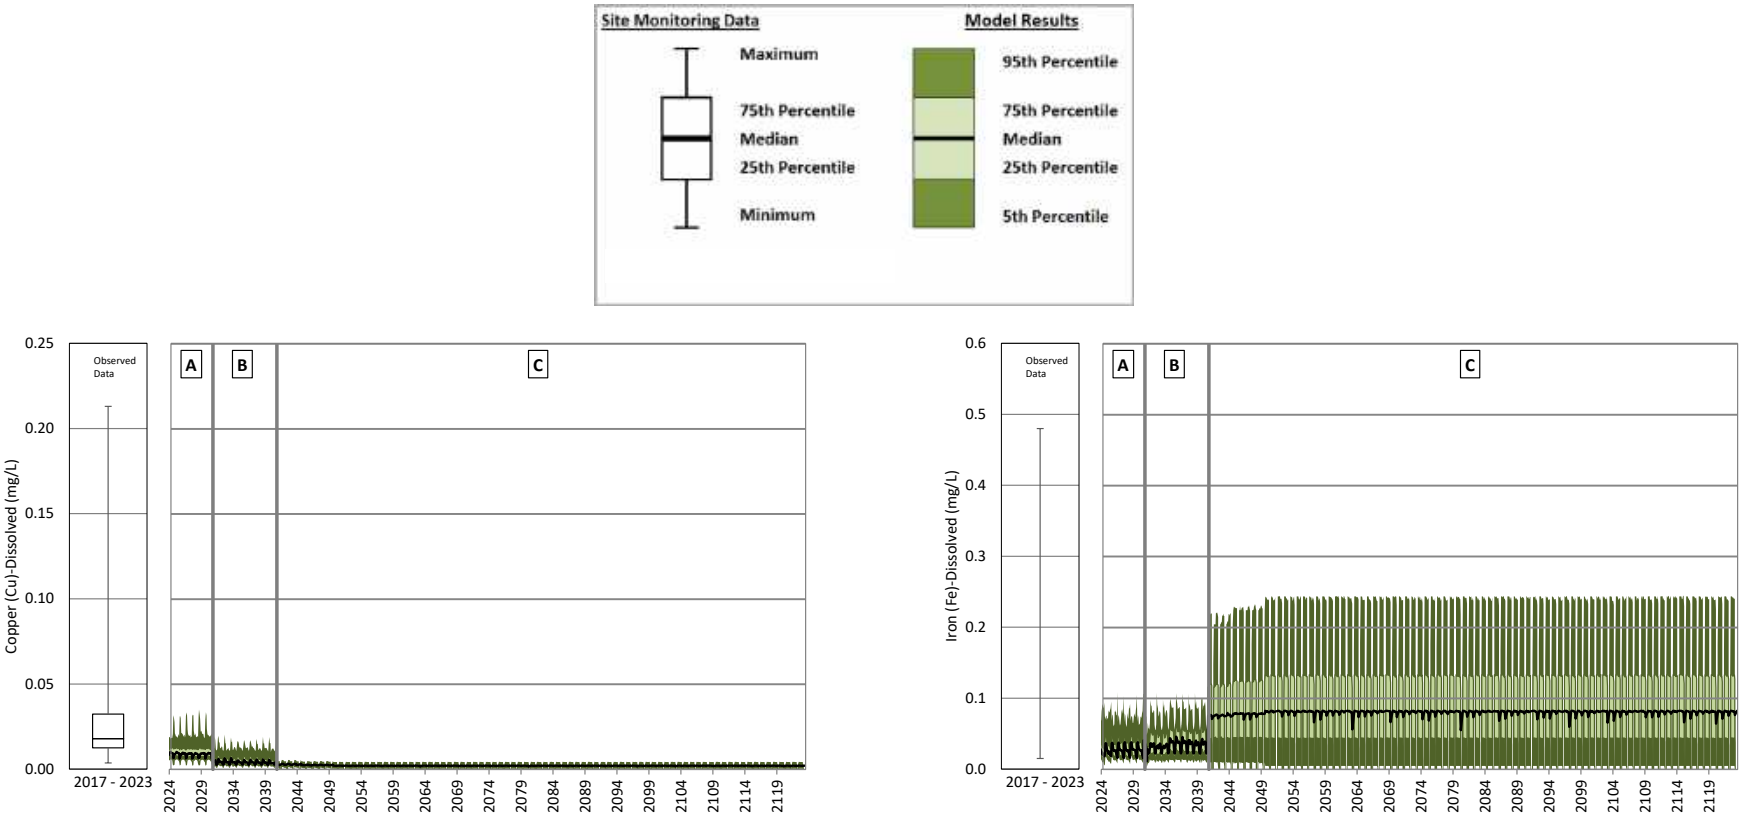

Figure B **90: Central Collection Sump Operations, Closure and Post-closure – Dissolved Boron and Dissolved Cadmium**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved chromium concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved chromium than the NAG waste rock and disturbed runoff water quality inputs. Dissolved cobalt concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

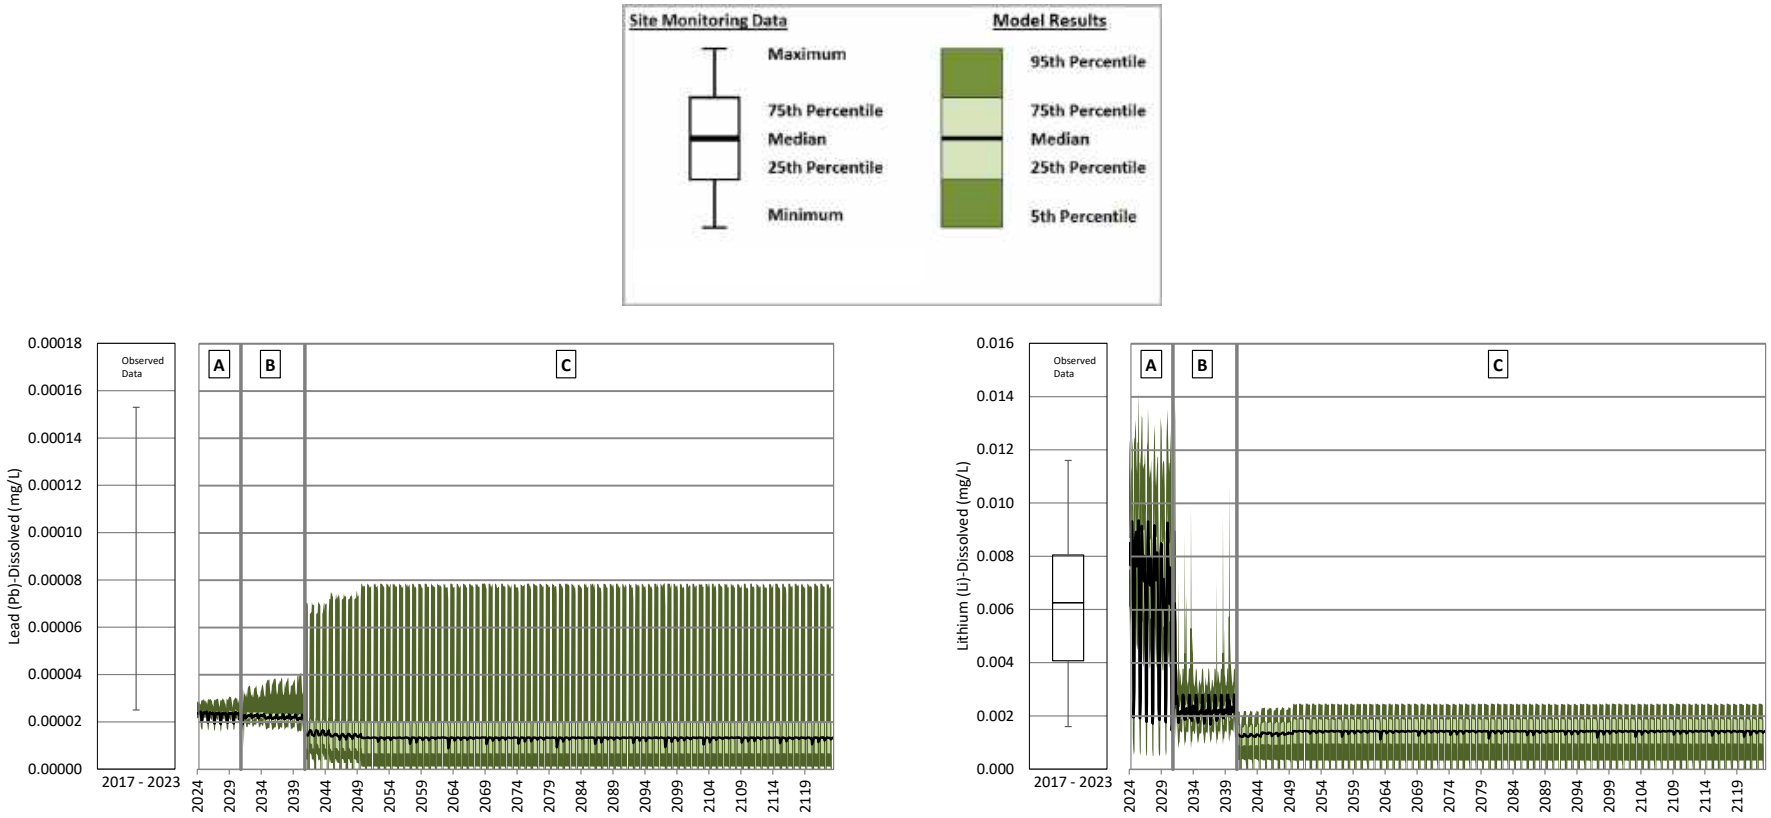

Figure B **91: Central Collection Sump Operations, Closure and Post-closure – Dissolved Chromium and Dissolved Cobalt**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved copper concentrations decrease from operations to closure and post-closure as runoff areas are remediated. Dissolved iron concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved iron than the NAG waste rock and disturbed runoff water quality inputs.

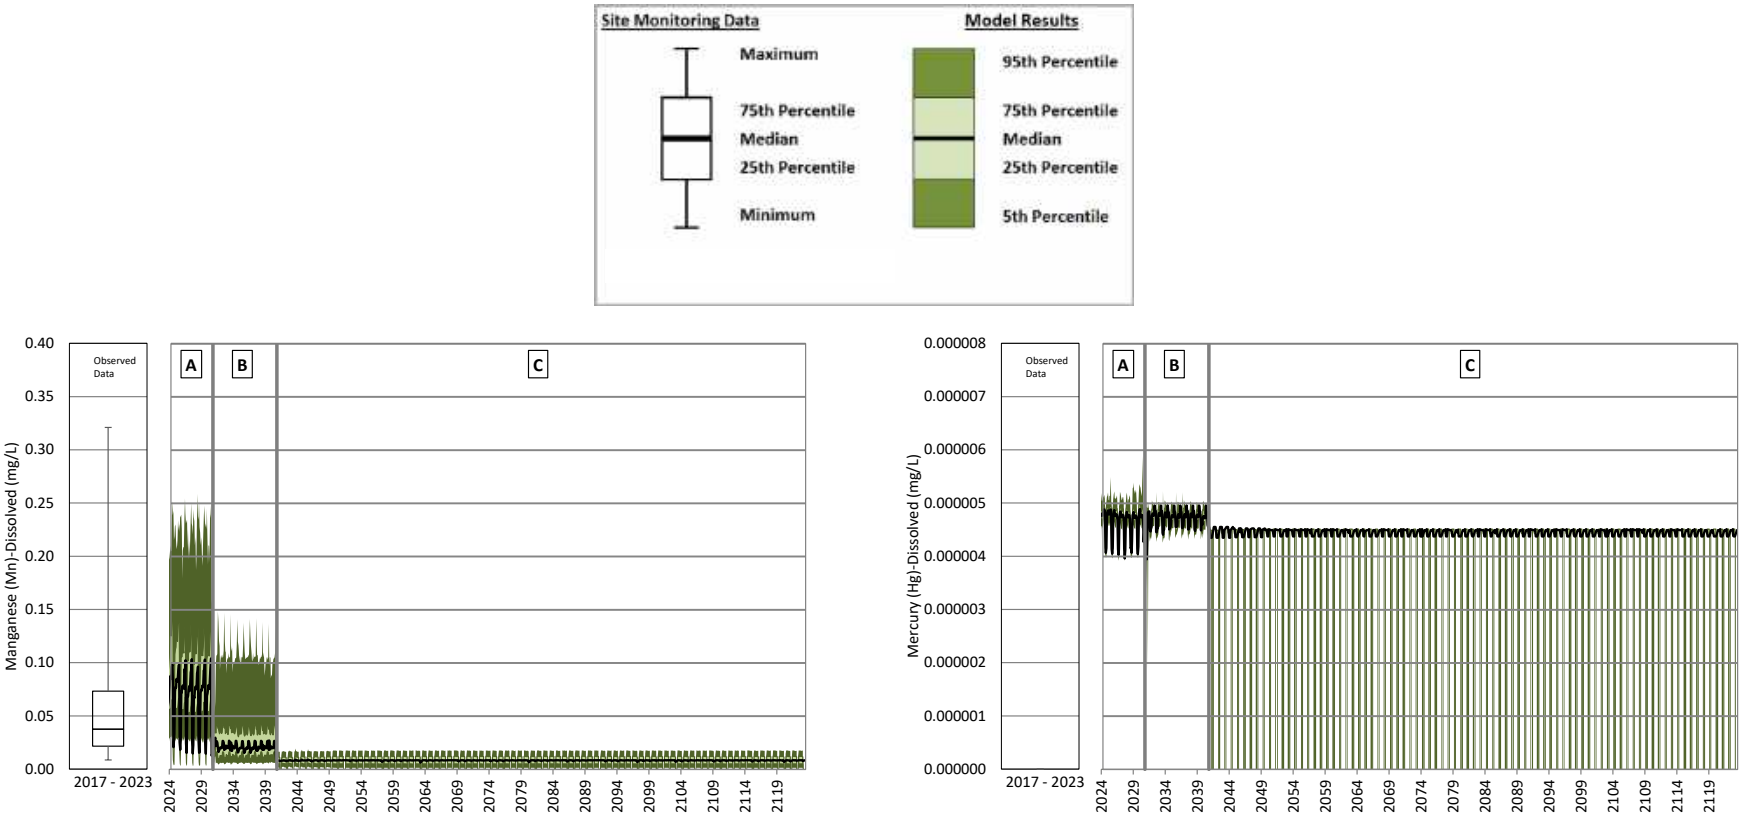

Figure B **92: Central Collection Sump Operations, Closure and Post-closure – Dissolved Copper and Dissolved Iron**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved lead concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved lead than the NAG waste rock and disturbed runoff water quality inputs. Dissolved lithium concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

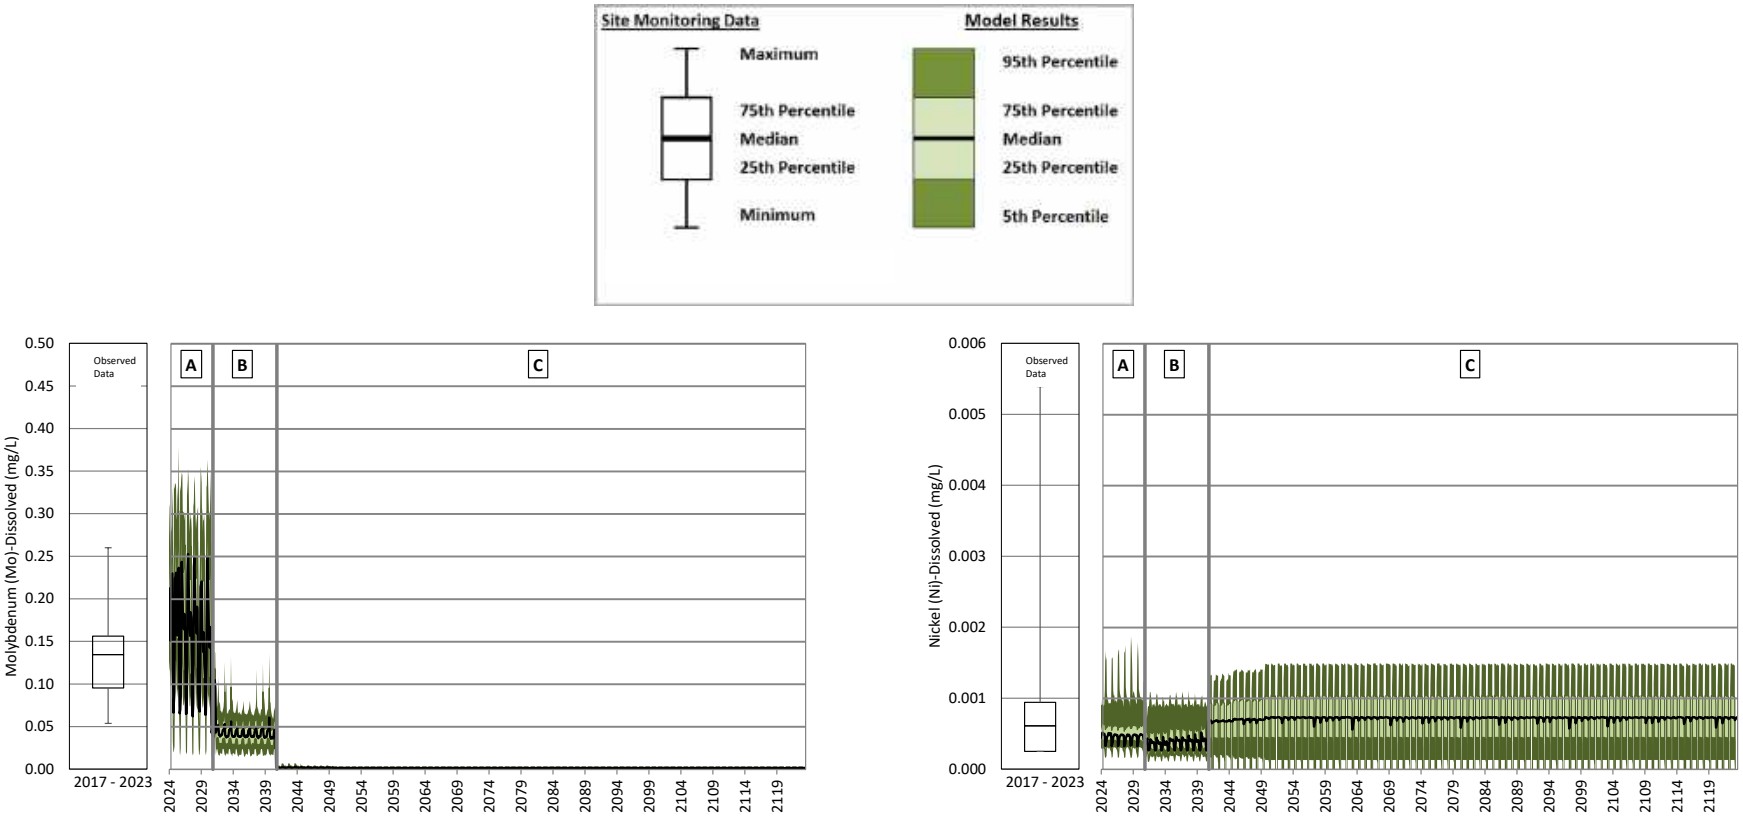

Figure B **93: Central Collection Sump Operations, Closure and Post-closure – Dissolved Lead and Dissolved Lithium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

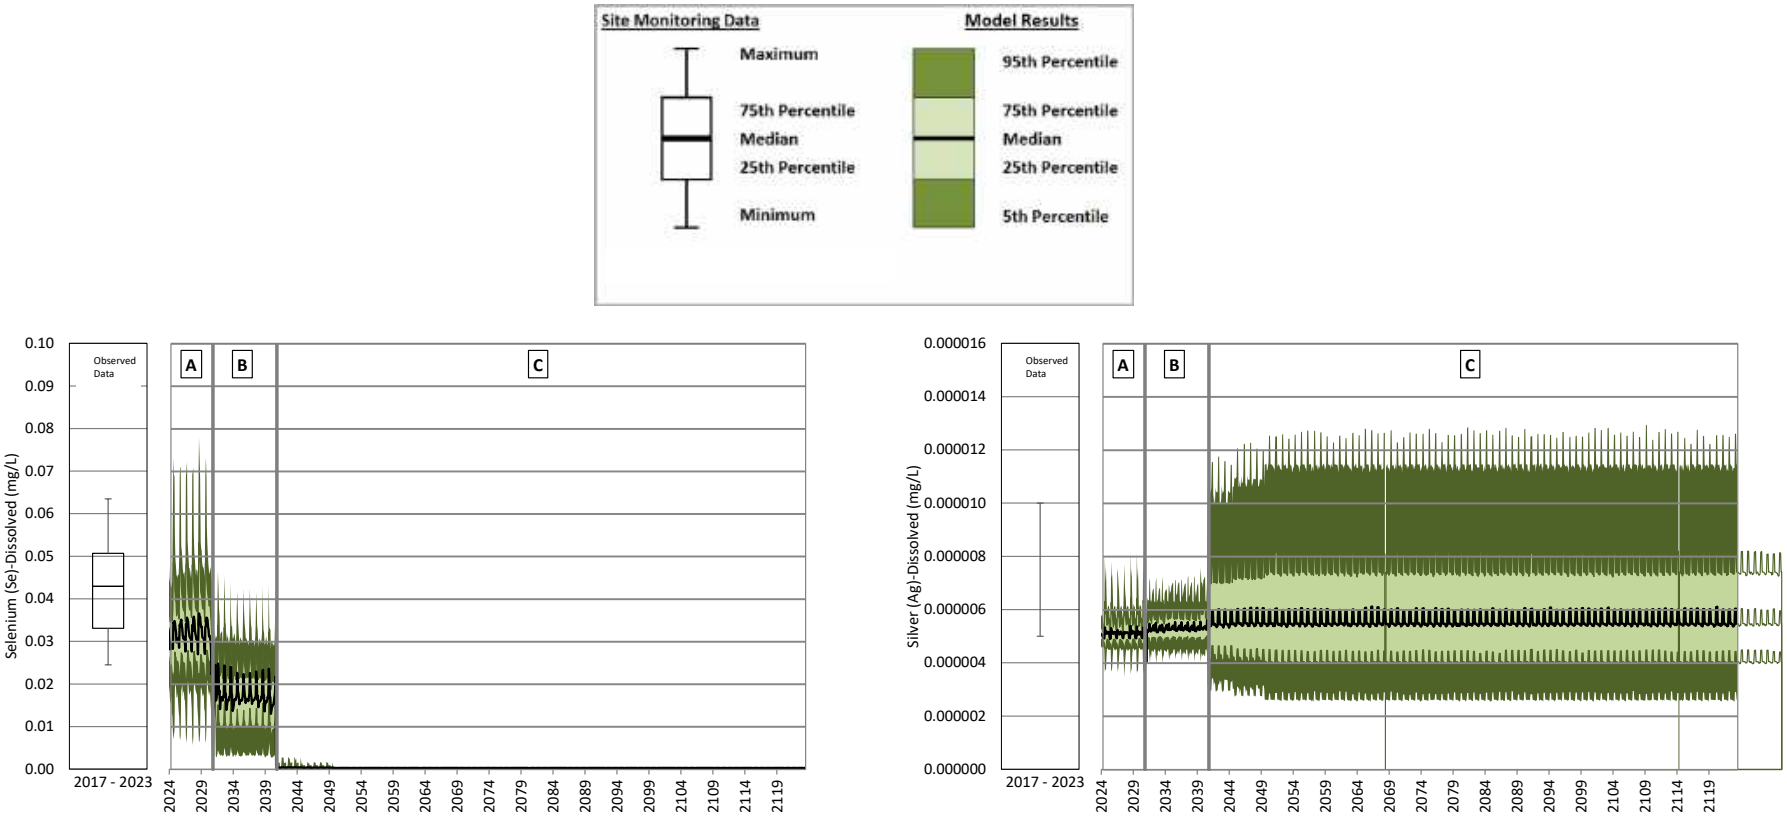

Figure B **94: Central Collection Sump Operations, Closure and Post-closure – Dissolved Manganese and Dbootissolved Mercury**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved molybdenum concentrations decrease from operations to closure and post-closure as runoff areas are remediated. Dissolved nickel concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved nickel than the NAG waste rock and disturbed runoff water quality inputs.

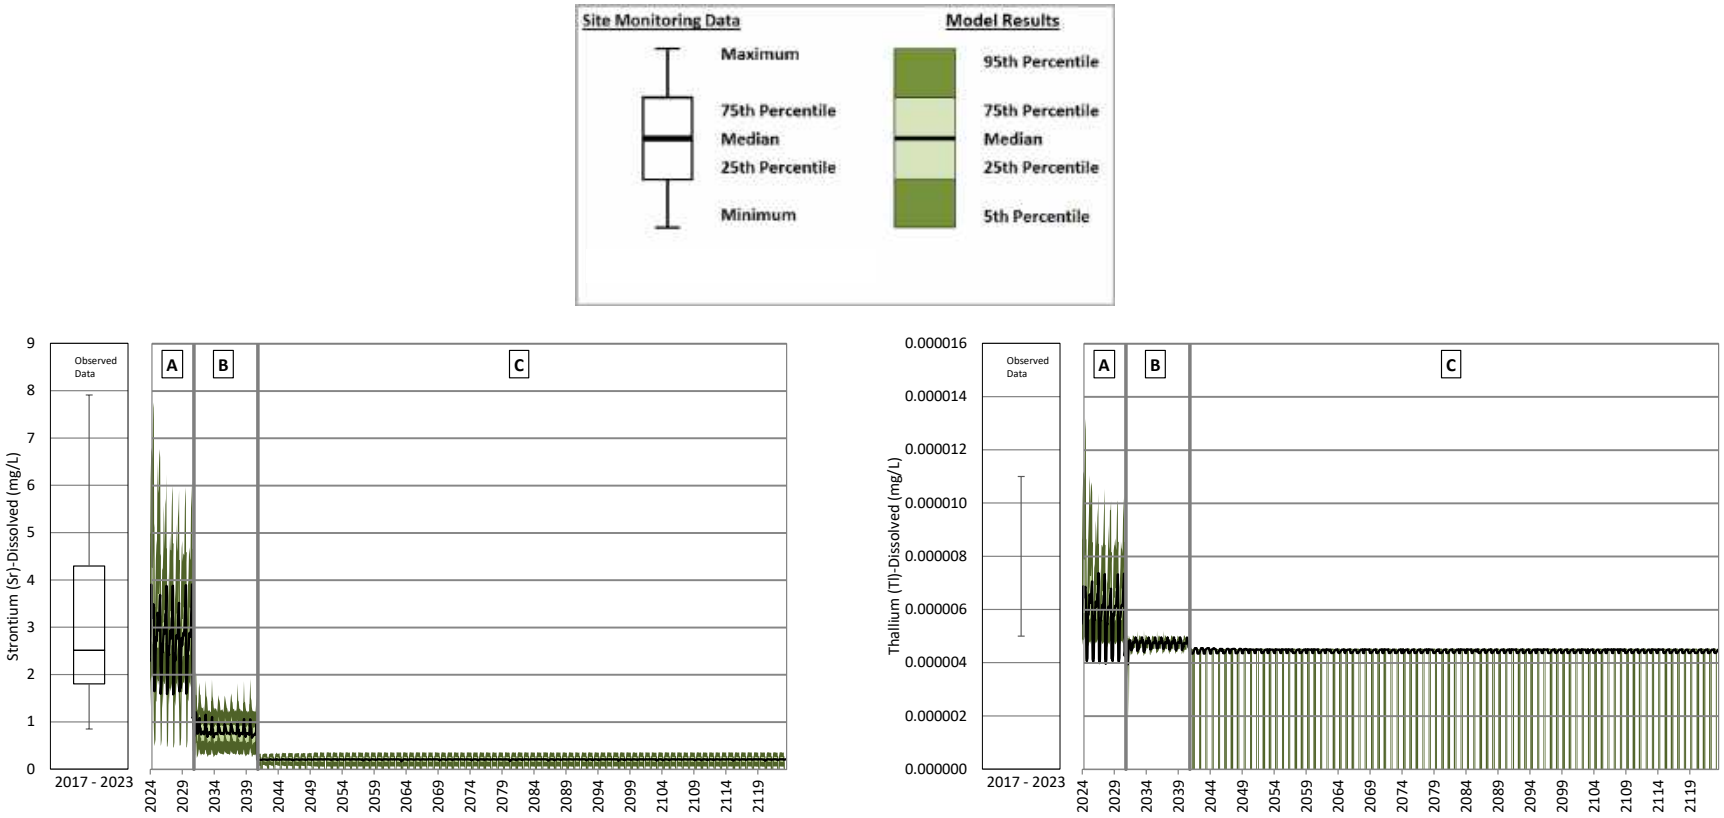

Figure B **95: Central Collection Sump Operations, Closure and Post-closure – Dissolved Molybdenum and Dissolved Nickel**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved selenium concentrations decrease from operations to closure and post-closure as runoff areas are remediated. Dissolved silver concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved silver than the NAG waste rock and disturbed runoff water quality inputs.

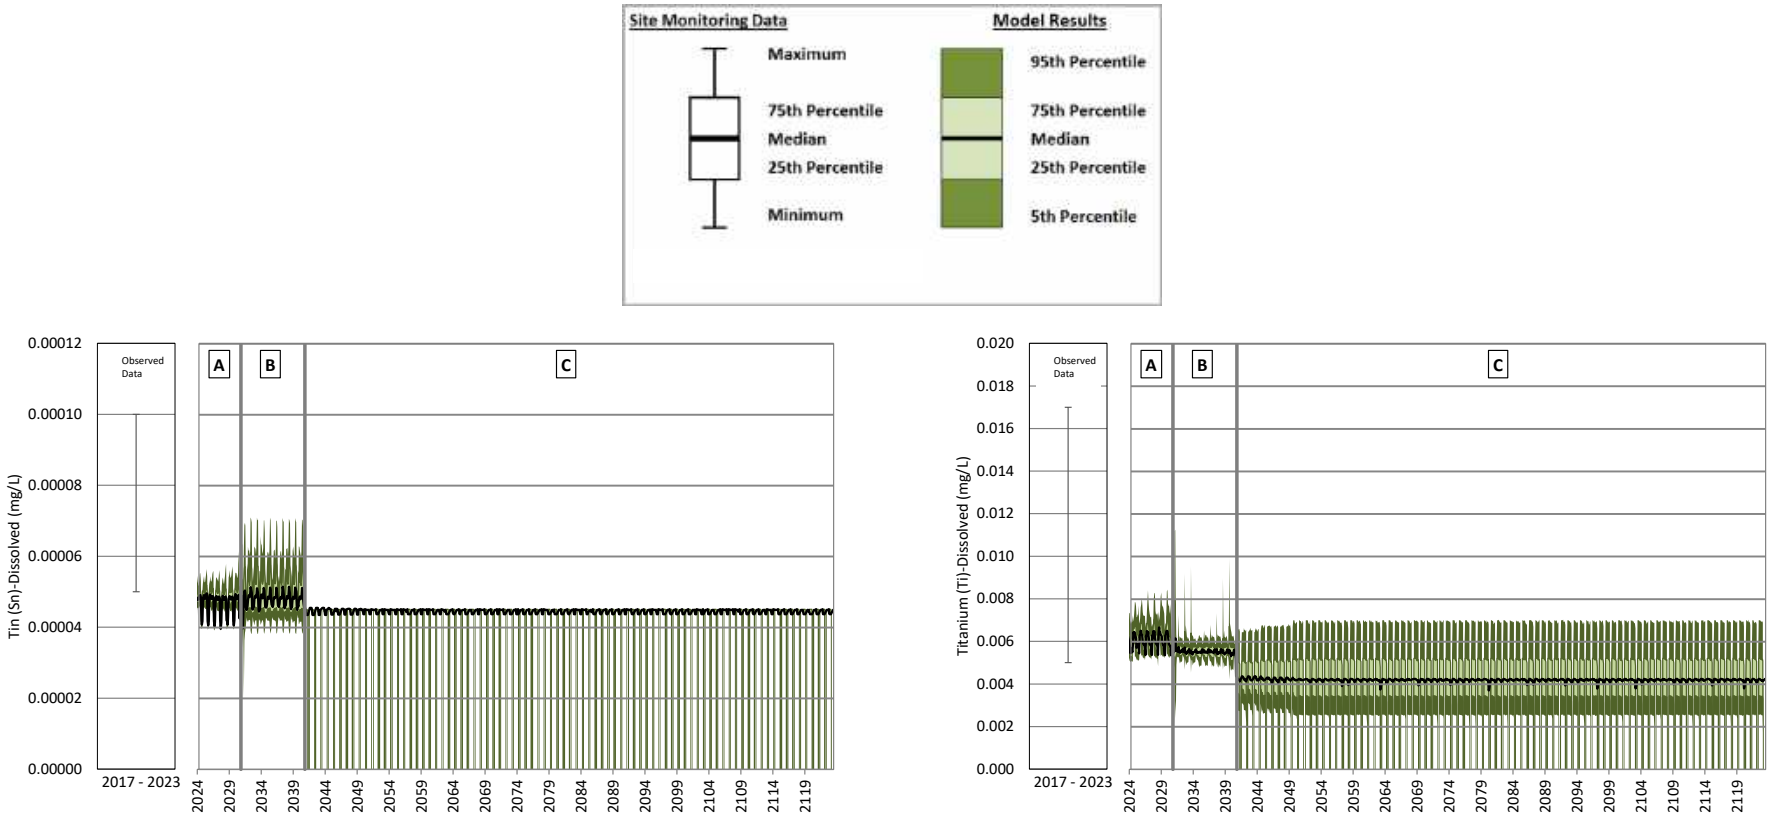

Figure B **96: Central Collection Sump Operations, Closure and Post-closure – Dissolved Selenium and Dissolved Silver**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

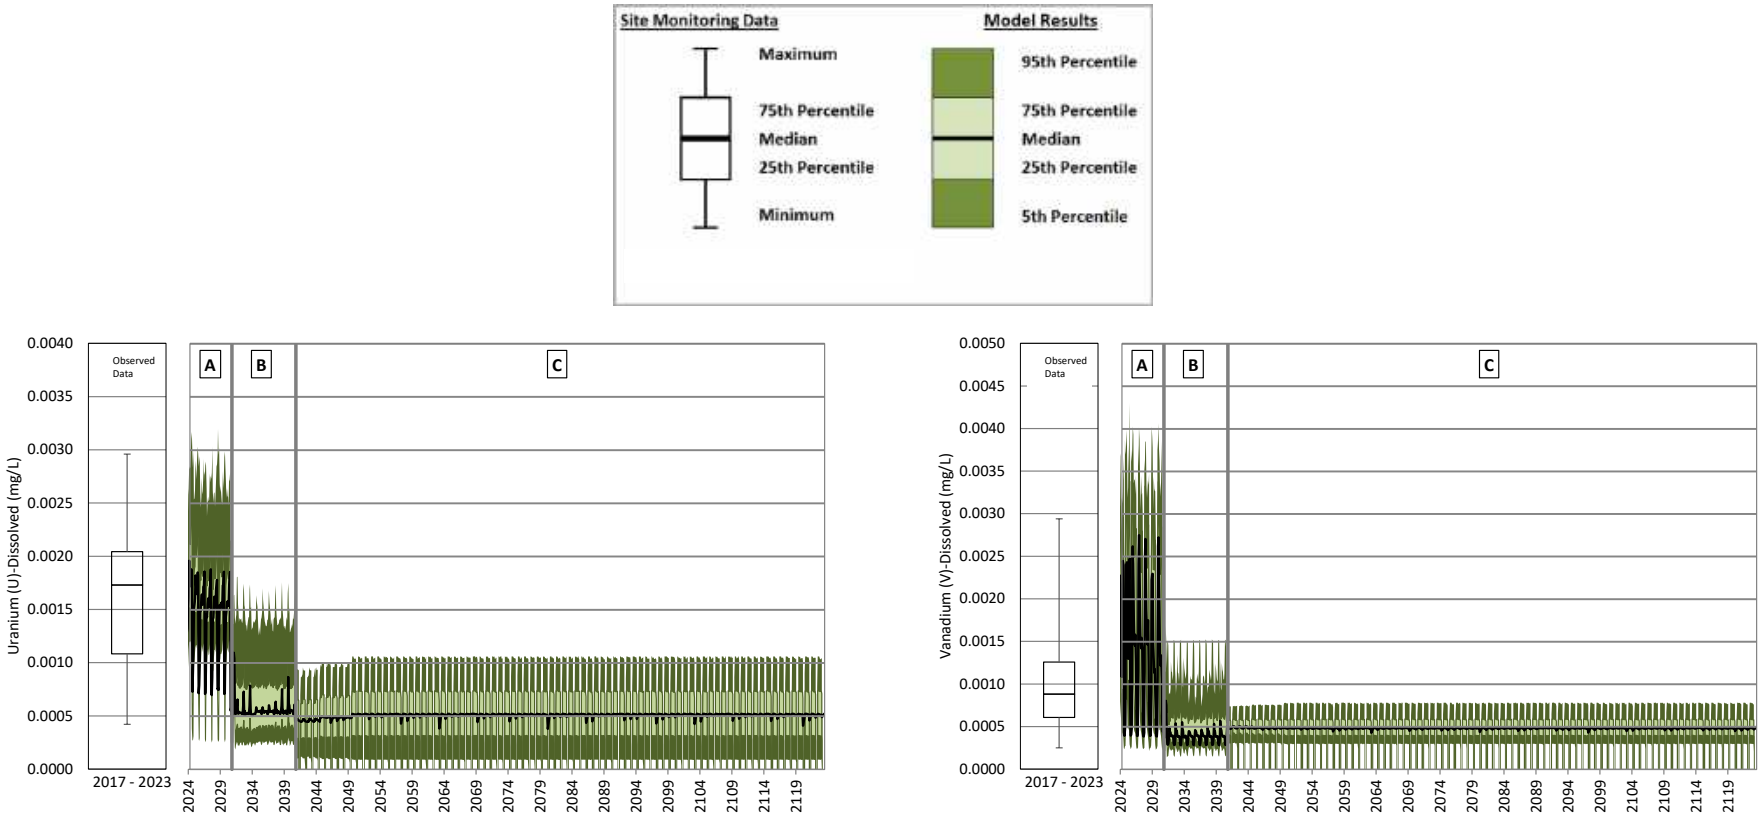

Figure B **97: Central Collection Sump Operations, Closure and Post-closure – Dissolved Strontium and Dissolved Thallium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

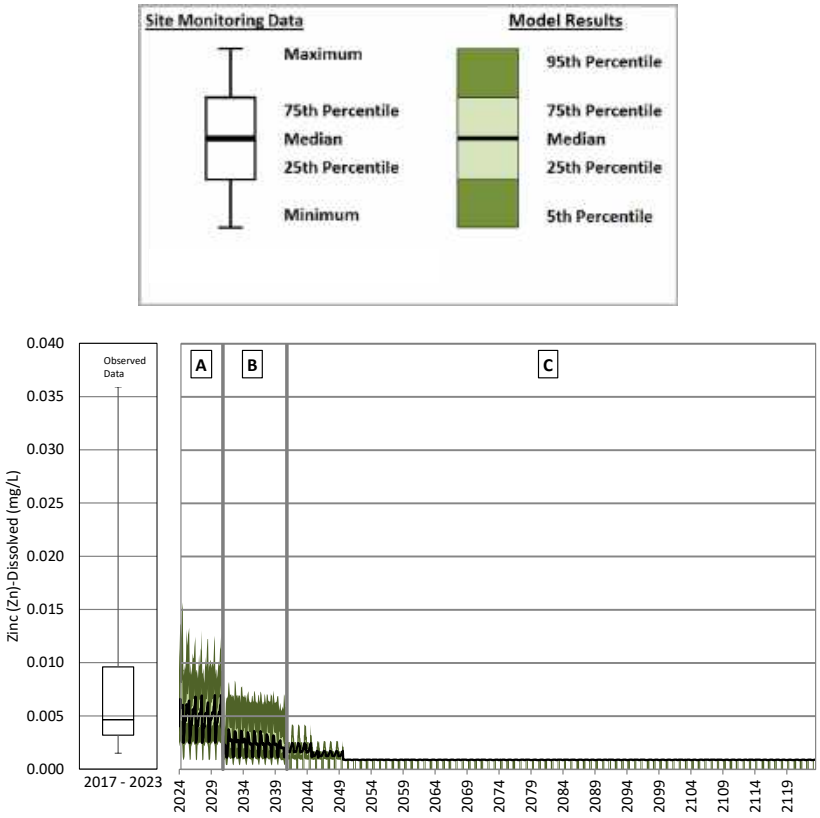

Figure B **98: Central Collection Sump Operations, Closure and Post-closure – Dissolved Tin and Dissolved Titanium**

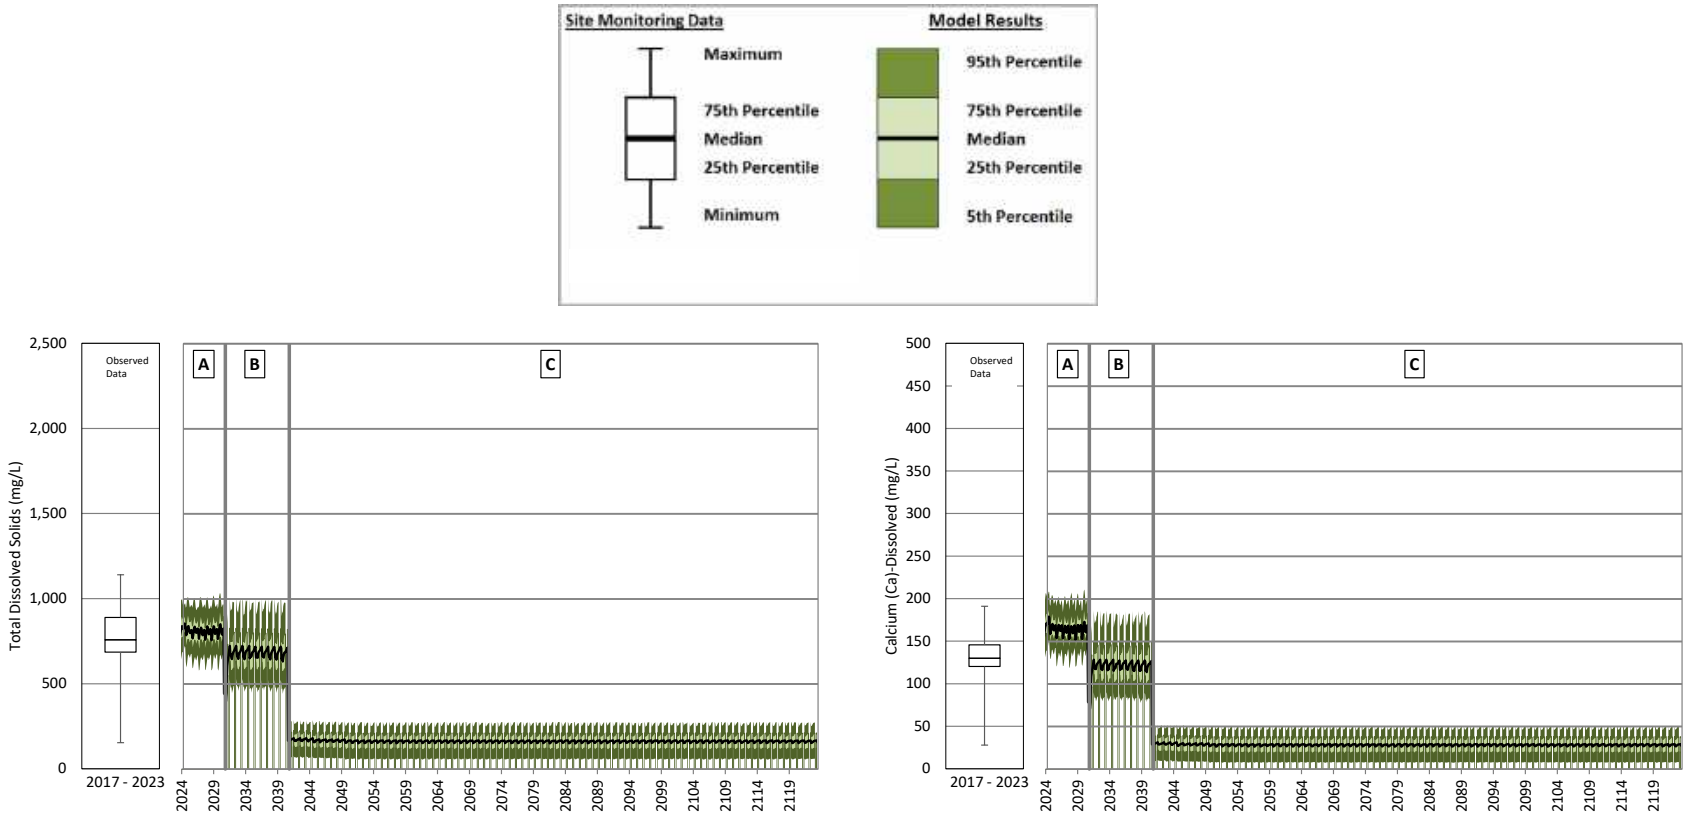
A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

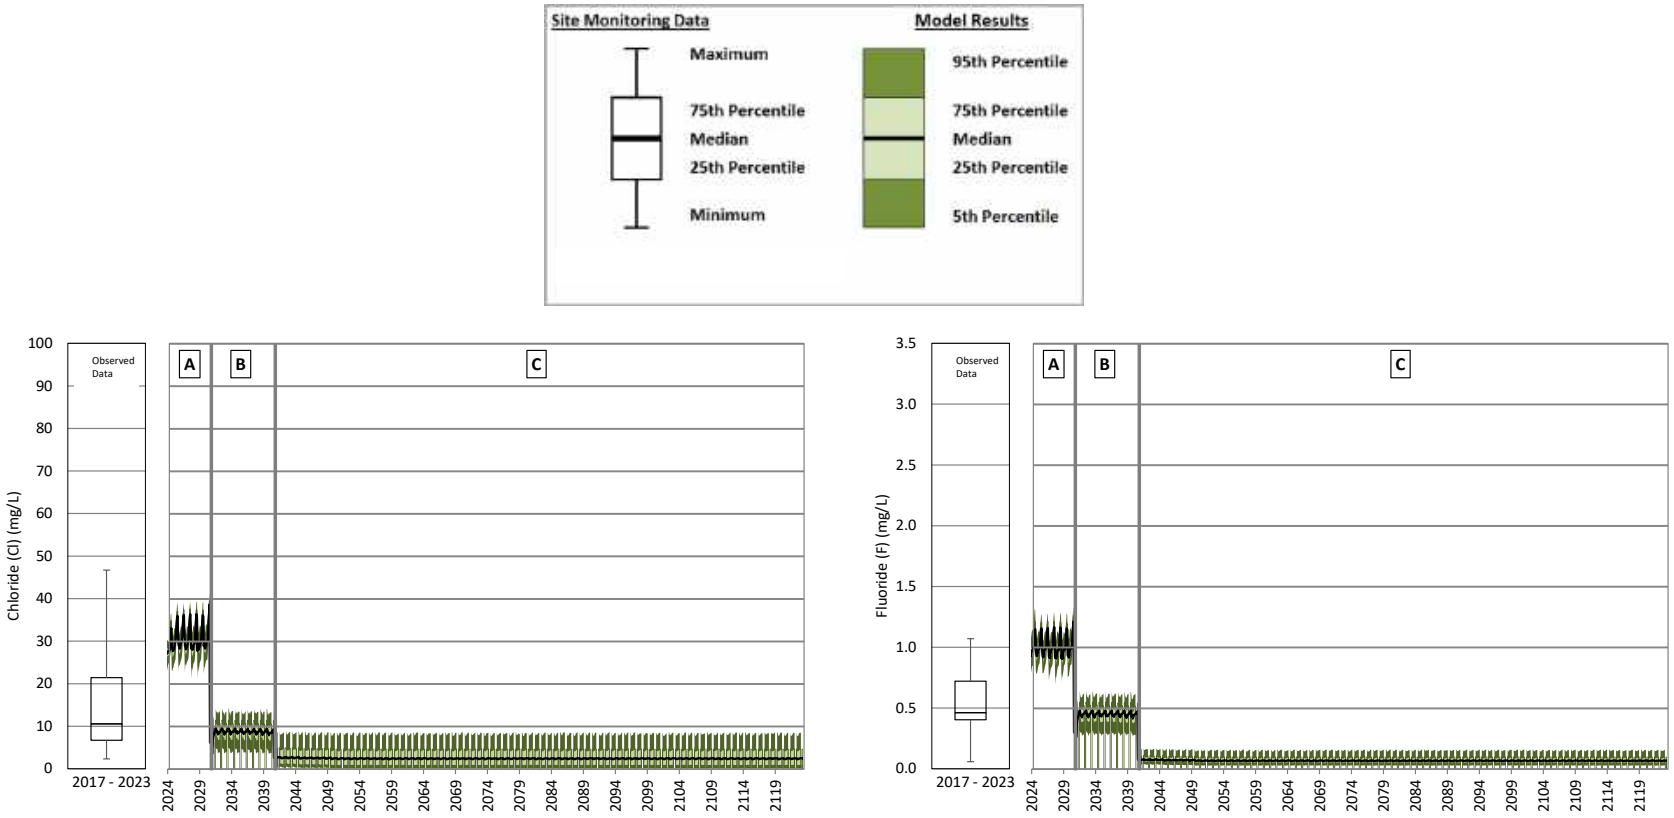
Figure B **99: Central Collection Sump Operations, Closure and Post-closure – Dissolved Uranium and Dissolved Vanadium**



A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure B **100: Central Collection Sump Operations, Closure and Post-closure – Dissolved Zinc**



Tailings Storage Facility Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

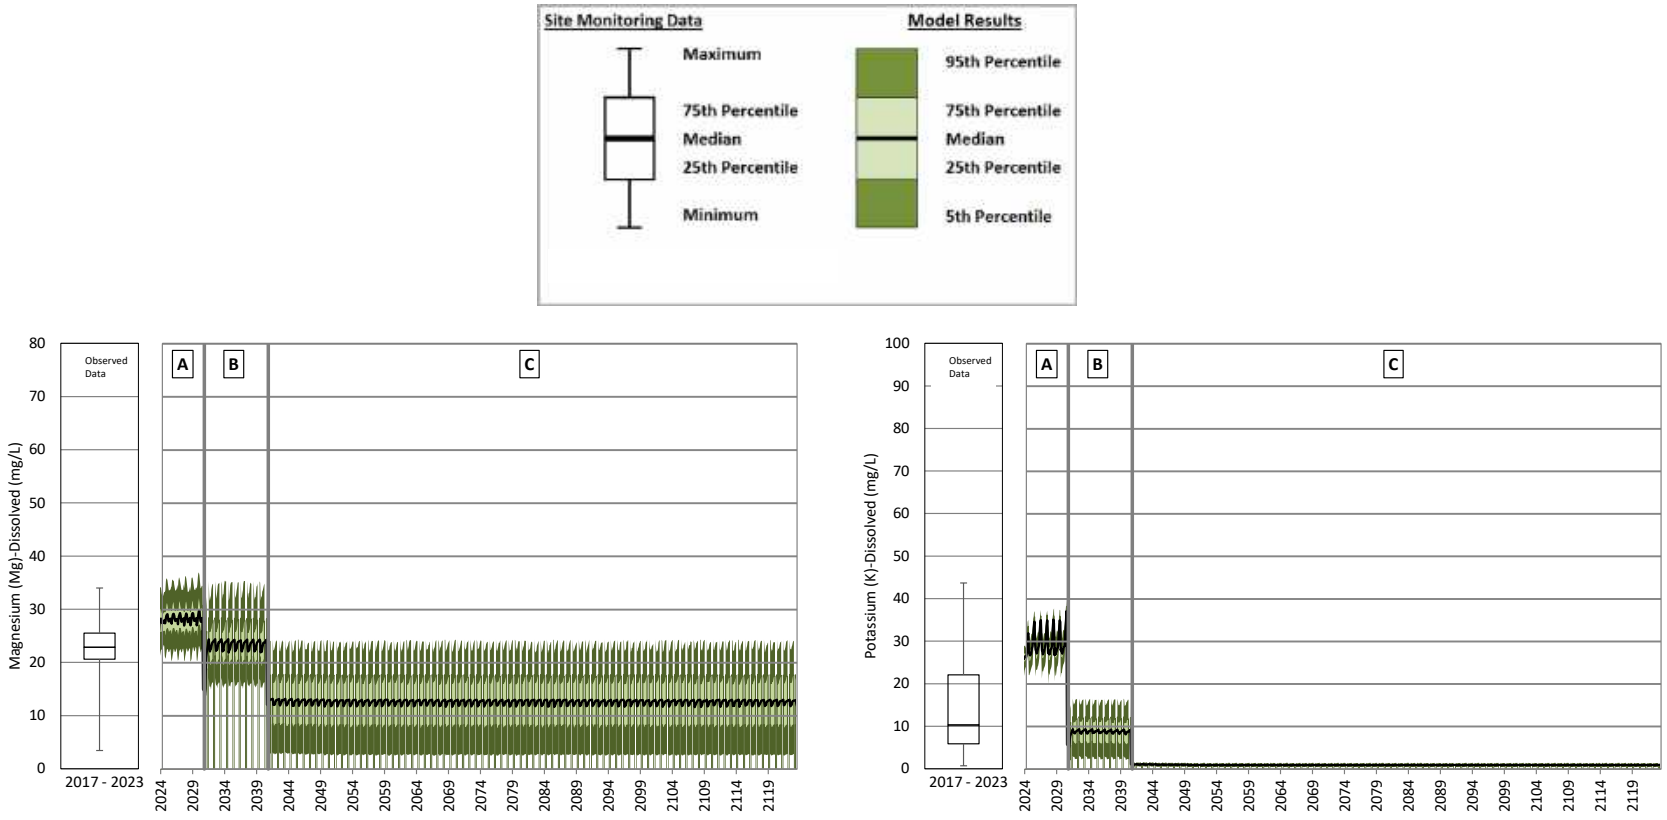


Figure B **101: Tailings Storage Facility Operations, Closure and Post-closure – Total Dissolved Solids and Calcium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

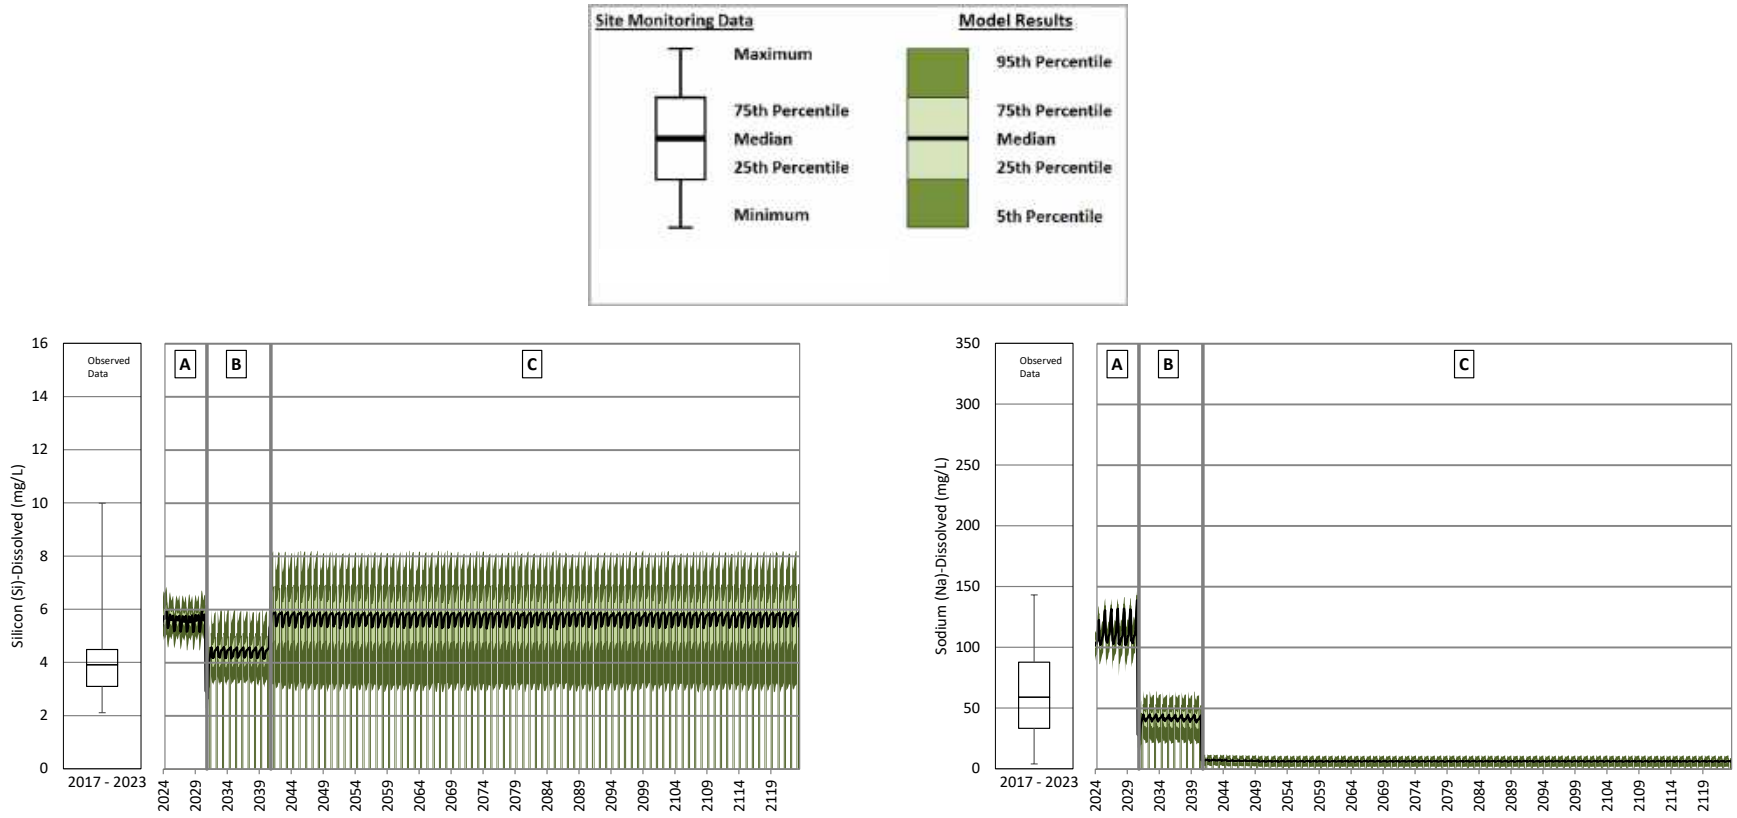

Figure B **102: Tailings Storage Facility Operations, Closure and Post-closure – Chloride and Fluoride**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

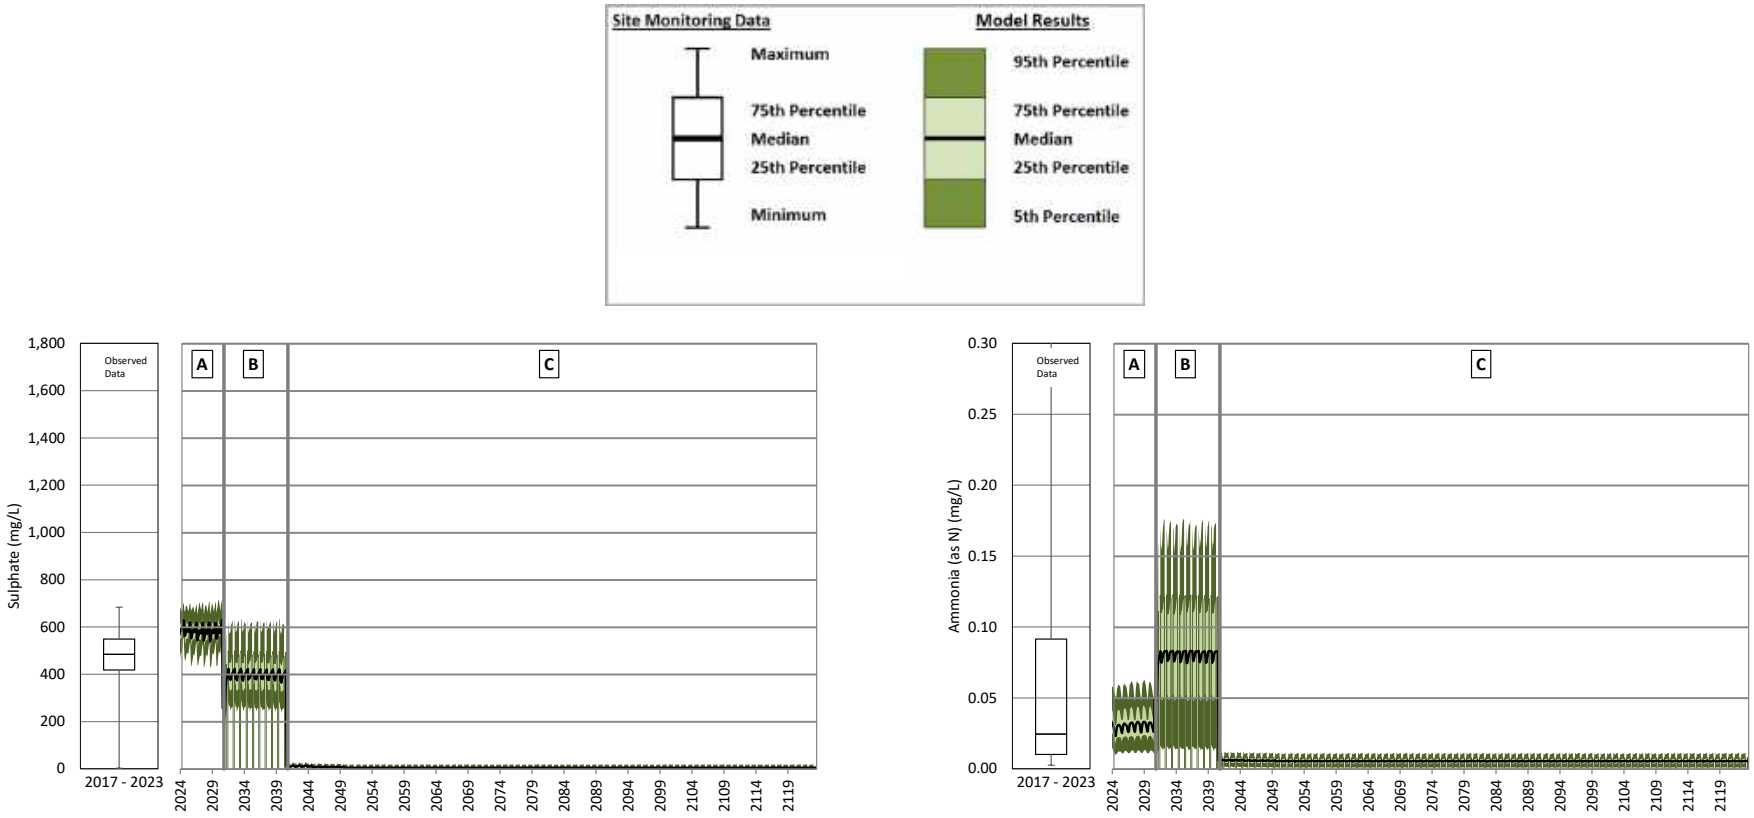

Figure B **103: Tailings Storage Facility Operations, Closure and Post-closure – Magnesium and Potassium**

A = Operations; B = Closure; C = Post-closure

Note: The increase in silicon concentrations from closure to post-closure is caused by runoff from areas that were assigned the disturbed water quality input being reclaimed and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher maximum silicon concentrations than the disturbed water quality input. Sodium concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

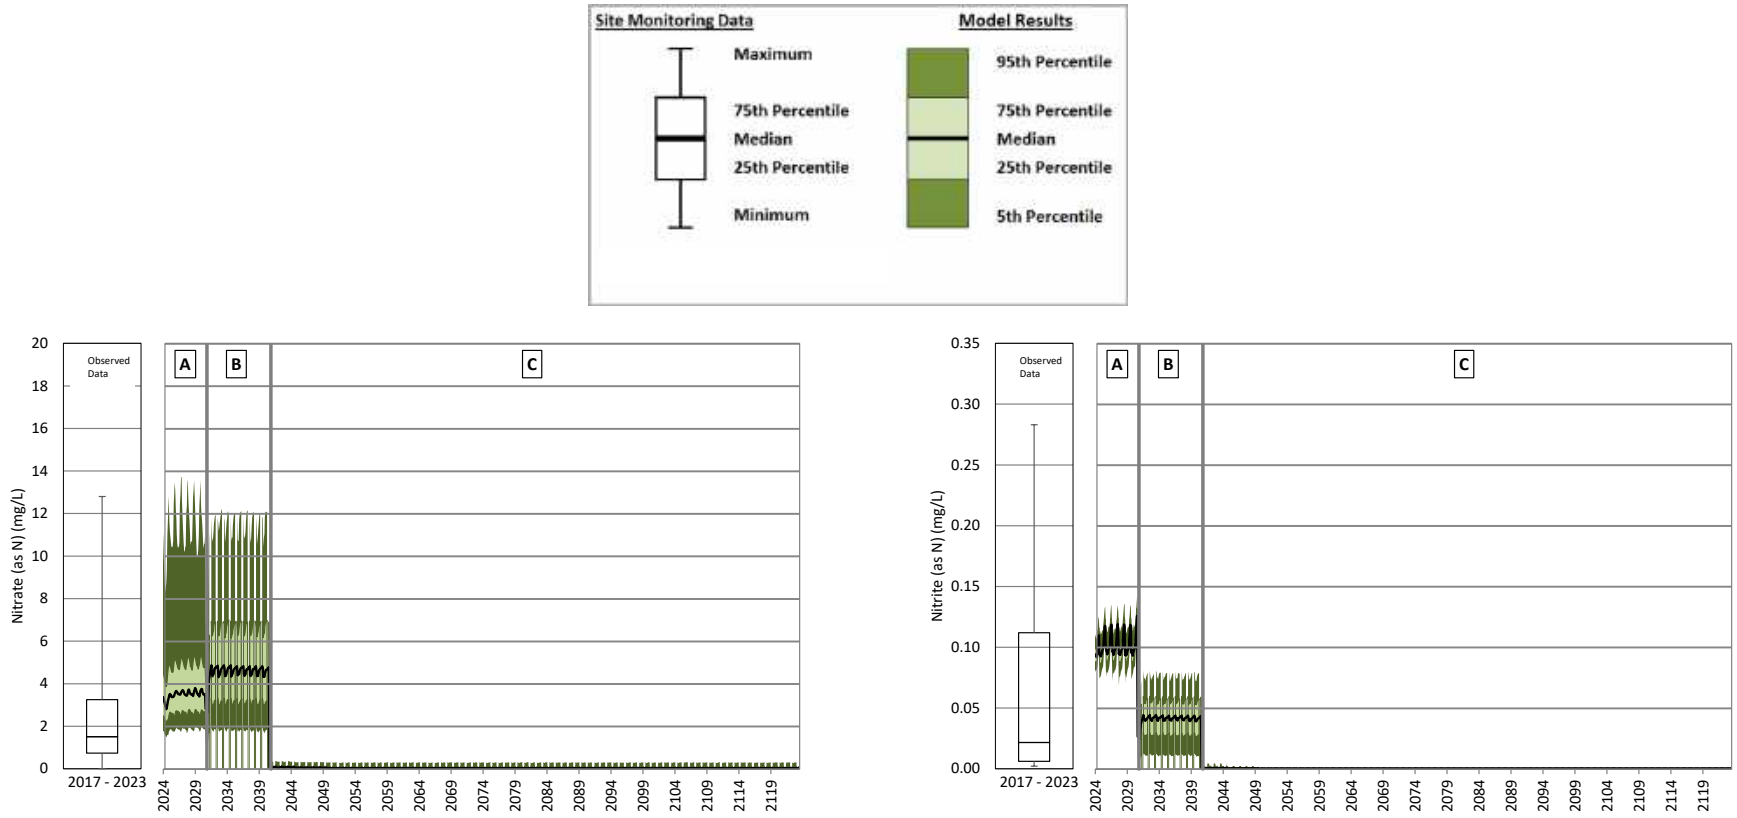

Figure B **104: Tailings Storage Facility Operations, Closure and Post-closure – Silicon and Sodium**

A = Operations; B = Closure; C = Post-closure

Note: Sulphate concentrations decrease from operations to closure and post-closure as runoff areas are remediated. The increase in total ammonia concentrations during closure is caused by the end of pumping from the Perimeter Embankment Till Borrow Pond (PETBP) to the TSF. Lower total ammonia concentrations in the PETBP causes dilution of the total ammonia concentrations in the TSF during operations. Total ammonia concentrations decrease from closure to post-closure as runoff areas are remediated.

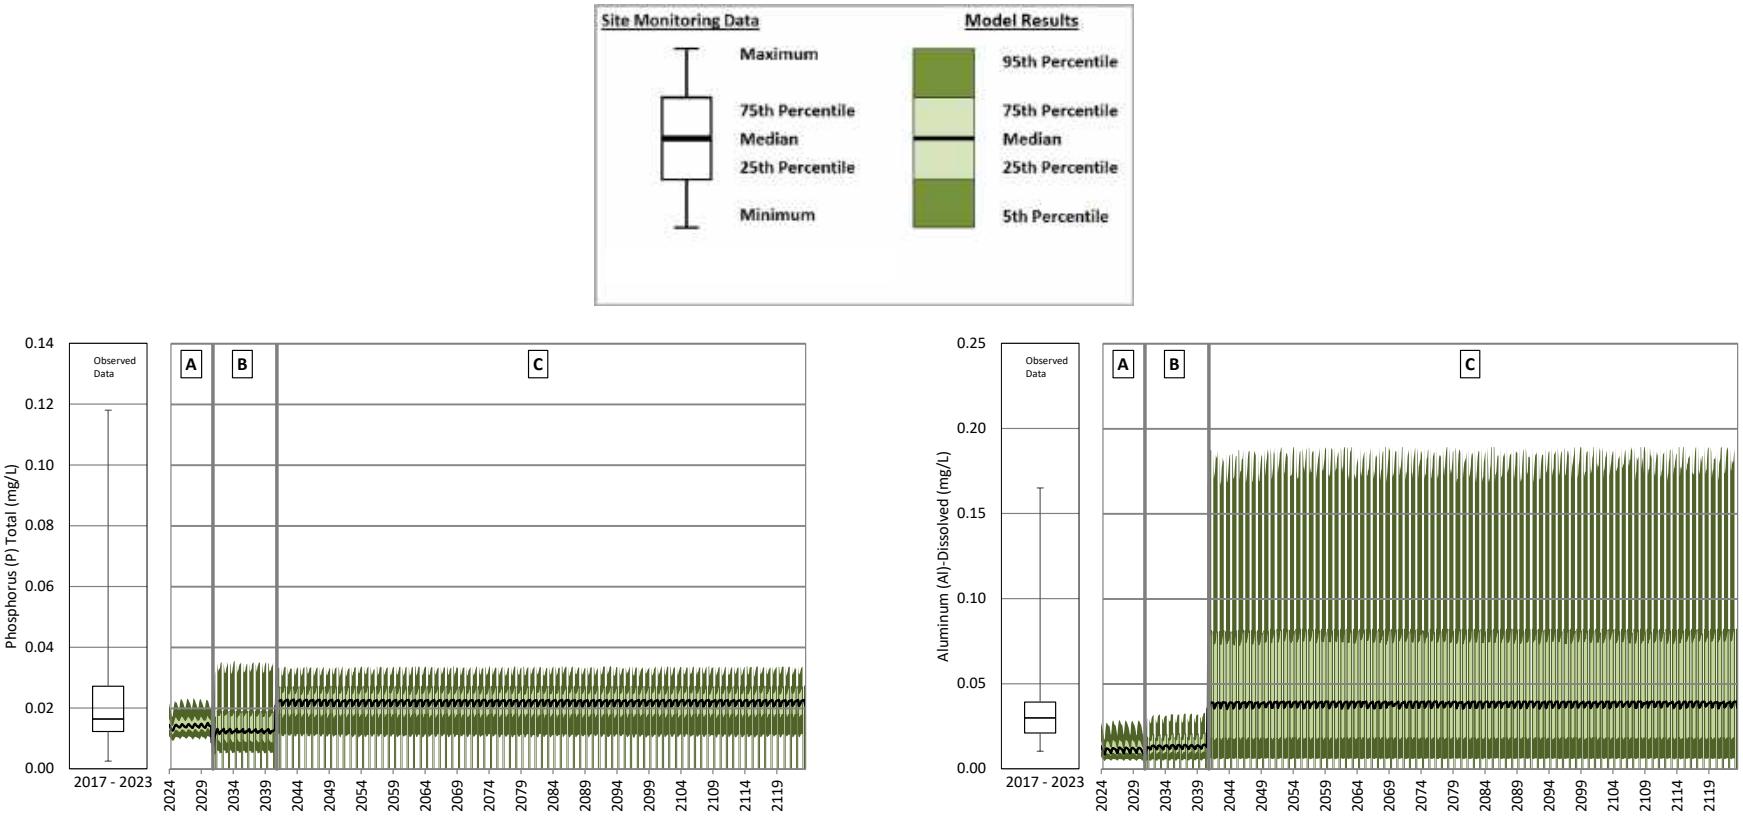

Figure B **105: Tailings Storage Facility Operations, Closure and Post-closure – Sulphate and Total Ammonia**

A = Operations; B = Closure; C = Post-closure

Note: The increase in nitrate concentrations during closure is caused by the end of pumping from the Perimeter Embankment Till Borrow Pond (PETBP) to the TSF. Lower nitrate concentrations in the PETBP causes dilution of the nitrate concentrations in the TSF during operations. Nitrate concentrations decrease from closure to post-closure as runoff areas are remediated. Nitrite concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

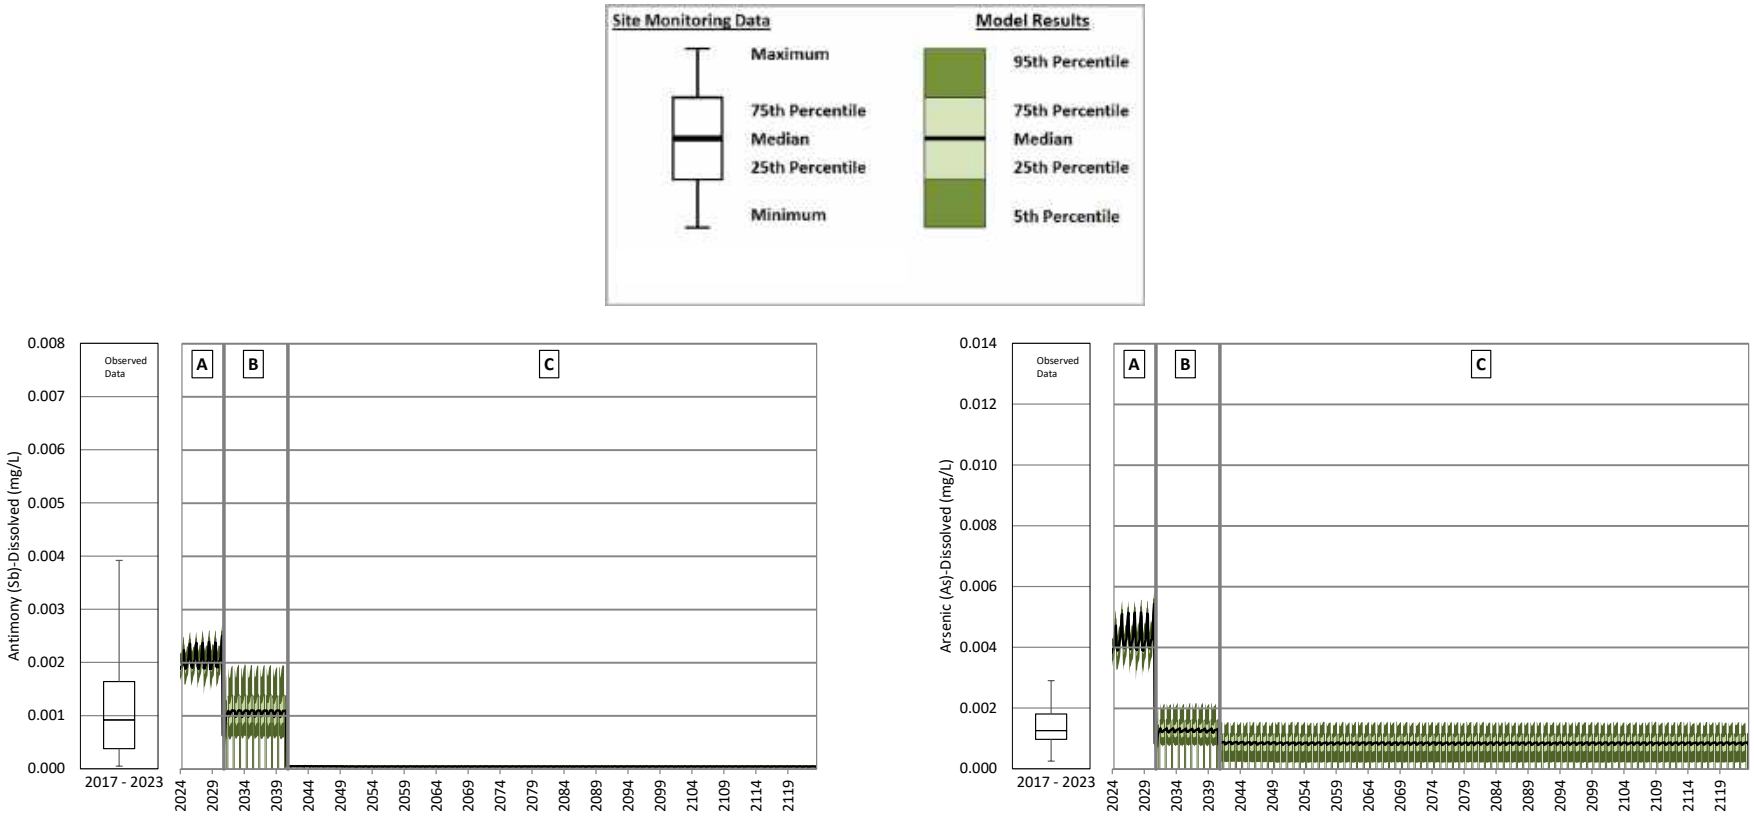

Figure B **106: Tailings Storage Facility Operations, Closure and Post-closure – Nitrate and Nitrite**

A = Operations; B = Closure; C = Post-closure

Note: Total phosphorus and dissolved aluminum concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for total phosphorus and dissolved aluminum than the NAG waste rock and disturbed runoff water quality inputs.

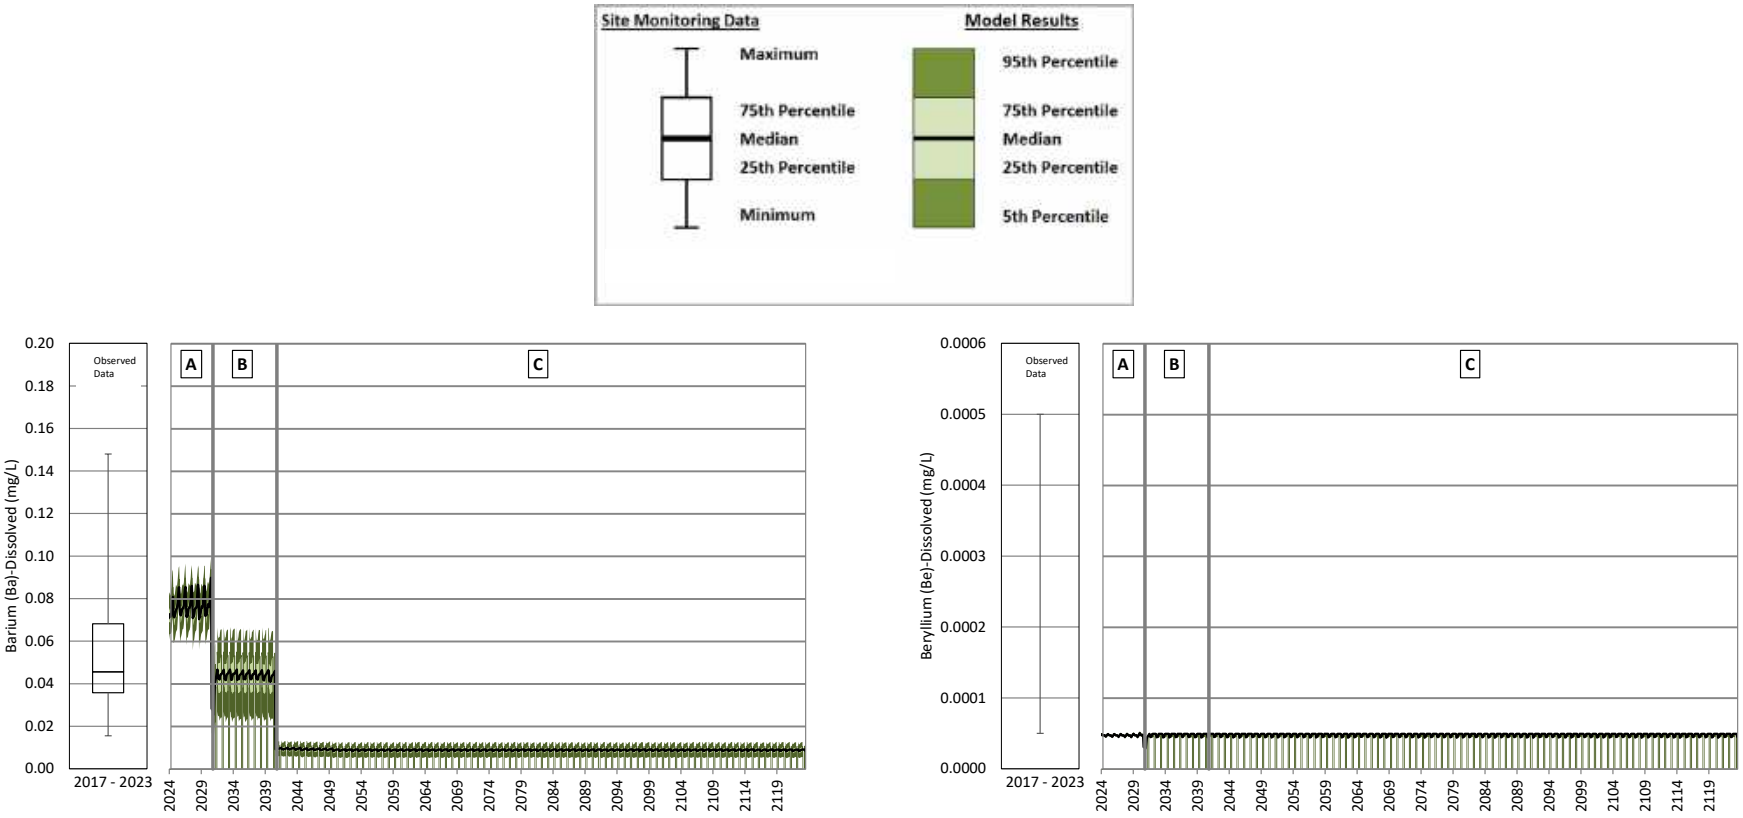

Figure B **107: Tailings Storage Facility Operations, Closure and Post-closure – Total Phosphorus and Dissolved Aluminum**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

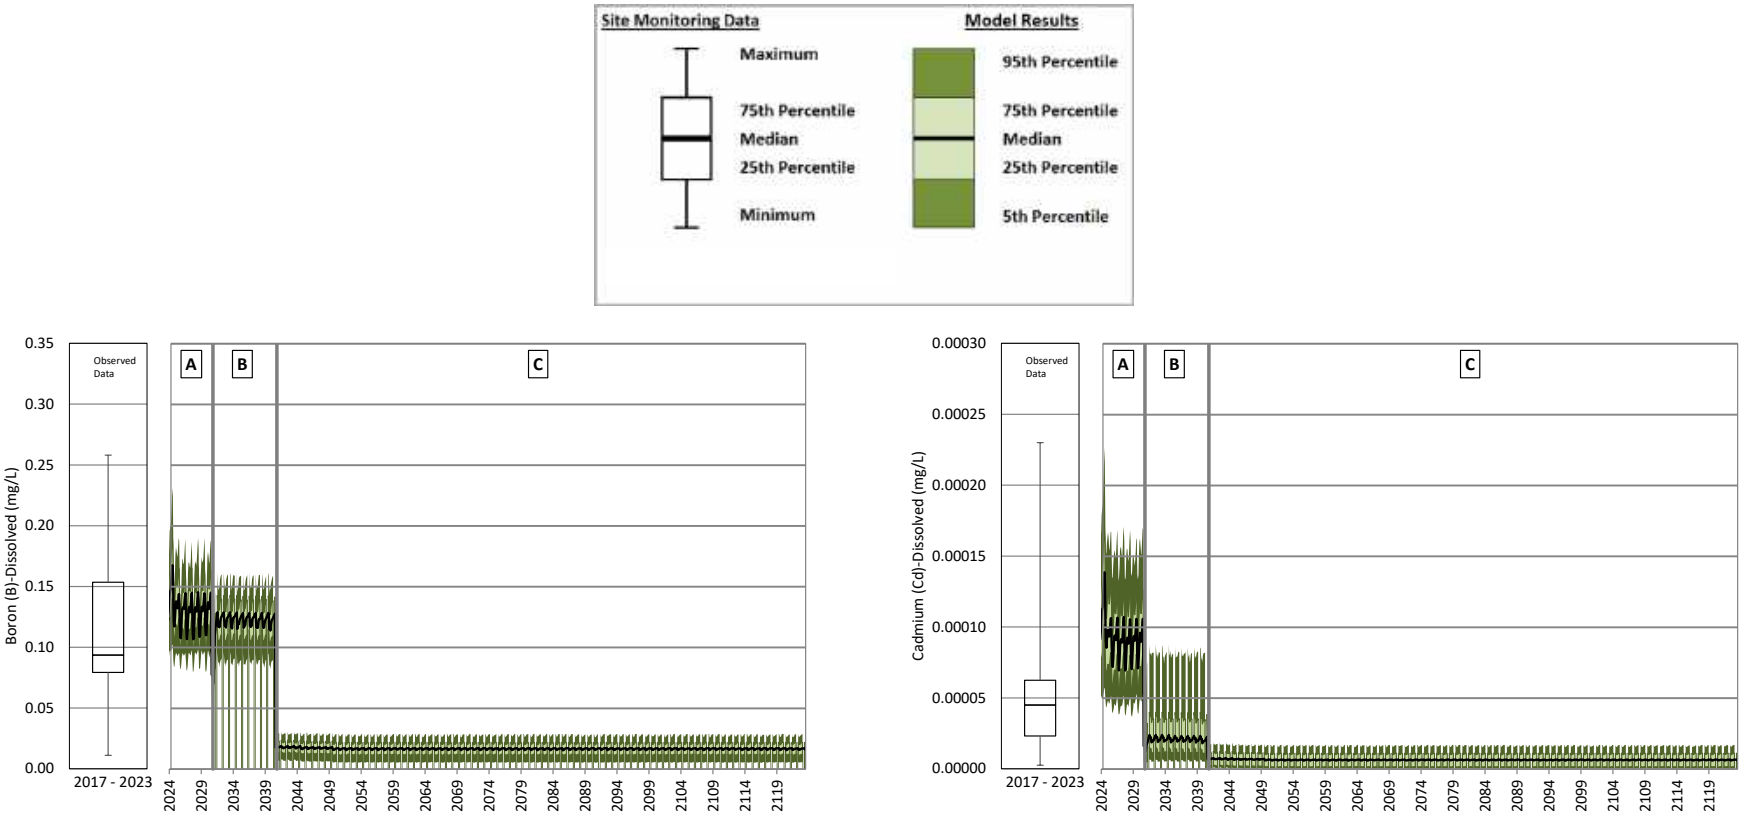

Figure B **108: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Antimony and Dissolved Arsenic**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

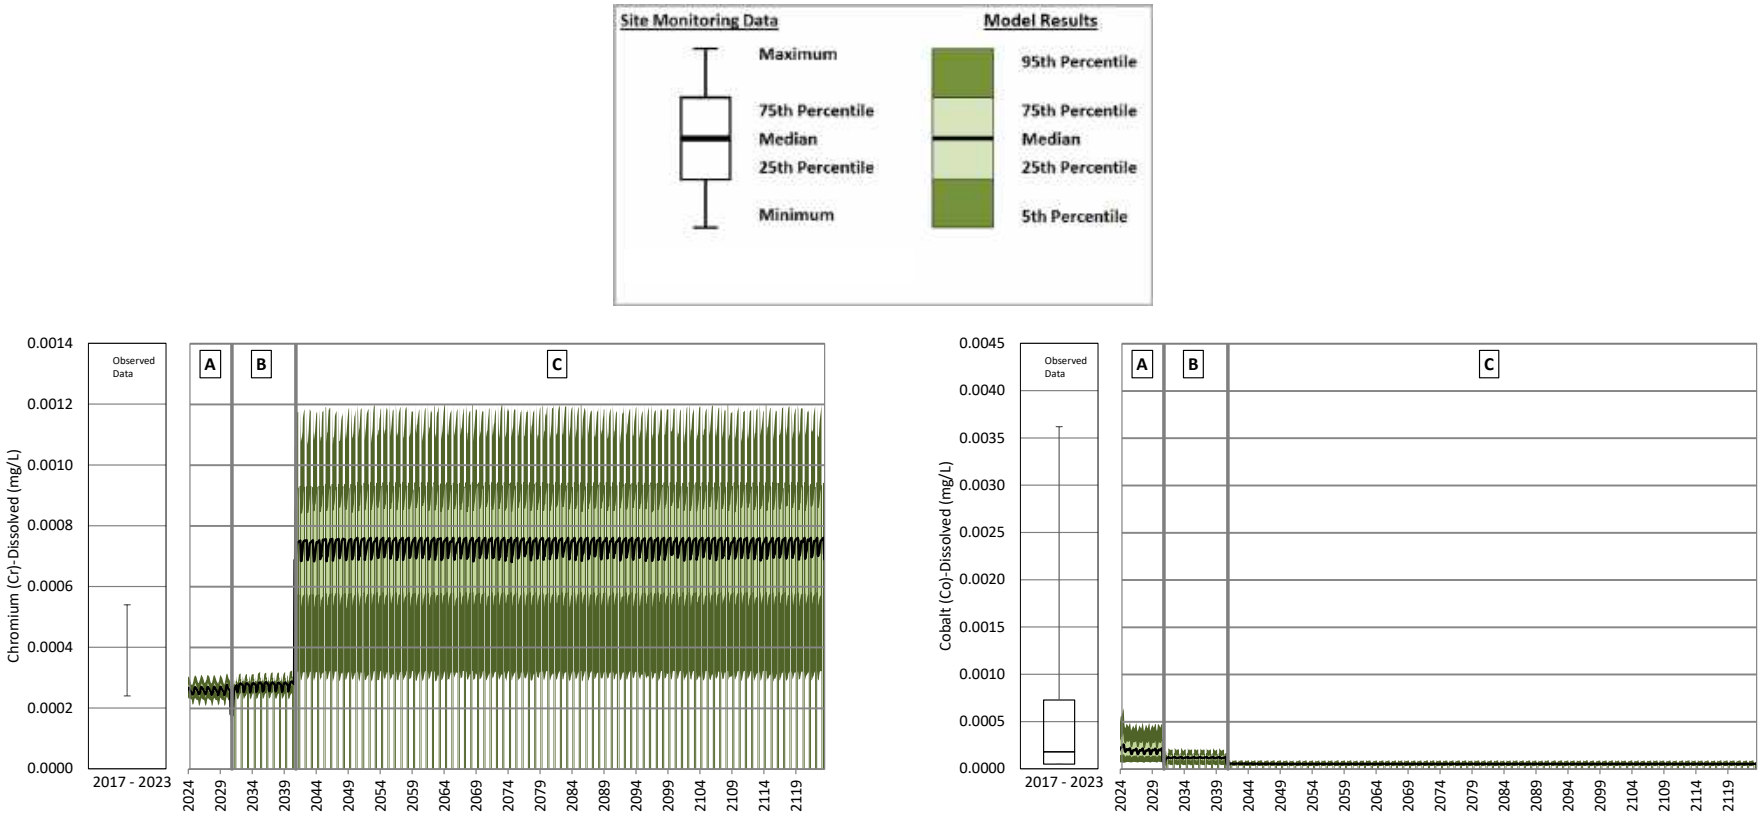

Figure B **109: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Barium and Dissolved Beryllium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

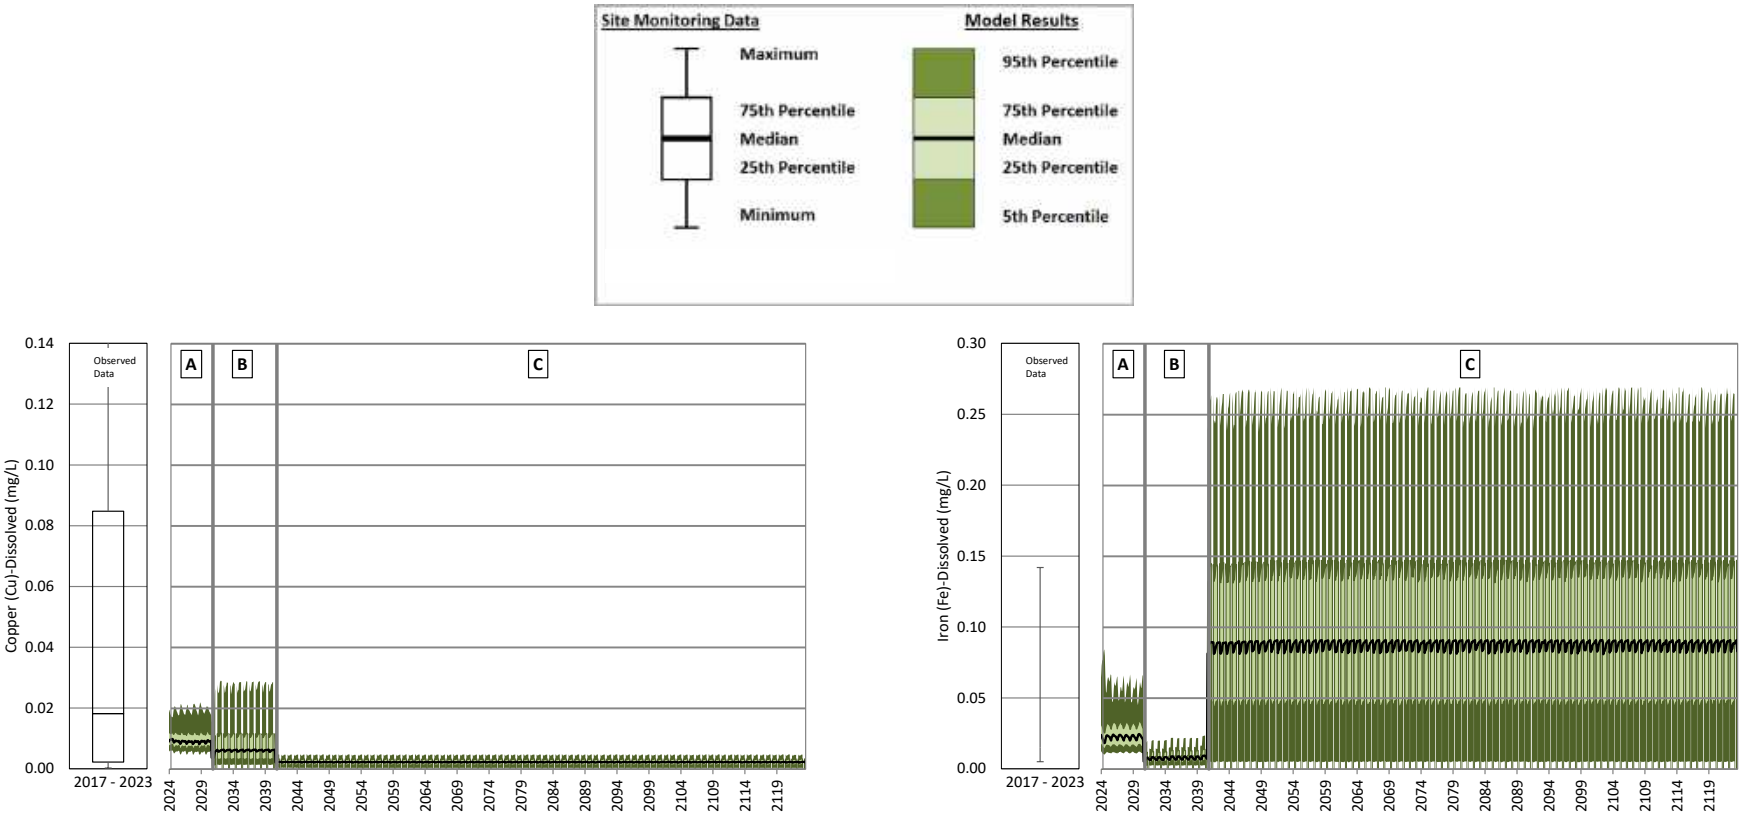

Figure B **110: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Boron and Dissolved Cadmium**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved chromium concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved chromium than the NAG waste rock and disturbed runoff water quality inputs. Dissolved cobalt concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

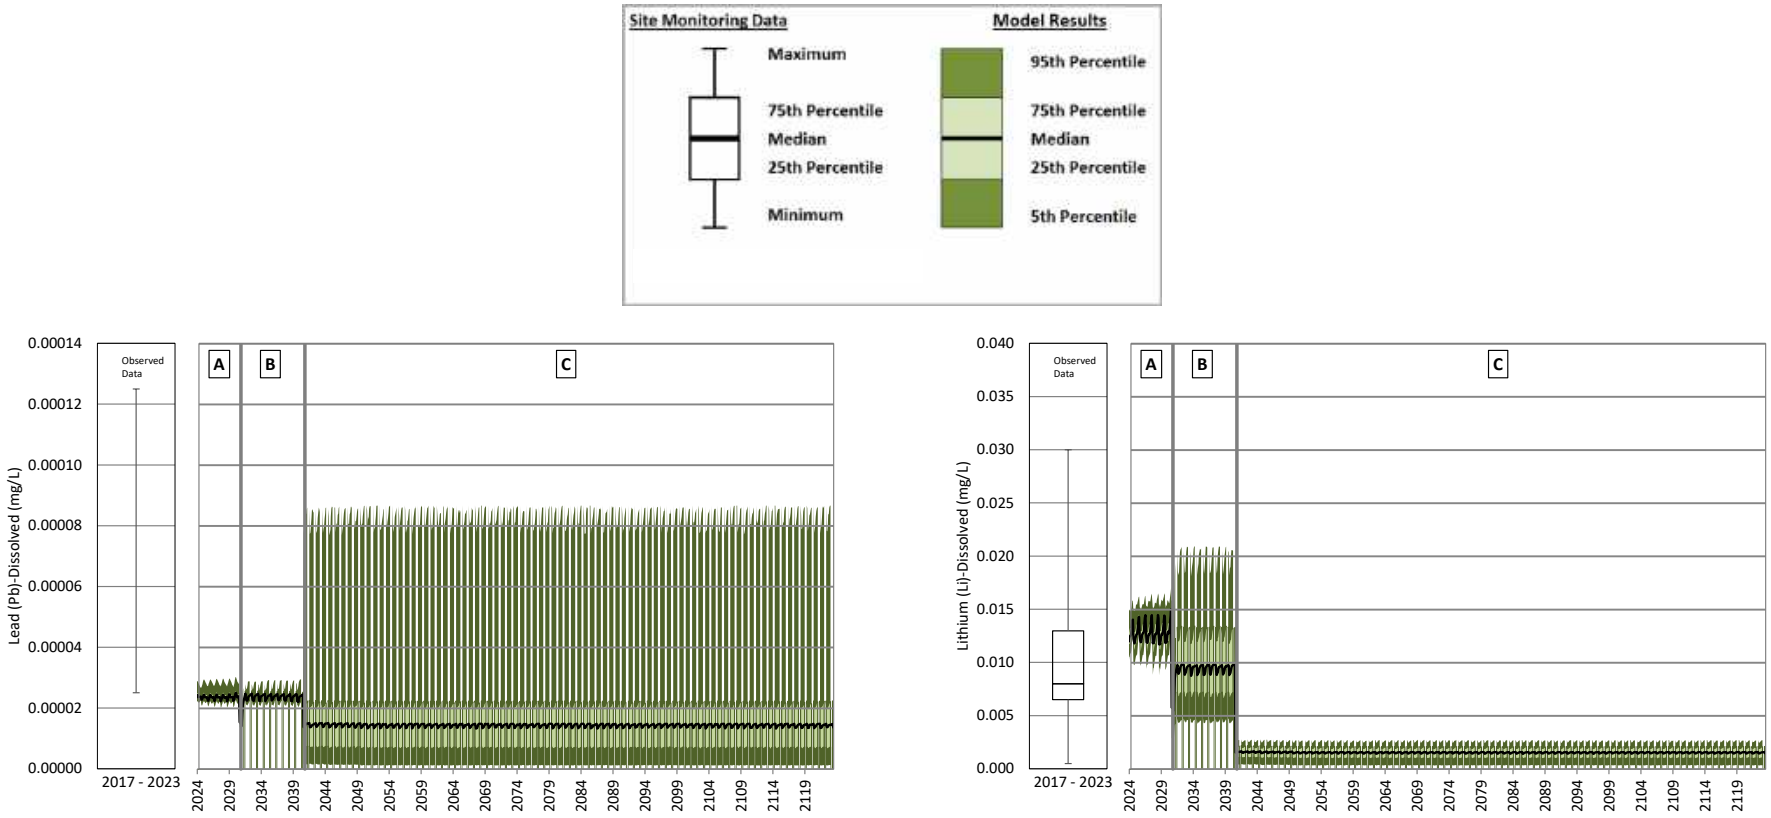

Figure B **111: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Chromium and Dissolved Cobalt**

A = Operations; B = Closure; C = Post-closure

Note: The increase in dissolved copper concentrations during closure is caused by the end of pumping from the Perimeter Embankment Till Borrow Pond (PETBP) to the Tailings Storage Facility (TSF). Lower dissolved copper concentrations in the PETBP causes dilution of the dissolved copper concentrations in the TSF during operations. Dissolved copper concentrations decrease from closure to post-closure as runoff areas are remediated. The decrease in dissolved iron concentrations during closure is caused by the end of pumping from the PETBP to the TSF. Higher dissolved iron concentrations in the PETBP causes increased concentrations of dissolved iron concentrations in the TSF during operations. Dissolved iron concentrations increase from closure to post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input that has higher dissolved iron concentrations than contact water.

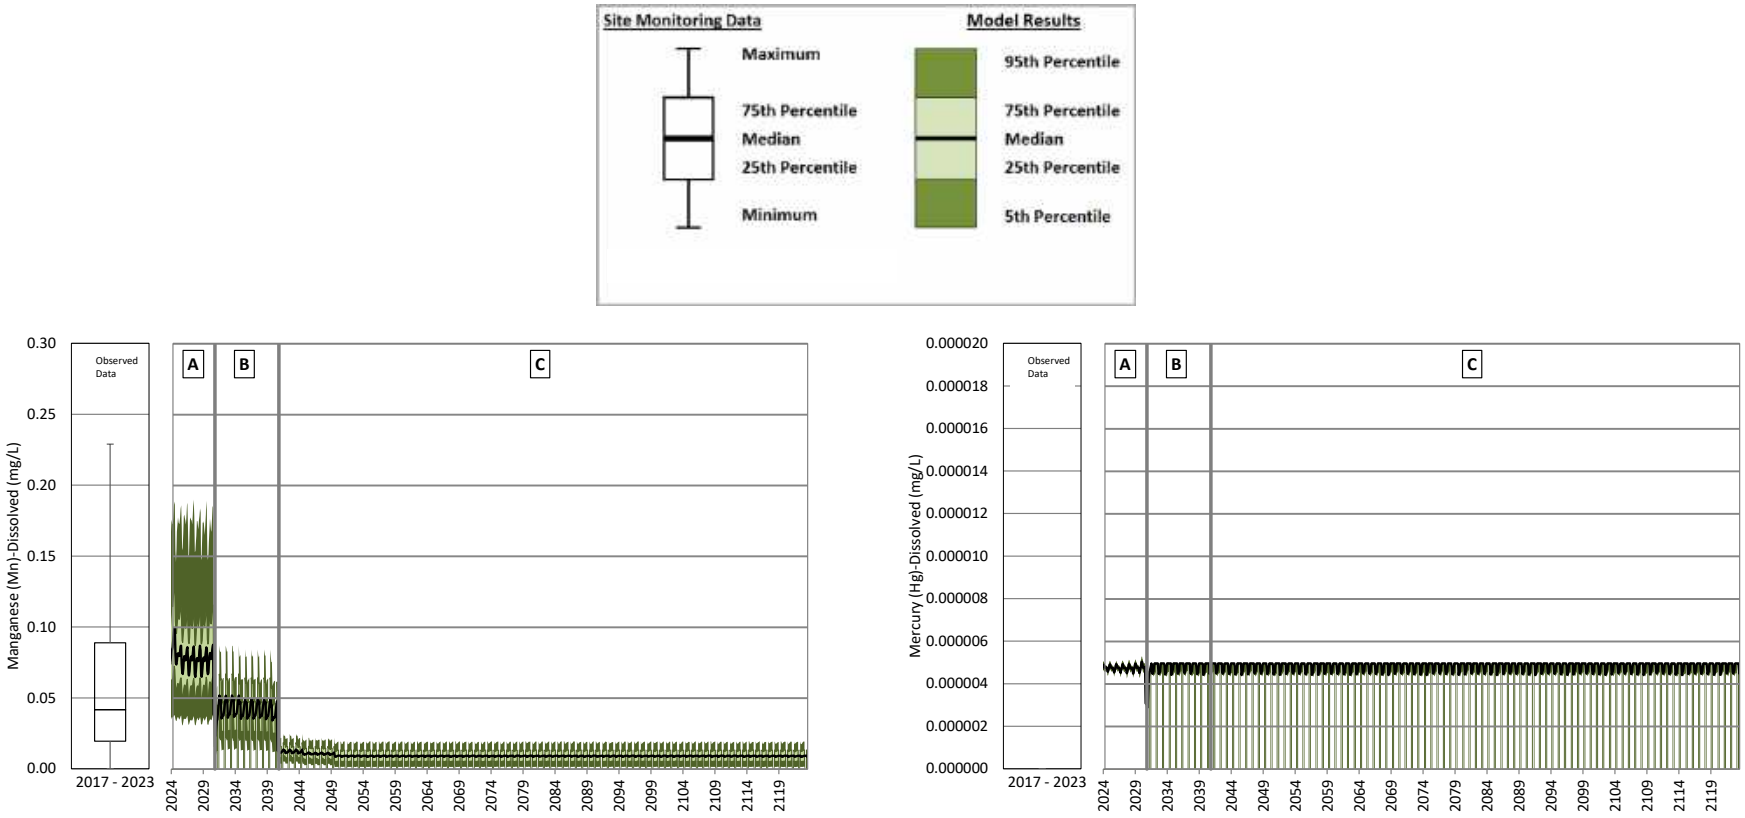

Figure B **112: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Copper and Dissolved Iron**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved lead concentrations increase from closure to post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved lead than the NAG waste rock and disturbed runoff water quality inputs. The decrease in dissolved lithium concentrations from 2031 to 2032 is due to the end of pumping from the mill processing plant to the Tailings Storage Facility (TSF). The increase in dissolved lithium concentrations during closure is caused by the end of pumping from the Perimeter Embankment Till Borrow Pond (PETBP) to the TSF. Lower dissolved lithium concentrations in the PETBP causes dilution of the dissolved lithium concentrations in the TSF during operations. Dissolved lithium concentrations decrease from closure to post-closure as runoff areas are remediated.

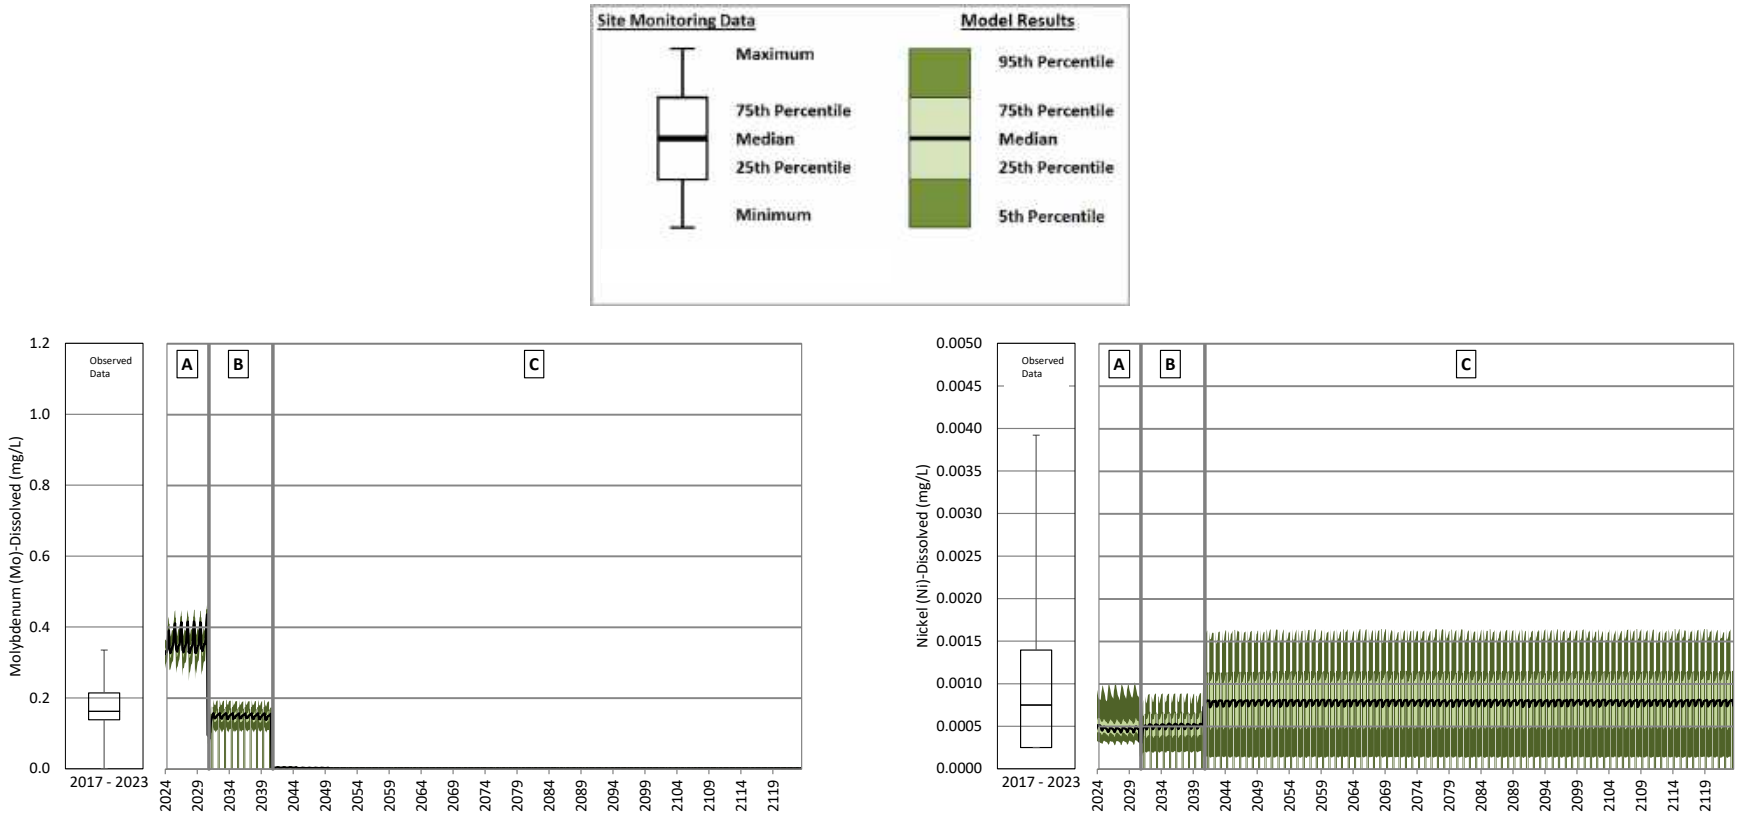

Figure B **113: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Lead and Dissolved Lithium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

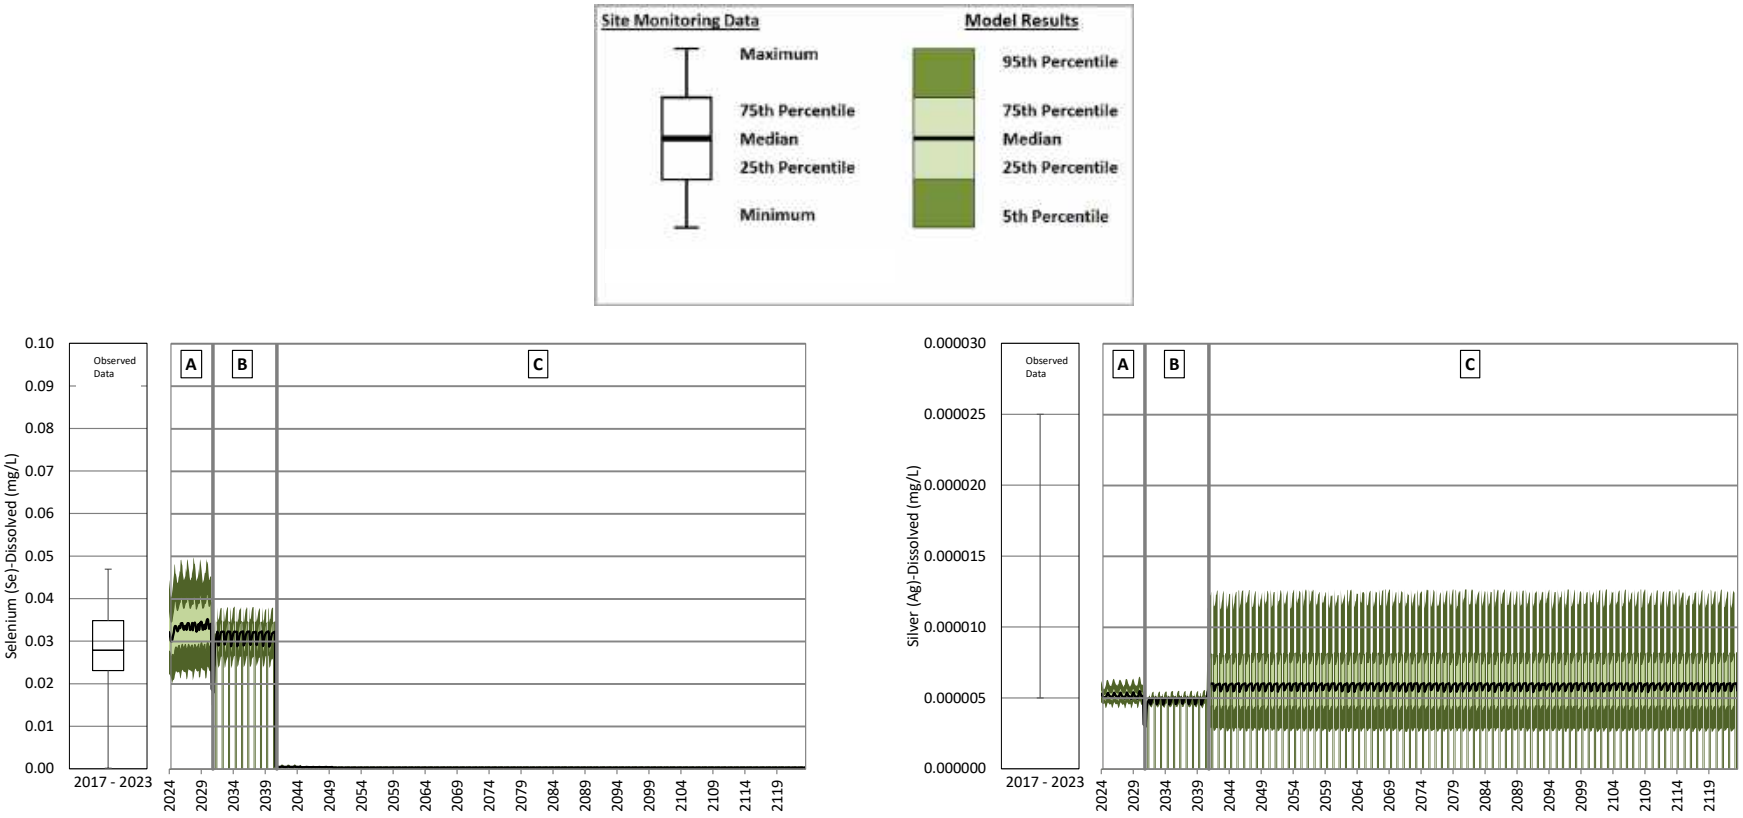

Figure B **114: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Manganese and Dissolved Mercury**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved molybdenum concentrations decrease from closure to post-closure as runoff areas are remediated. Dissolved nickel concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved nickel than the NAG waste rock and disturbed runoff water quality inputs.

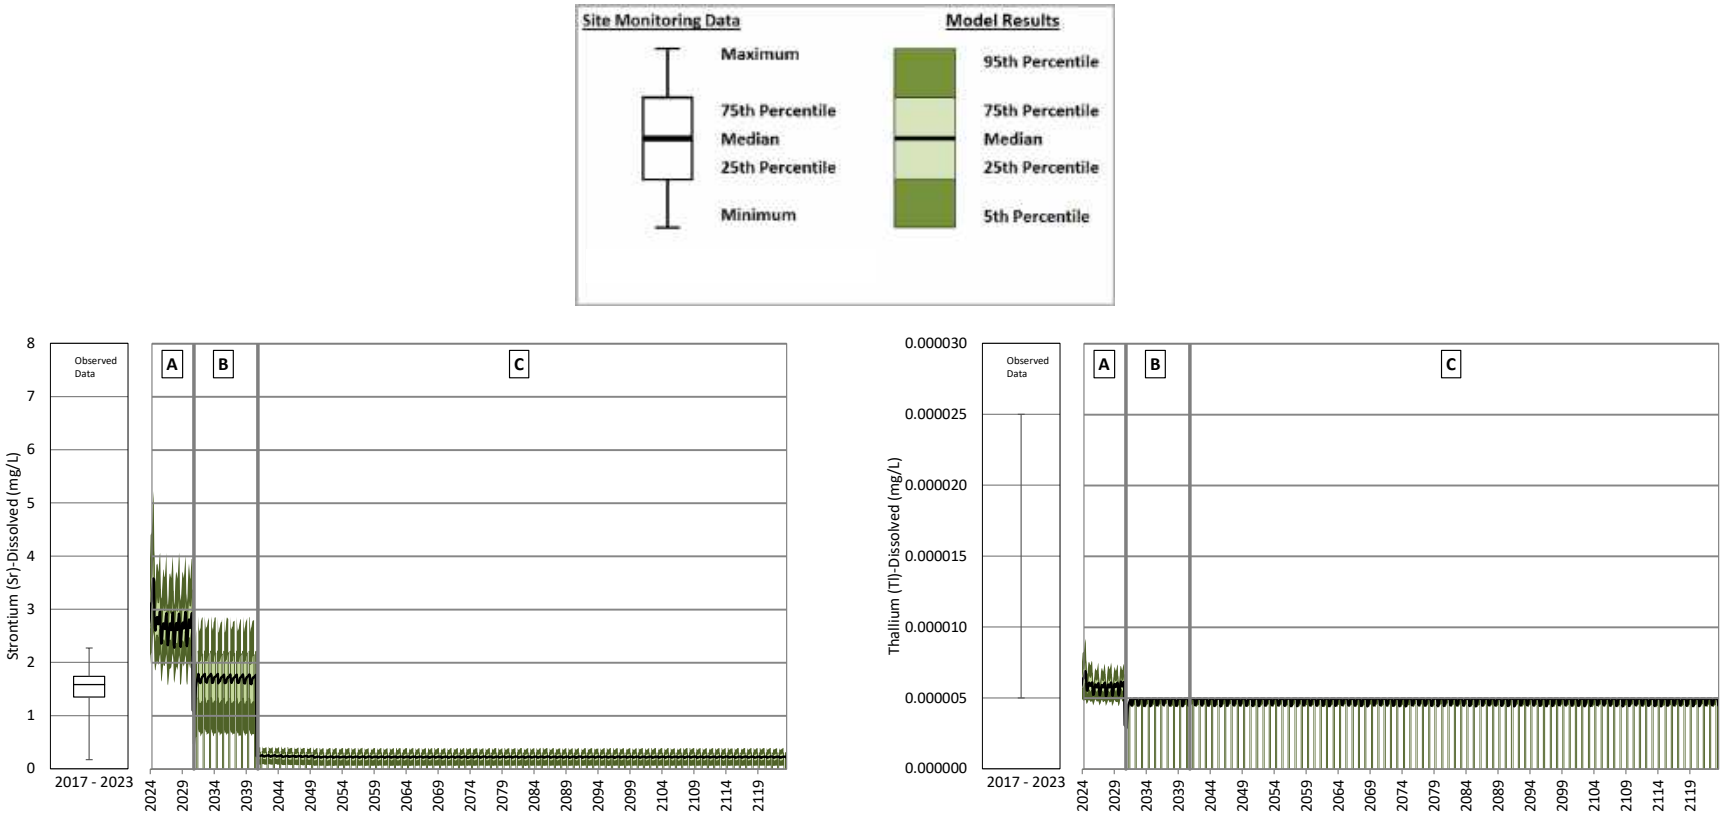

Figure B **115: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Molybdenum and Dissolved Nickel**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved selenium concentrations decrease from closure to post-closure as runoff areas are remediated. Dissolved silver concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved silver than the NAG waste rock and disturbed runoff water quality inputs.

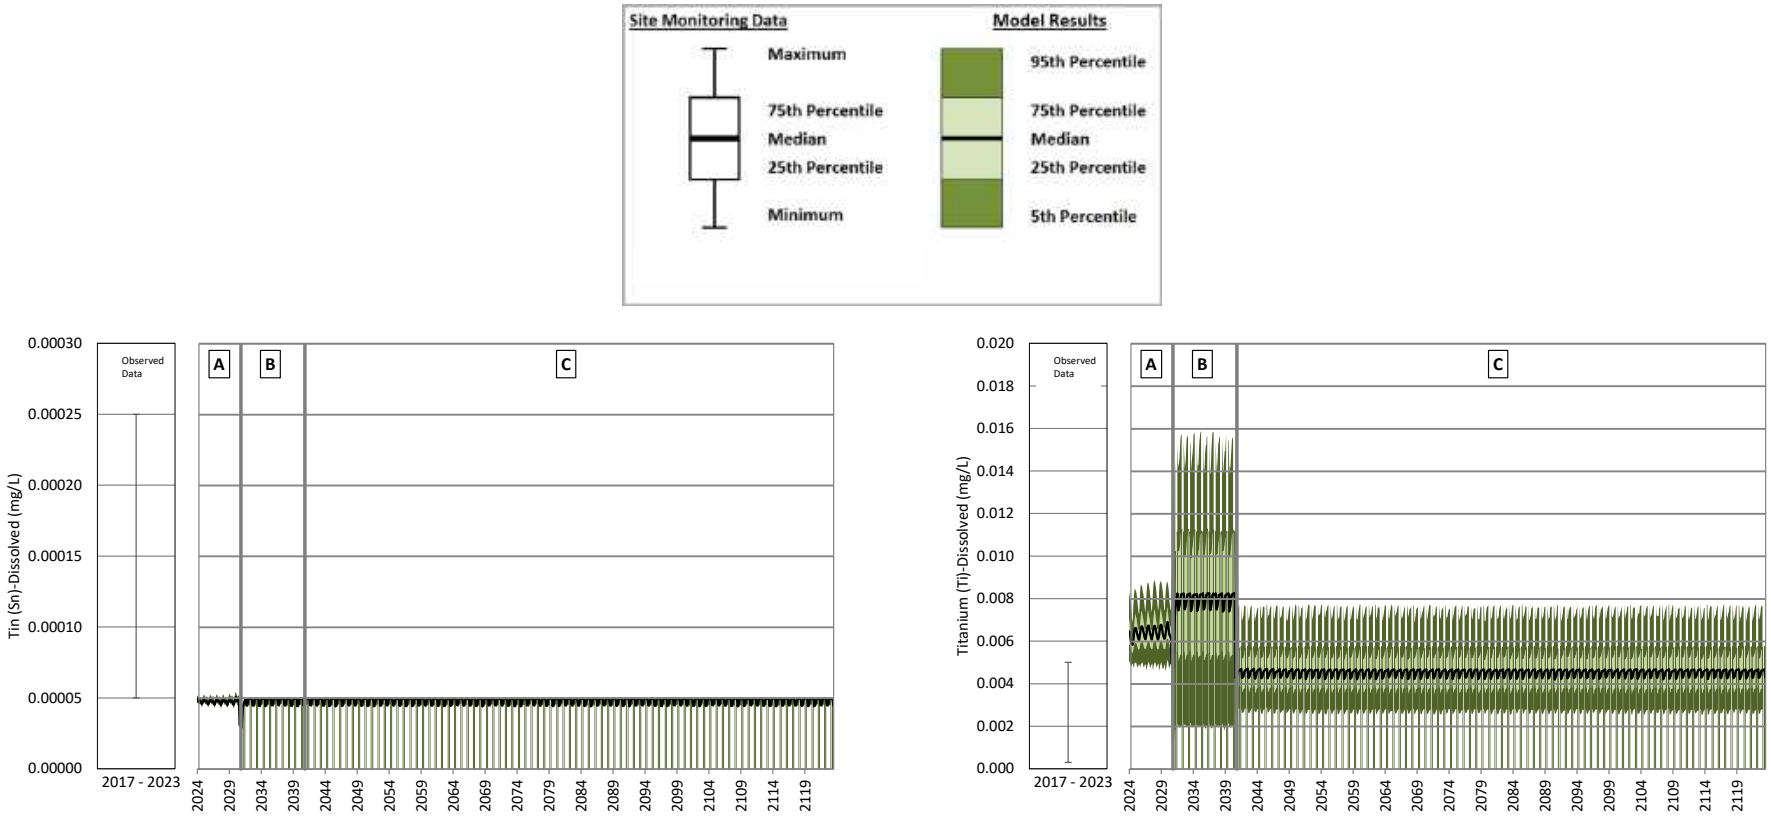

Figure B **116: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Selenium and Dissolved Silver**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

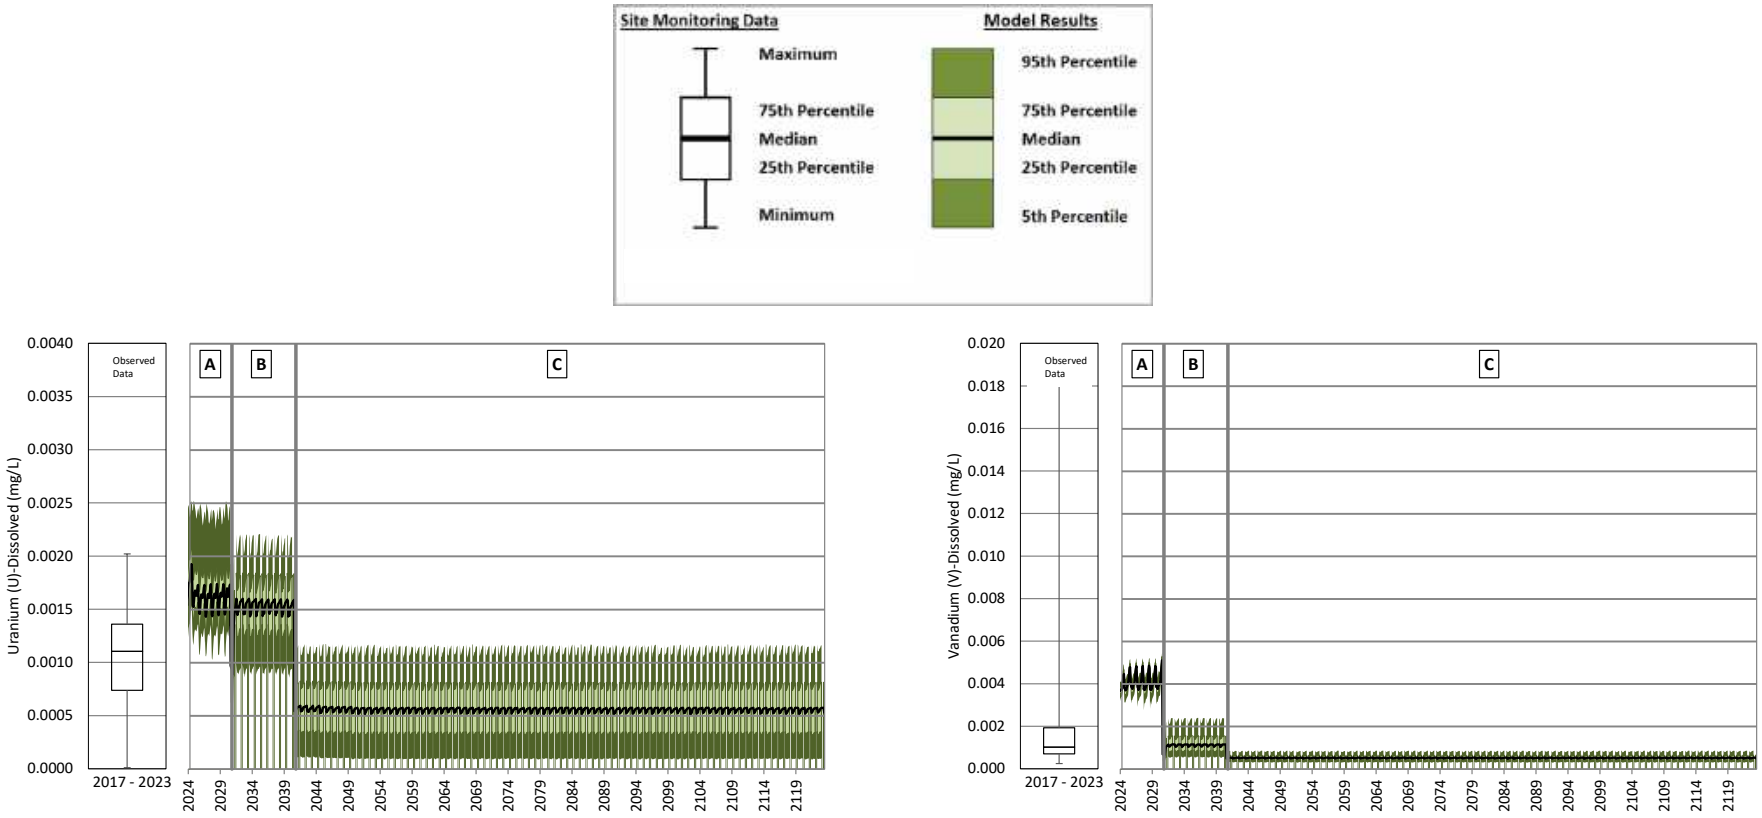

Figure B **117: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Strontium and Dissolved Thallium**

A = Operations; B = Closure; C = Post-closure

Note: The increase in dissolved titanium concentrations during closure is caused by the end of pumping from the Perimeter Embankment Till Borrow Pond (PETBP) to the Tailings Storage Facility (TSF). Lower dissolved titanium concentrations in the PETBP causes dilution of the dissolved titanium concentrations in the TSF during operations. Dissolved titanium concentrations decrease from closure to post-closure as runoff areas are remediated.

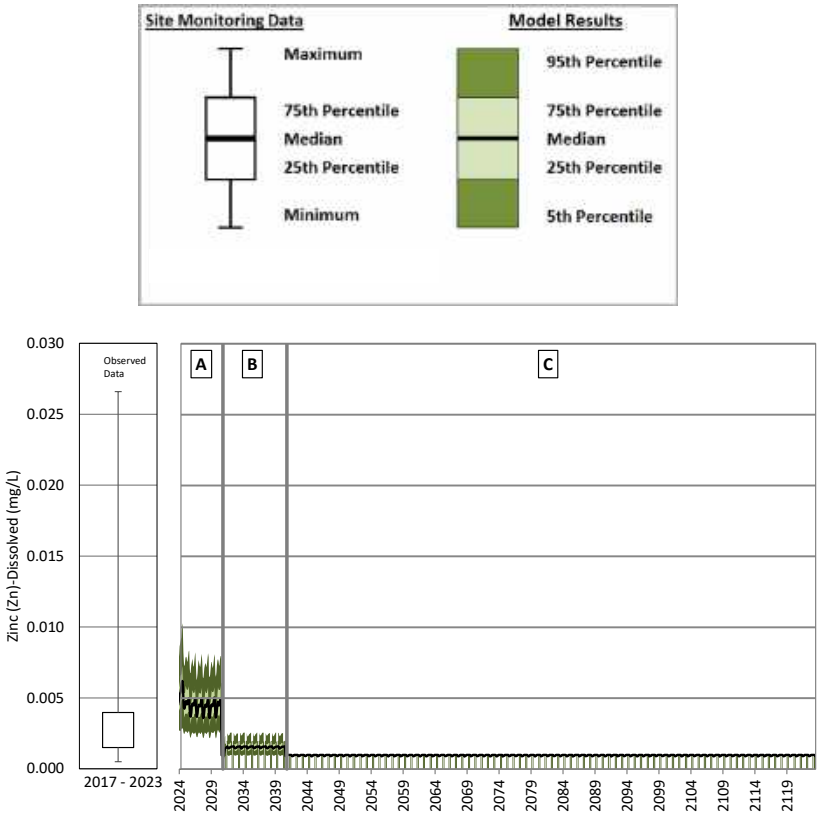

Figure B **118: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Tin and Dissolved Titanium**

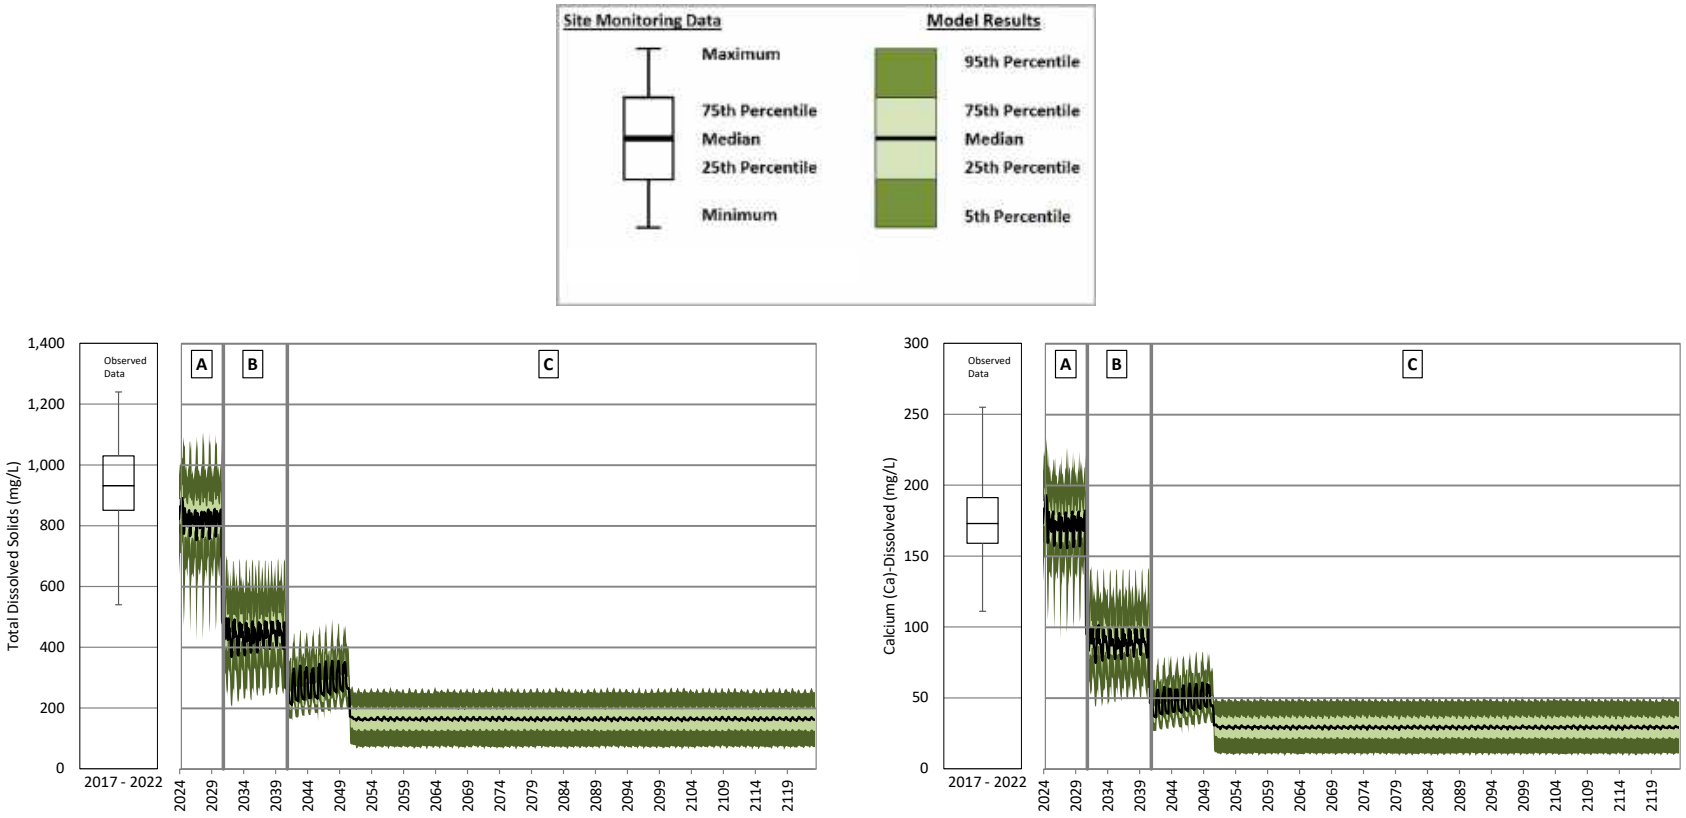
A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

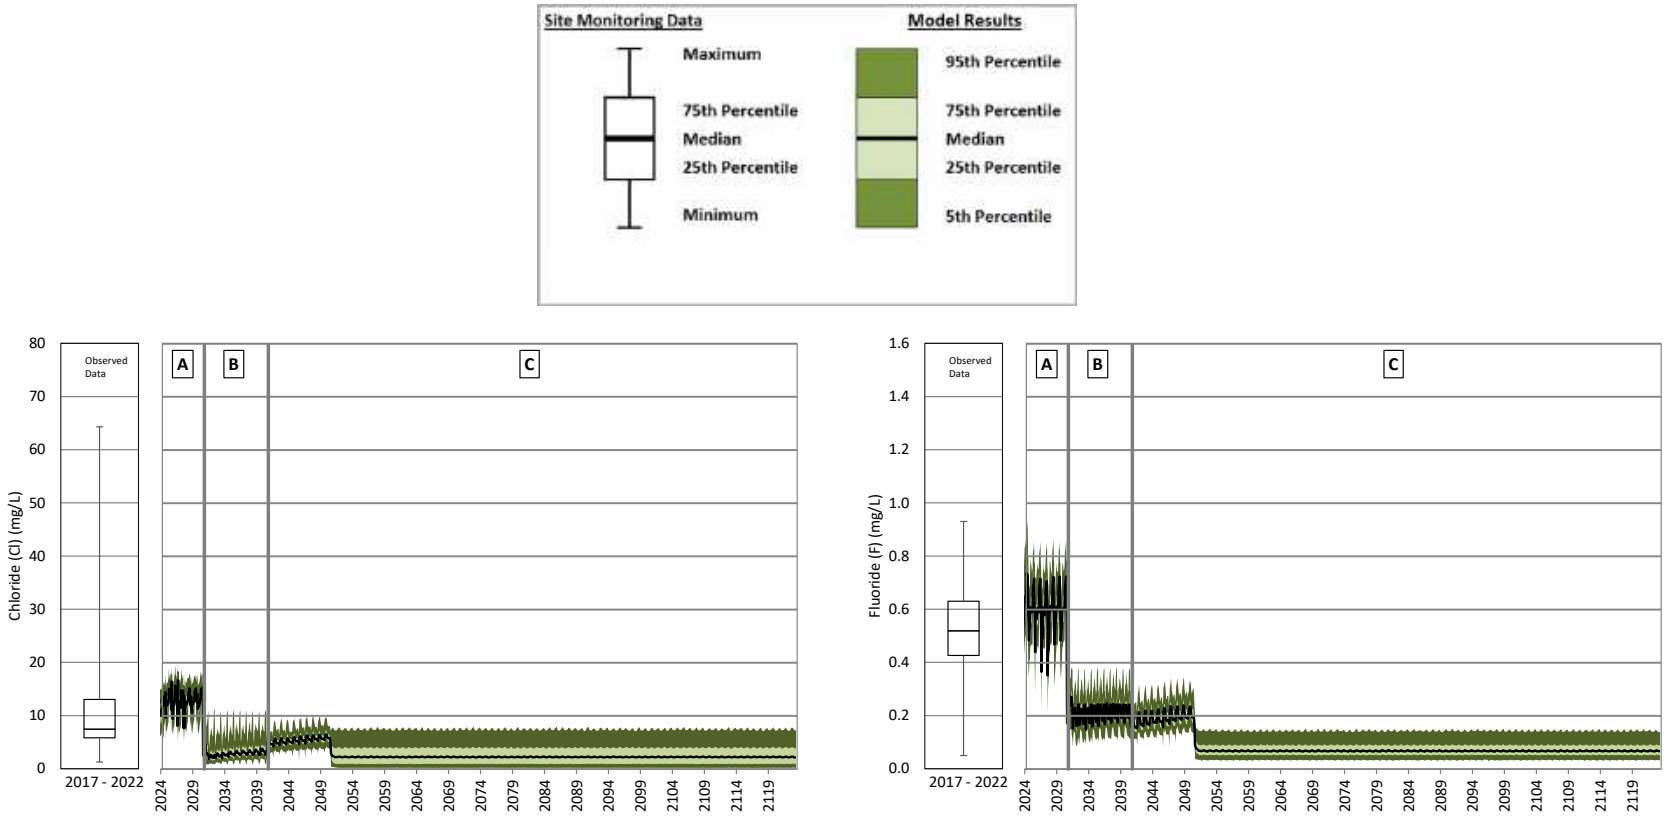
Figure B **119: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Uranium and Dissolved Vanadium**



A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure B **120: Tailings Storage Facility Operations, Closure and Post-closure – Dissolved Zinc**



Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

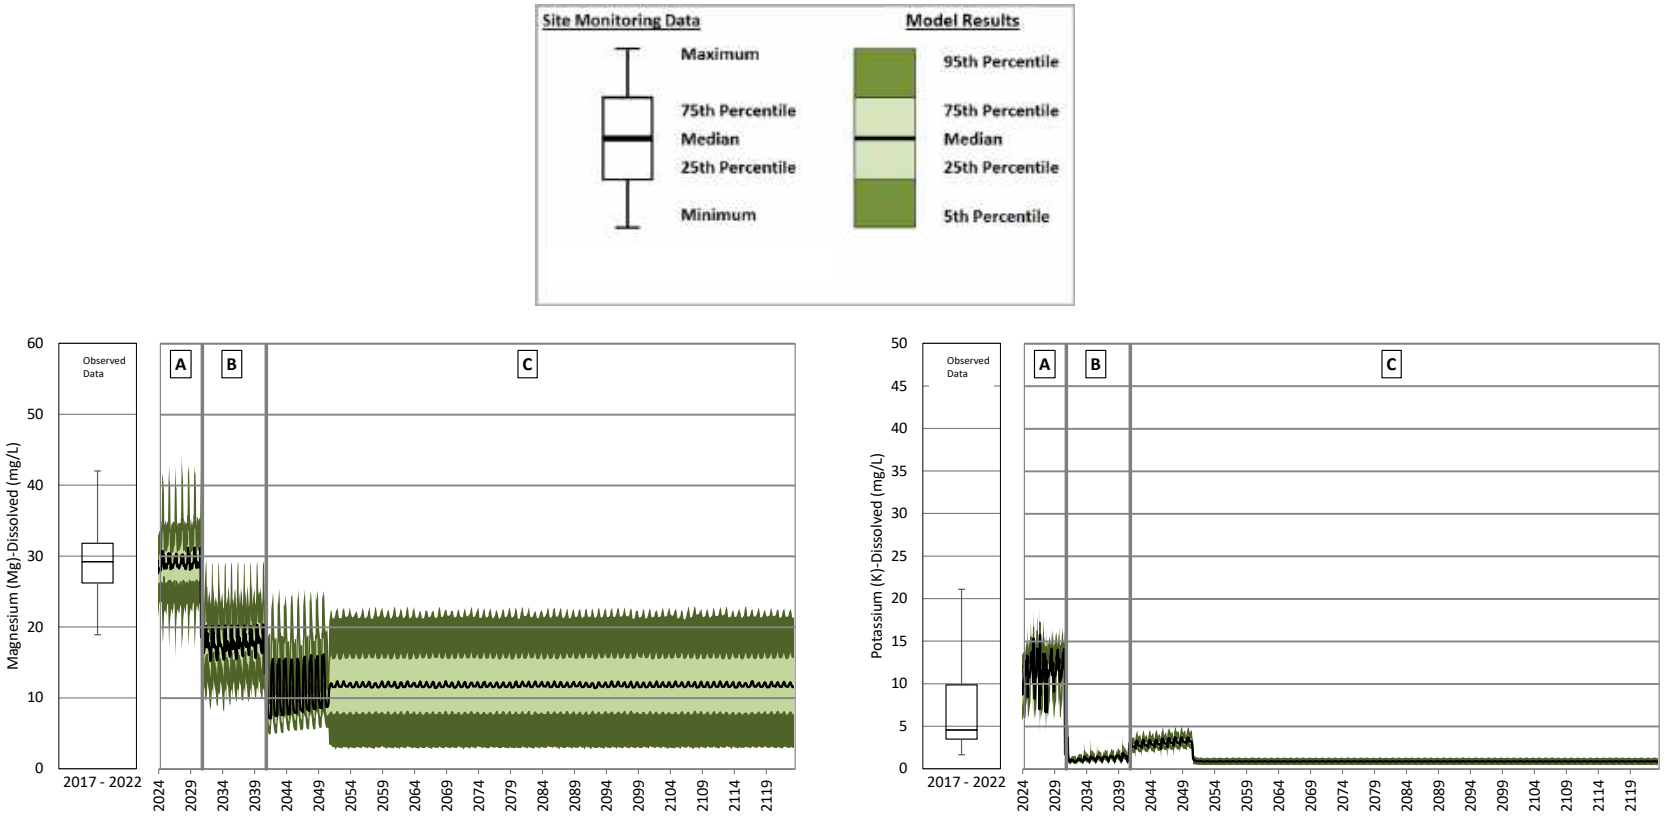


Figure B **121: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Total Dissolved Solids and Calcium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

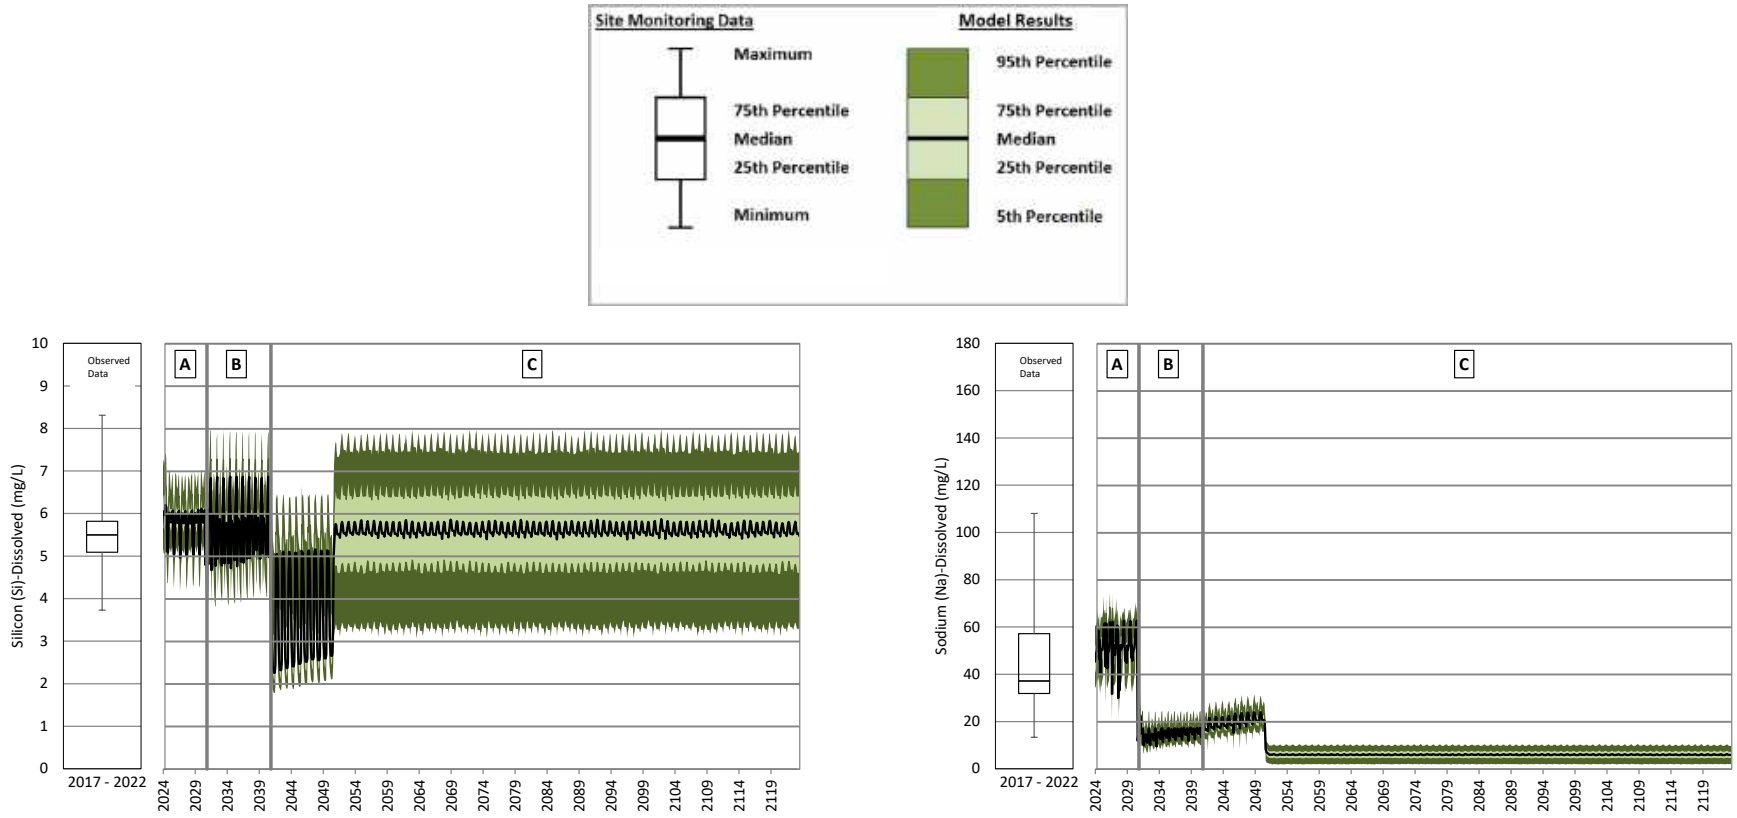

Figure B **122: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Chloride and Fluoride**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

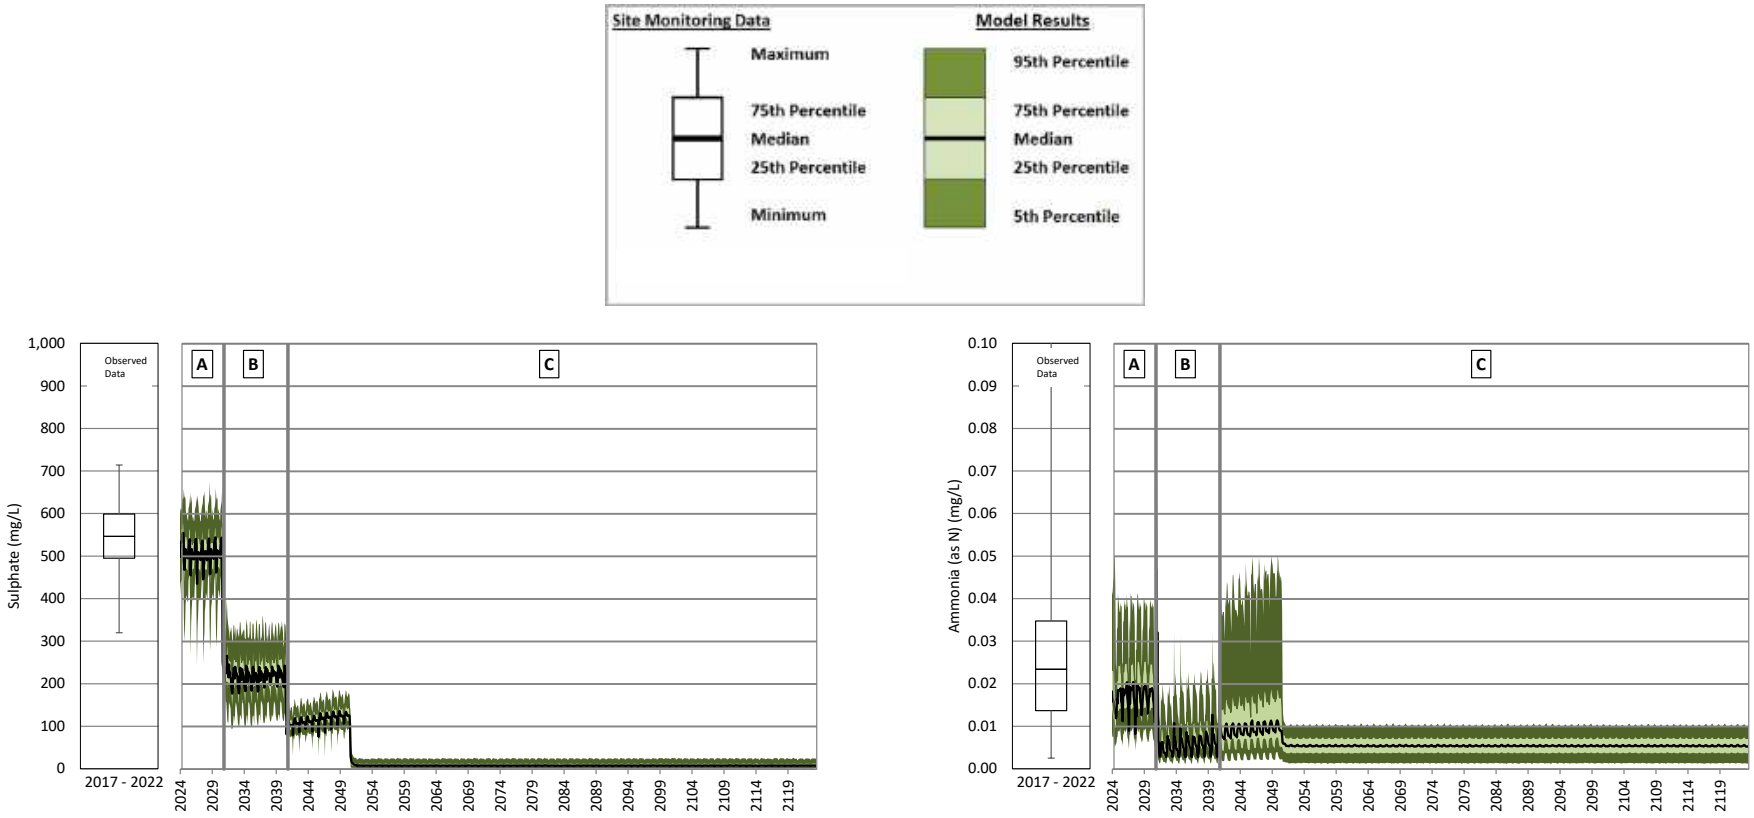

Figure B **123: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Magnesium and Potassium**

A = Operations; B = Closure; C = Post-closure

Note: The increase in silicon concentrations from operations to closure and post-closure is caused by runoff from areas being reclaimed and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher maximum silicon concentrations than the disturbed water quality input. Sodium concentrations decrease from operations to closure and post-closure as runoff areas are remediated. The increase in sodium concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

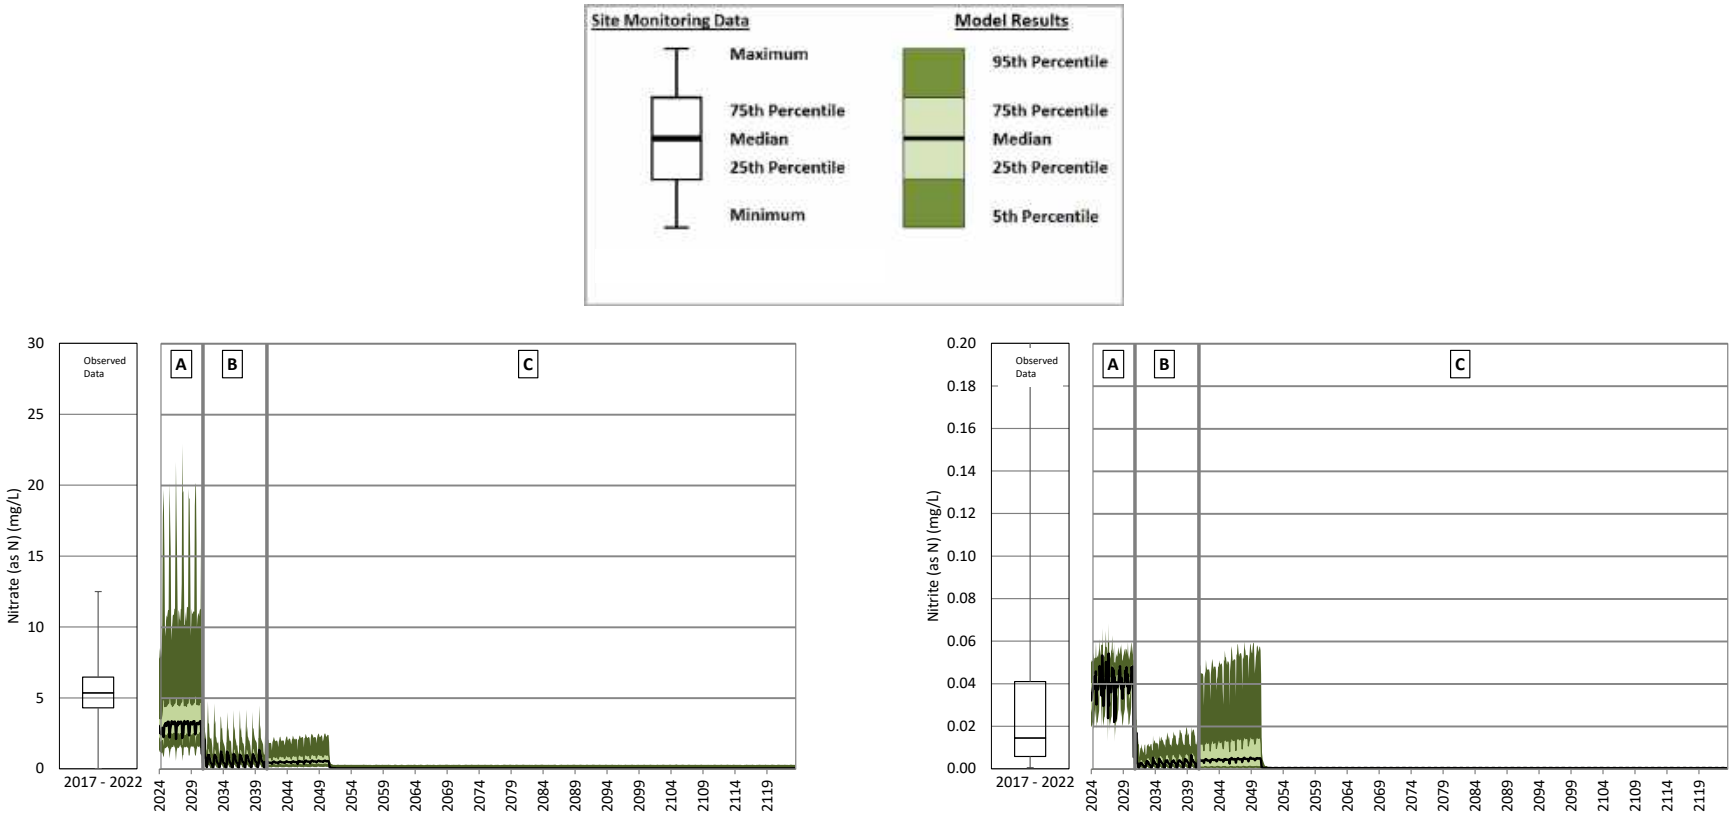

Figure B **124: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Silicon and Sodium**

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

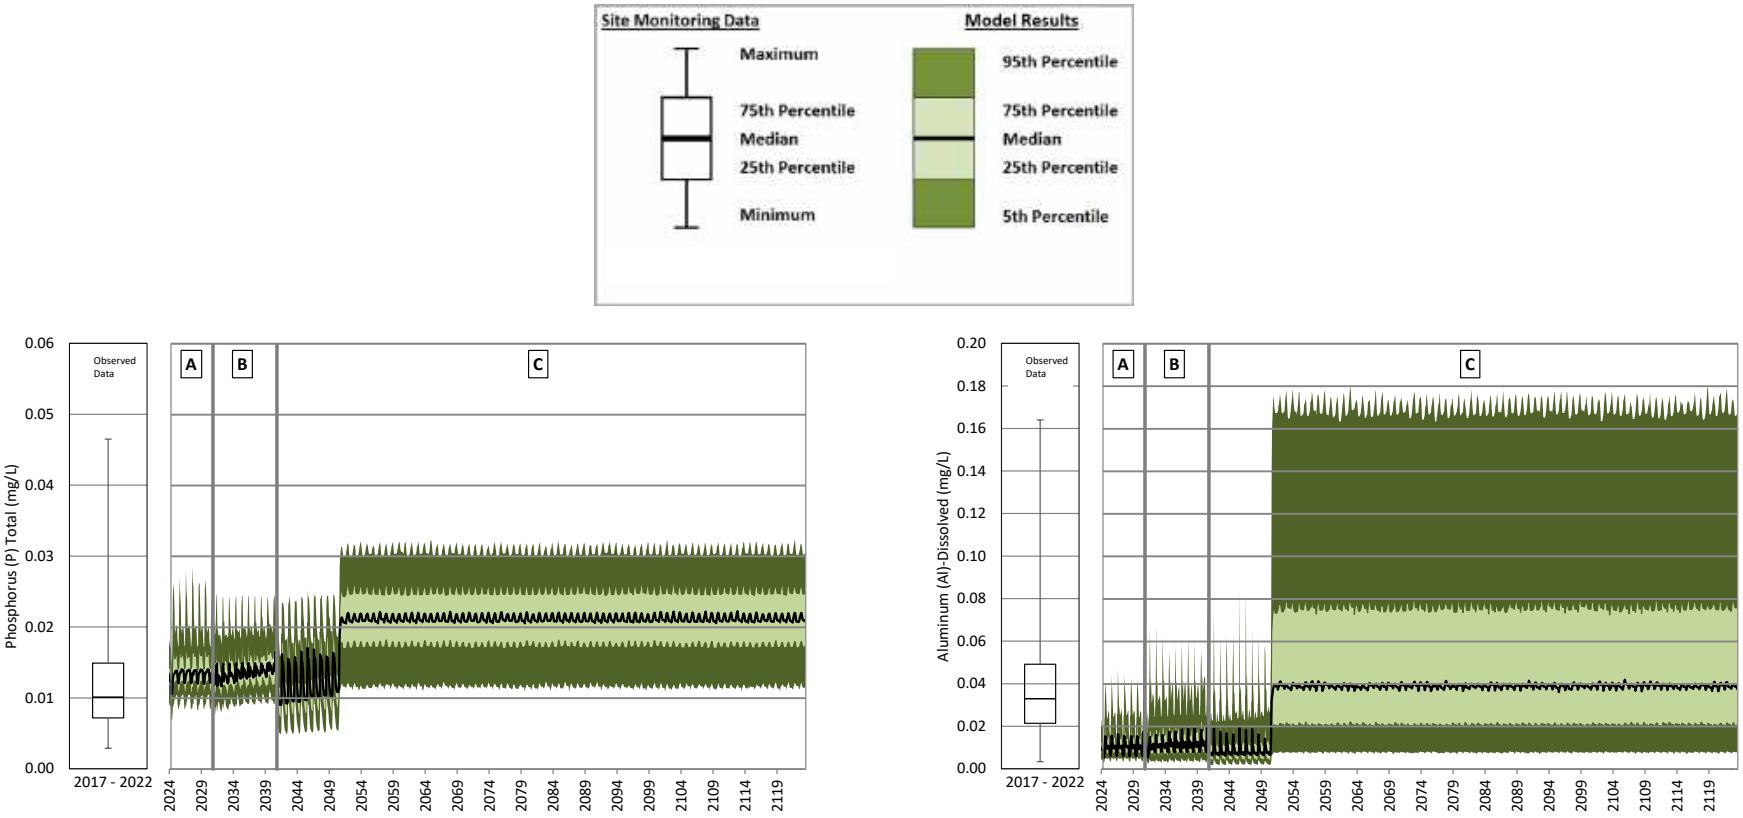

Figure B **125: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Sulphate and Total Ammonia**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

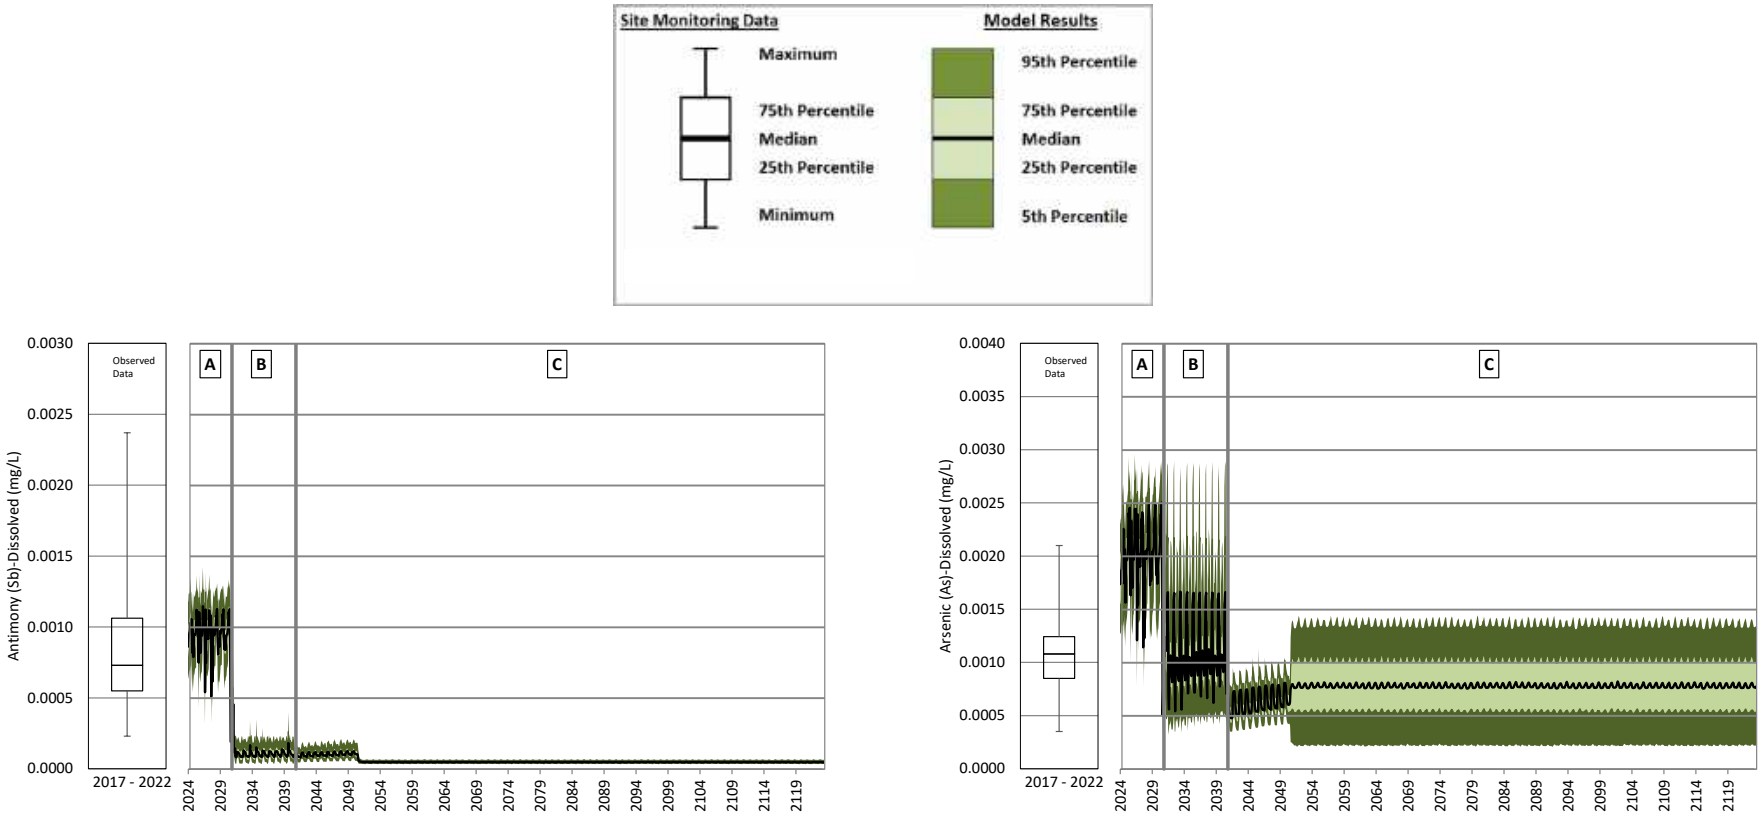

Figure B **126: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Nitrate and Nitrite**

A = Operations; B = Closure; C = Post-closure

Note: Total phosphorus and dissolved aluminum concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for total phosphorus and dissolved aluminum than the NAG waste rock and disturbed runoff water quality inputs.

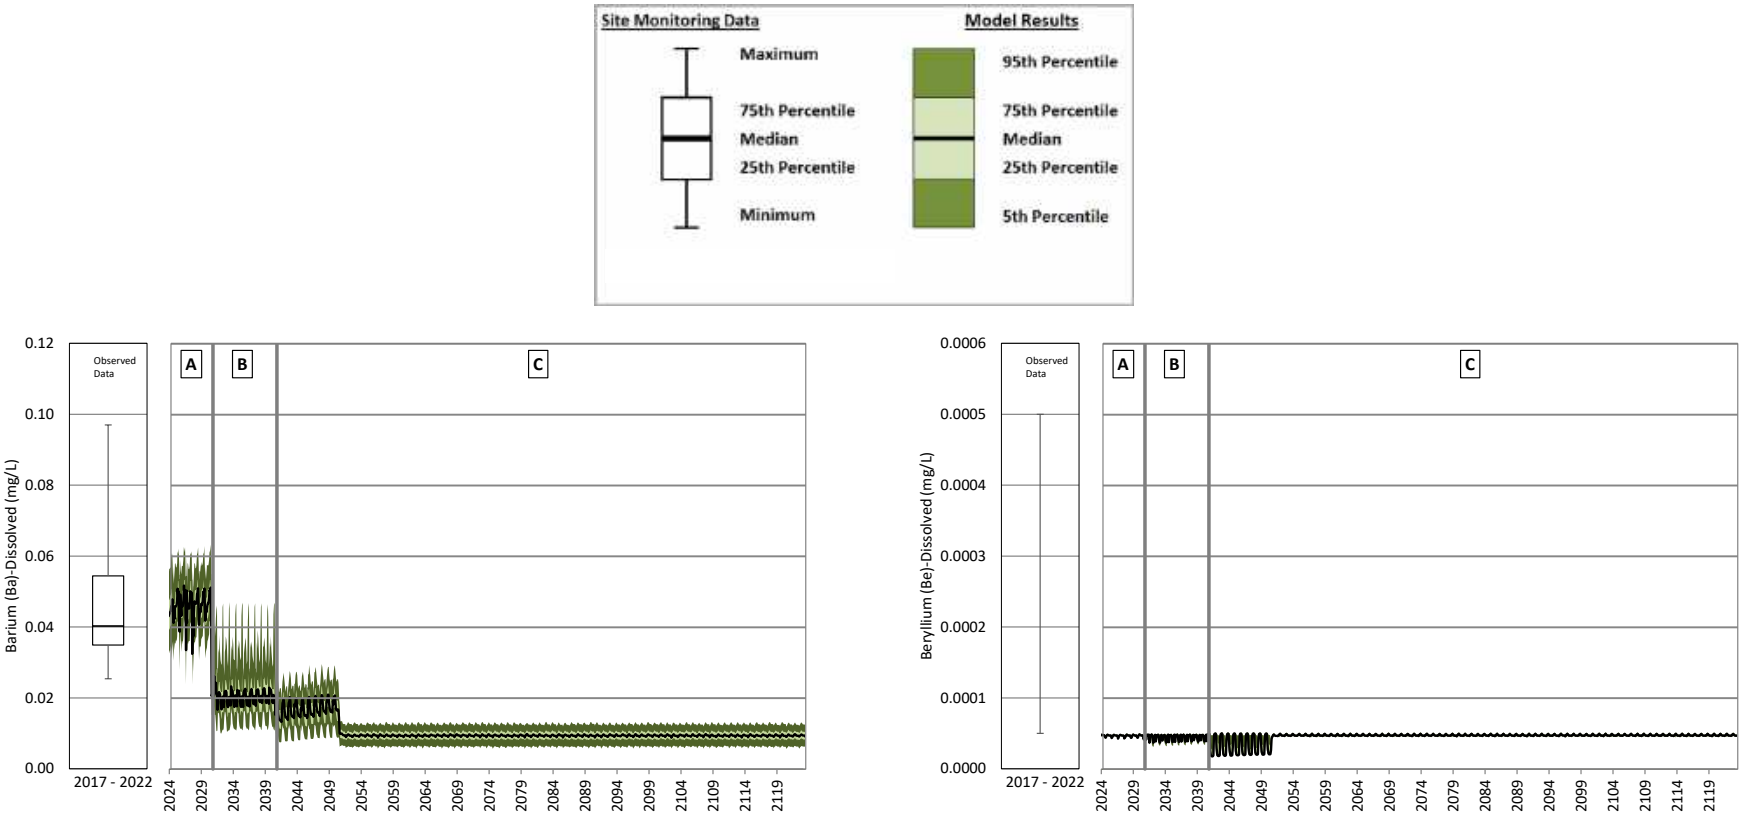

Figure B **127: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Total Phosphorus and Dissolved Aluminum**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

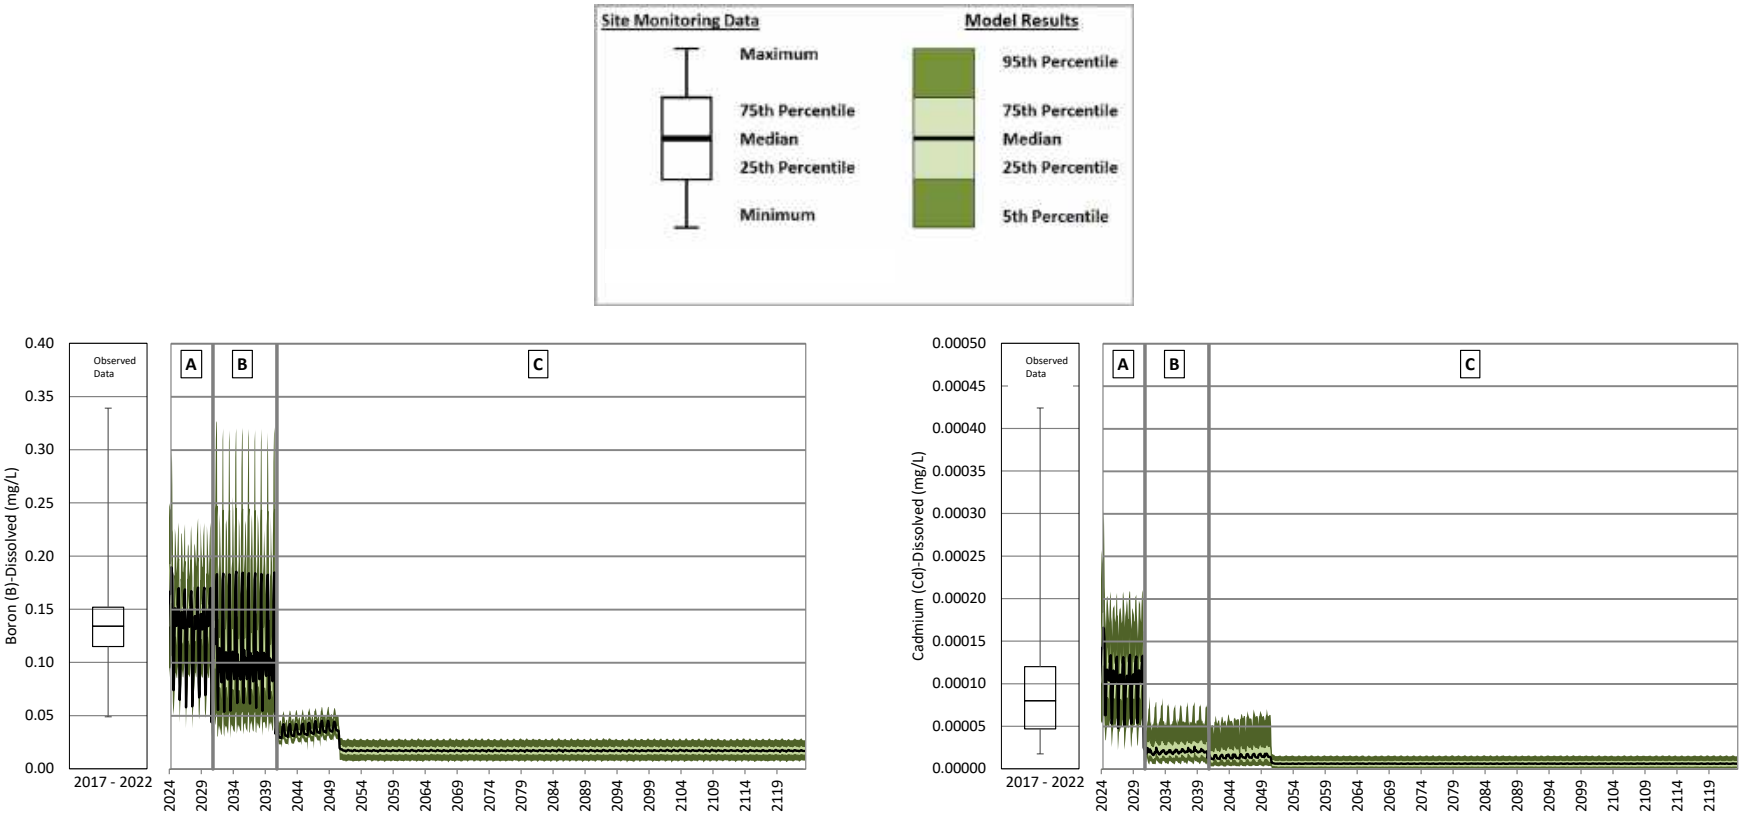

Figure B **128: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Antimony and Dissolved Arsenic**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

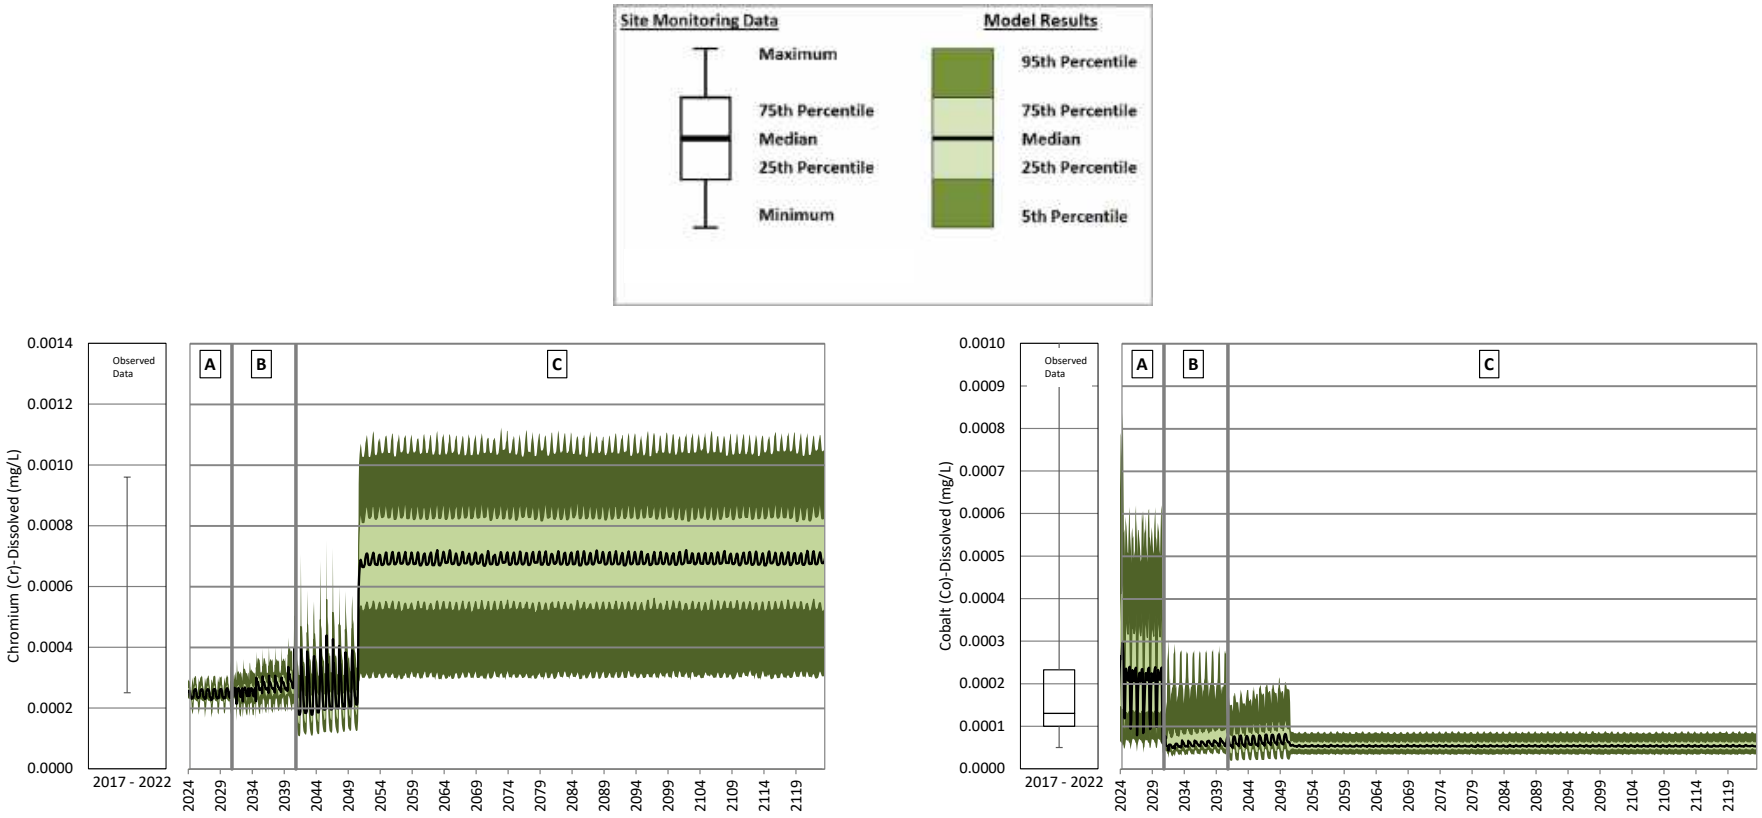

Figure B **129: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Barium and Dissolved Beryllium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

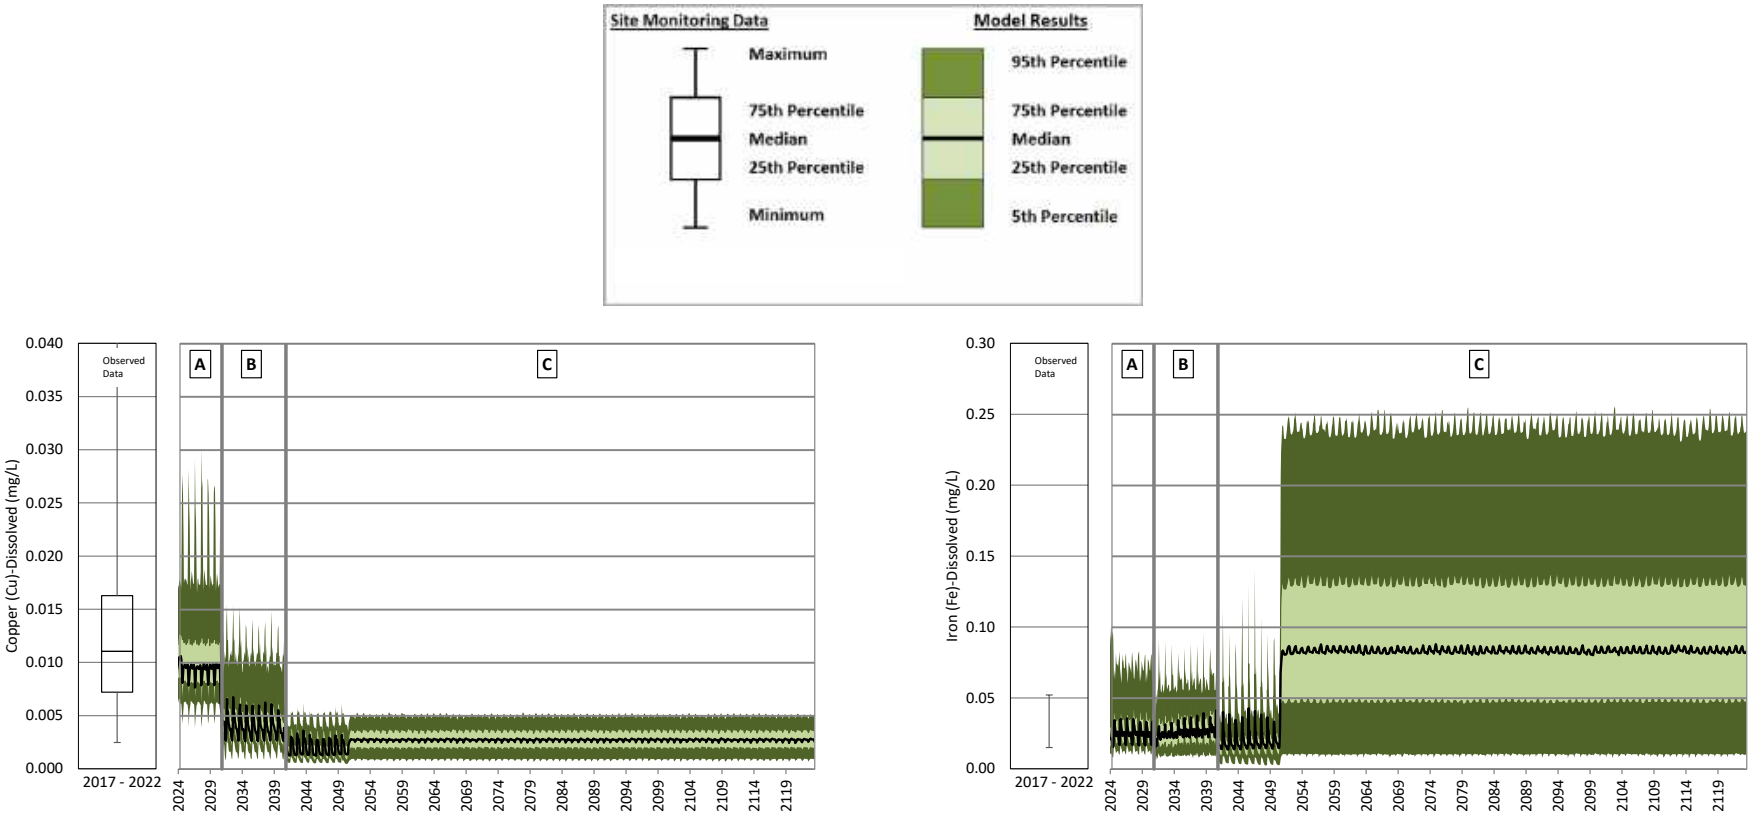

Figure B **130: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Boron and Dissolved Cadmium**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved chromium concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved chromium than the NAG waste rock and disturbed runoff water quality inputs. Dissolved cobalt concentrations decrease from operations to closure and post-closure as runoff areas are remediated. The increase in cobalt concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

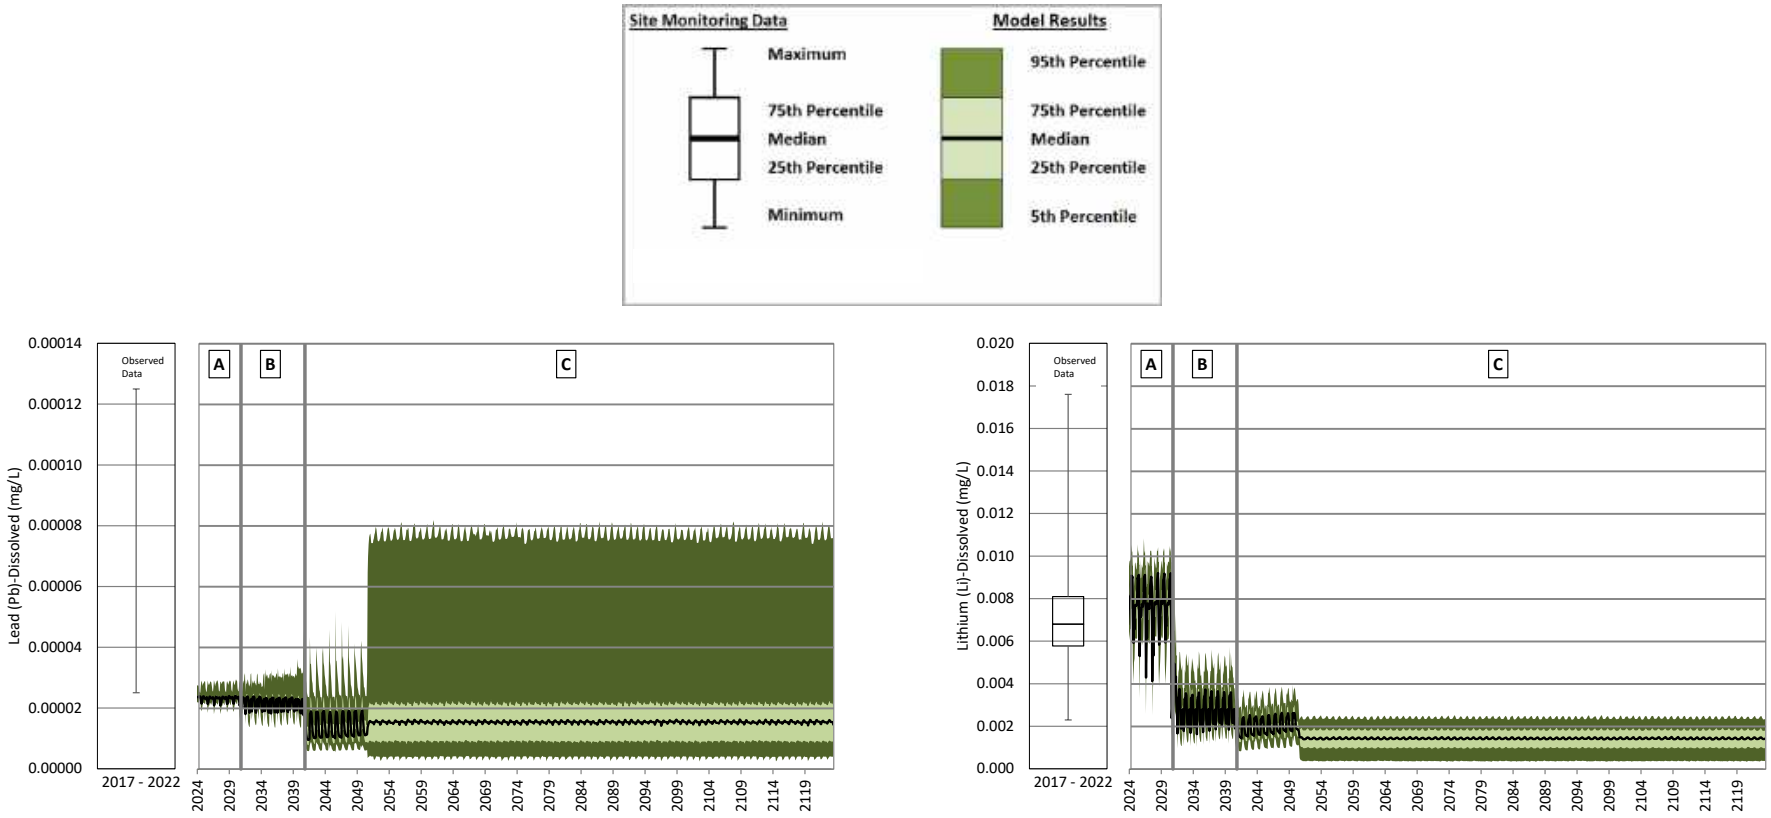

Figure B **131: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Chromium and Dissolved Cobalt**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved copper concentrations decrease from operations to closure and post-closure as runoff areas are remediated. Dissolved iron concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed water quality input has higher concentrations for dissolved iron than the NAG waste rock and disturbed runoff water quality inputs.

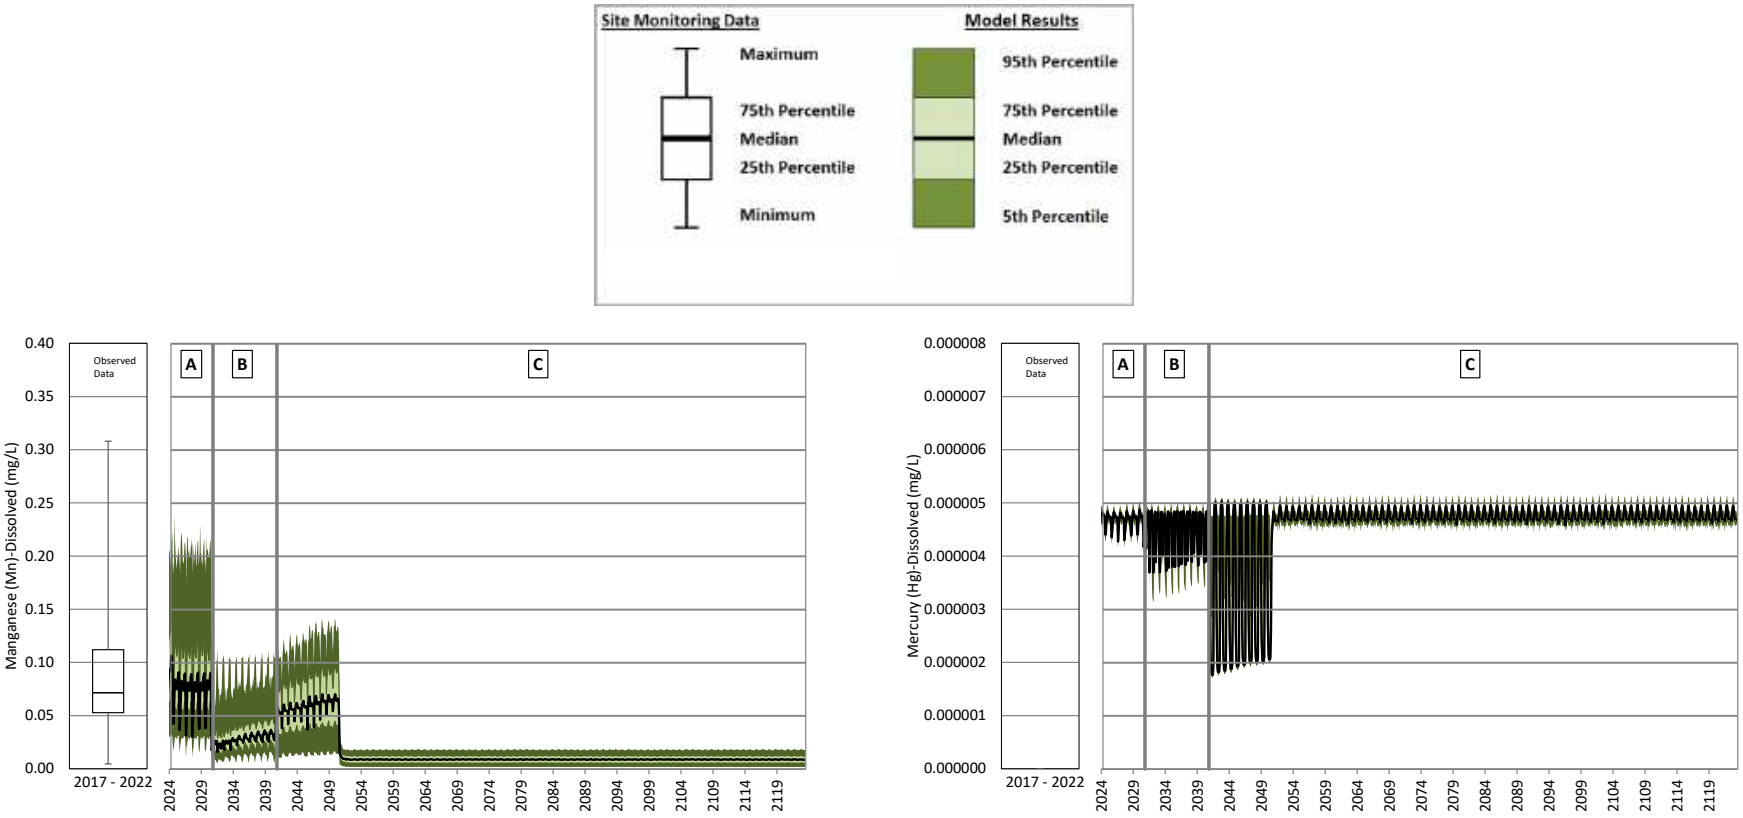

Figure B **132: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Copper and Dissolved Iron**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved lead concentrations increase from operations to closure and post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved lead than the NAG waste rock and disturbed runoff water quality inputs. Dissolved lithium concentrations decrease from operations to closure and post-closure as runoff areas are remediated. The increase in lithium concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

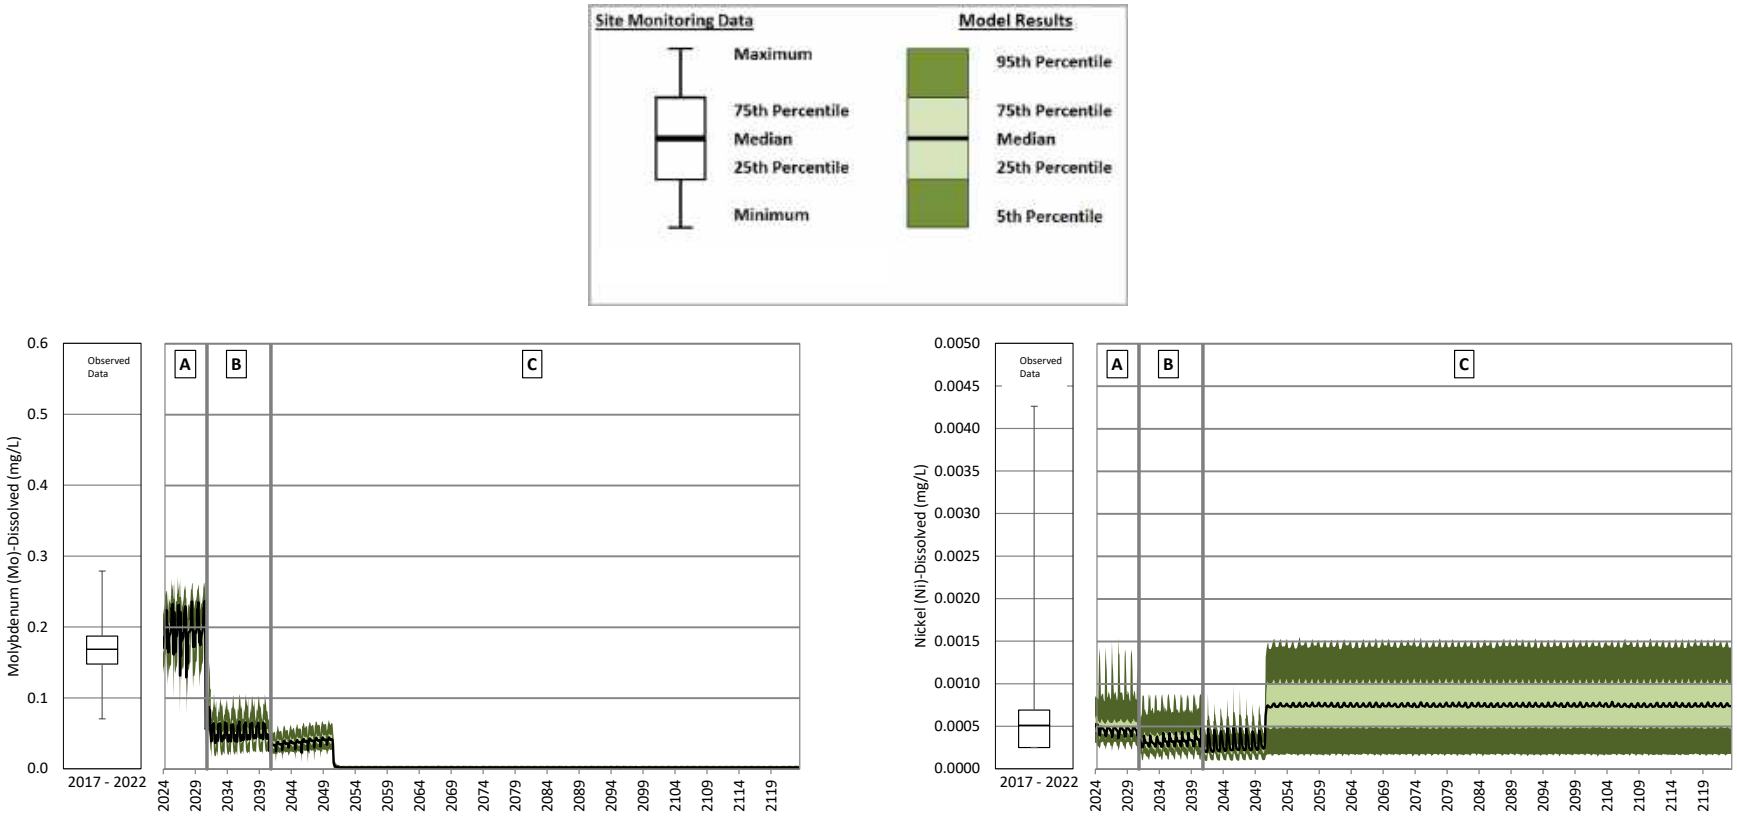

Figure B **133: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Lead and Dissolved Lithium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

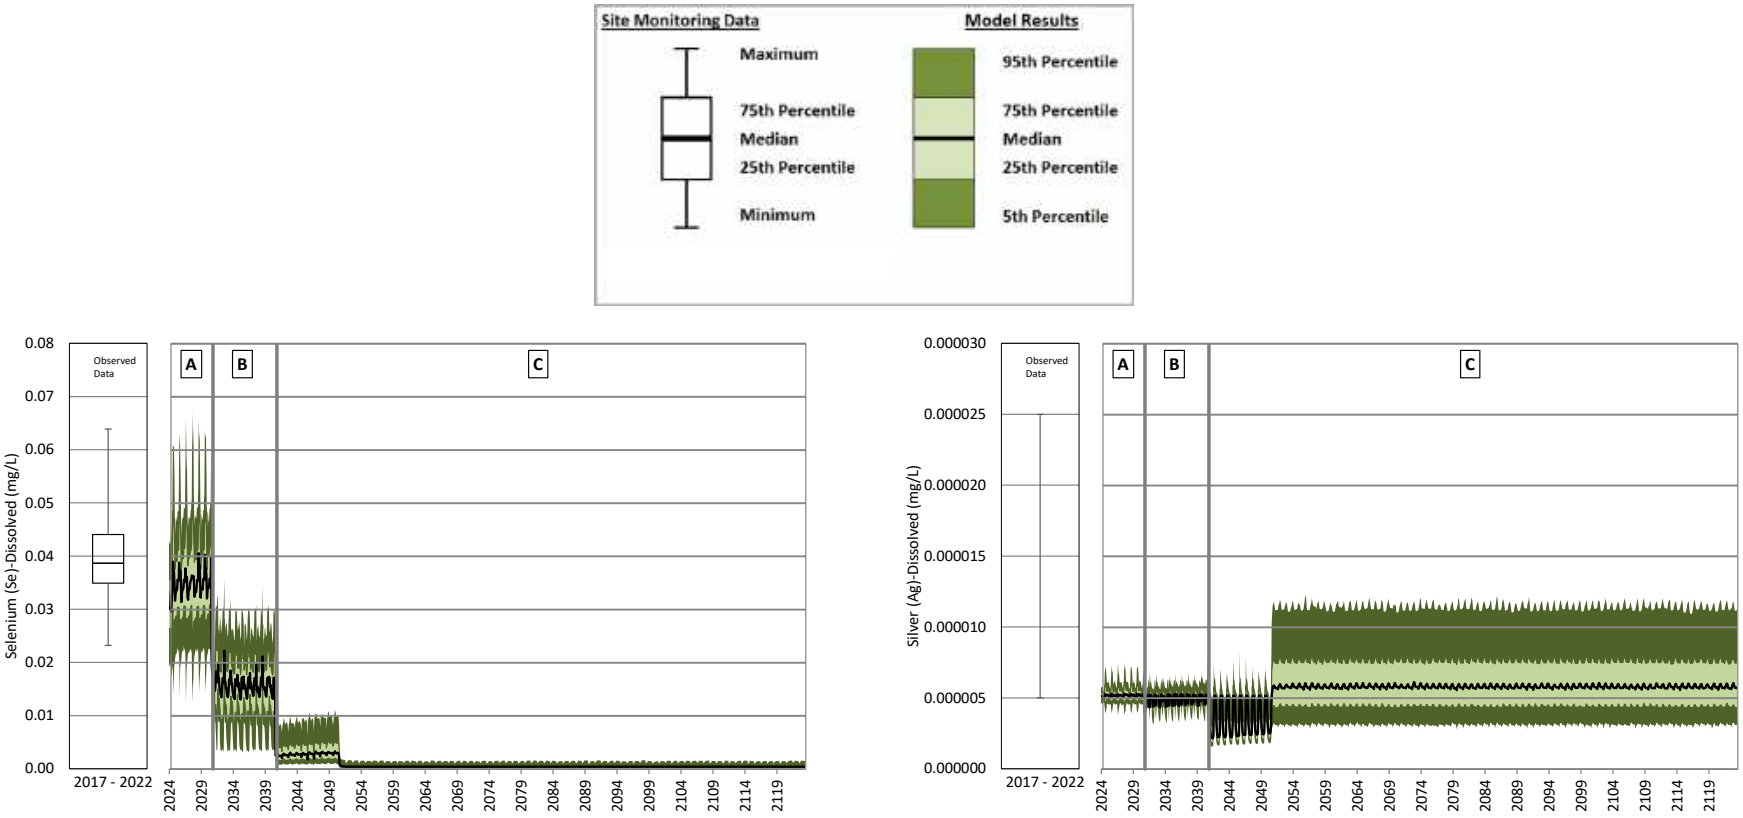

Figure B **134: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Manganese and Dissolved Mercury**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved molybdenum concentrations decrease from closure to post-closure as runoff areas are remediated. Dissolved nickel concentrations increase in post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved nickel than the NAG waste rock and disturbed runoff water quality inputs. The increase in molybdenum concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

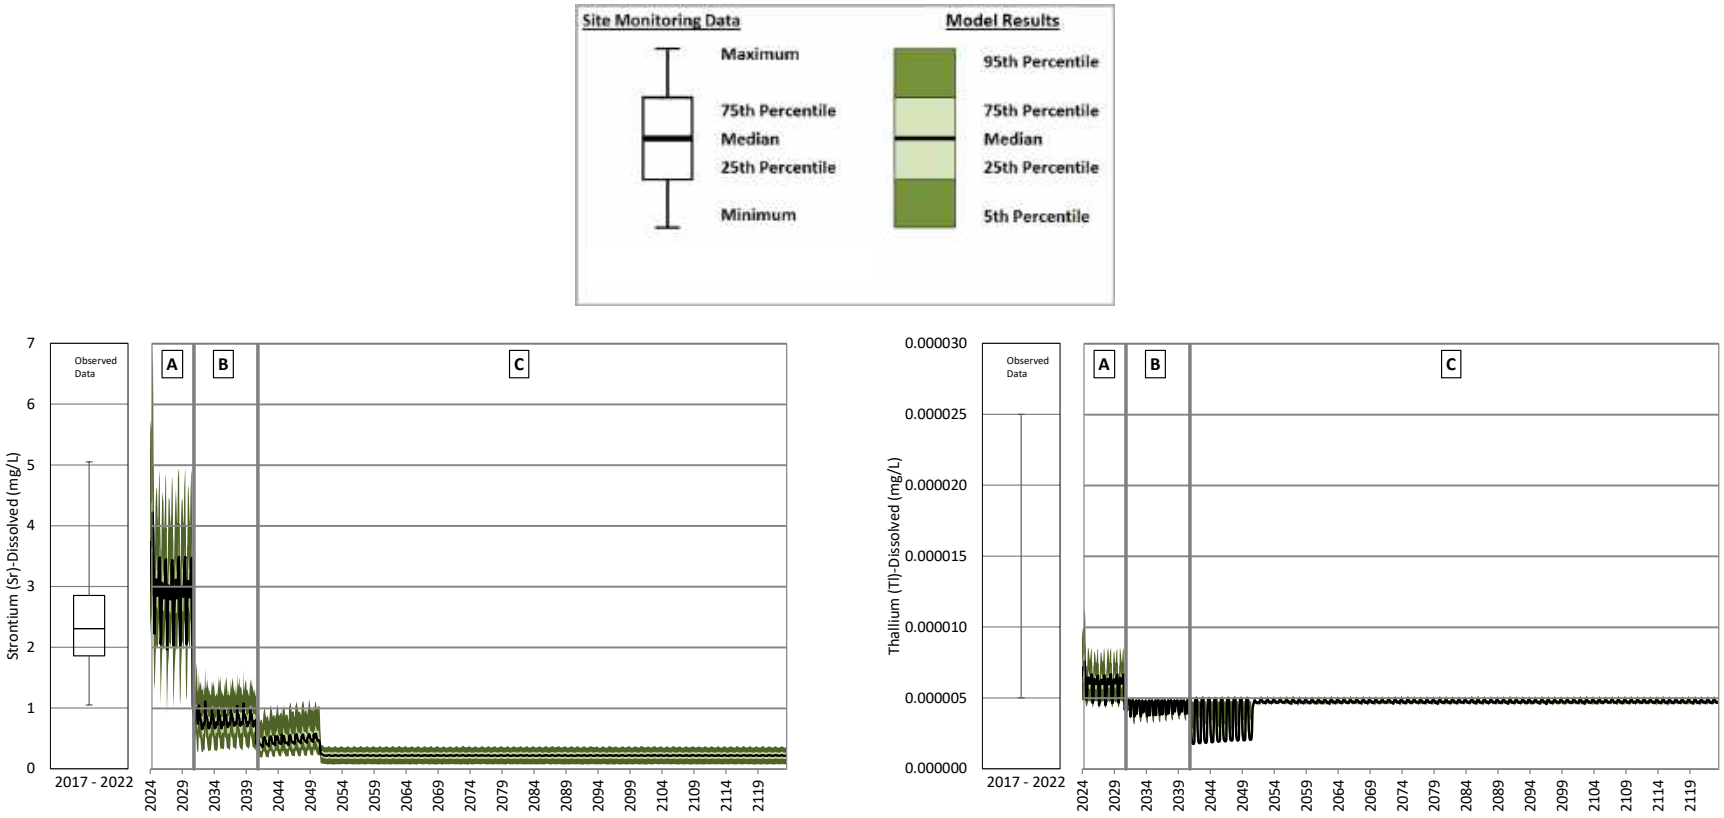

Figure B **135: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Molybdenum and Dissolved Nickel**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved selenium concentrations decrease from closure to post-closure as runoff areas are remediated. Dissolved silver concentrations increase in post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved silver than the NAG waste rock and disturbed runoff water quality inputs. The increase in selenium concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

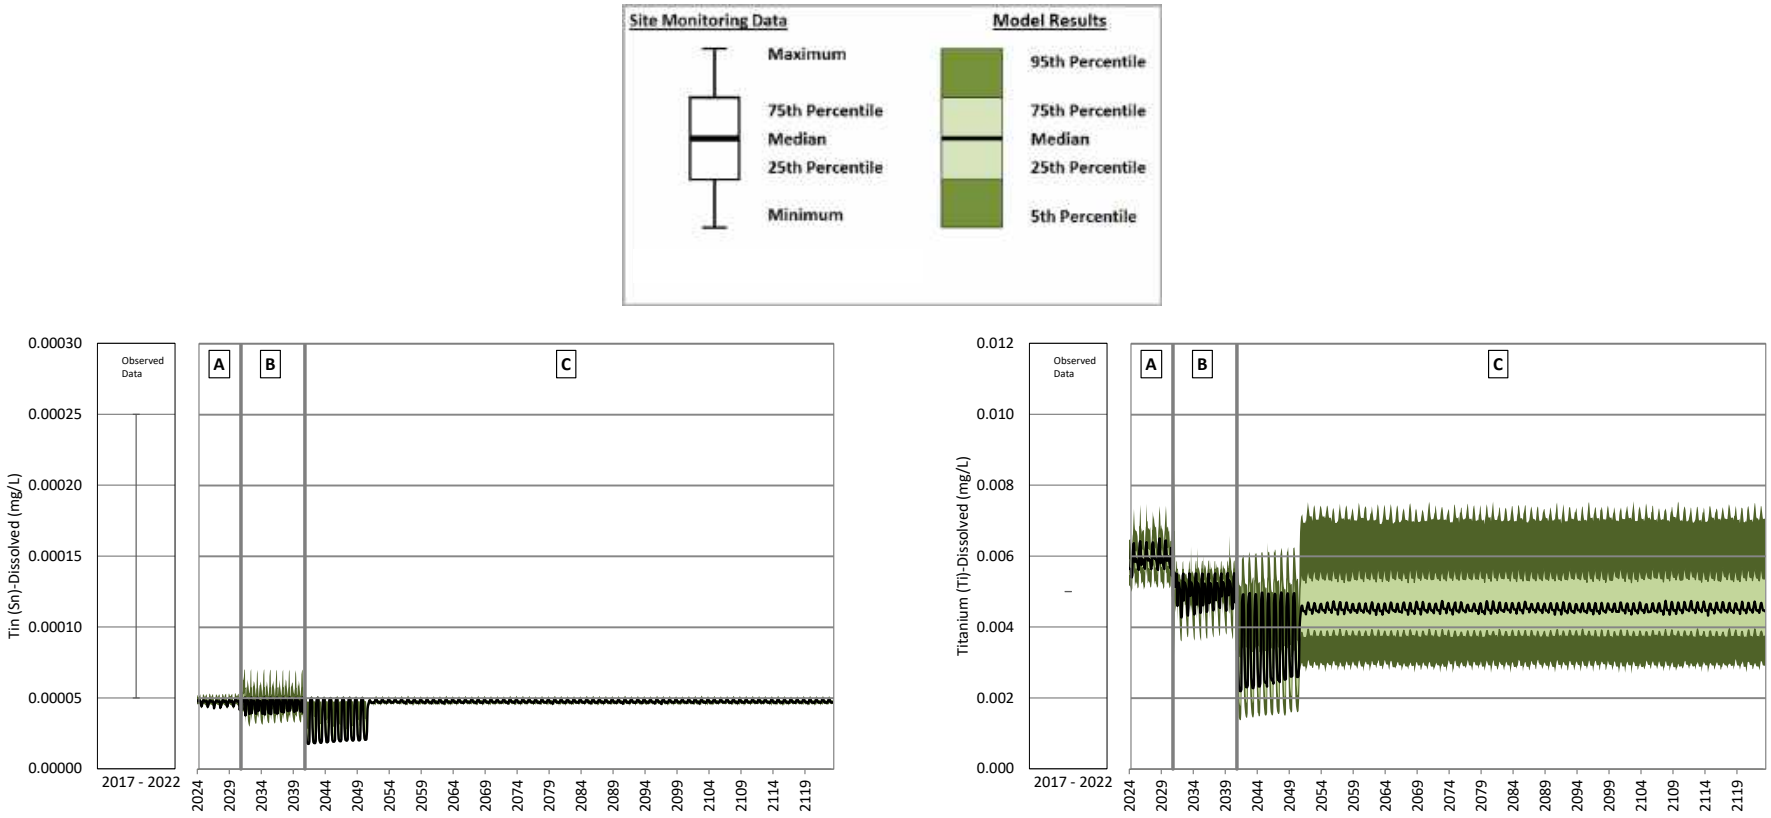

Figure B **136: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Selenium and Dissolved Silver**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

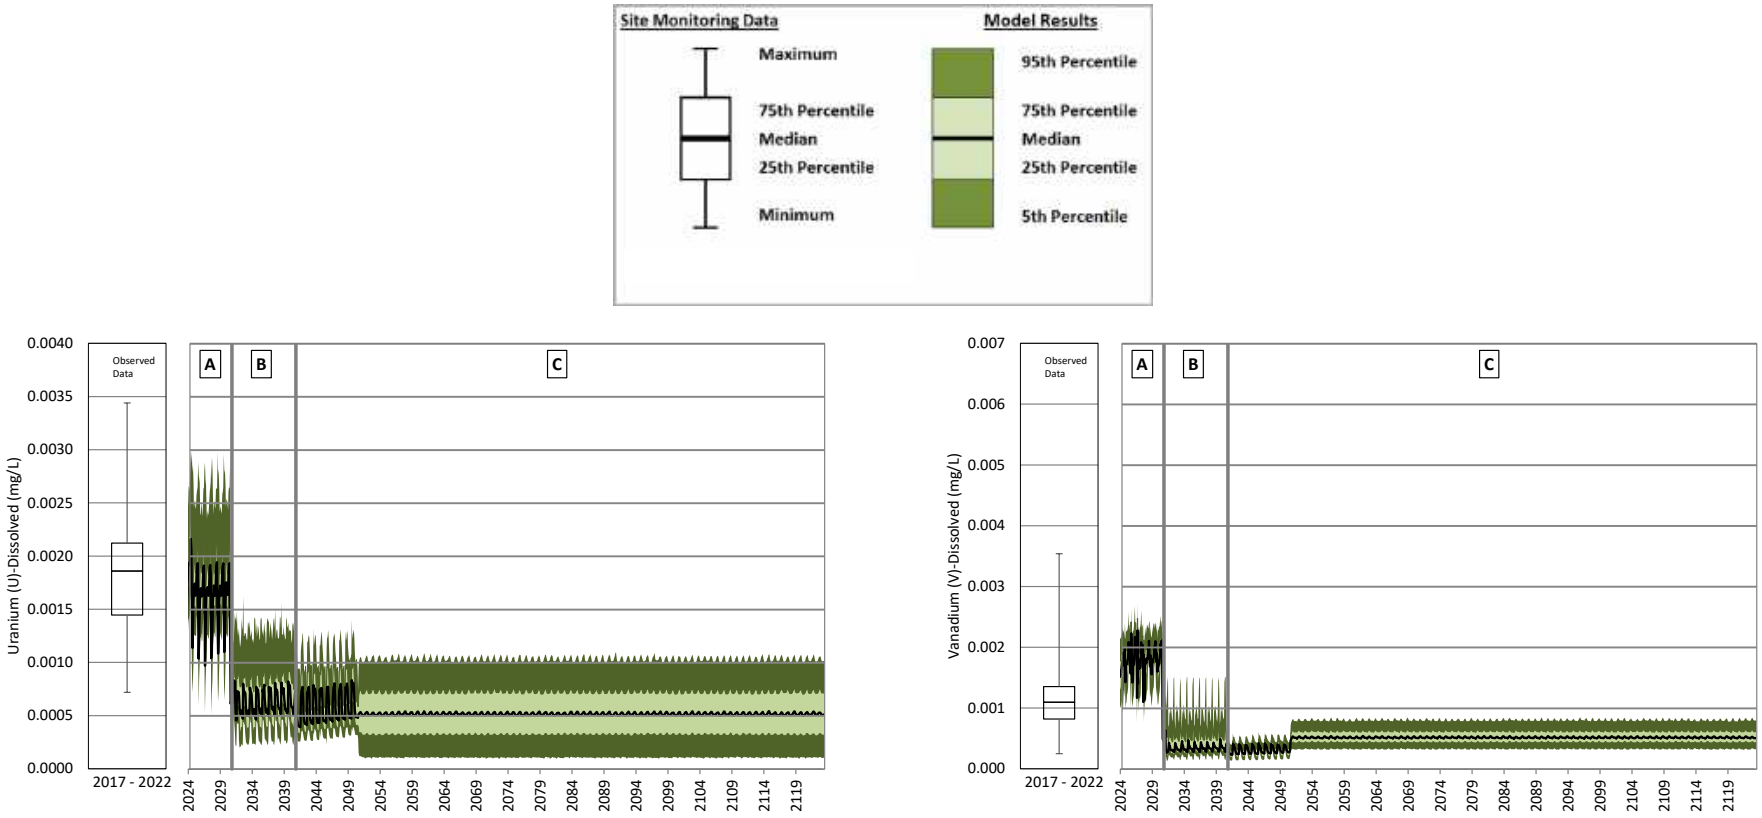

Figure B **137: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Strontium and Dissolved Thallium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Dissolved titanium concentrations increase in post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved titanium than the NAG waste rock and disturbed runoff water quality inputs. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

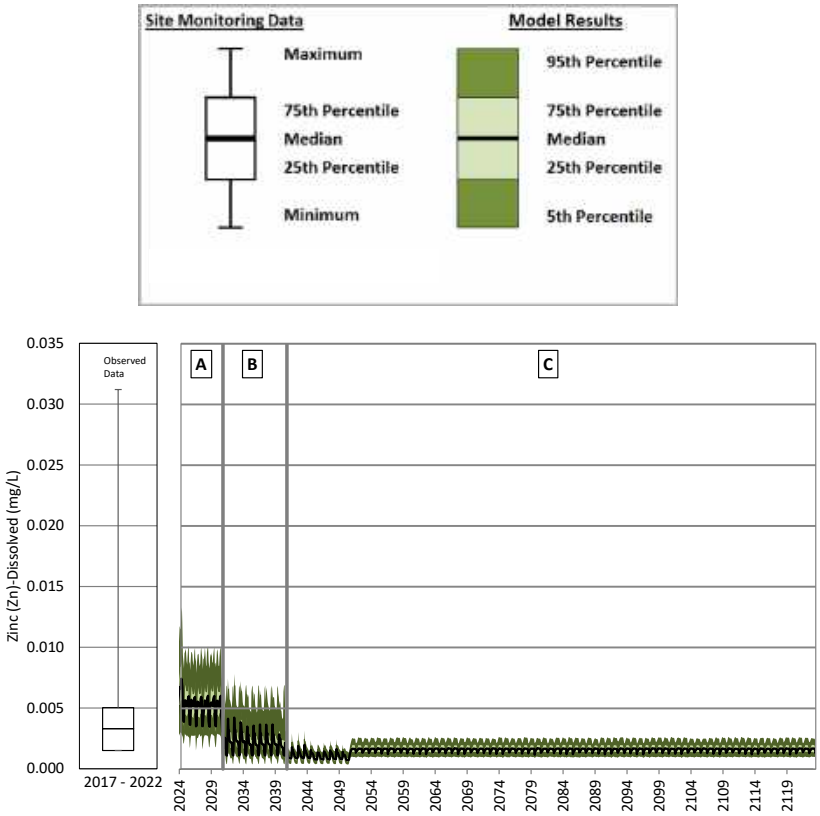

Figure B **138: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Tin and Dissolved Titanium**

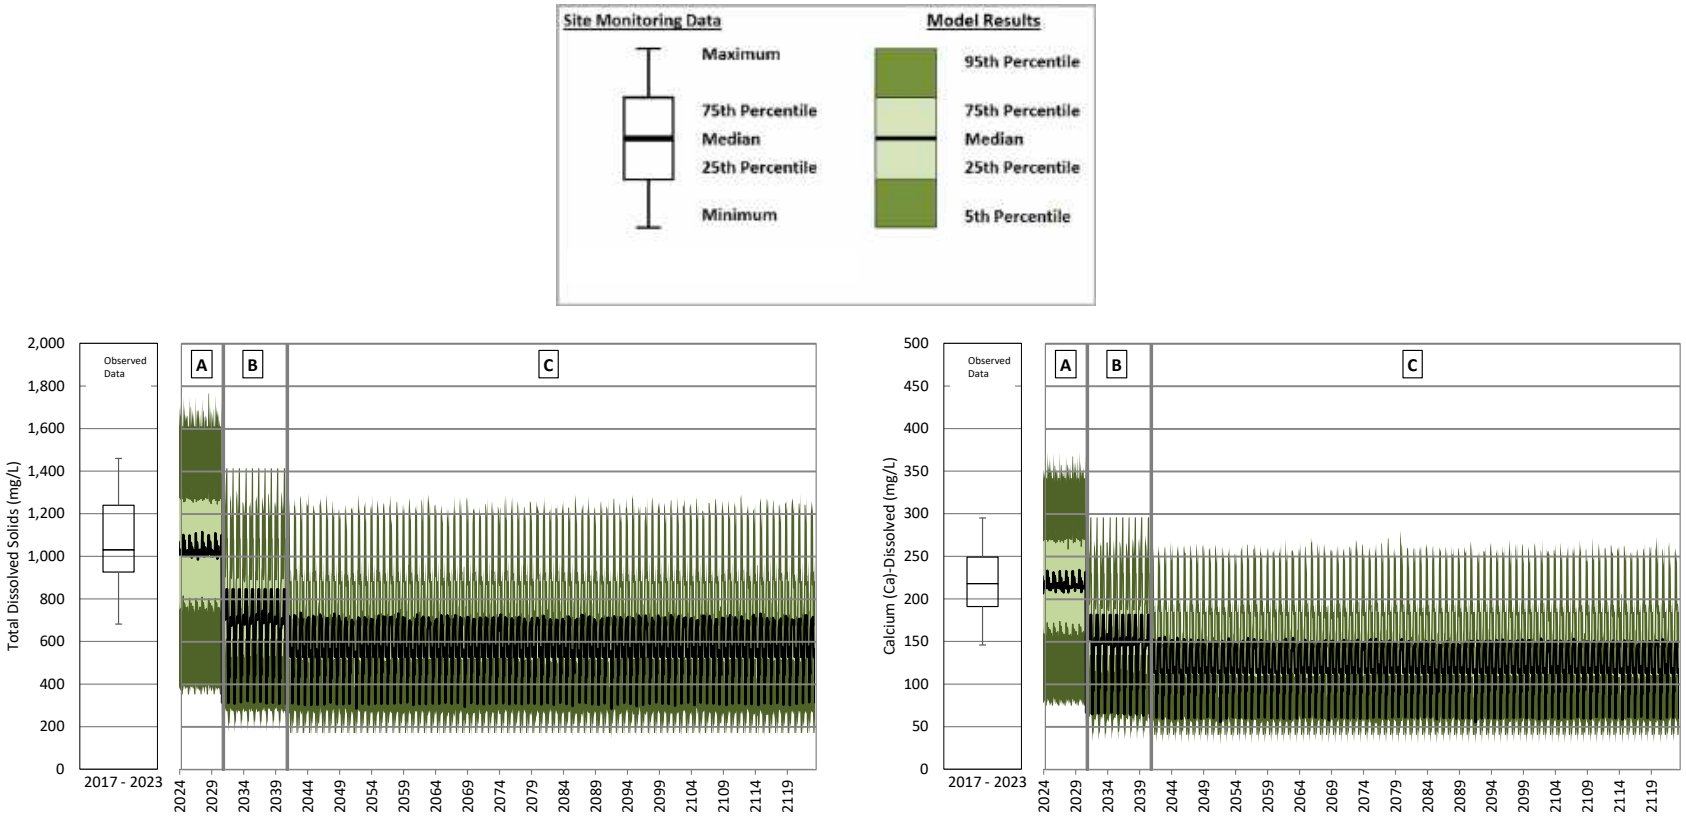
A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete. The increase in concentrations from 2041 to 2051 is caused by pumping from the MESCP to the PETBP which ends in 2051.

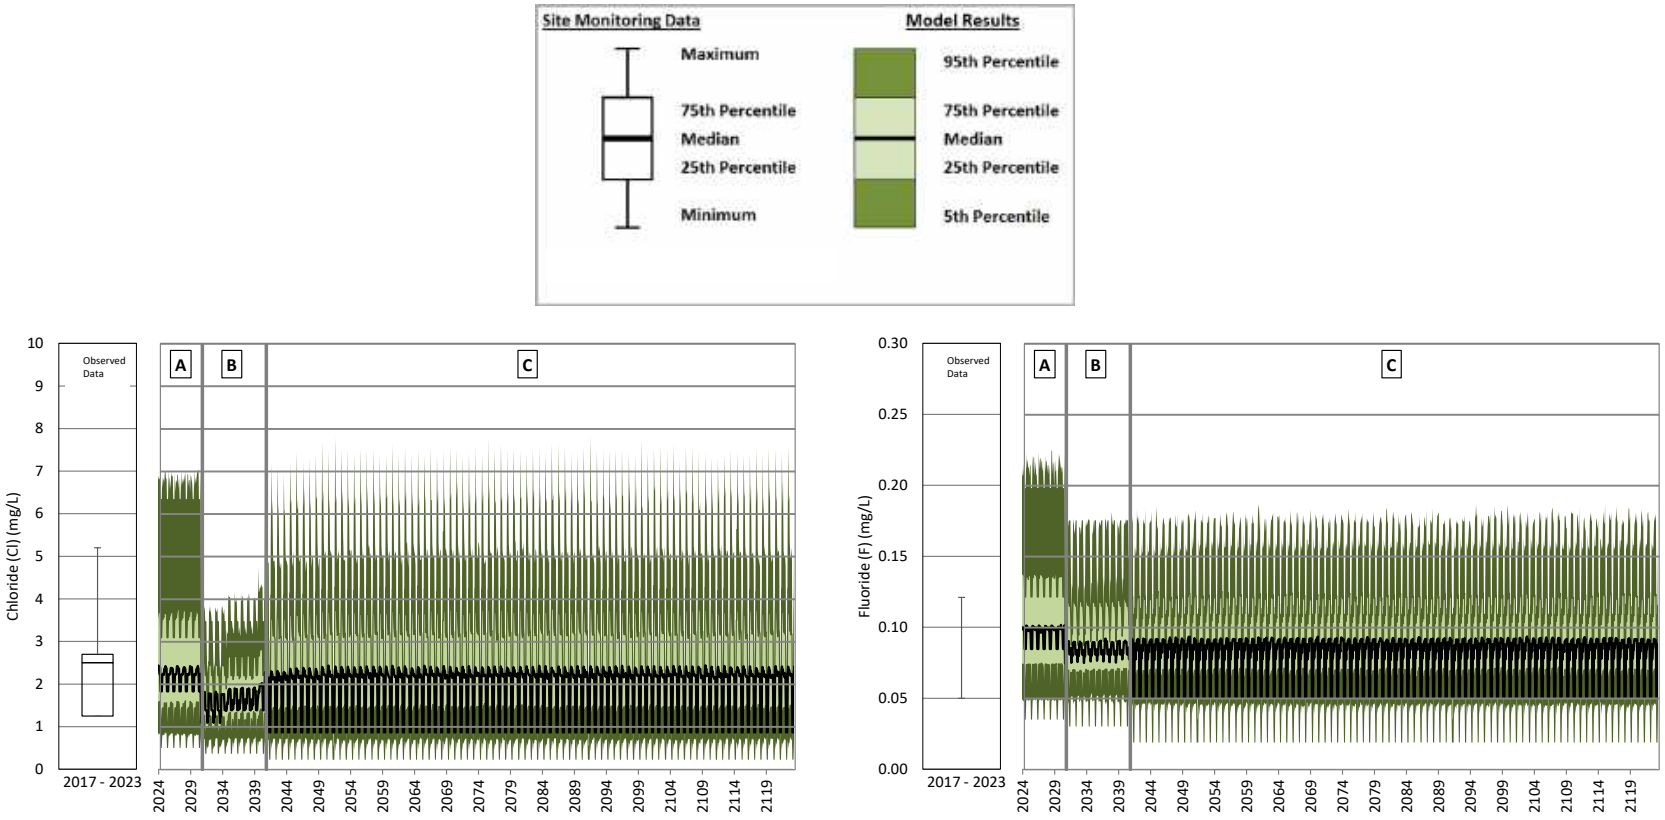
Figure B **139: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Uranium and Dissolved Vanadium**



A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

Figure B **140: Perimeter Embankment Till Borrow Pond Operations, Closure and Post-closure – Dissolved Zinc**



9K Sump Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

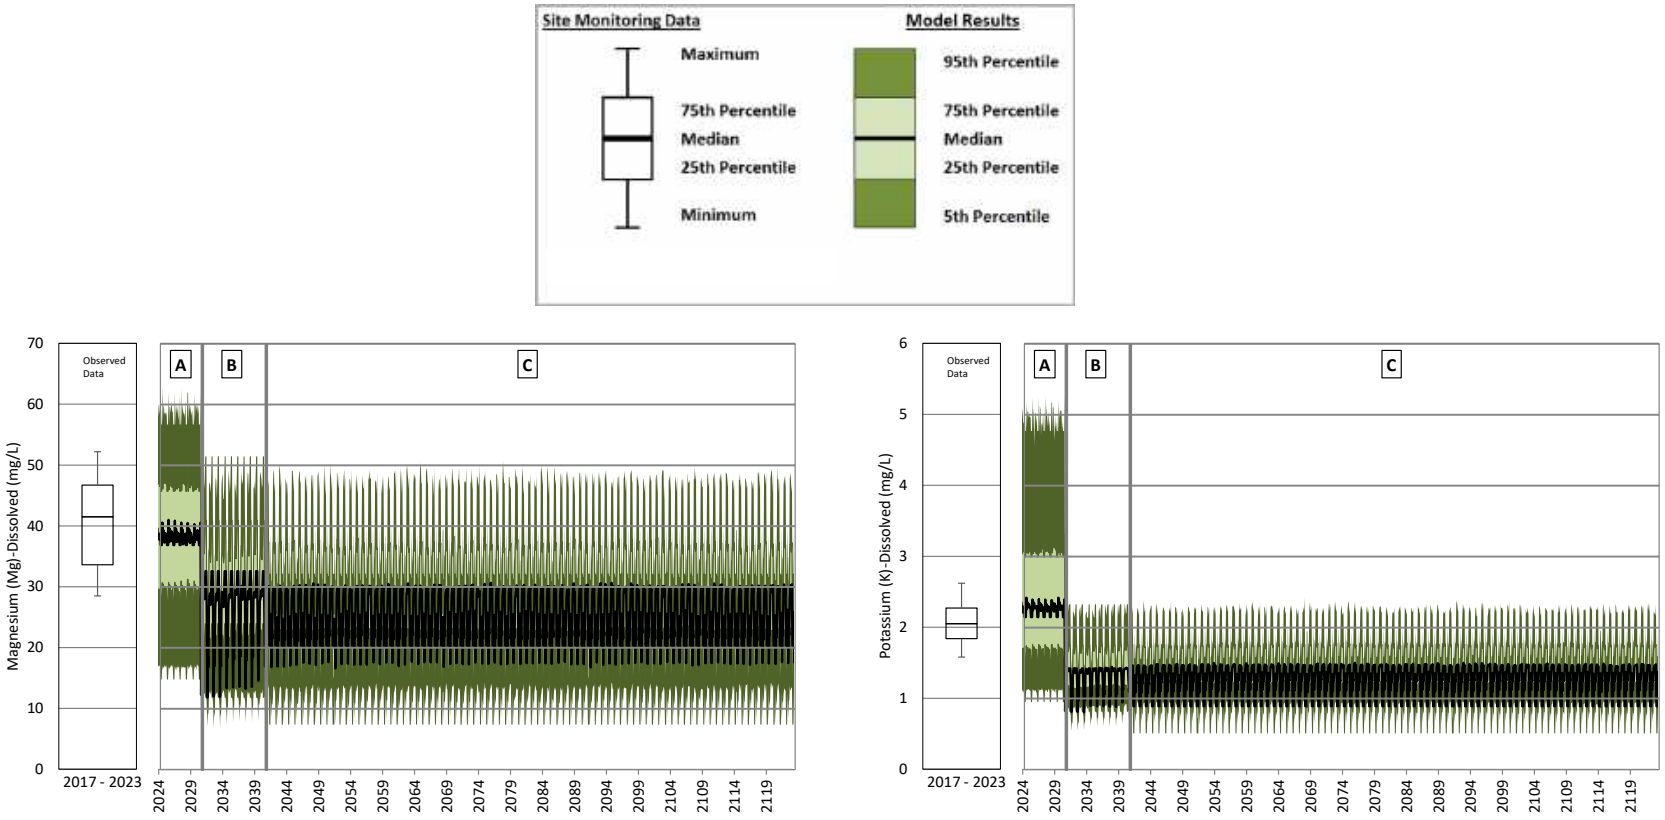


Figure B **141: 9K Sump Operations, Closure and Post-closure – Total Dissolved Solids and Calcium**

A = Operations; B = Closure; C = Post-closure

Note: Chloride concentrations increase from closure to post-closure as disturbed runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for chloride than the disturbed runoff water quality input. Fluoride concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

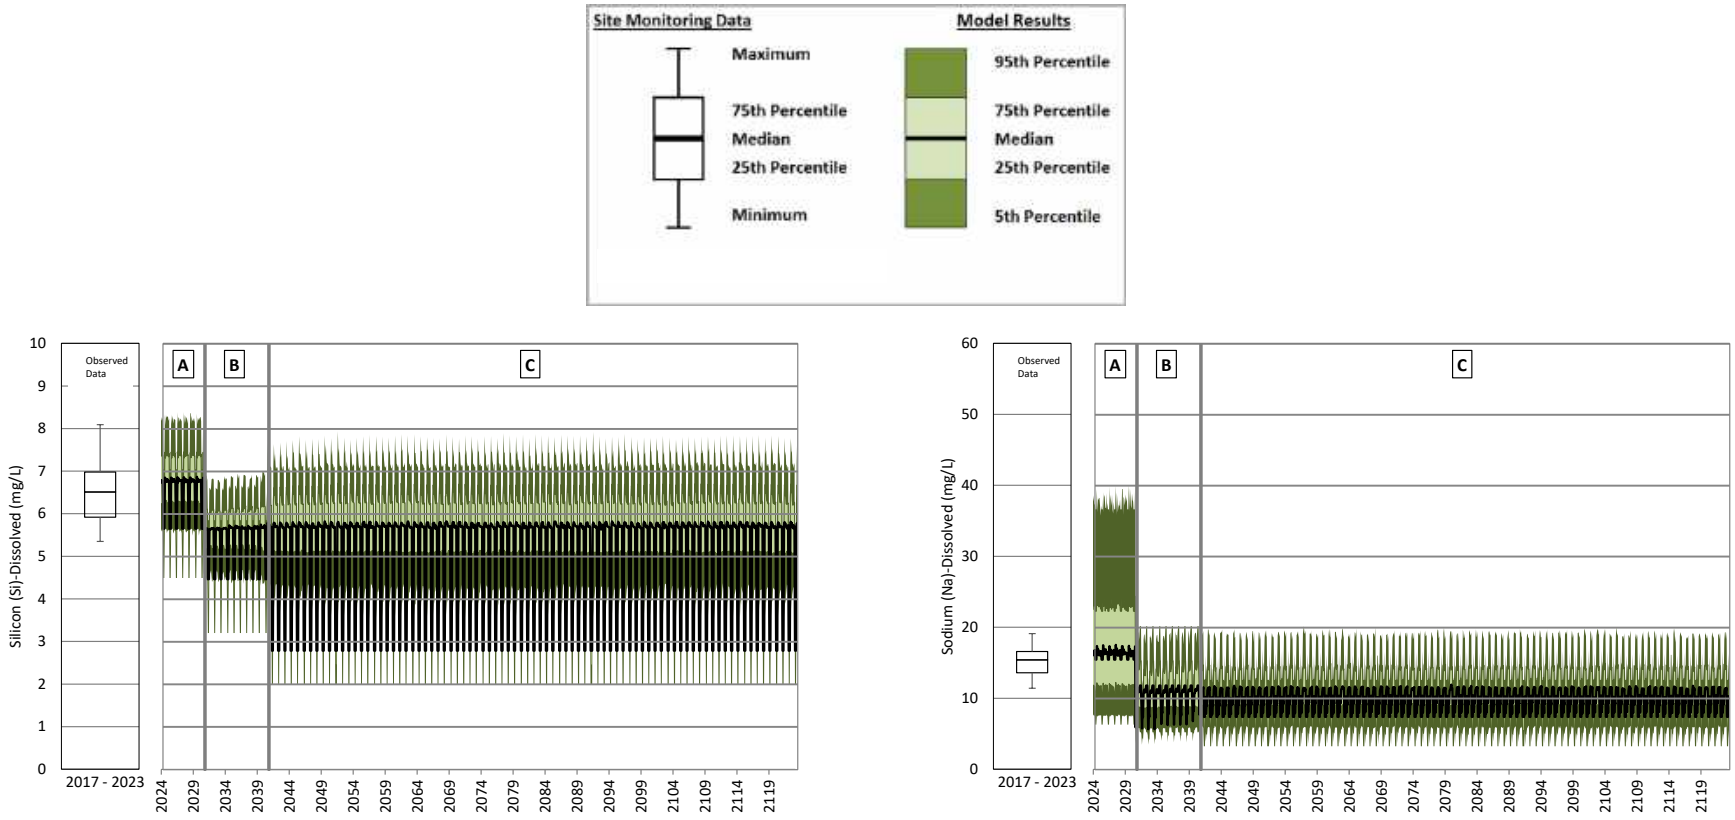

Figure B **142: 9K Sump Operations, Closure and Post-closure – Chloride and Fluoride**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

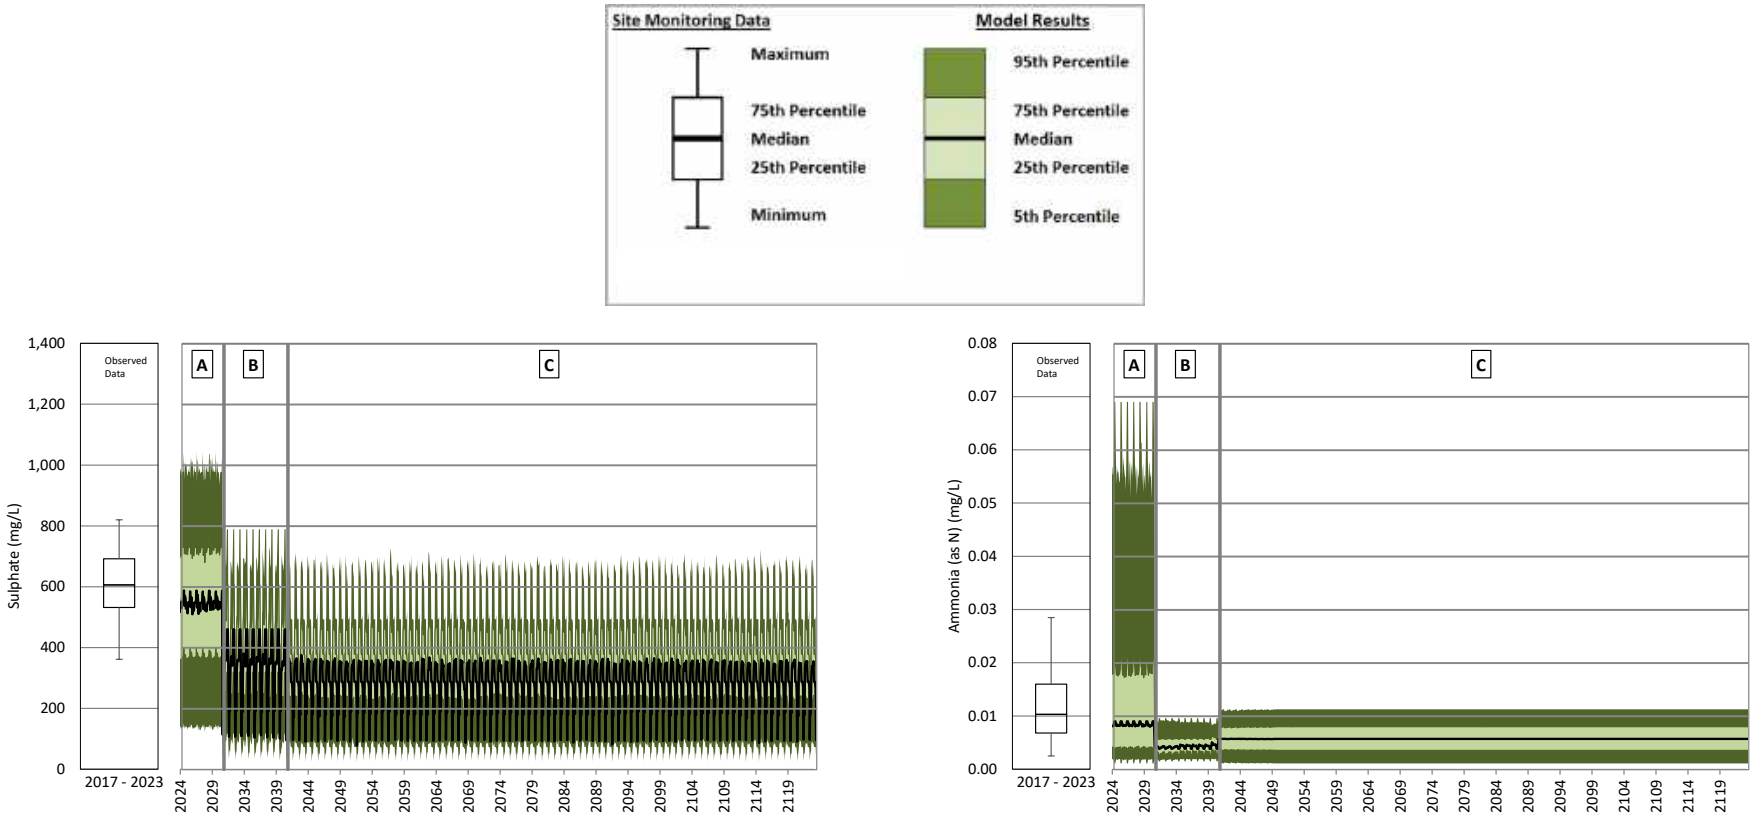

Figure B **143: 9K Sump Operations, Closure and Post-closure – Magnesium and Potassium**

A = Operations; B = Closure; C = Post-closure

Note: Silicon concentrations increase from closure to post-closure as disturbed runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for silicon than the disturbed runoff water quality input. Sodium concentrations decrease from operations to closure and post-closure as runoff areas are remediated.

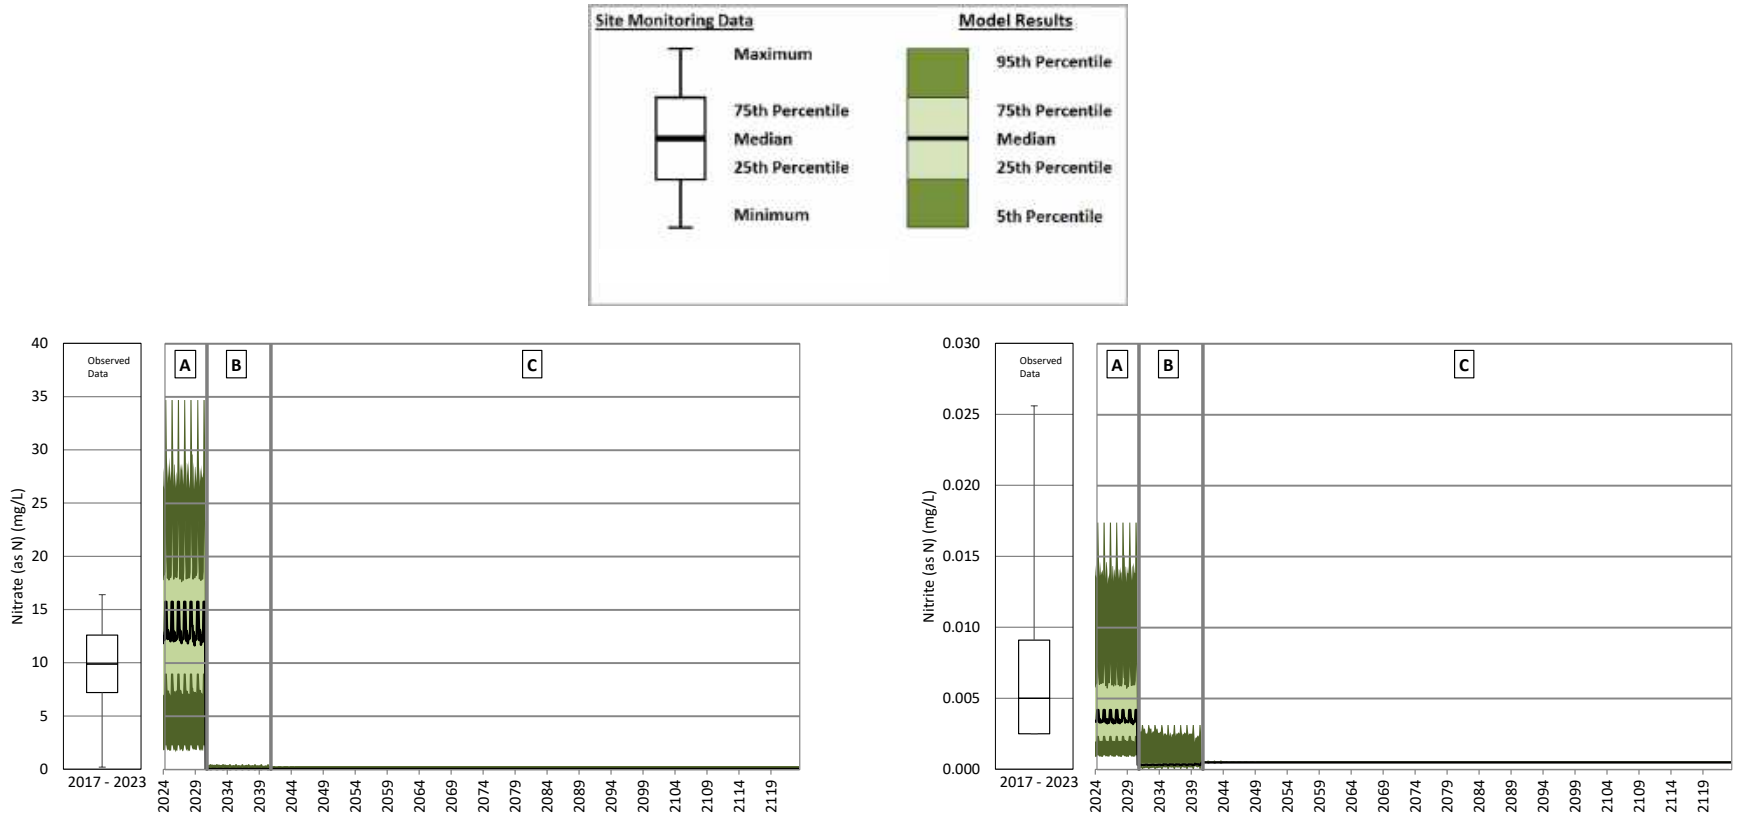

Figure B **144: 9K Sump Operations, Closure and Post-closure – Silicon and Sodium**

A = Operations; B = Closure; C = Post-closure

Note: Sulphate concentrations decrease from operations to closure and post-closure as runoff areas are remediated. Total ammonia concentrations increase from closure to post-closure as disturbed runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for total ammonia than the disturbed runoff water quality input.

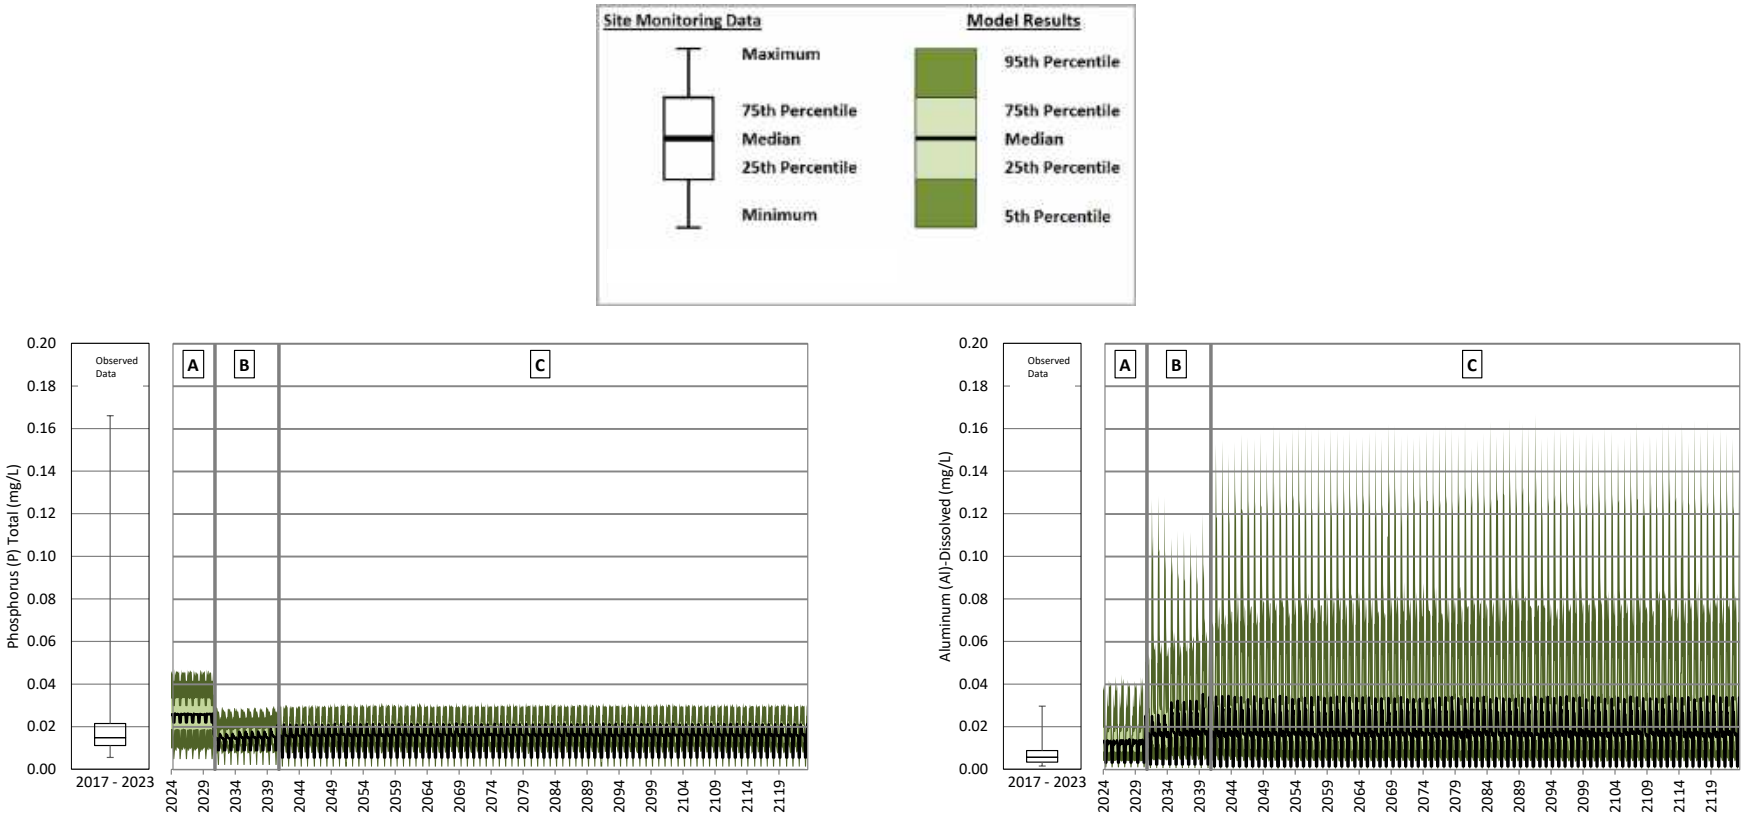

Figure B **145: 9K Sump Operations, Closure and Post-closure – Sulphate and Total Ammonia**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

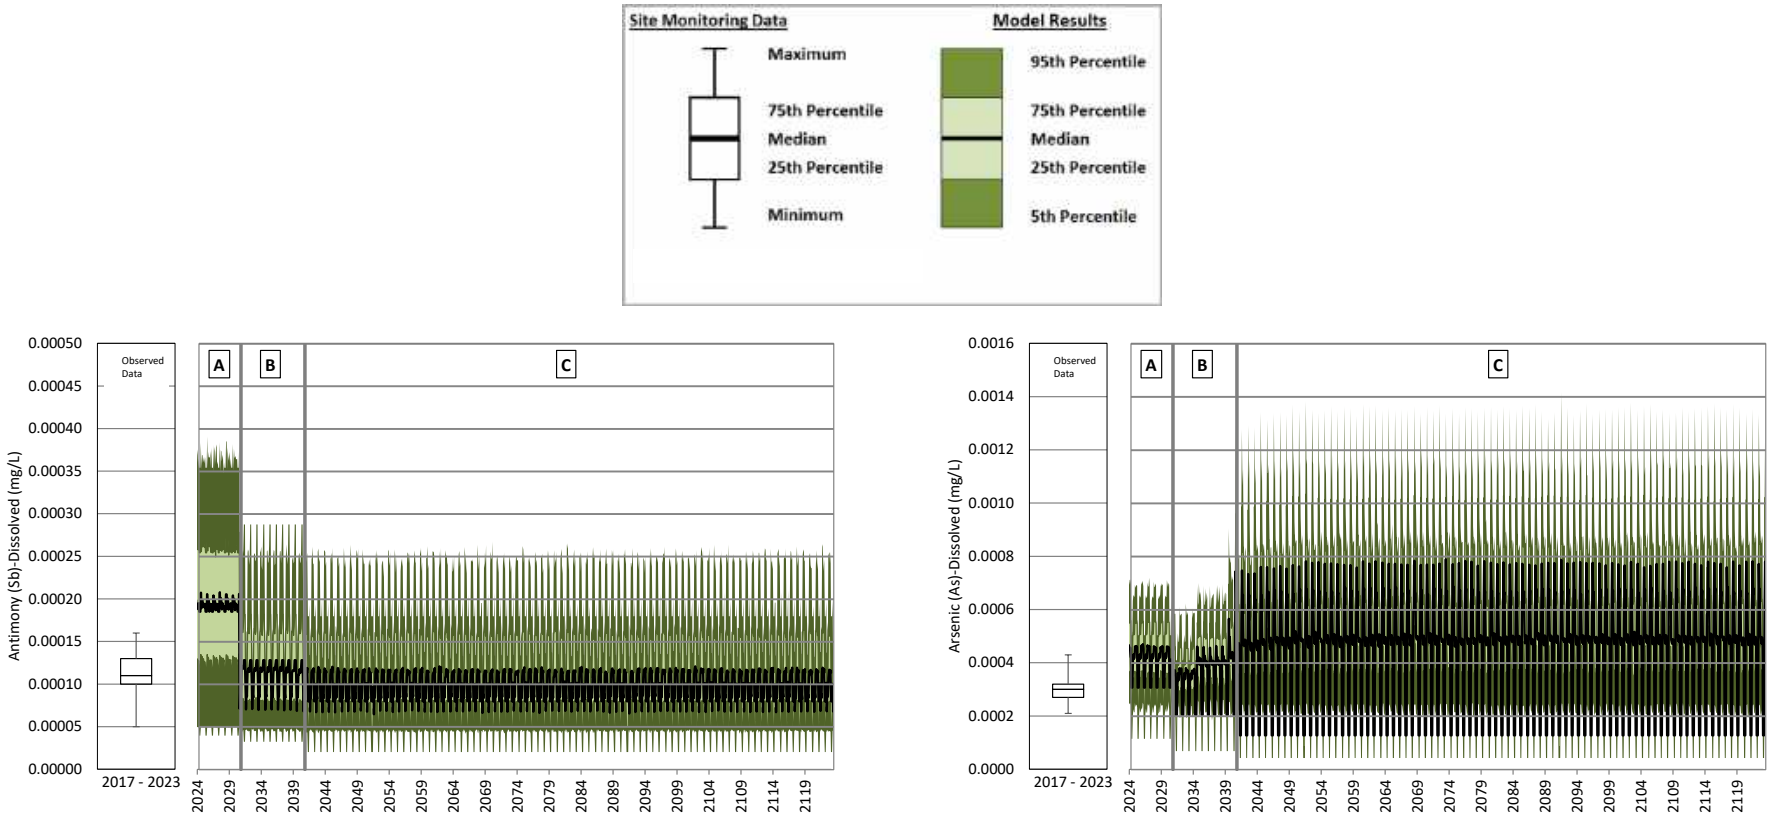

Figure B **146: 9K Sump Operations, Closure and Post-closure – Nitrate and Nitrite**

A = Operations; B = Closure; C = Post-closure

Note: Total phosphorus and dissolved aluminum concentrations increase from closure to post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for total phosphorus and dissolved aluminum than the NAG waste rock and disturbed runoff water quality inputs.

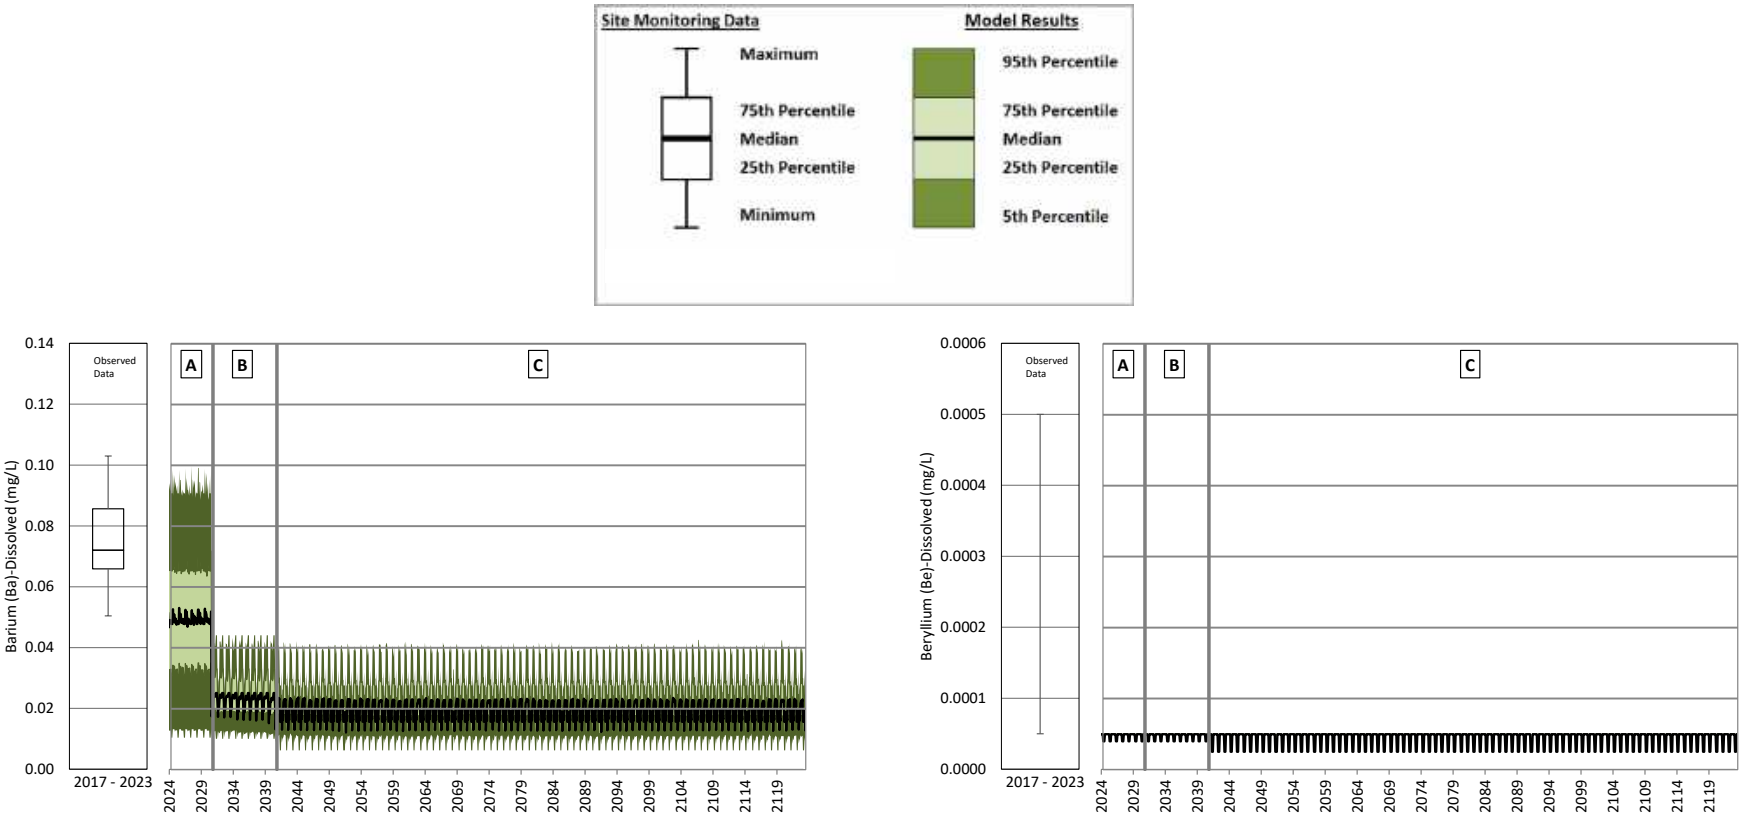

Figure B **147: 9K Sump Operations, Closure and Post-closure – Total Phosphorus and Dissolved Aluminum**

A = Operations; B = Closure; C = Post-closure

Note: Dissolved antimony concentrations decrease from operations to closure and post-closure as runoff areas are remediated. Dissolved arsenic concentrations increase from closure to post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed water quality input has higher concentrations for dissolved arsenic than the NAG waste rock and disturbed runoff water quality inputs.

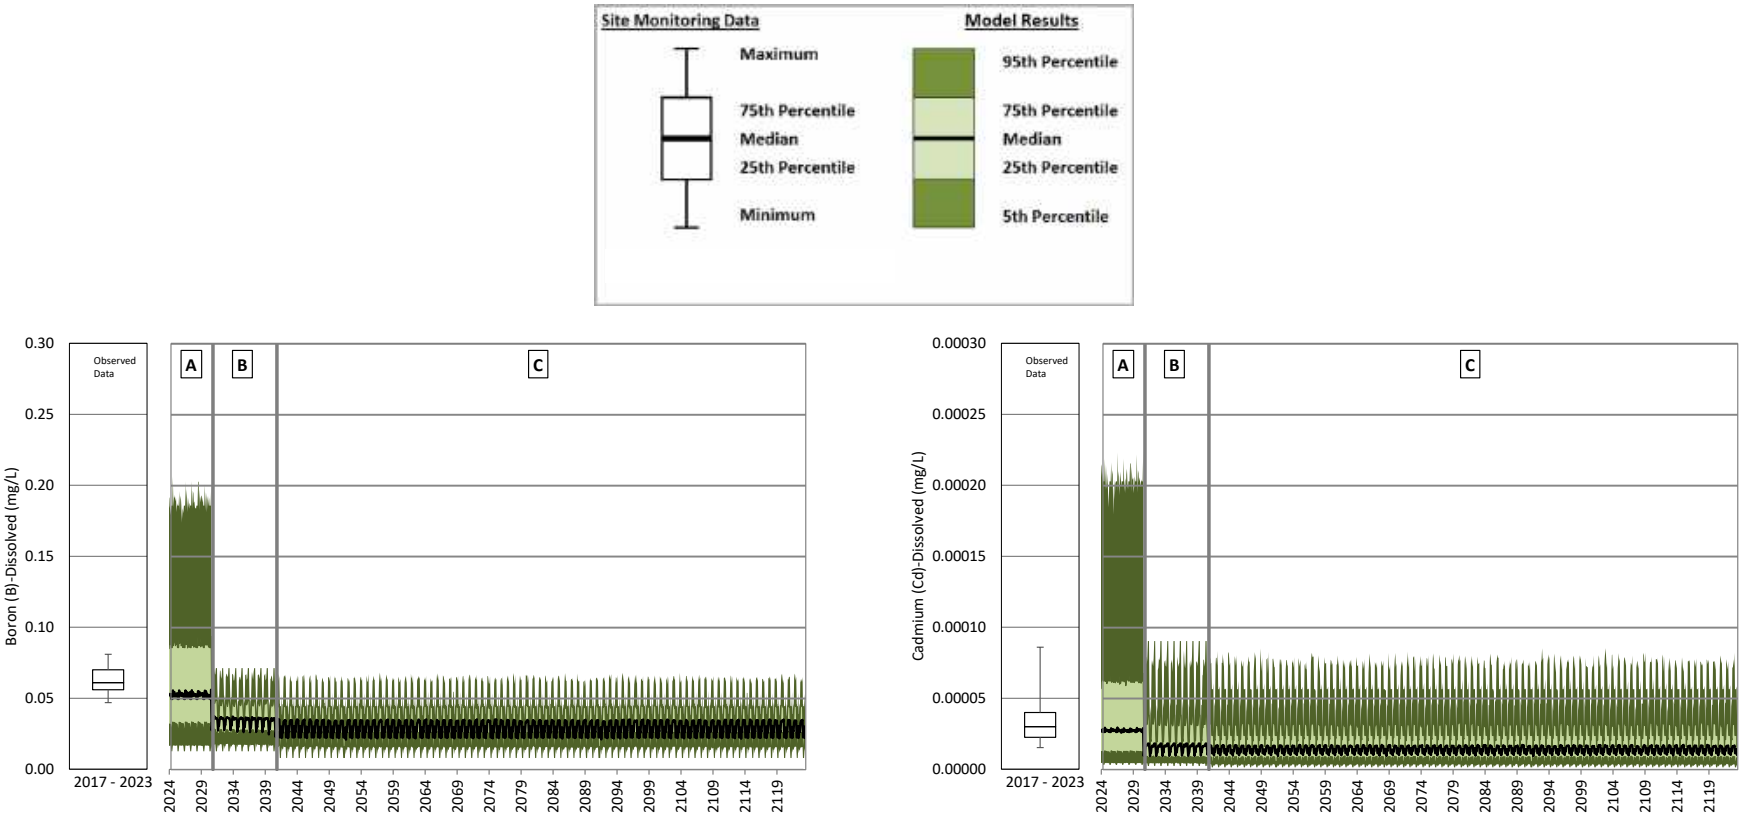

Figure B **148: 9K Sump Operations, Closure and Post-closure – Dissolved Antimony and Dissolved Arsenic**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

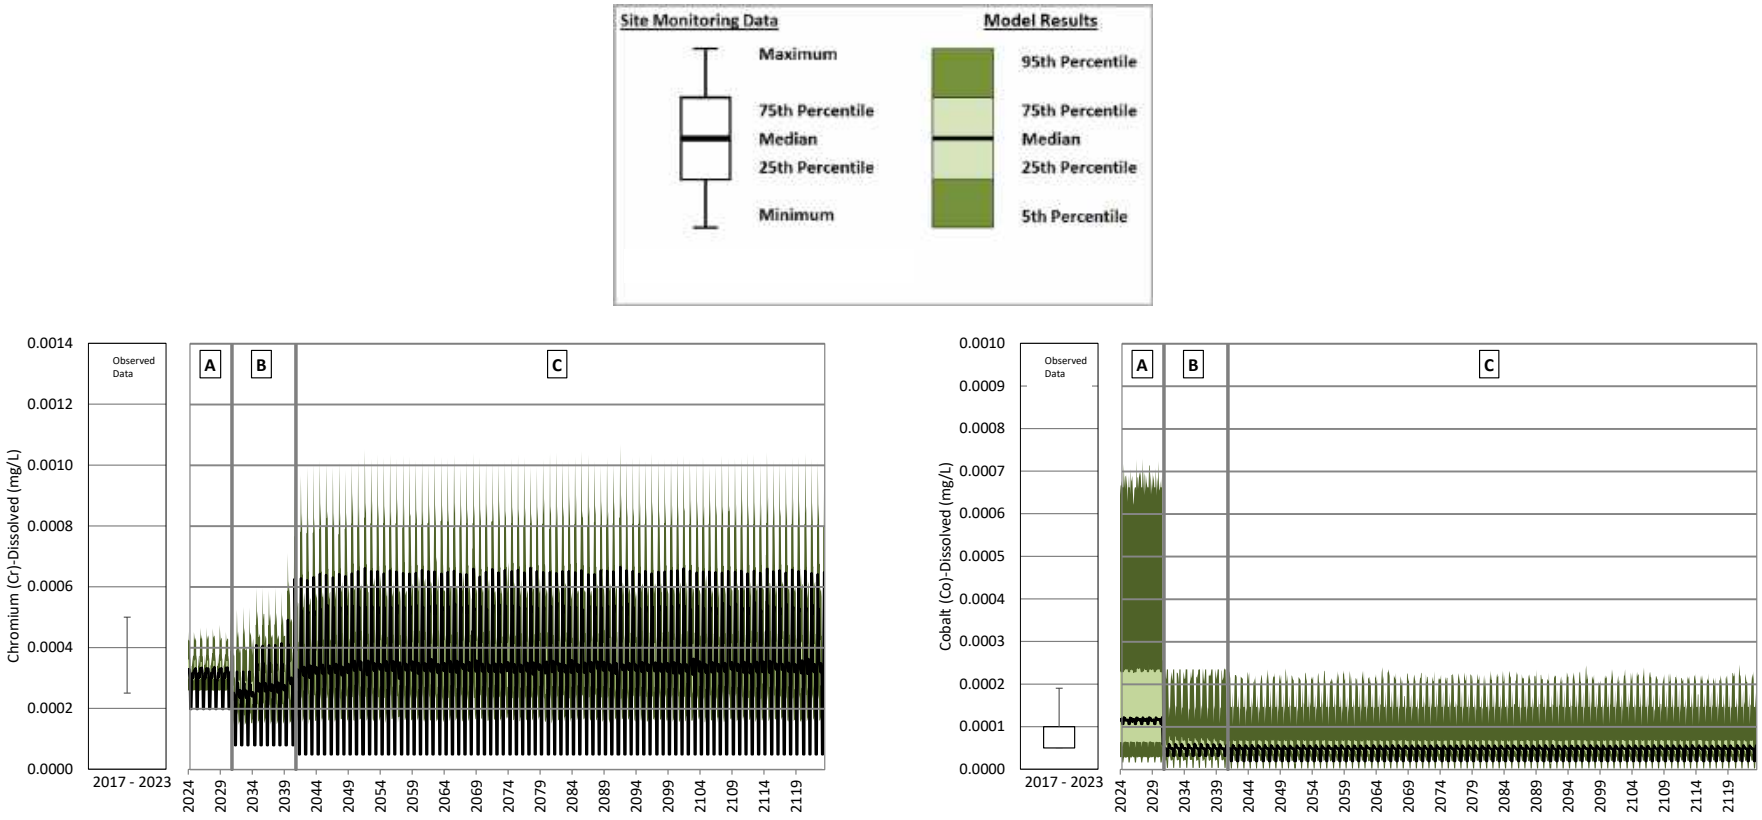

Figure B **149: 9K Sump Operations, Closure and Post-closure – Dissolved Barium and Dissolved Beryllium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

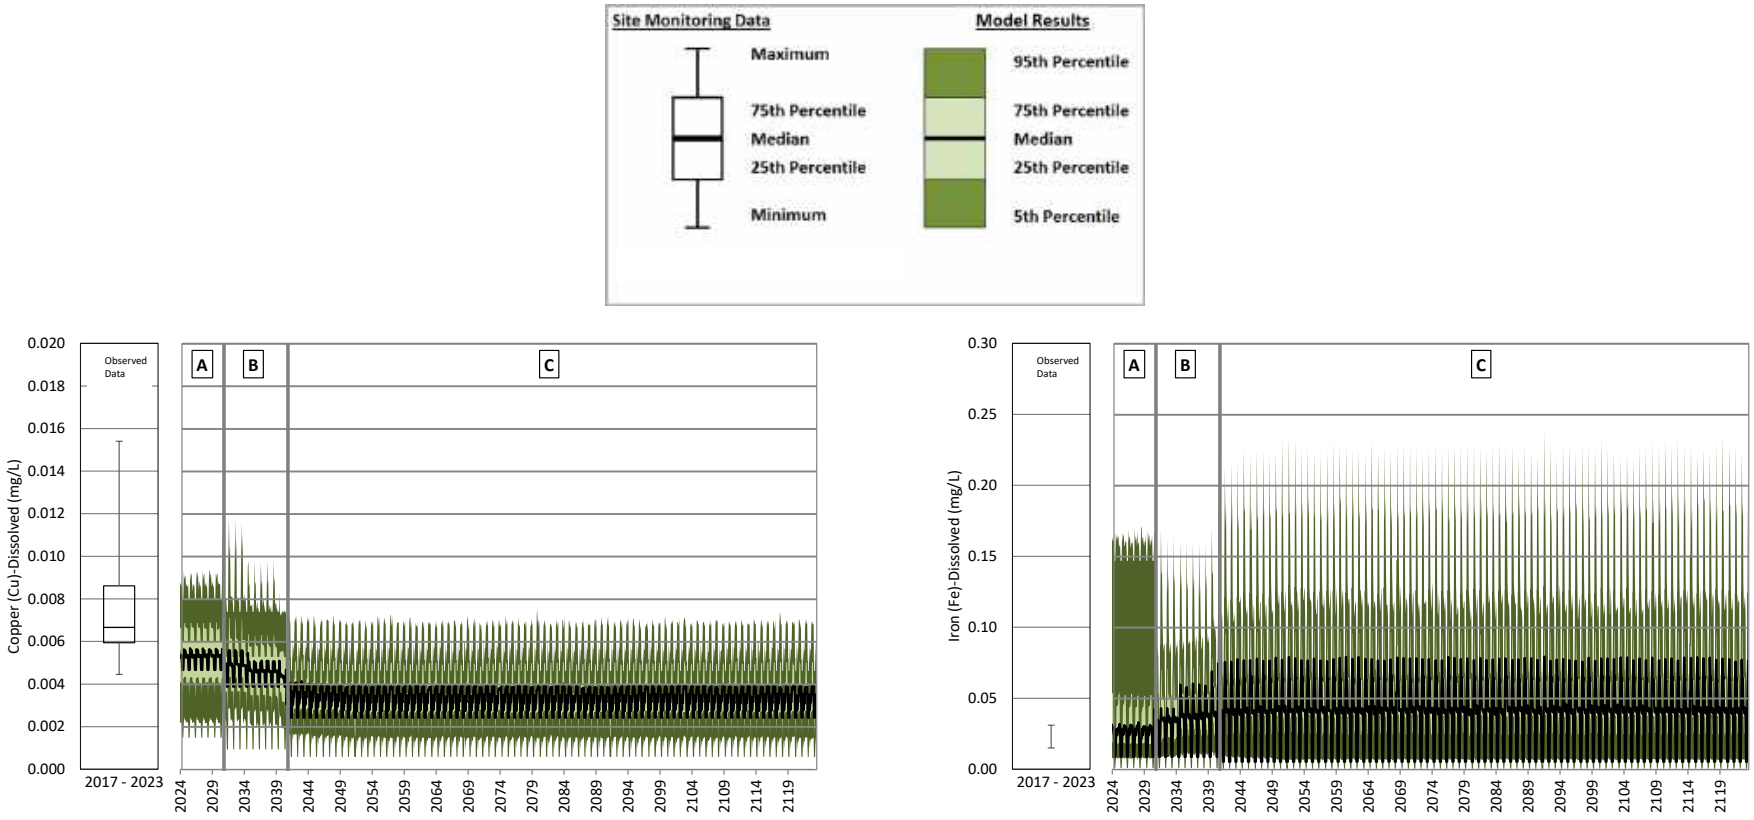

Figure B **150: 9K Sump Operations, Closure and Post-closure – Dissolved Boron and Dissolved Cadmium**

Figure B **196: South Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Selenium and Dissolved Silver**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas The increase in concentrations from 2031 to 2074 is due to decreases in the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility.

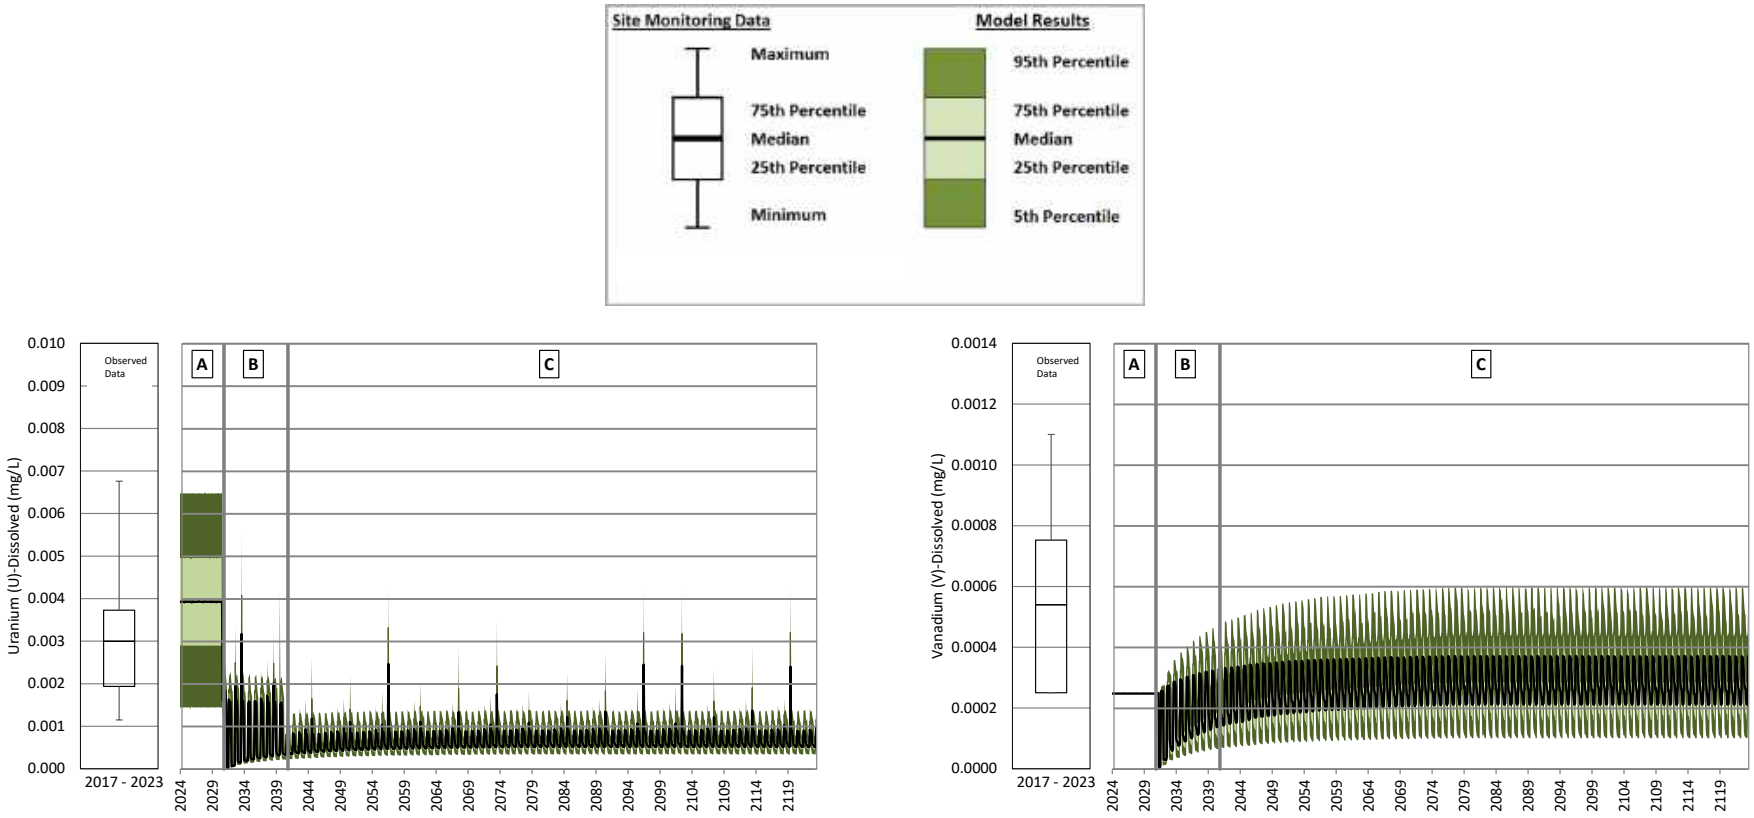

Figure B **197: South Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Strontium and Dissolved Thallium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas The increase in concentrations from 2031 to 2074 is due to decreases in the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility.

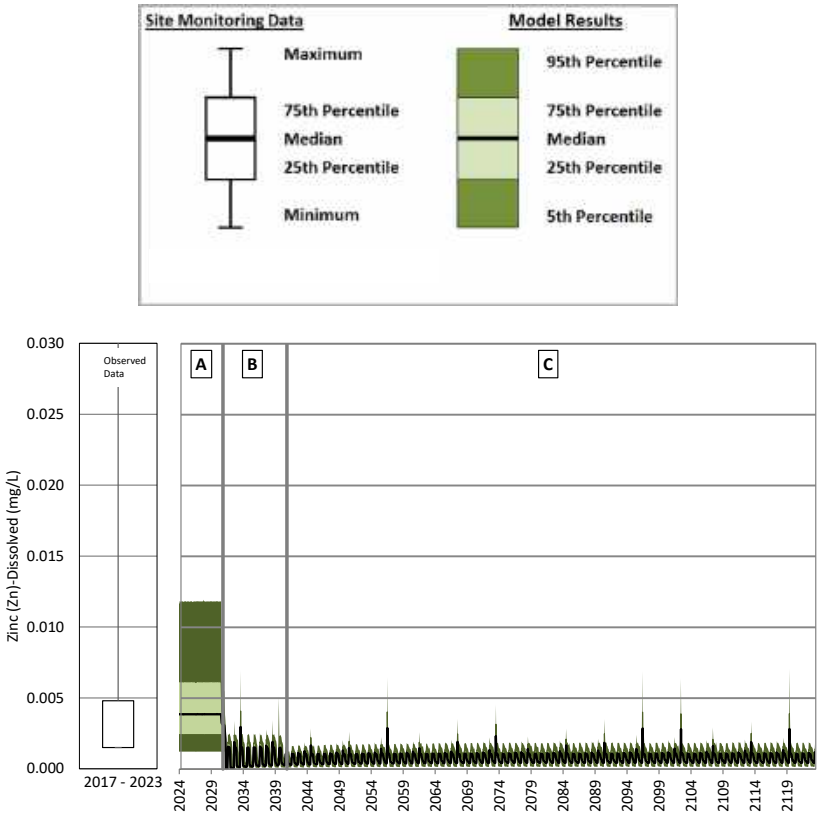

Figure B **198: South Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Tin and Dissolved Titanium**

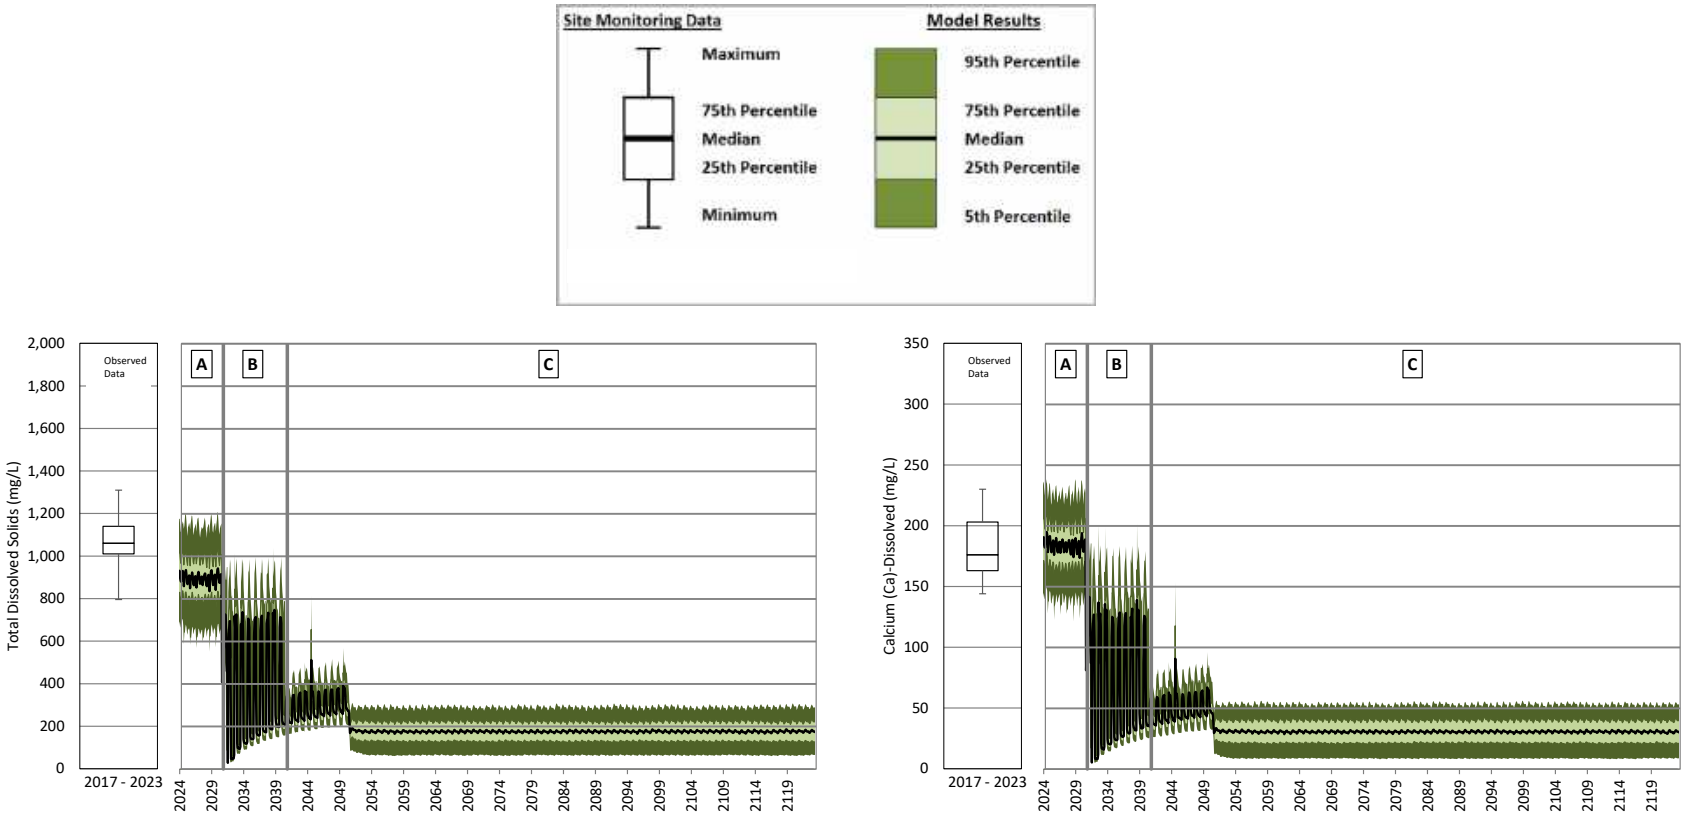
A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2074 is due to decreases in the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility.

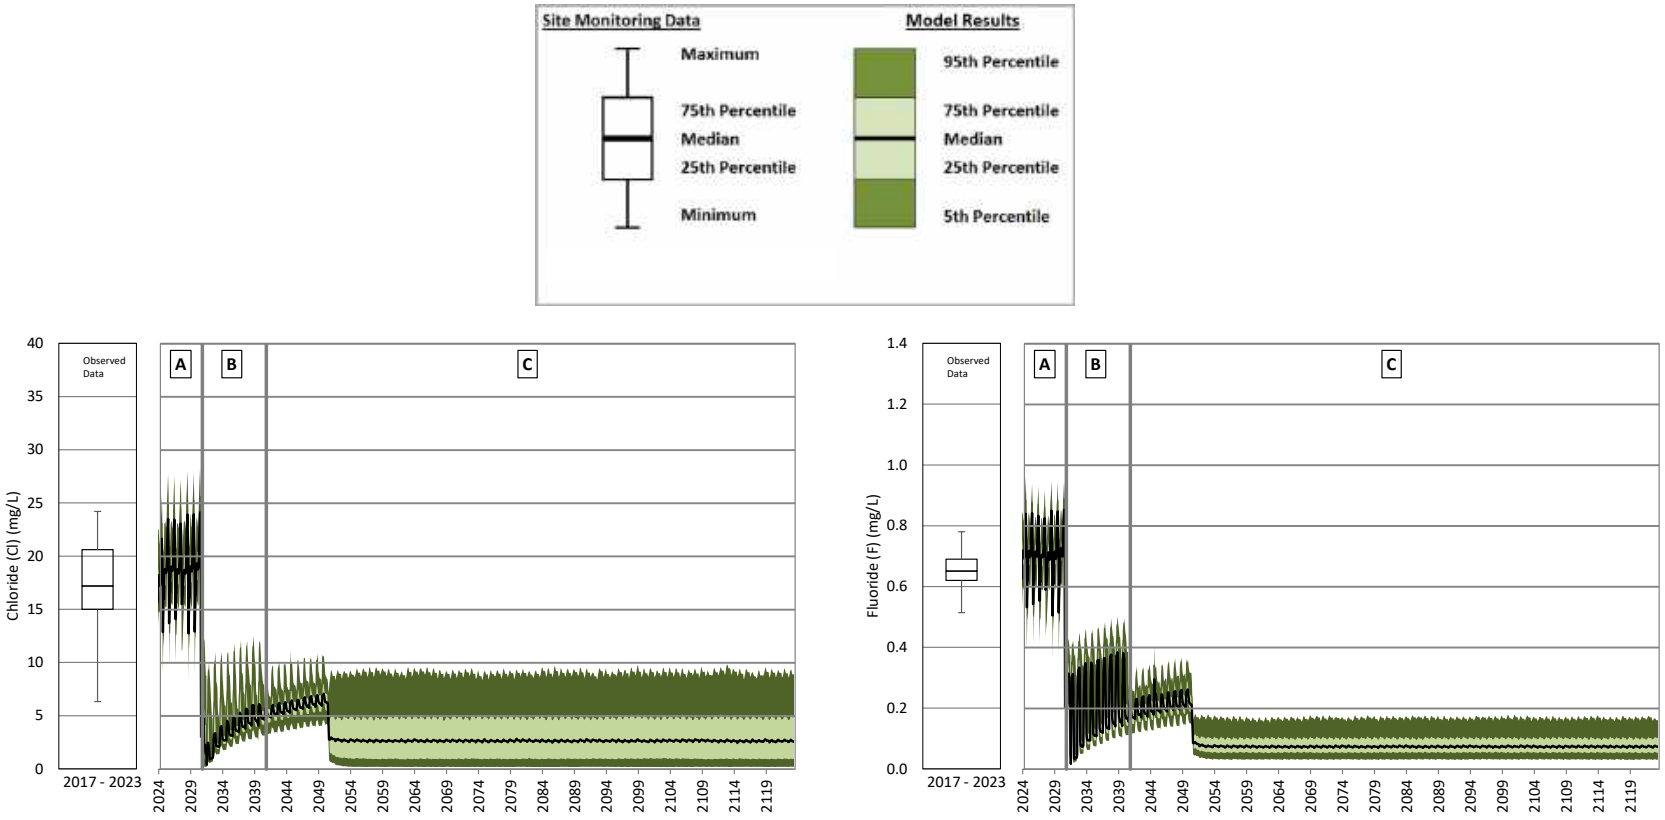
Figure B **199: South Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Uranium and Dissolved Vanadium**



A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2074 is due to decreases in the proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility.

Figure B **200: South Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Zinc**



Main Embankment Seepage Collection Pond Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

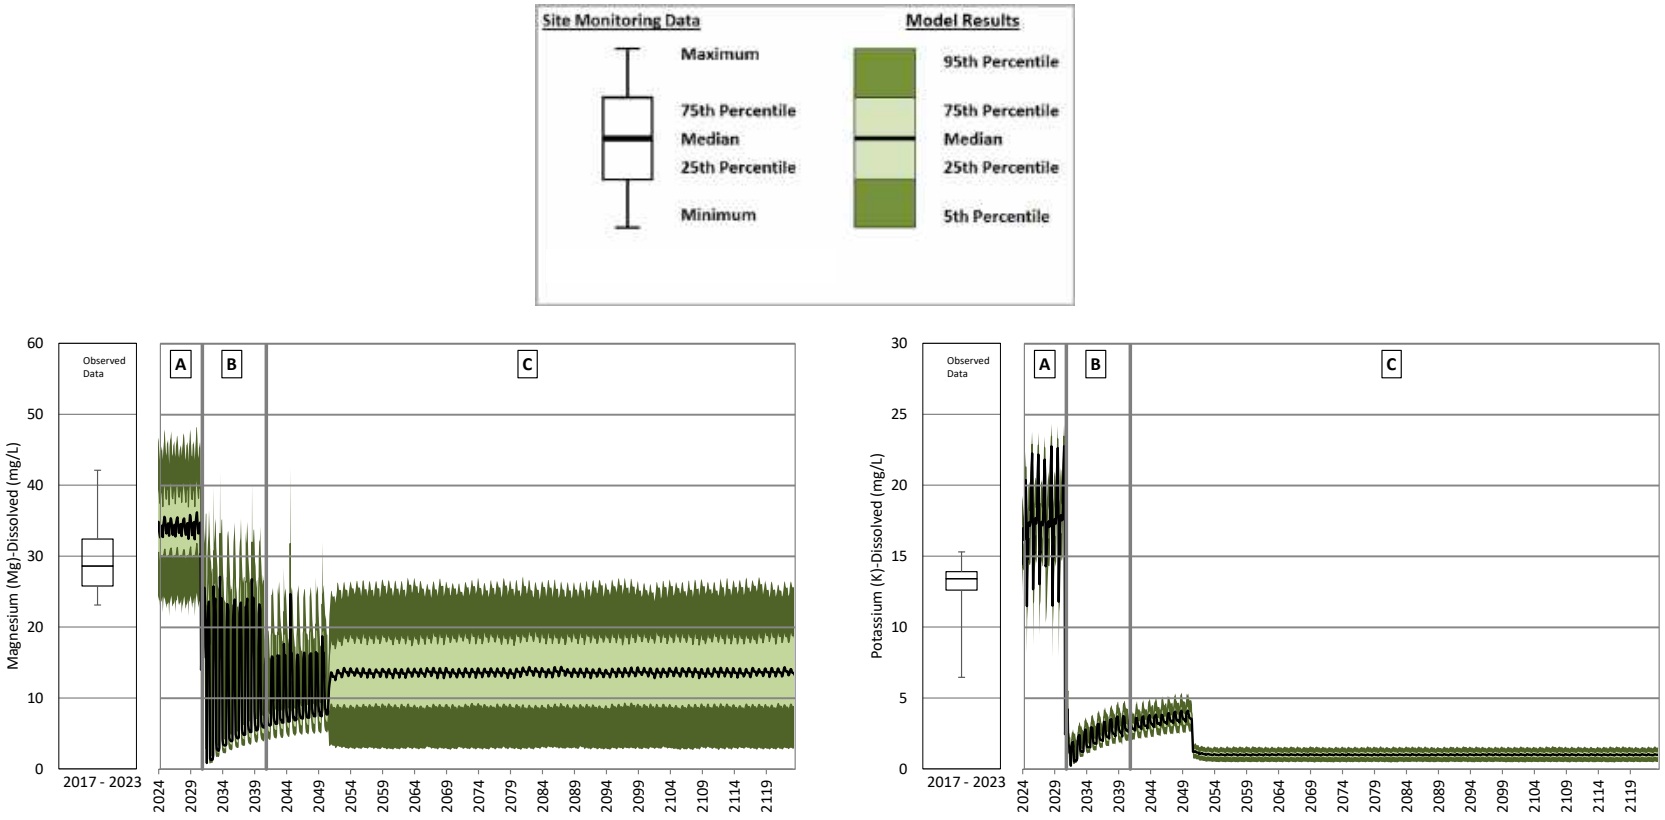


Figure B **201: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Total Dissolved Solids and Calcium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

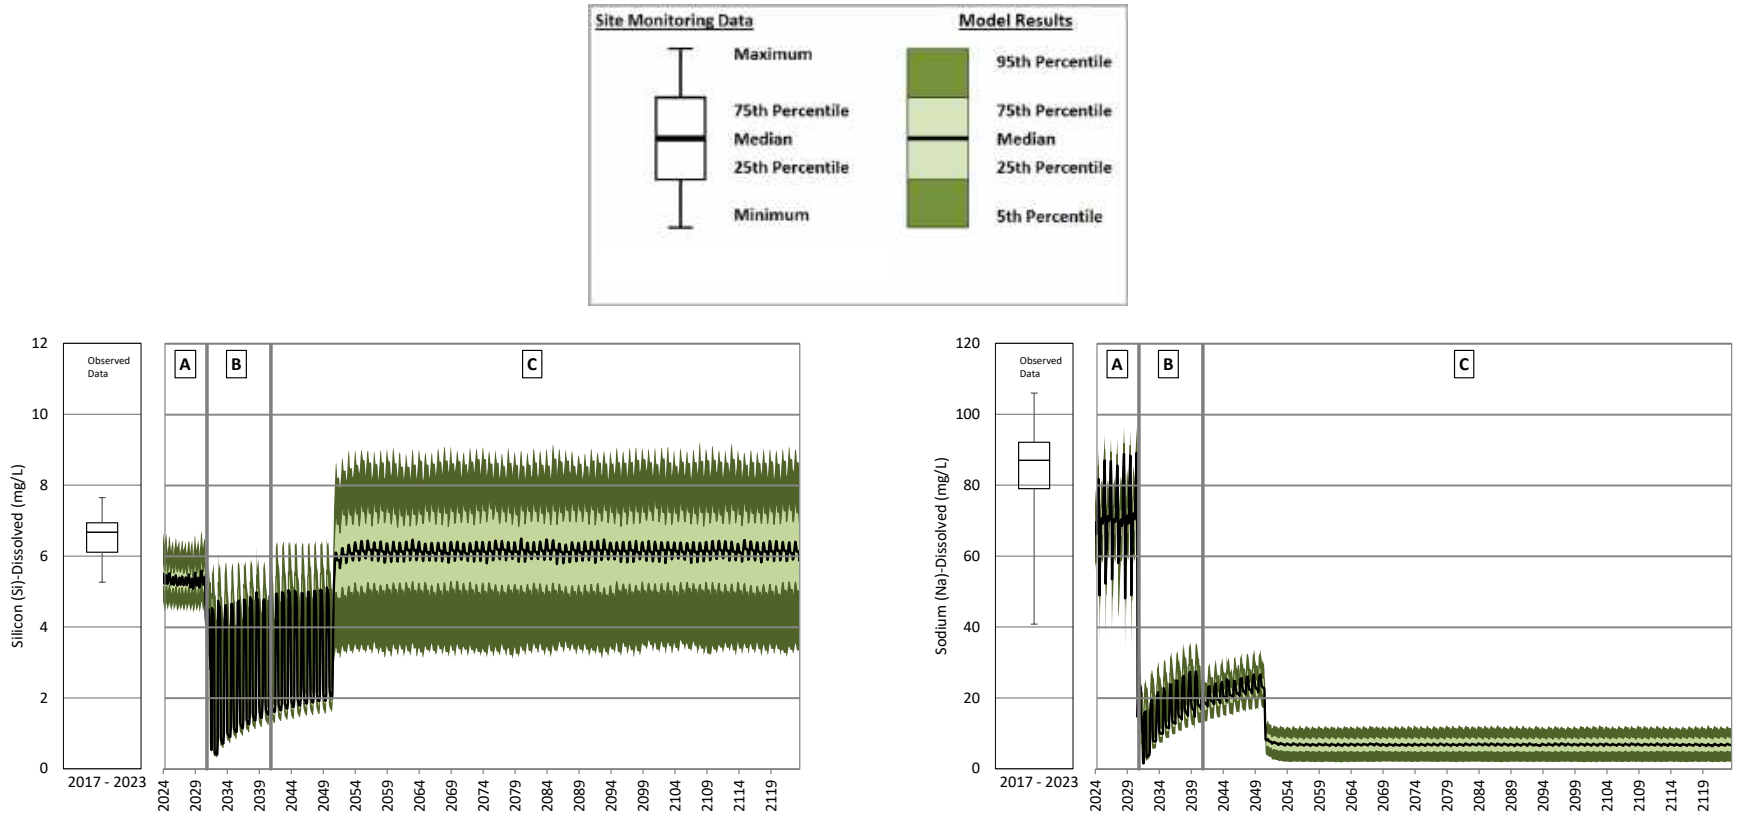

Figure B **202: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Chloride and Fluoride**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

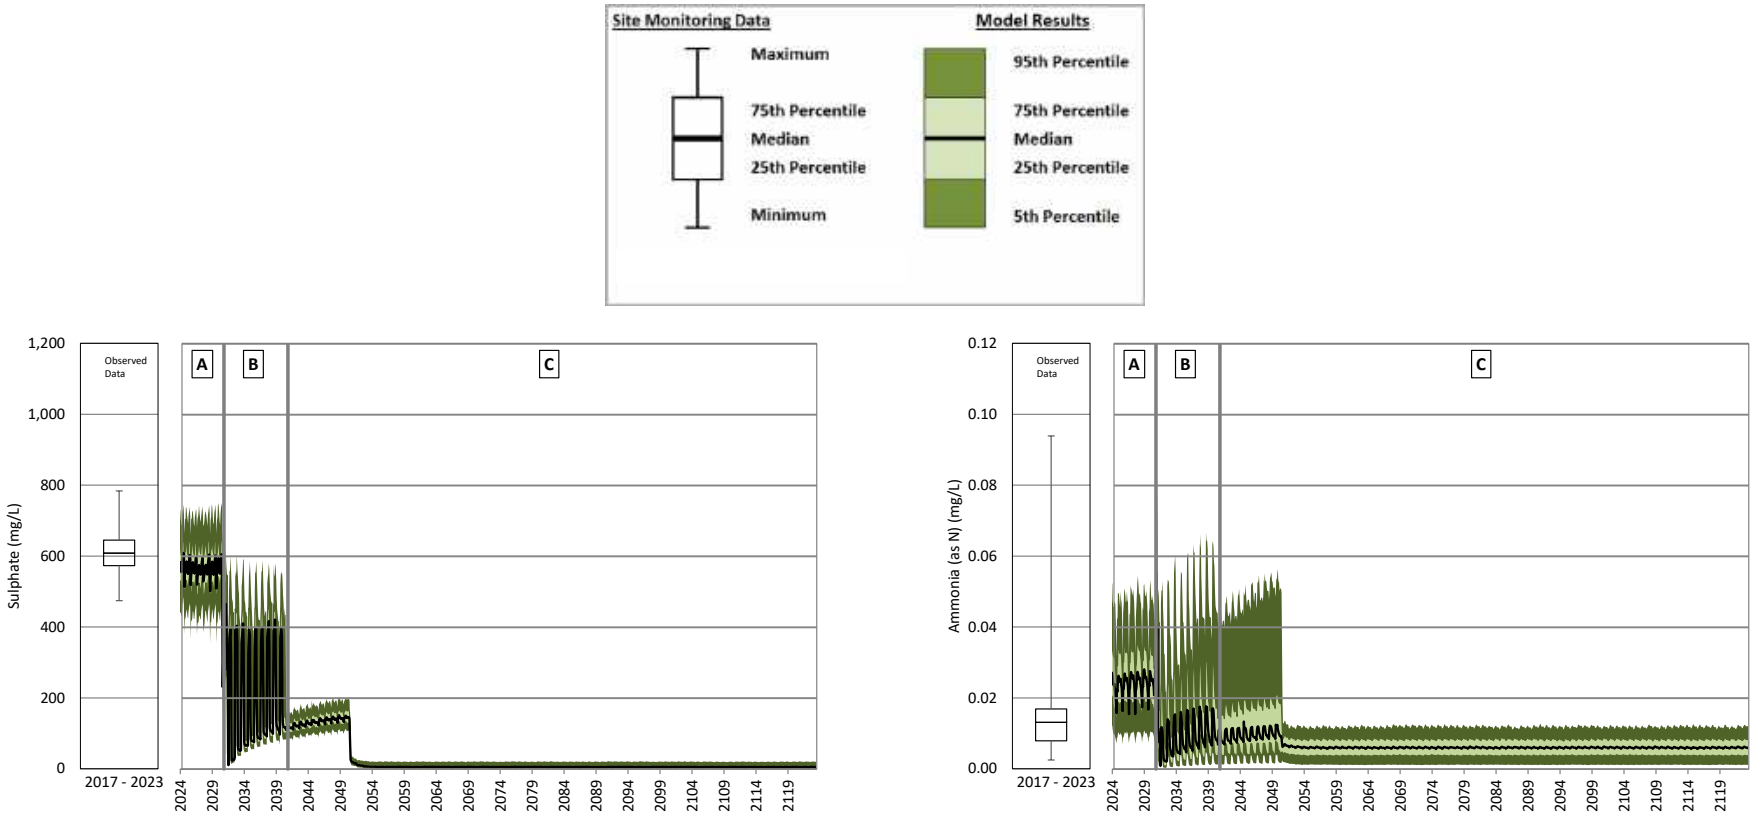

Figure B **203: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Magnesium and Potassium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Silicon concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for silicon than the disturbed runoff water quality input.

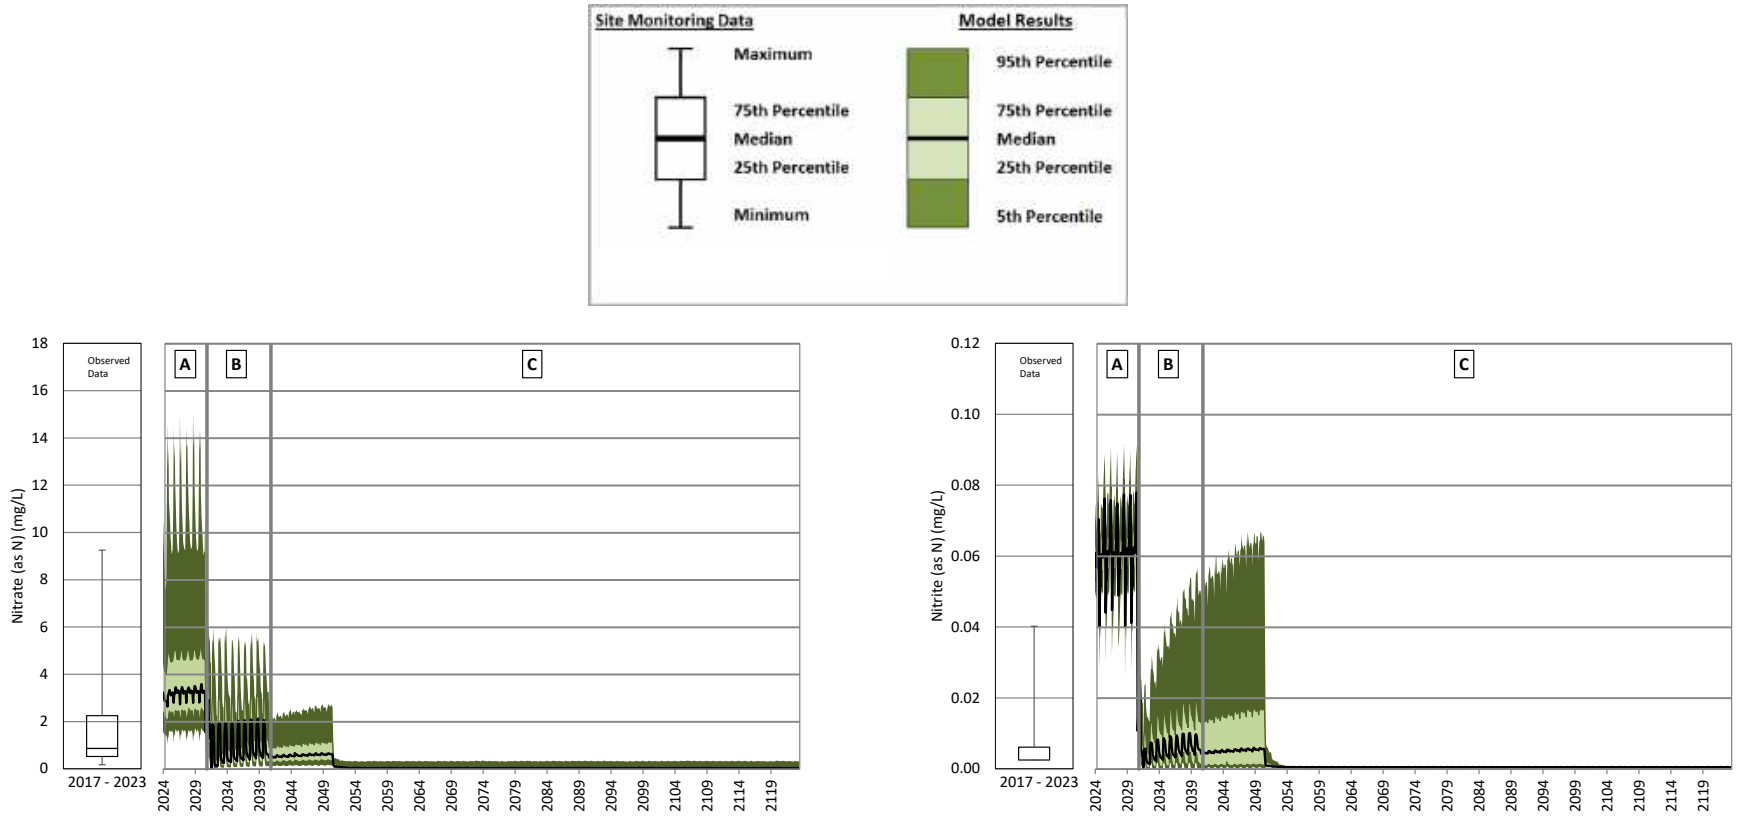

Figure B **204: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Silicon and Sodium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

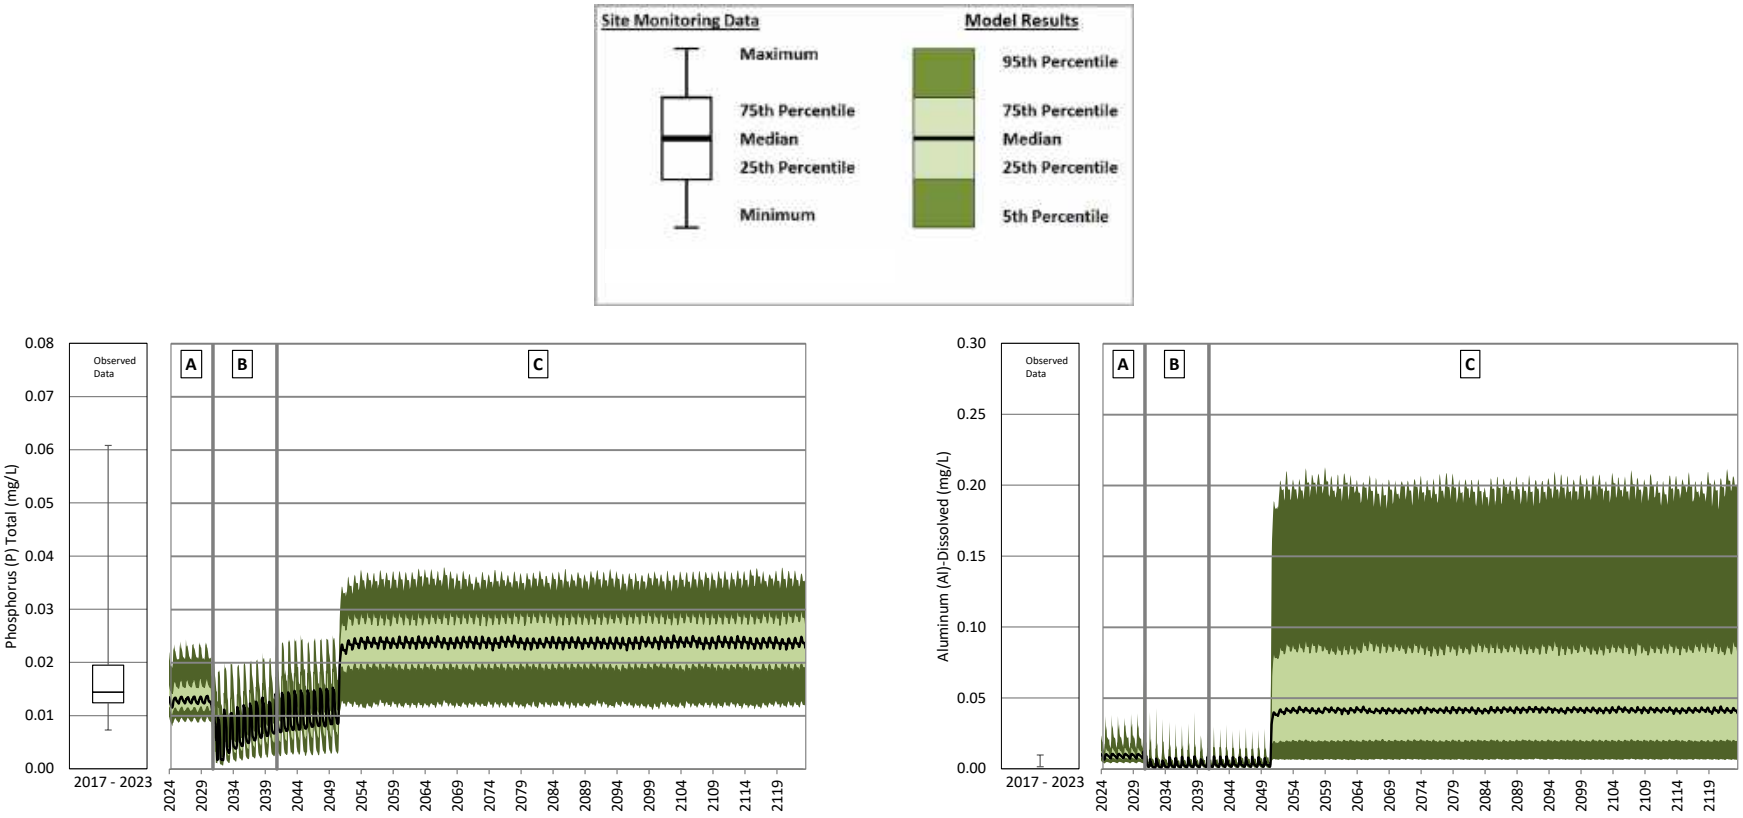

Figure B **205: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Sulphate and Total Ammonia**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

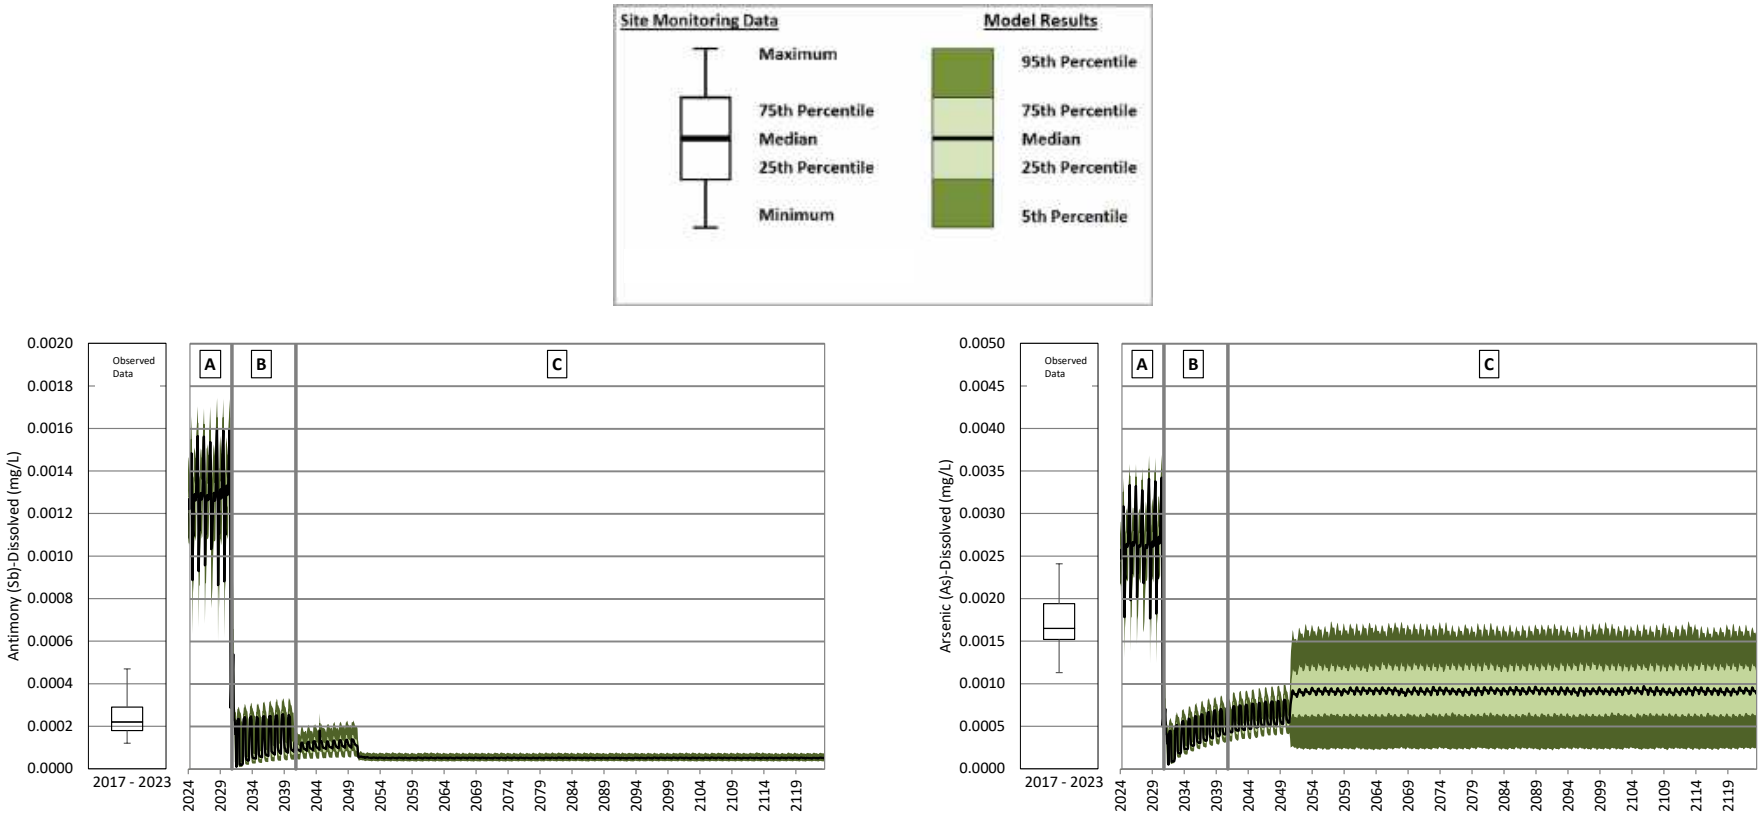

Figure B **206: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Nitrate and Nitrite**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Total phosphorus and dissolved aluminum concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for total phosphorus and dissolvedaluminum than the disturbed runoff water quality input.

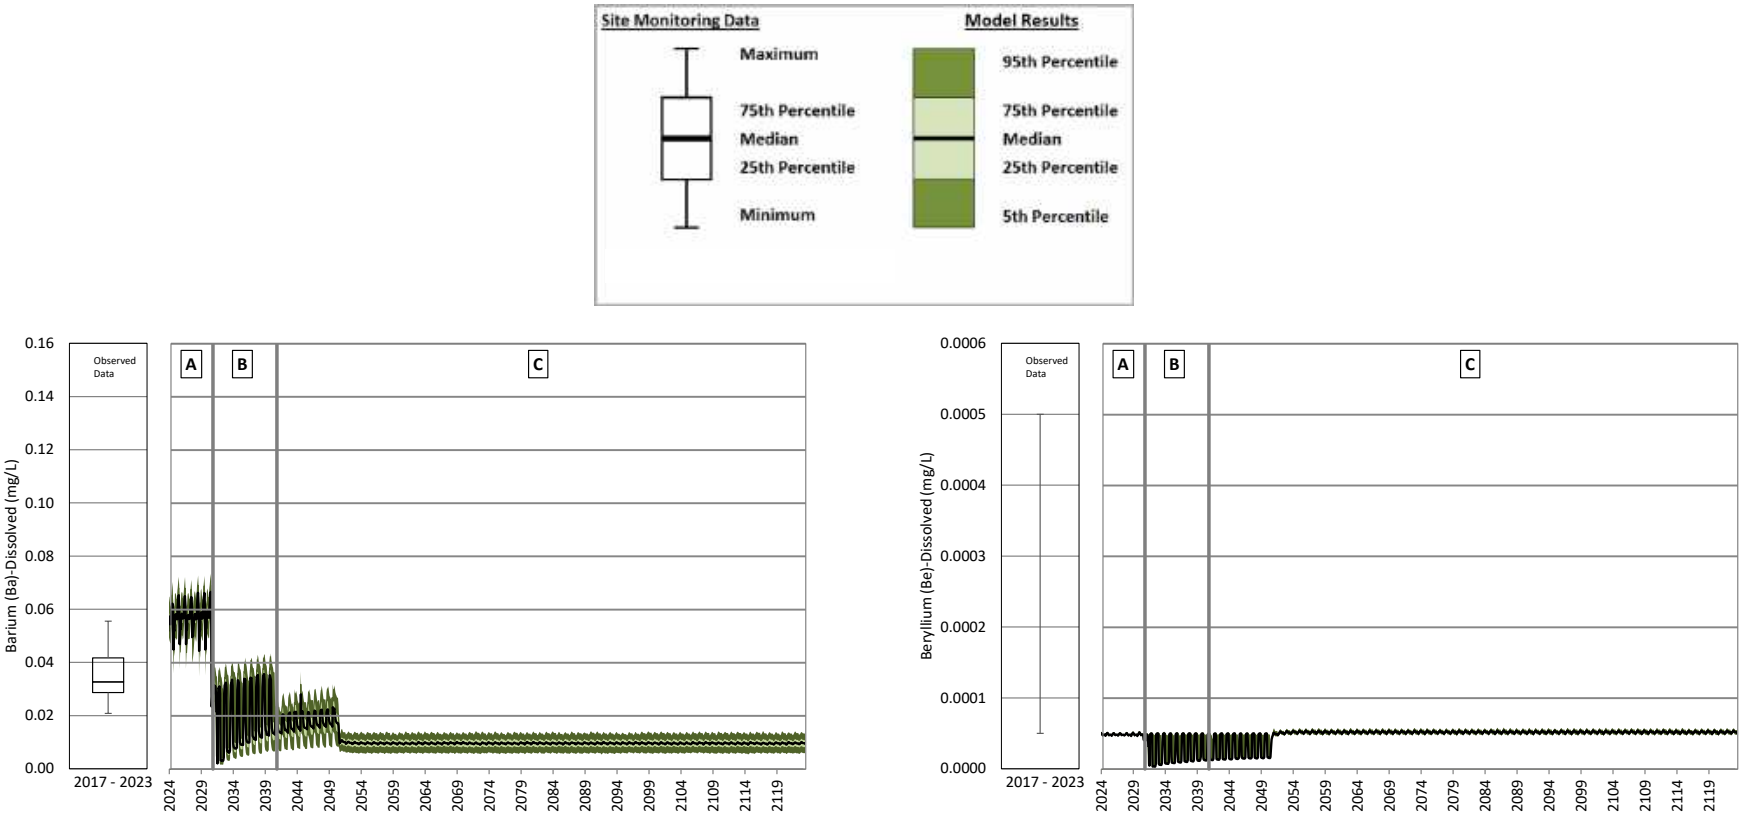

Figure B **207: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Total Phosphorus and Dissolved Aluminum**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved arsenic concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved arsenic than the disturbed runoff water quality input. .

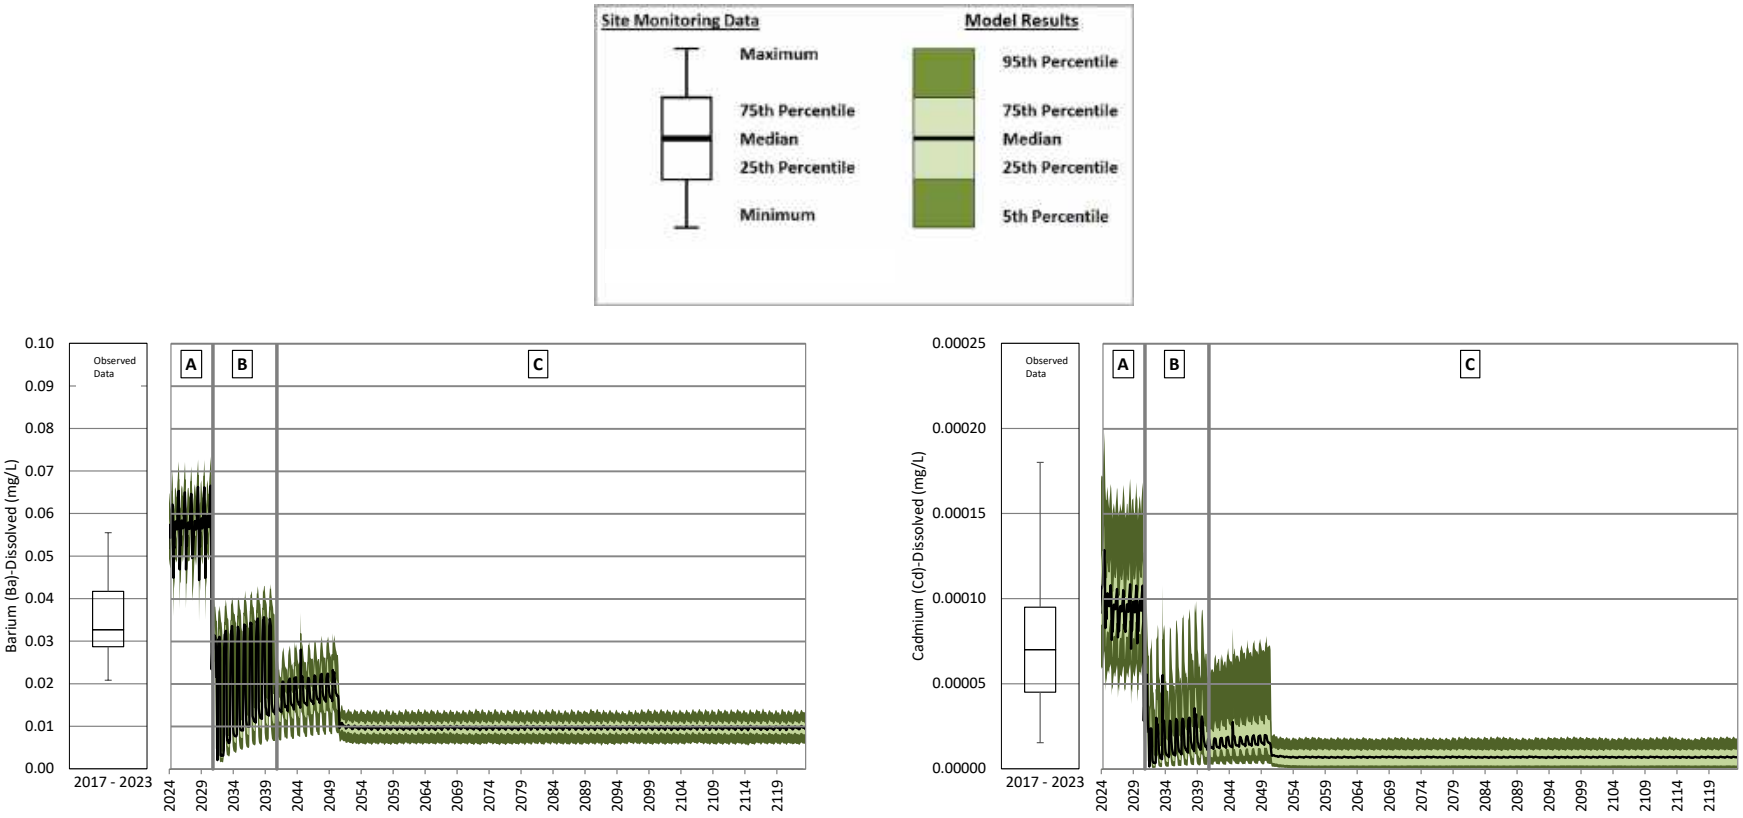

Figure B **208: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Antimony and Dissolved Arsenic**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

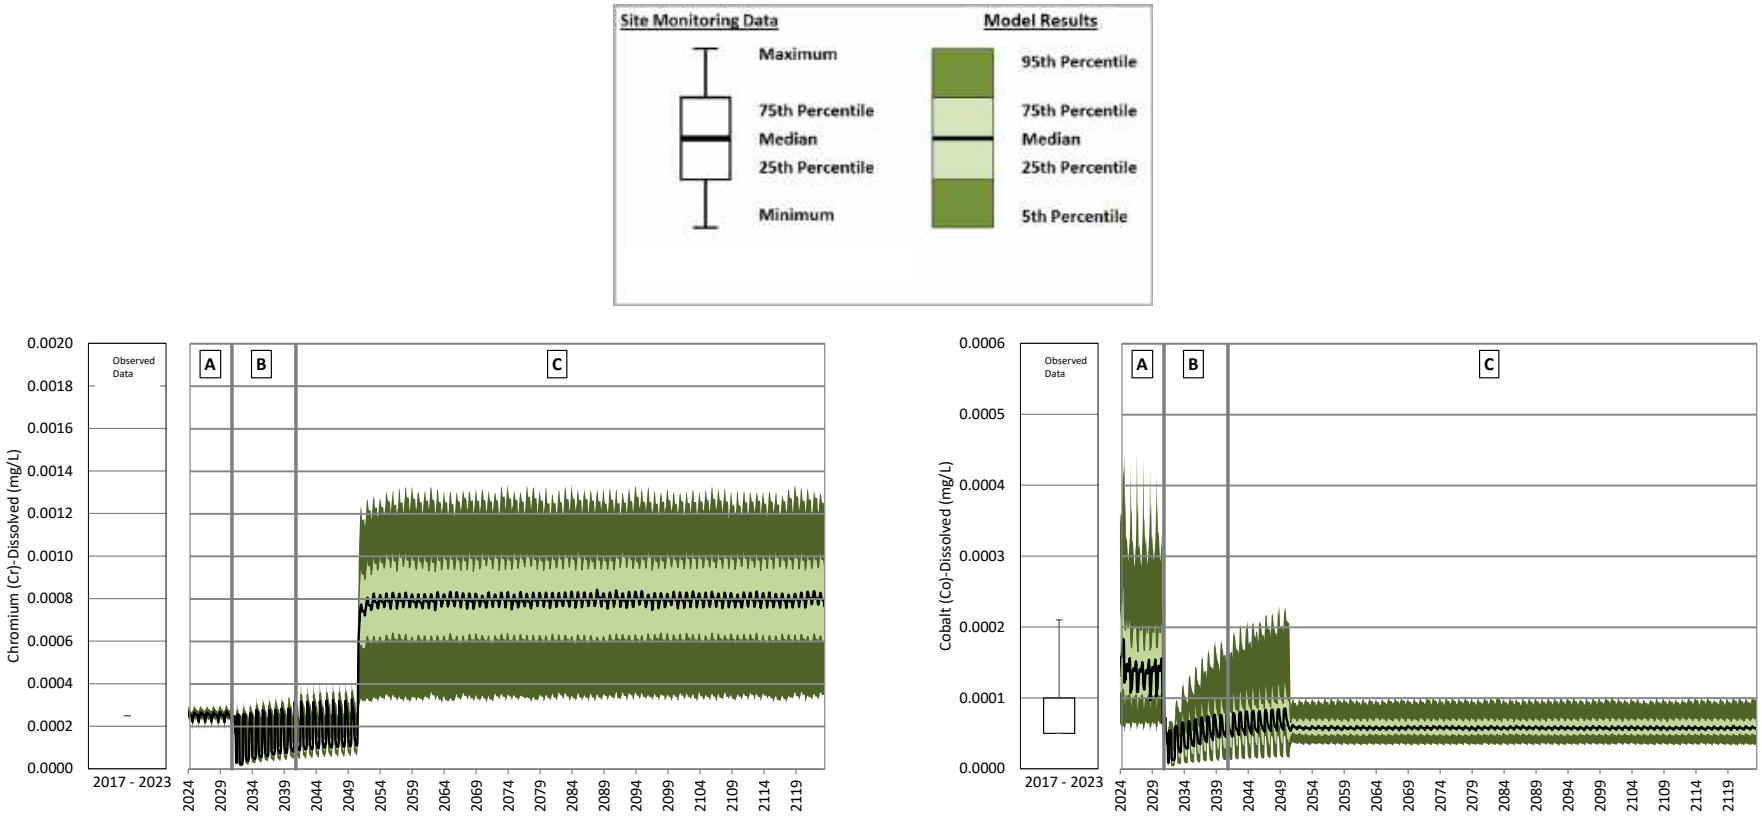

Figure B **209: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Barium and Dissolved Beryllium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

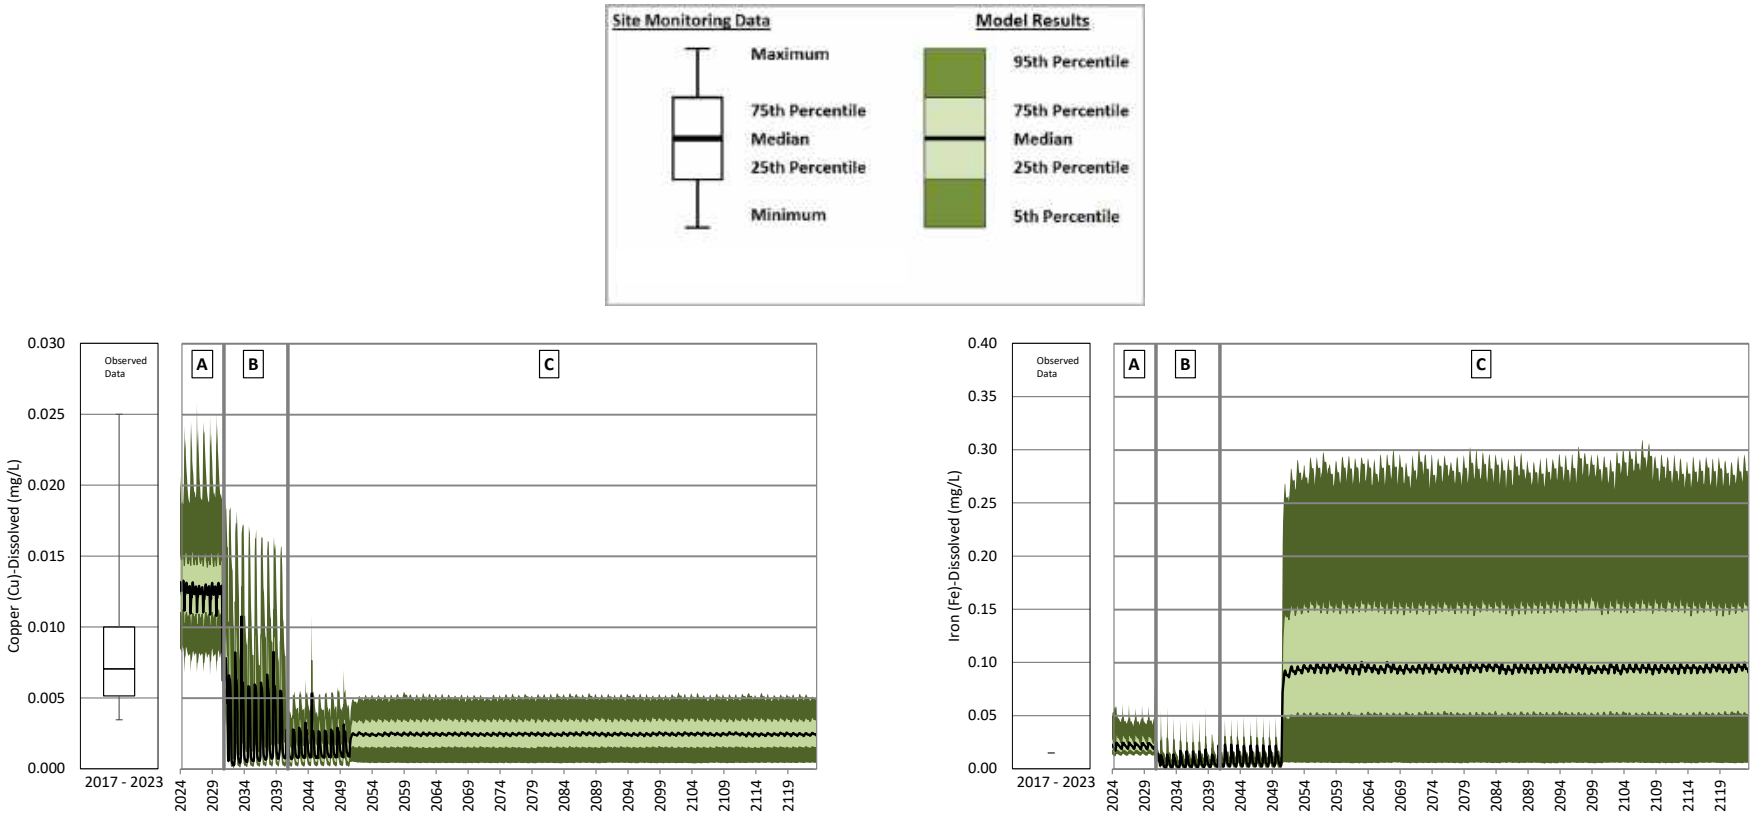

Figure B **210: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Boron and Dissolved Cadmium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved chromium concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved chromium than the disturbed runoff water quality input.

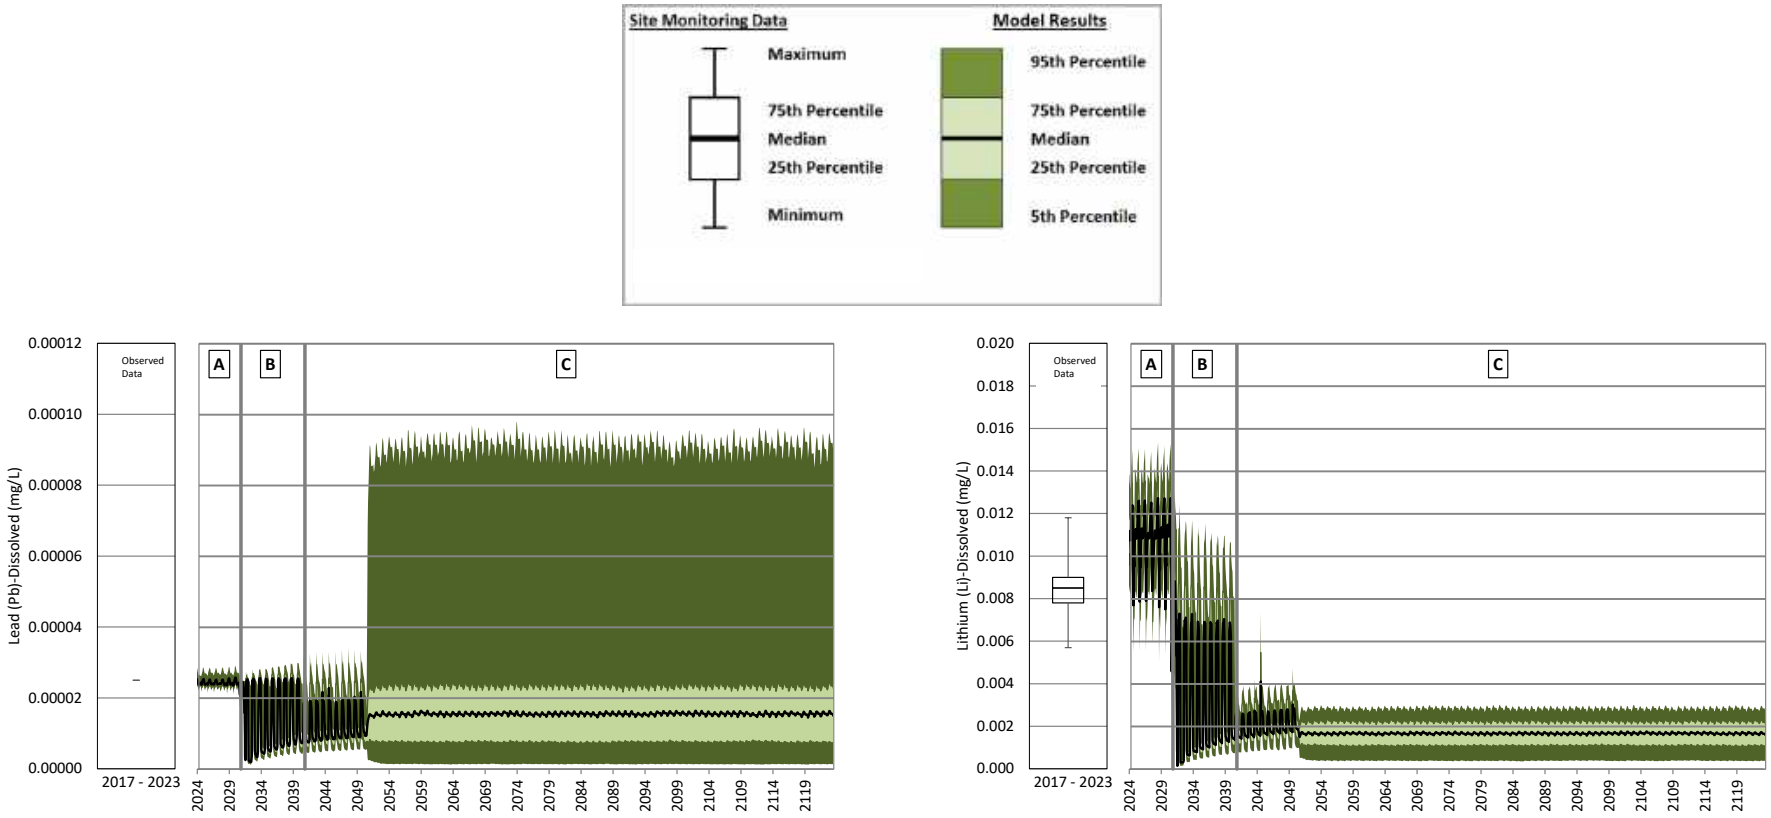

Figure B **211: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Chromium and Dissolved Cobalt**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved iron concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved iron than the disturbed runoff water quality input.

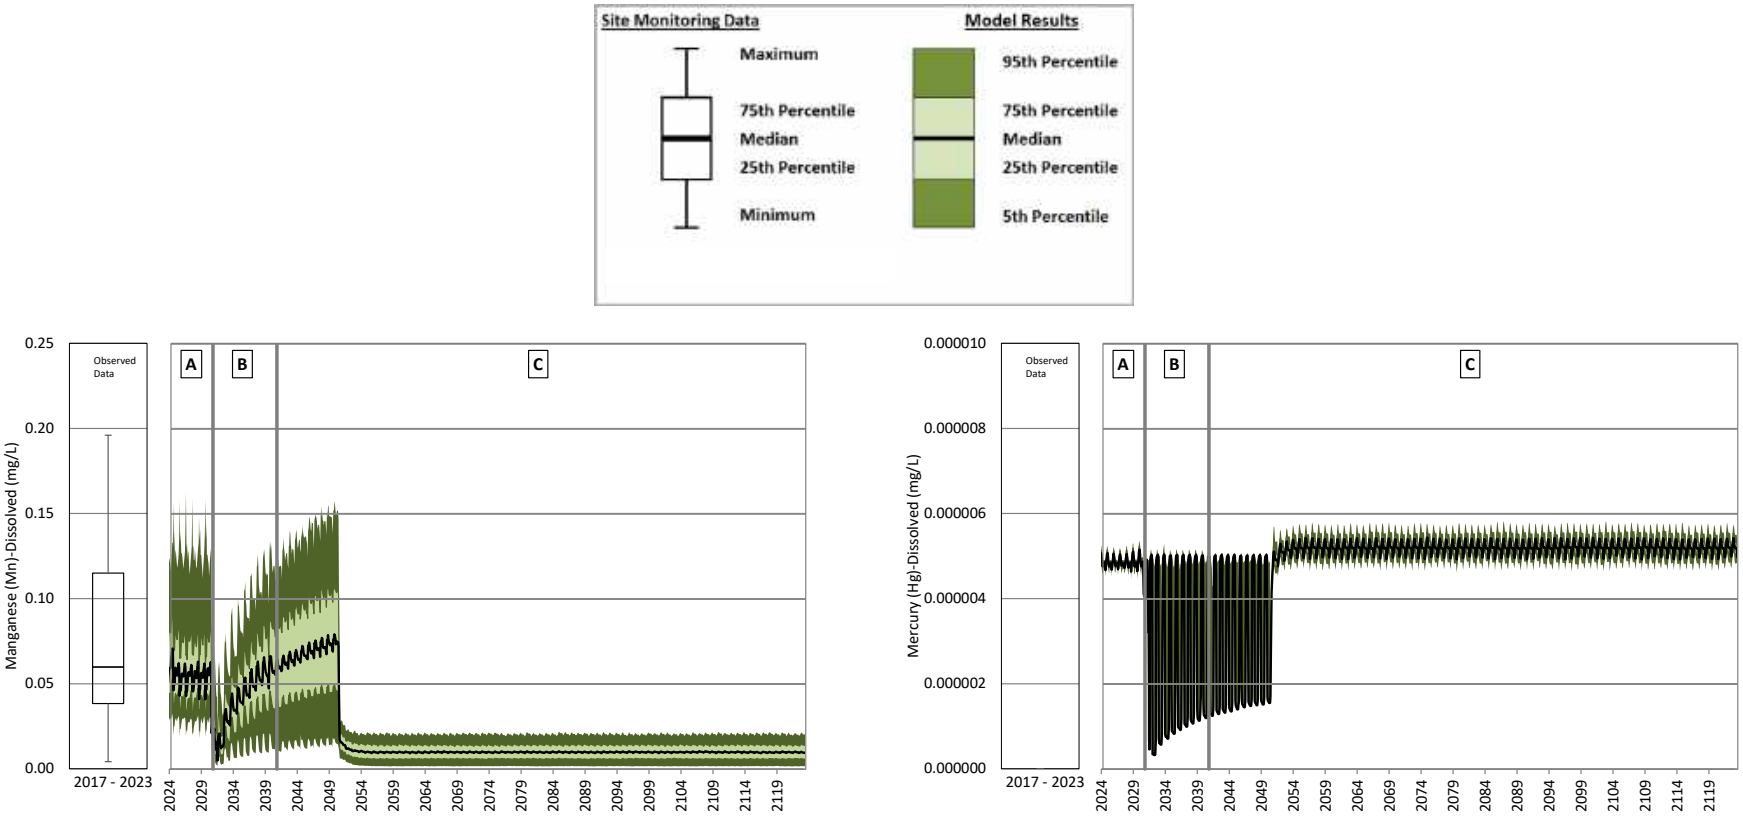

Figure B **212: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Copper and Dissolved Iron**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved lead concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved lead than the disturbed runoff water quality input.

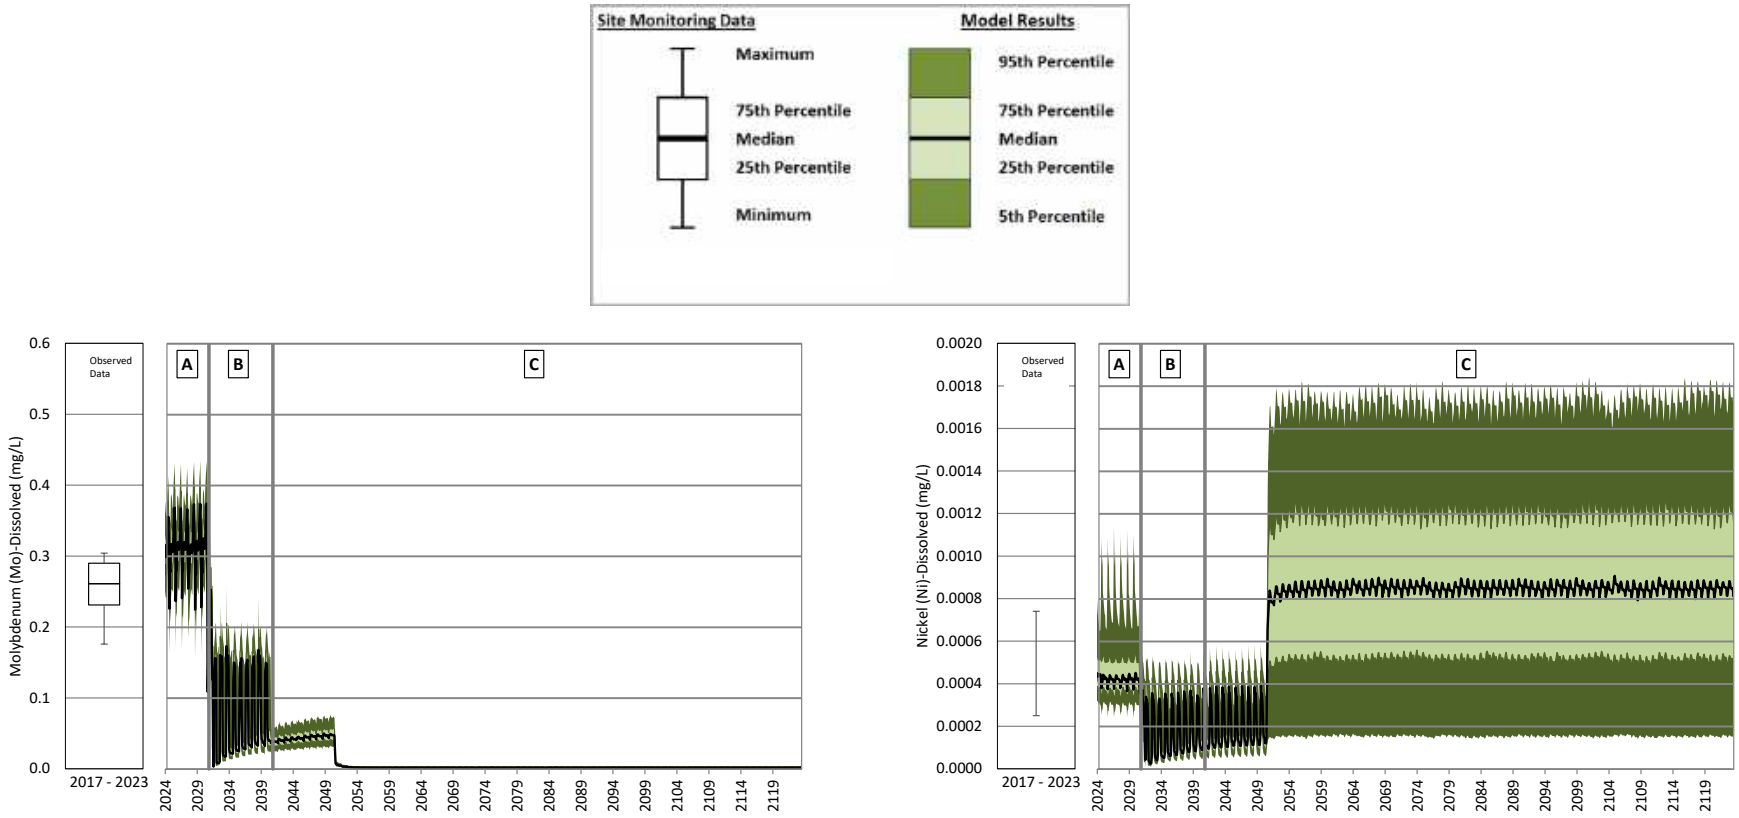

Figure B **213: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Lead and Dissolved Lithium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

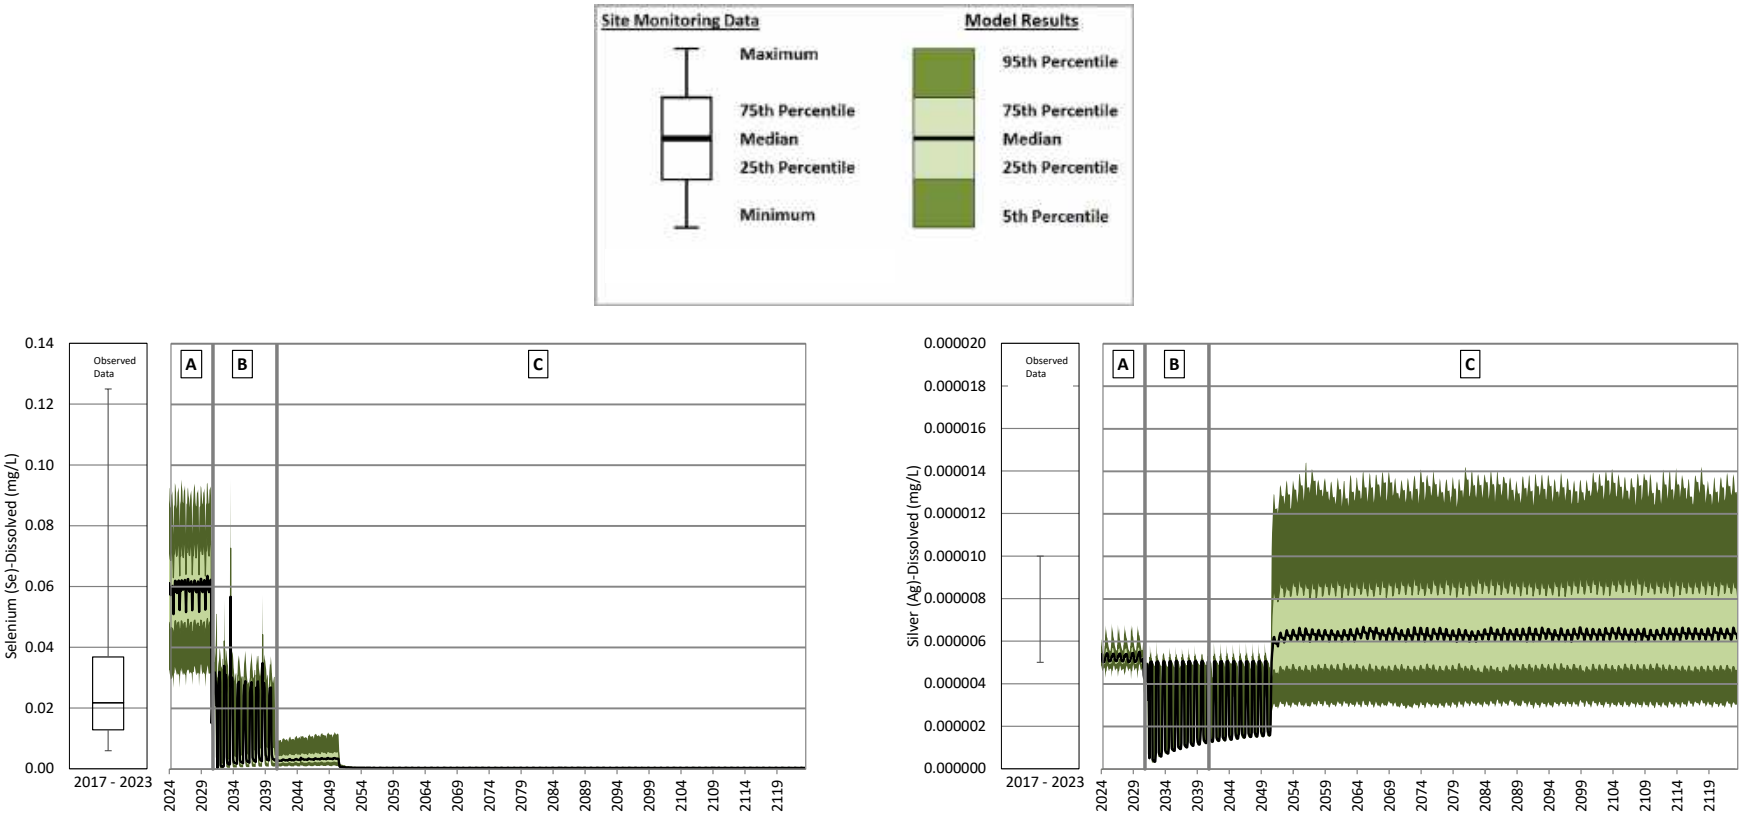

Figure B **214: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Manganese and Dissolved Mercury**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved nickel concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved nickel than the disturbed runoff water quality input.

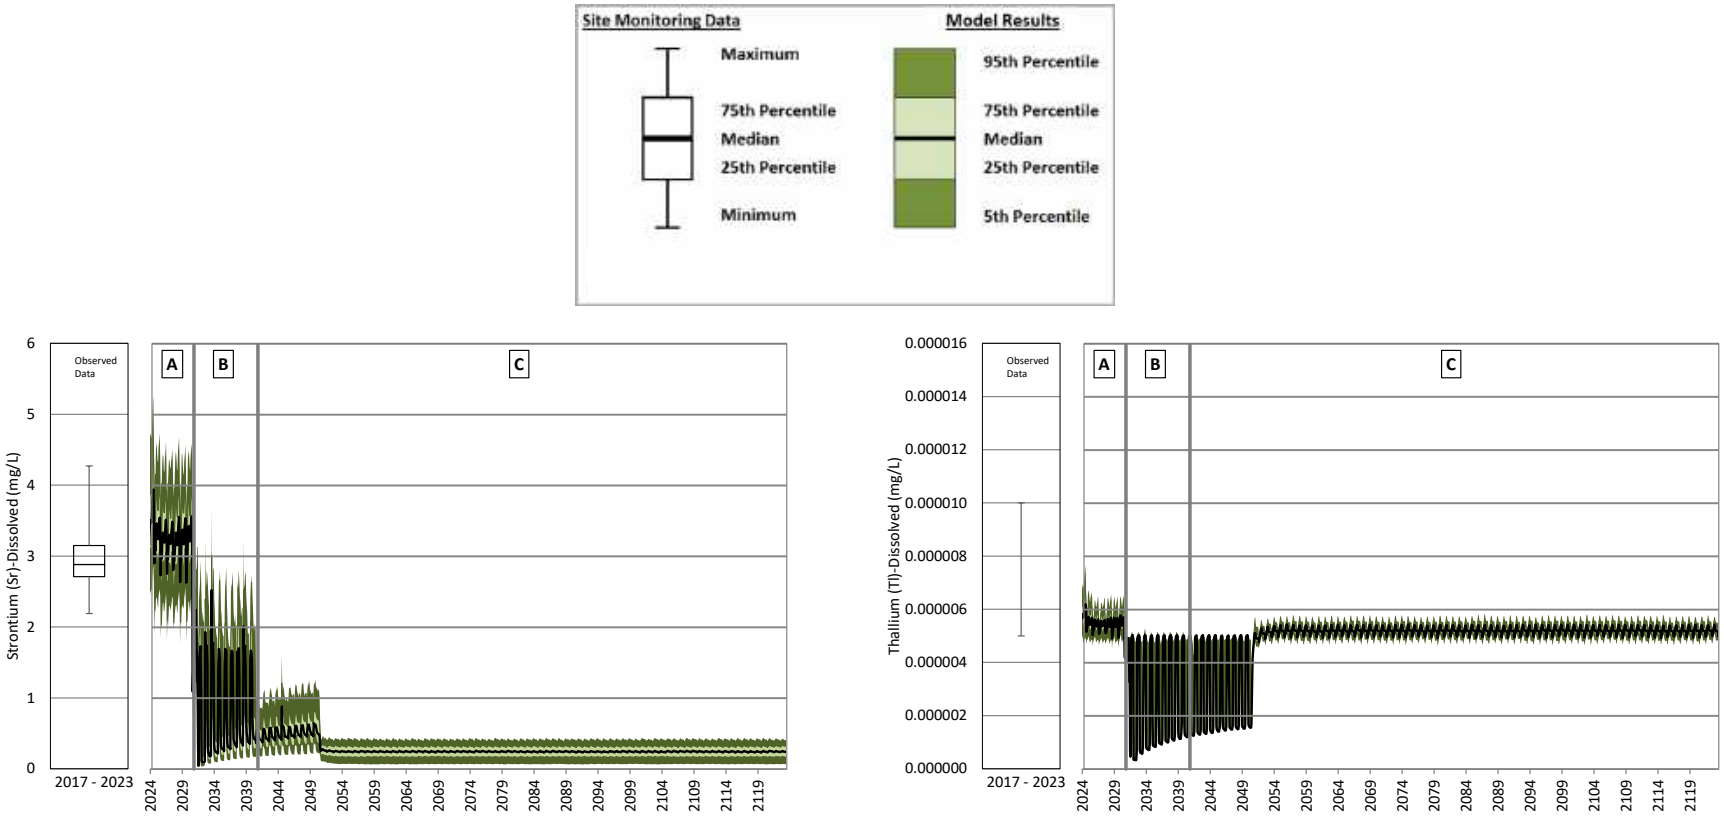

Figure B **215: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Molybdenum and Dissolved Nickel**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved silver concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved silver than the disturbed runoff water quality input.

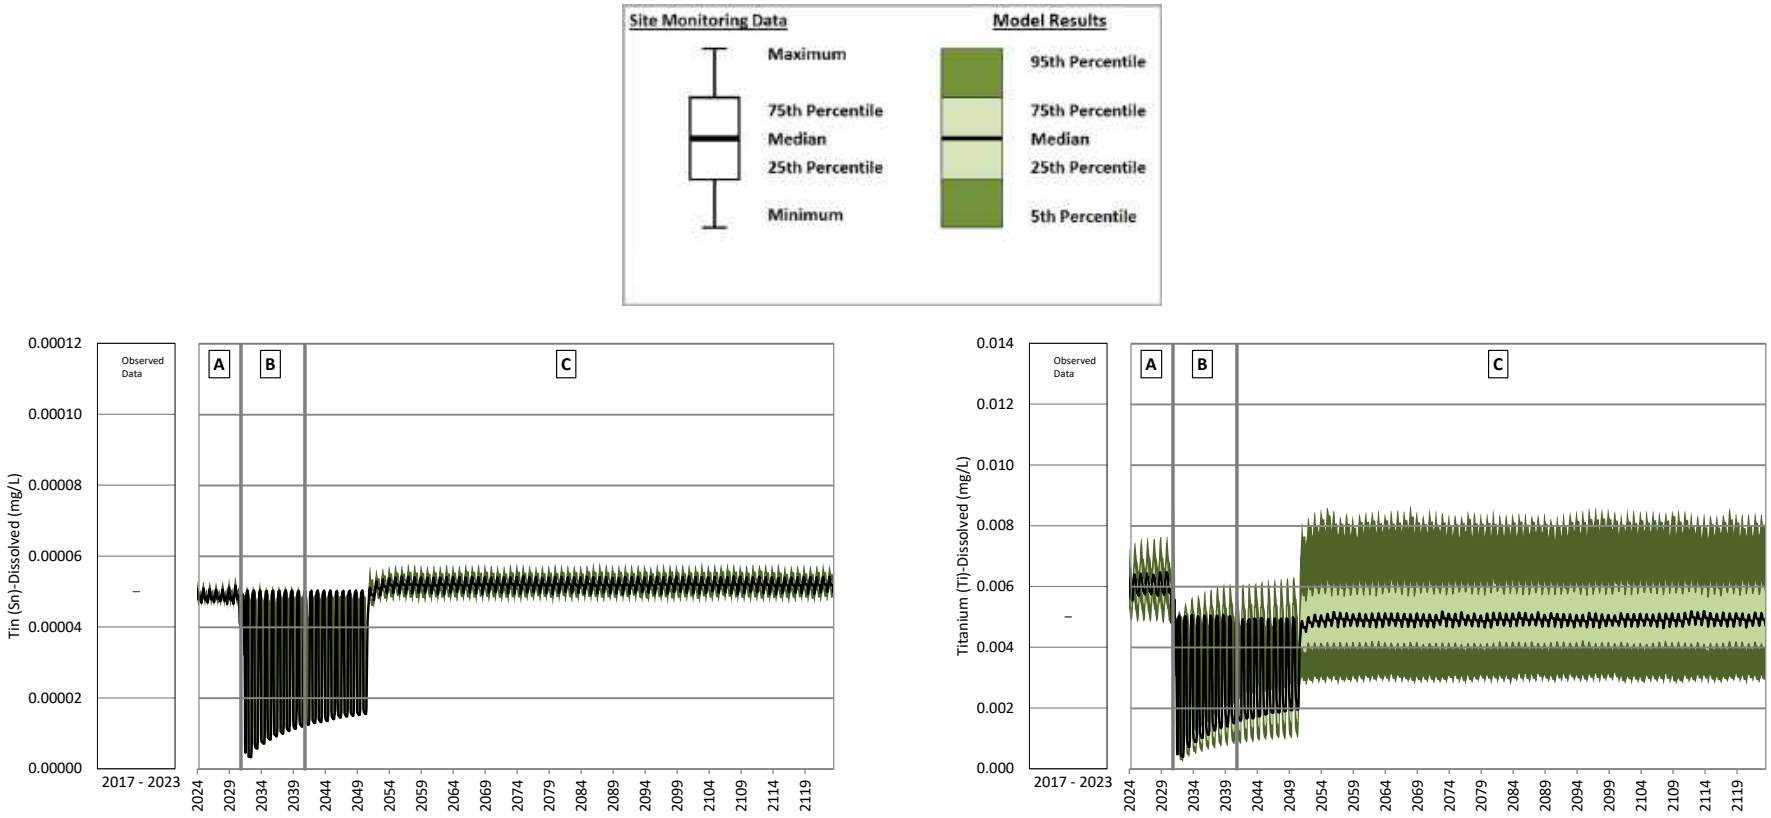

Figure B **216: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Selenium and Dissolved Silver**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

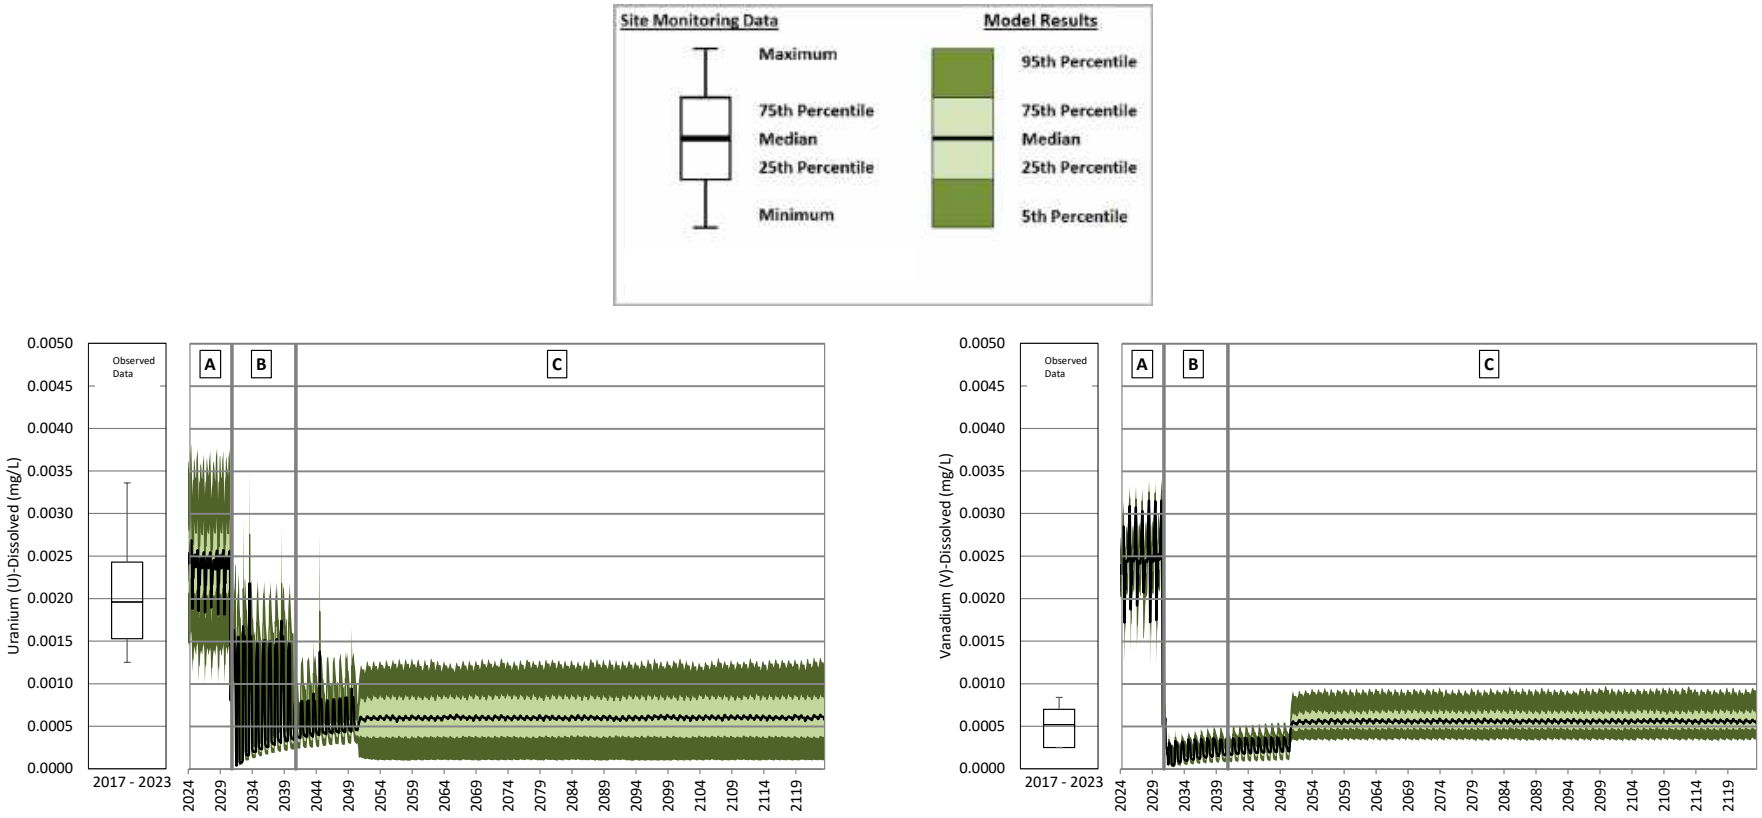

Figure B **217: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Strontium and Dissolved Thallium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved titanium concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved titanium than the disturbed runoff water quality input.

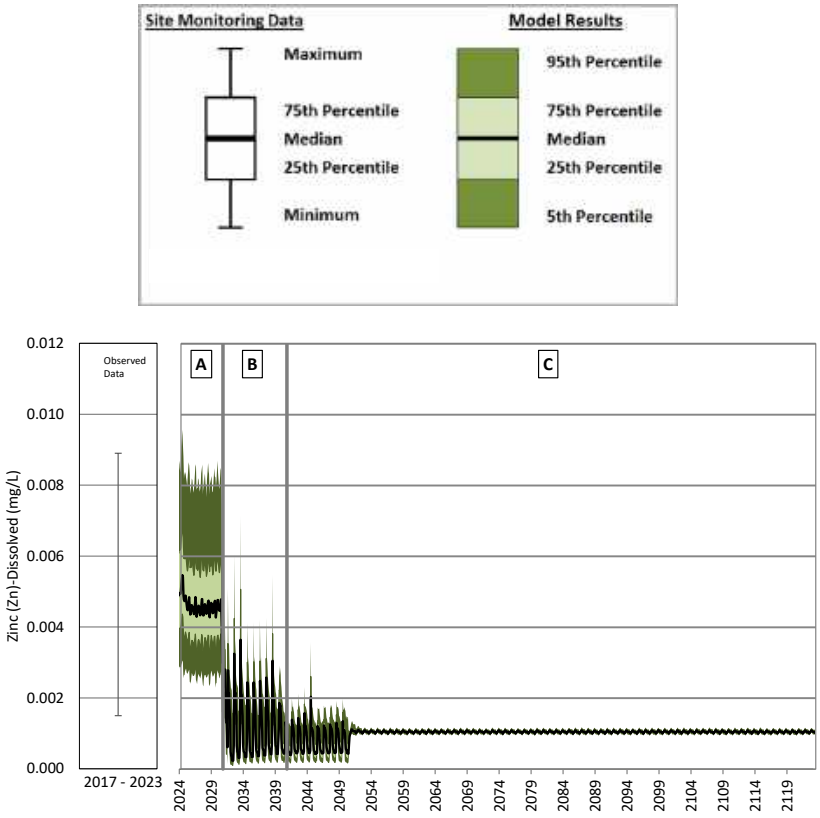

Figure B **218: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Tin and Dissolved Titanium**

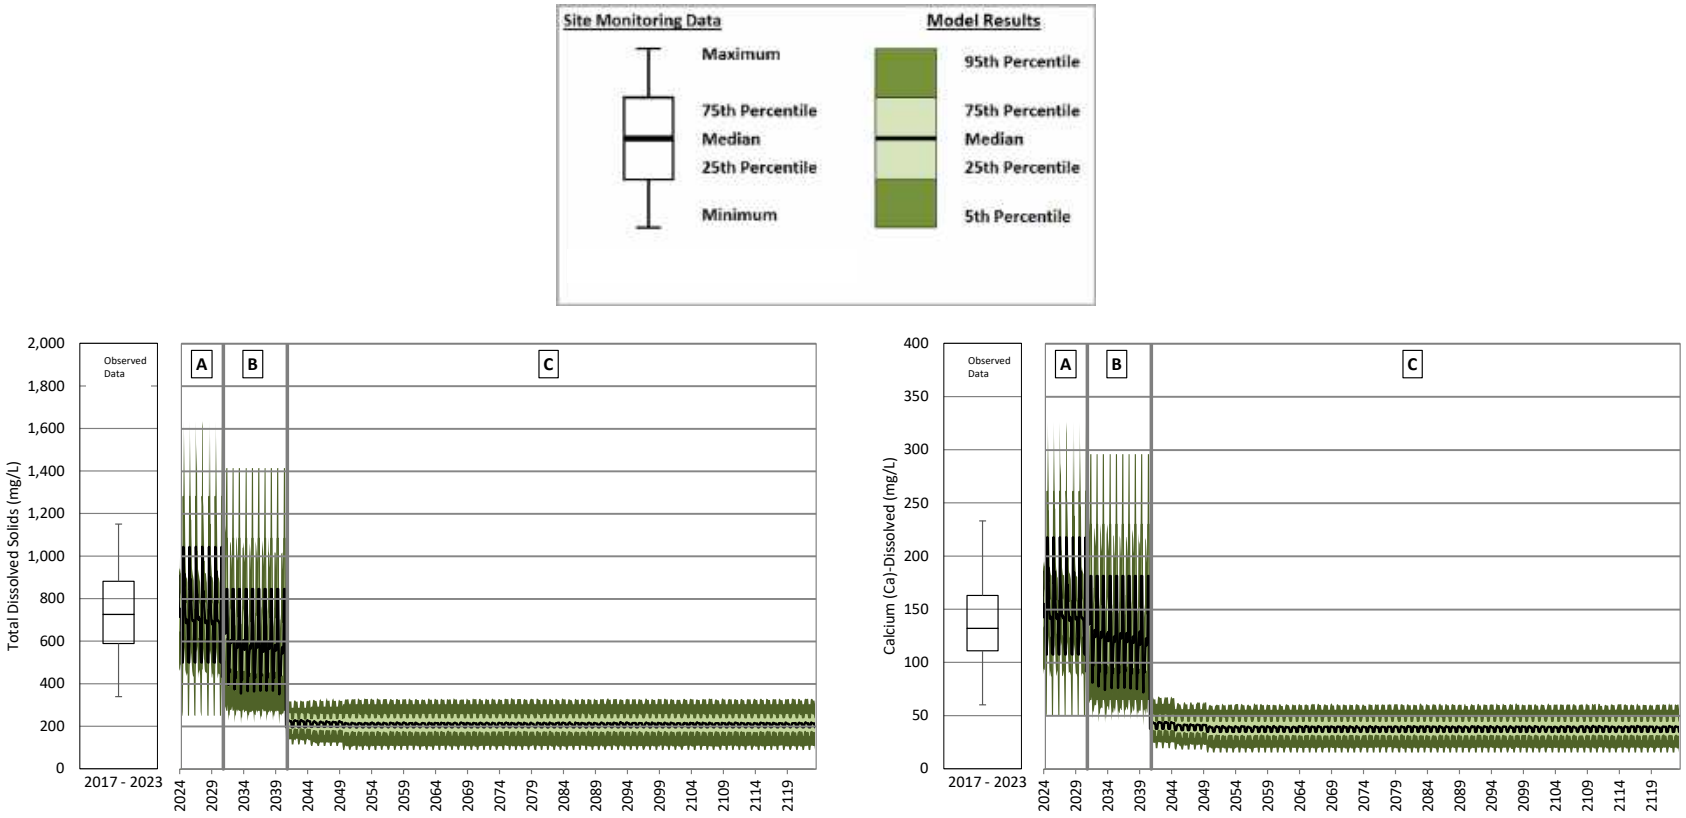
A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051. Dissolved vanadium concentrations increase ten years after the start of post-closure as mine site areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher concentrations for dissolved vanadium than the disturbed runoff water quality input.

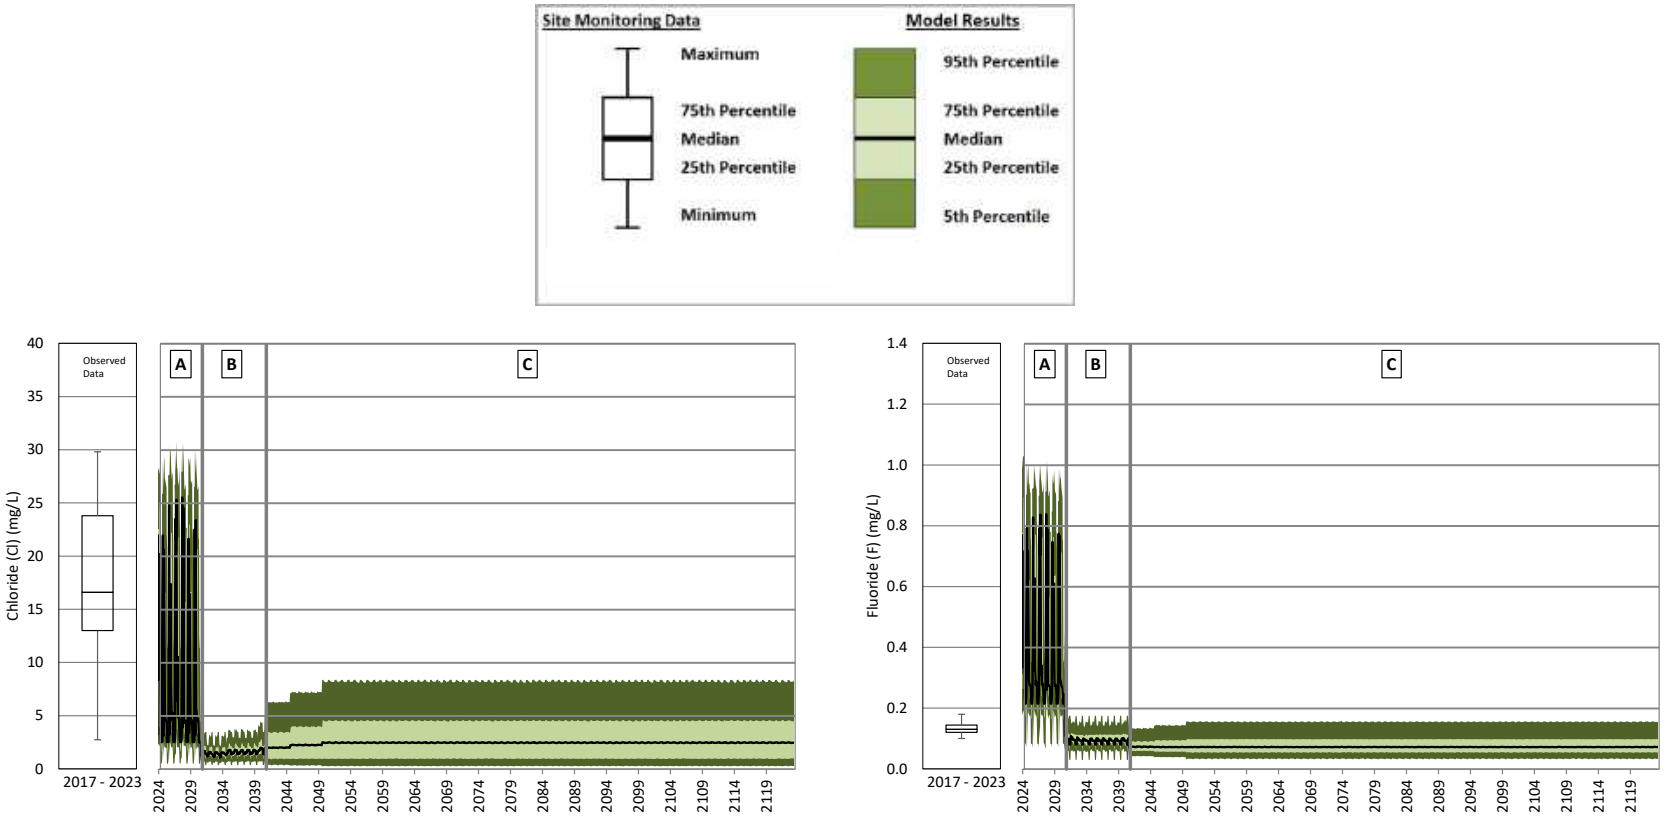
Figure B **219: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Uranium and Dissolved Vanadium**



A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and post-closure is caused by the reclamation of runoff areas. The increase in concentrations from 2031 to 2051 is due to pumping from the SESCP to the MESCP which ends in 2051.

Figure B **220: Main Embankment Seepage Collection Pond Operations, Closure and Post-closure – Dissolved Zinc**



Mine Drainage Creek Sump Operations, Closure and Post-closure

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure and into early post-closure is caused by reclamation of mine site areas. Predicted concentrations reach a steady state 10 years after the start of post-closure when reclamation of the mine site areas is complete.

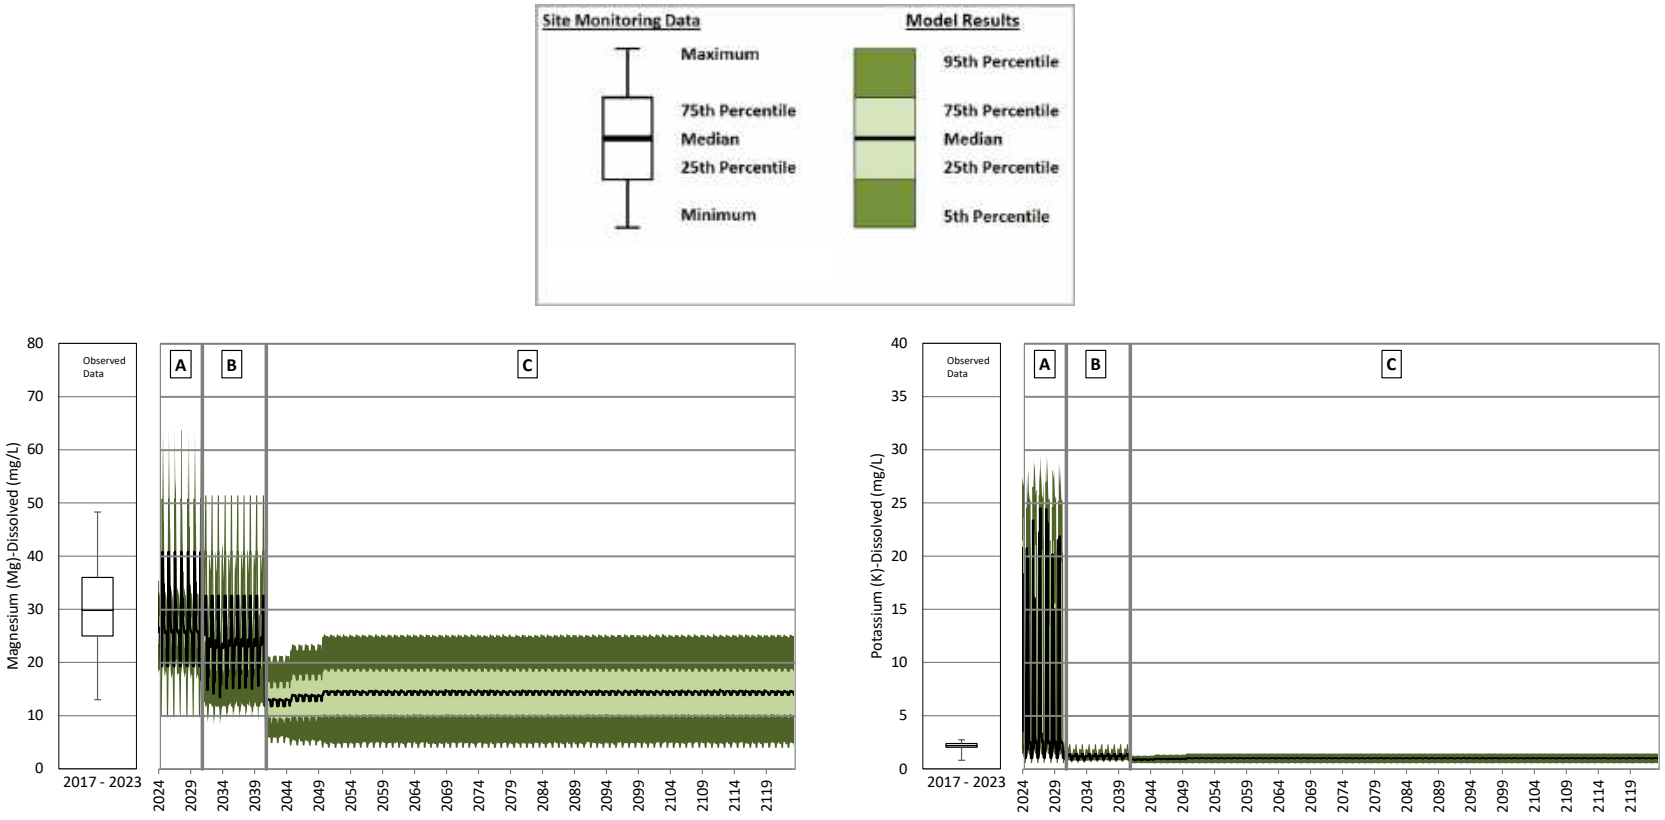


Figure B **221: Mine Drainage Creek Sump Operations, Closure and Post-closure – Total Dissolved Solids and Calcium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas. Chloride and fluoride concentrations increase from closure to post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher maximum concentrations for chloride and fluoride than the disturbed runoff water quality inputs.

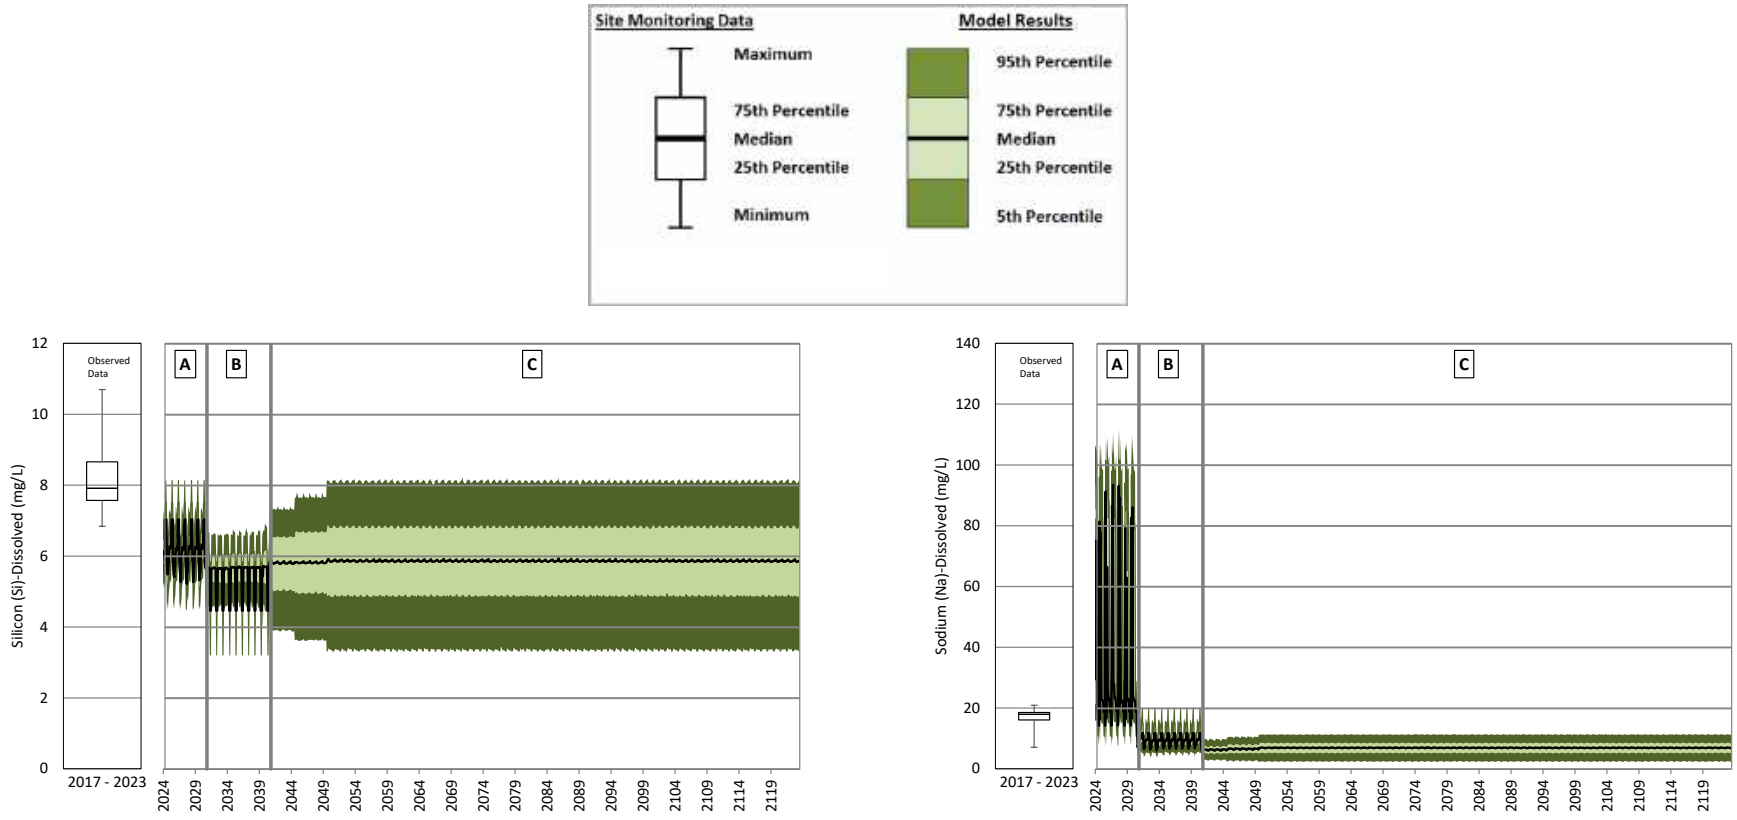

Figure B **222: Mine Drainage Creek Sump Operations, Closure and Post-closure – Chloride and Fluoride**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas. Magnesium concentrations increase from the start of post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher maximum concentrations for magnesium than the disturbed runoff water quality inputs.

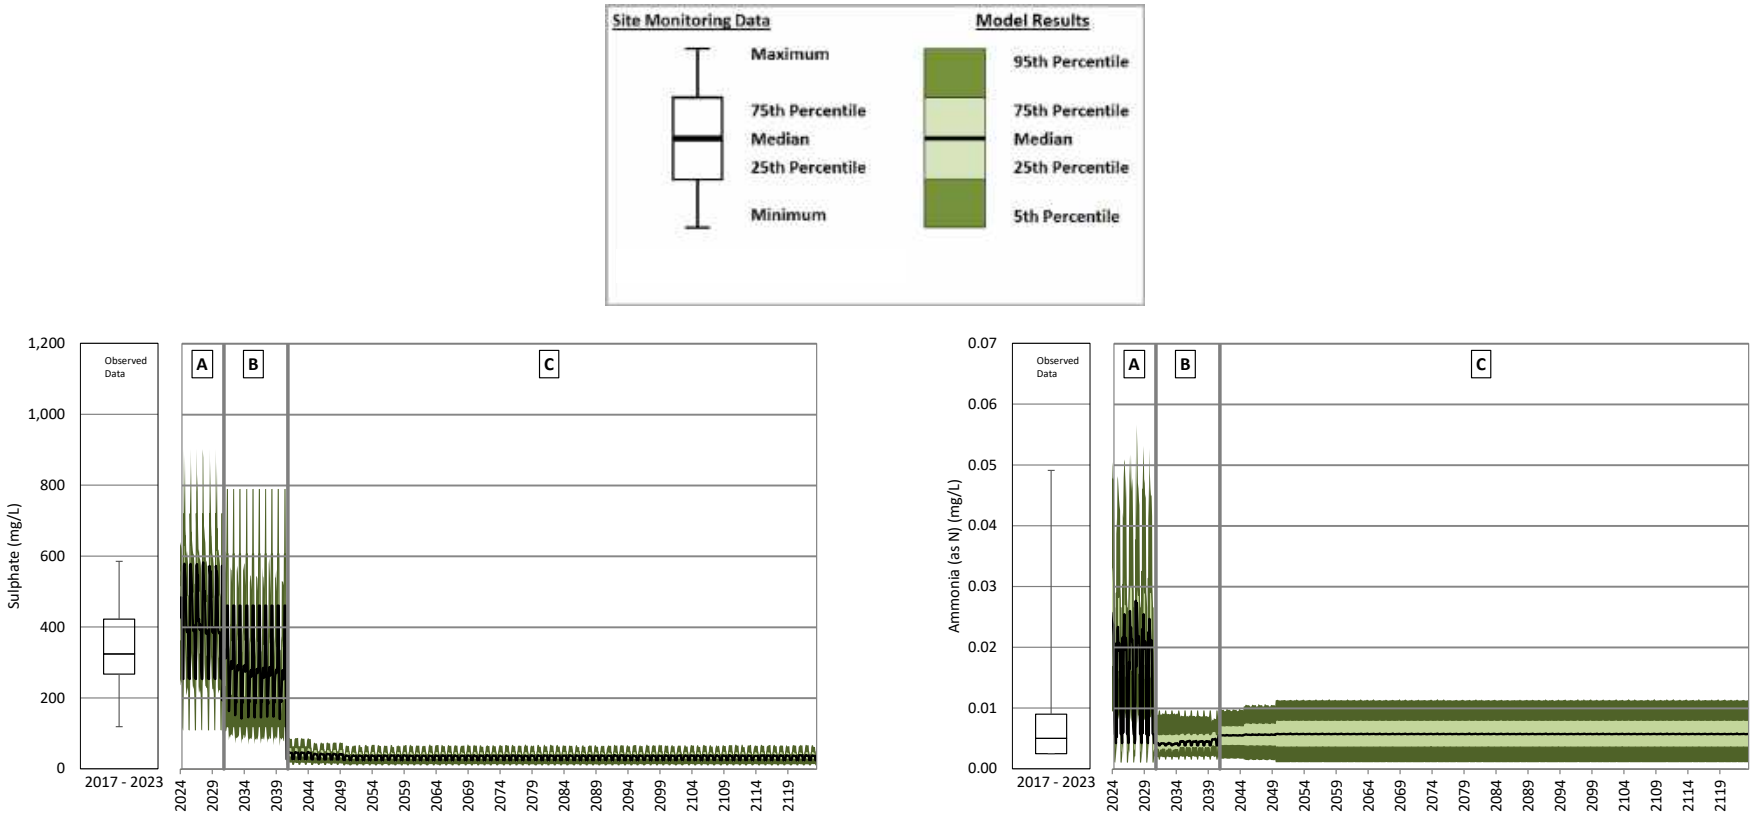

Figure B **223: Mine Drainage Creek Sump Operations, Closure and Post-closure – Magnesium and Potassium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas. Silicon concentrations increase from the start of post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher maximum concentrations for silicon than the disturbed runoff water quality inputs.

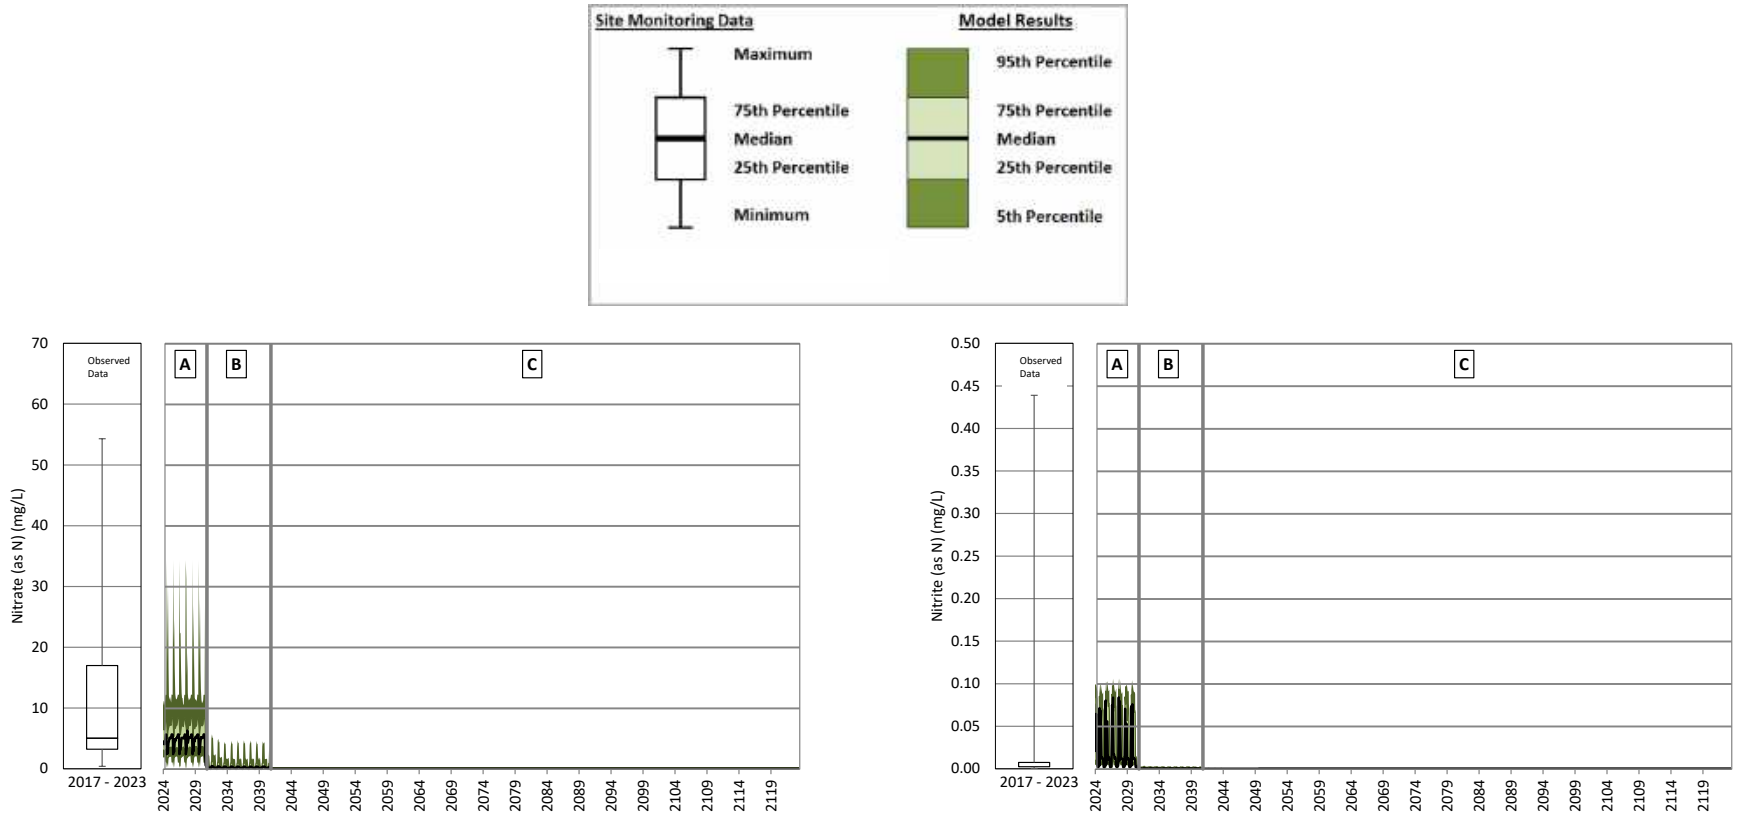

Figure B **224: Mine Drainage Creek Sump Operations, Closure and Post-closure – Silicon and Sodium**

A = Operations; B = Closure; C = Post-closure

Note: The change in concentrations from operations to closure is caused by the reclamation of runoff areas. Total ammonia concentrations increase from the start of post-closure as runoff areas are remediated and assigned the undisturbed runoff water quality input. The undisturbed runoff water quality input has higher maximum concentrations for total ammonia than the disturbed runoff water quality inputs.

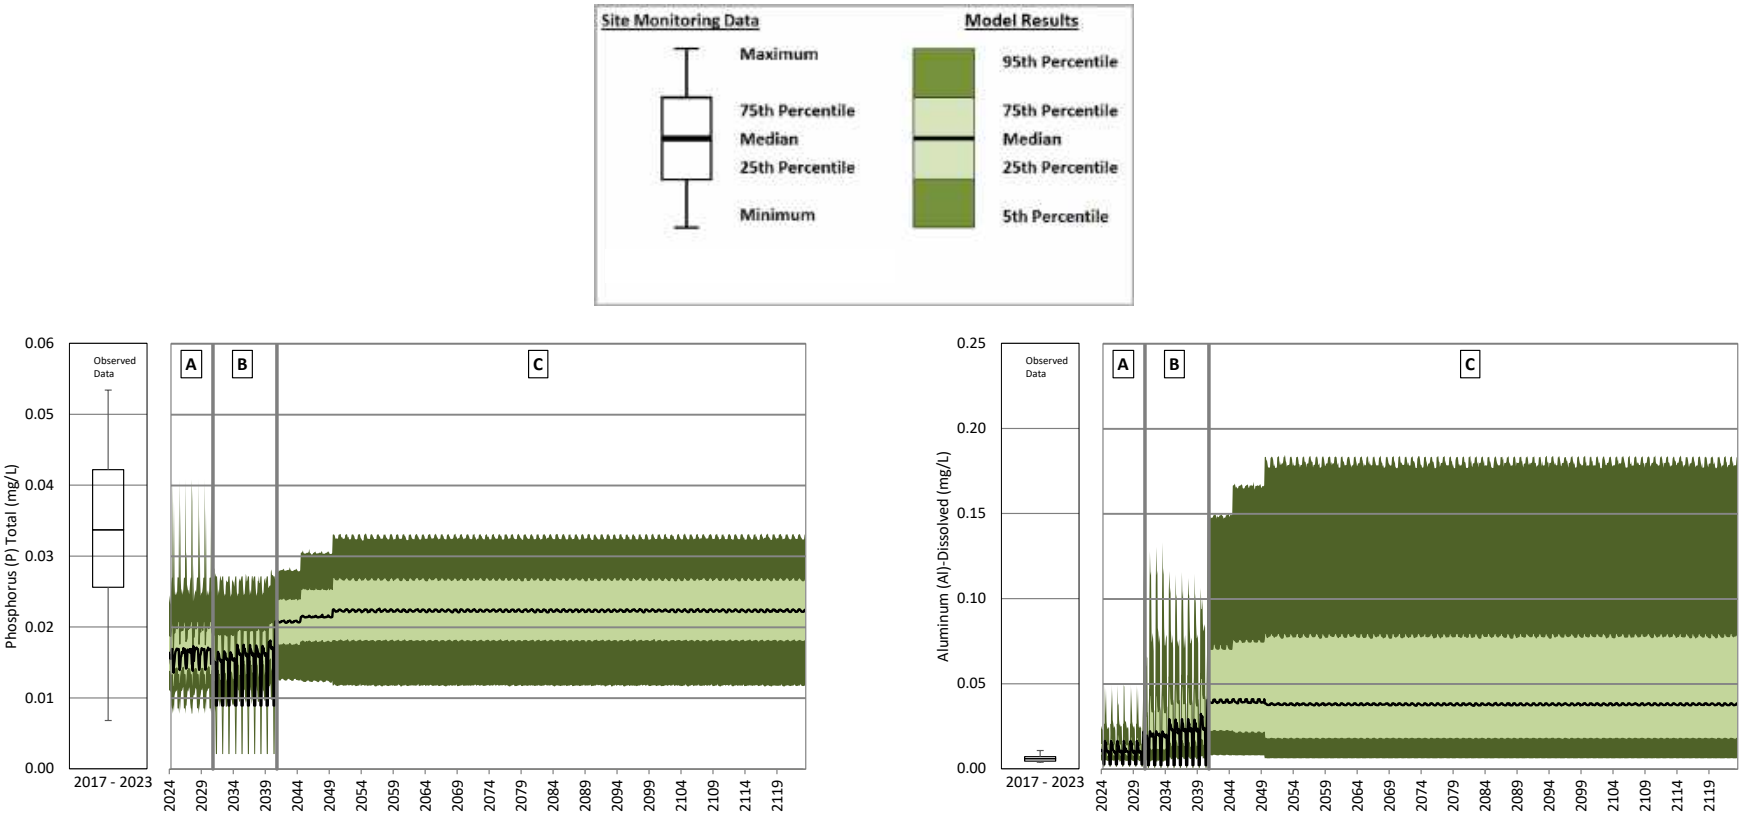

Figure B **225: Mine Drainage Creek Sump Operations, Closure and Post-closure – Sulphate and Total Ammonia**

A = Operations; B = Closure; C = Post-closure

APPENDIX 9-4B: 2024 Water Management Plan Remodeling Summary

TECHNICAL MEMORANDUM

DATE March 21, 2024 **Reference No.** CA0020527.4505-025-TM-Rev0-31146

TO Matt O'Leary
Mount Polley Mining Corporation

FROM Gonzalo Donoso and Jesse Maddaloni **EMAIL gonzalo.donoso@wsp.com; jesse.maddaloni@wsp.com**

2024 WATER MANAGEMENT PLAN REMODELING SUMMARY

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) retained WSP Canada Inc. (WSP) to address a new M-200 permit requirement, introduced in May 2023, to provide a Water Management Plan (WMP) for the Mount Polley Mine (the Mine) annually (by March 31). A 2023 WMP has been recently produced by WSP Canada Inc. (WSP 2023) in December 2023 regarding the Mine's proposed Springer Expansion operations phase. Since the production of that WMP, MPMC is installing new water transfer infrastructure on-site that was not considered in the 2023 WMP. The new transfer infrastructure allows greater transfer capacity to Wight Pit before contact water reaches the Tailings Storage Facility (TSF). This technical memorandum describes the transfer capacity changes made in the model, presents updated water balance and water quality model results, compares revised results to 2023 WMP results, and discusses the overall impact to water management during operations due to these transfer changes.

This transfer capacity change will impact the water balance results presented in the 2023 WMP, notably the amount of water temporarily retained in Wight Pit and the TSF. The 2024 remodeling has not resulted in any major water quality concentration changes between revised predictions and the predictions presented in the 2023 WMP. Some water quality parameter concentrations are modeled to increase or decrease compared to 2023 WMP results, but these revised 2024 predictions do not impact which parameters are considered constituents of concern (COC).

This technical memorandum is to be submitted with the 2023 WMP to satisfy the M-200 annual WMP submission for 2024.

2.0 MODEL CHANGES

Water balance flow diagrams are presented in Attachment 1, which show the configuration of water balance models and summarize the model element names discussed below. Figure 1 in Attachment 1 shows the water balance model configuration for the Mine during operations assumed in the 2023 WMP. Figure 2 in Attachment 1 shows the water balance model configuration for the Mine during operations assumed for this 2024 WMP remodeling update.

The following parameter changes have been made in the water balance model for the purpose of this 2024 WMP remodeling update:

- Pumping pipeline capacity to Wight Pit, model element P30. The P30 transfer no longer intakes from the Tailings Storage Facility (TSF) and now intakes from the Southeast Rock Disposal Site (SERDS) sump. This allows mine contact water to be transferred to Wight Pit for storage before reaching the TSF. The P30 transfer still discharges to Wight Pit. In the 2023 WMP model, the P30 maximum transfer capacity was set at 10,000 m3/day. For this 2024 remodeling update, the P30 maximum transfer capacity has been increased to 55,200 m3/day. MPMC also has the ability to relocate the P30 intake from the SERDS sump to the Central Collection Sump (CCS), if desired, which is located downstream of the SERDS sump (downstream by gravity). Both intake positions allow transfer of contact water to Wight Pit before the water enters the TSF.
- Pumping pipeline addition from Long Ditch to SERDS sump, model element P36. This added transfer allows contact water collected in Long Ditch to be pumped to the SERDS sump, and ultimately to Wight Pit. For this 2024 remodeling update, the P36 maximum transfer capacity has been set at 14,400 m3/day.
- Pumping pipeline capacity from Wight Pit to Long Ditch, model element P21. In the 2023 WMP, the P21 maximum transfer capacity was set at 14,088 m^3/day. For this 2024 remodeling update, the P21 maximum transfer capacity has been set at 32,488 m^3/day.
- Some pumps are shared between P30 and P21. During freshet, pumps are allocated to P30 to transfer contact water to Wight Pit. During Wight Pit dewatering (following freshet), some pumps are re-allocated to P21 to allow treatment of contact water stored in Wight Pit. Logic has been added to the water balance model for this 2024 remodeling update to prevent P21 simultaneously operating while P30 is operational.

All other parameters, inputs, and assumptions remain as described in the 2023 WMP.

3.0 MODEL RESULTS

The Site-Wide Water Balance Model (SWWBM) and Site-Wide Water Quality Model (SWWQM) were re-run for the estimated operational phase of the Mine (May 2, 2023 to March 31, 2031) with the model changes noted in Section 2.0.

The SWWBM and SWWQM use stochastic model elements, allowing uncertainty to be represented in model input data. This stochastic analysis is described in detail in Section 4.3.1.5 of the 2023 WMP, including a description of interpreting percentile category results from the stochastic analysis. For this 2024 model re-run, the stochastic generator was set to perform 1,000 realizations to create a sample size that was sufficiently large to account for a range of conceivable climatic scenarios for this analysis.

3.1 Water Balance

Results presented here should be directly compared to the corresponding results in the 2023 WMP in Section 4.3.3. Results are presented for quantity of site discharge (annual volume requiring treatment and discharge), water volume stored in the TSF, and water volume stored in Wight Pit. Results for water volume in Springer Pit and Cariboo Pit are not presented, as these values are not notably impacted by the current model changes.

3.1.1 Quantity of Discharge

The Mine has a positive contact water balance, meaning that treated water discharge from the Mine is required every year to not store excess contact water year over year. This estimated annual volume is shown in Table 1 for the 2024 remodeling and should be compared to annual volumes shown in Table 34 of the 2023 WMP.

Table 1: WTP Annual Volume Requiring Treatment during Operations (M-m^3)

Year	Annual Volume Requiring Treatment at WTP (M-m^3)		
	50th Percentile	90th percentile	99.5th percentile
2023[(a)]	4.52	4.93	5.88
2024	4.52	5.89	7.22
2025	3.30	4.57	6.31
2026	3.35	4.59	6.13
2027	3.36	4.77	6.27
2028	3.40	4.77	6.49
2029	3.40	4.68	6.00
2030	3.31	4.63	6.20
2031	5.52	7.27	9.81

(a) Model simulation start date: May 2, 2023.

If annual treatment volume estimates for individual years are compared, then moderate differences can be seen between the 2023 WMP volume estimates and the estimates shown in Table 1. Due to the SWWBM having stochastic climate inputs, differences on a yearly basis can occur, as randomized inputs may not align for specific years. It is more appropriate to consider the average of values across all operational years instead of comparing individual years during the operational period.

The average volumes across the proposed operational years for each percentile category differ by 5% or less between the Table 1 2024 remodeling results and the corresponding results in Table 34 of the 2023 WMP. The model changes discussed in Section 2 do not result in a notable change to the estimated annual discharge volume.

3.1.2 Tailings Storage Facility

The estimated volume of water stored in the TSF is a SWWBM result that is impacted by the model changes discussed in Section 2, as contact water is modeled to be diverted to Wight Pit before reaching the TSF. Table 2 and Figure 1 show the estimated TSF water volume resulting from the 2024 remodeling. TSF water volume estimates from the 2024 remodeling shown in Table 2 and Figure 1 should be compared to the TSF water volume estimates shown in Table 35 and Figure 17 of the 2023 WMP, respectively.

Table 2: TSF Water Volume during Operations (M-m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	1.22	1.32	1.41
	Average	1.46	1.53	1.71
	Maximum	1.60	1.70	2.53

Note: Table values do not include 2023 model results seen in Figure 1, as starting year model results are impacted by model starting conditions and are not reflective of average conditions during the operational period.

For all percentile categories, maximum TSF water volume is reduced in the 2024 remodeling estimates compared to the 2023 WMP estimates. This is due to contact water now being pumped to Wight Pit prior to reaching the TSF.

Table 2 results are shown graphically in Figure 1. Maximum TSF water volume in the first modeled year of operation (2023) is shown higher in Figure 1 than listed in Table 2, only due to the high TSF volume assumed for the model starting condition. Annual TSF volume for the remainder of the proposed operations years beyond the starting condition coincides with the values shown in Table 2.

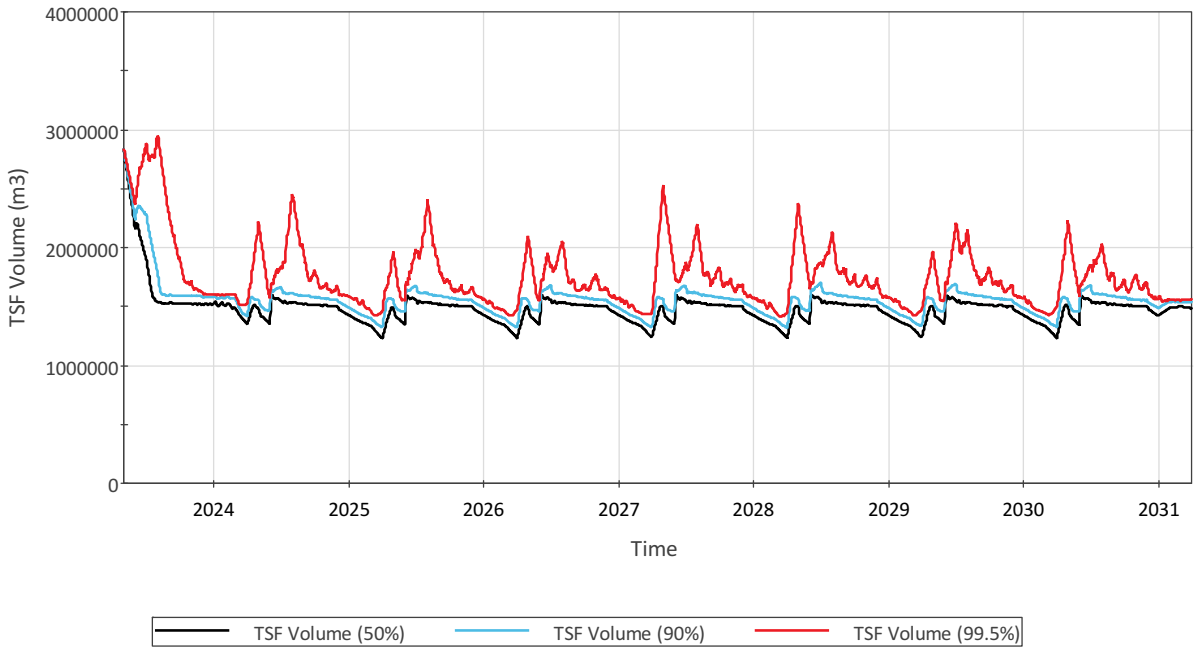

Figure 1: TSF Water Volume during Operations

3.1.3 Wight Pit

The estimated volume of water stored in Wight Pit is a SWWBM result that is impacted by the model changes discussed in Section 2. Table 3 and Figure 2 show the estimated Wight Pit water volume resulting from the 2024 remodeling. Wight Pit water volume estimates from the 2024 remodeling shown in Table 3 and Figure 2 should be compared to the Wight Pit water volume estimates shown in Table 38 and Figure 19 of the 2023 WMP, respectively.

Table 3: Wight Pit Water Volume (M-m^3)

Phase	Bound	50th Percentile	90th Percentile	99.5th Percentile
Operations	Minimum	0	0	0
	Average	0.63	0.98	1.58
	Maximum	3.58	3.69	3.78

Wight Pit average and maximum volume estimates for all percentile categories are increased in the 2024 remodeling estimates compared to the 2023 WMP estimates. This is due to additional contact water now being pumped to Wight Pit prior to reaching the TSF.

Table 3 results are shown graphically in Figure 2. Figure 2 below, compared to Figure 19 in the 2023 WMP, shows increased Wight Pit water volumes for all percentile categories. Even though water volumes are estimated to increase in Wight Pit, transfer capacity is still sufficient to empty Wight Pit of contact water annually, even for the estimated 99.5th percentile category.

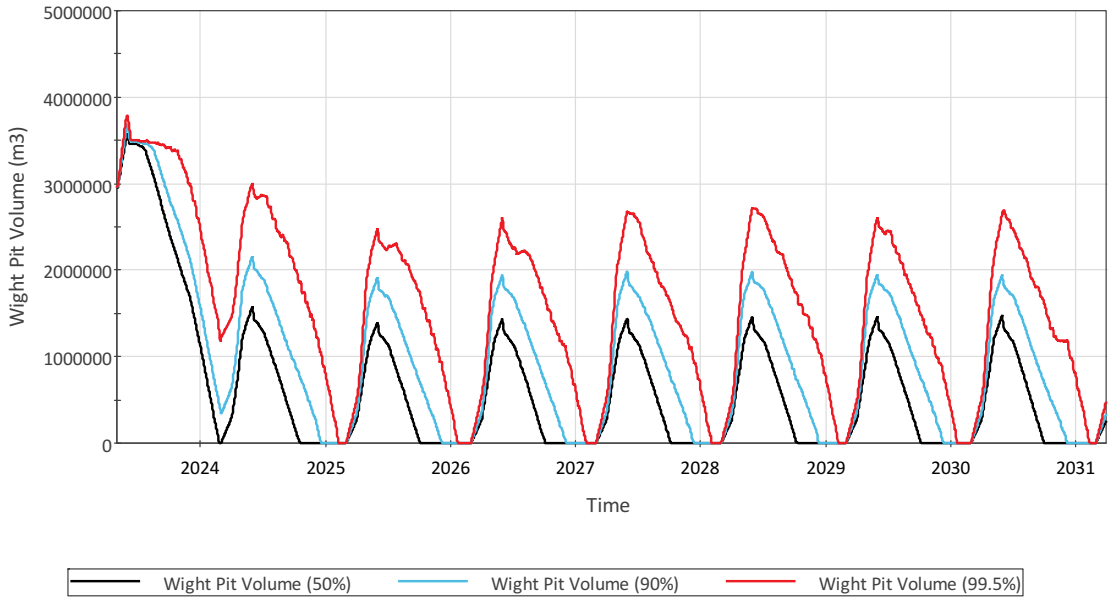

Figure 2: Wight Pit Water Volume during Operations

3.2 Water Quality and Water Treatment

The SWWQM was re-run for the anticipated operational phase of the Mine with the model changes noted in Section 2.0. All of the same water quality predictions were modeled compared to the water quality predictions presented in the 2023 WMP. No water quality source terms were adjusted for this 2024 remodeling, only the pumping capacity changes noted in Section 2; therefore, only a select portion of water quality modeling results are presented in this 2024 remodeling summary: at the Water Treatment Plant (WTP) inlet.

Water quality results are presented in Table 4, showing the maximum of 95th percentile predictions for the Perimeter Embankment Till Borrow Pond (PETBP), which is the single influent source to the WTP, and discharges to the only contact water discharge point from the Mine. The 2024 remodeling results shown in Table 4 should be compared to the PETBP water quality predictions shown in Table 46 of the 2023 WMP, which are repeated here in Table 4 (values within square brackets). Results for the PETBP are presented here as this location represents the central point in which all contact water is collected prior to treatment and discharge from the Mine to the receiving environment. Minor changes to water quality predictions may exist at other collection points at the Mine, but presenting results for the PETBP indicate any water quality changes that may affect contact water treatment prior to discharge to the receiving environment.

Table 4: Predicted Water Quality Concentrations and Permit Limits for Treatment During Operations

Parameter	Unit	EMA Permit 11678 WTP Discharge Limit	PETBP – Maximum of 95th Percentile Predicted Concentrations [Results from 2023 WMP]
Major Ions			
Total Sulphate	mg/L	1,100	790 [681]
Nutrients			
Total Ammonia	mg/L (as N)	1.30	0.05 [0.06]
Total Nitrate	mg/L (as N)	34	16 [23]
Total Phosphorus	mg/L	0.09	0.03 [0.03]
Total Metals			
Arsenic	mg/L	0.028	0.004 [0.003]
Chromium	mg/L	0.004	0.001 [0.001]
Copper	mg/L	0.033	**0.190 [0.190]**
Iron	mg/L	1.00	0.58 [0.58]
Manganese	mg/L	3.4	0.22 [0.26]
Molybdenum	mg/L	0.36	0.32 [0.28]
Selenium	mg/L	0.075	**0.087** [0.074]
Zinc	mg/L	0.059	0.013 [0.019]
Dissolved Metals			
Cadmium	mg/L	0.00034	0.00026 **[0.00036]**

Note(s):

1. **Bold and underlined** values exceed permitted discharge limits. These EMA Permit 11678 discharge limits apply to the effluent of the WTP, and not to the PETBP (WTP influent). PETBP water quality predictions are shown to demonstrate the requirement for treatment of a water quality parameter. The SWWBM was developed to predict water quality conservatively; where uncertainty exists in the model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected.
2. Values in square brackets are SWWQM water quality predictions from the 2023 WMP (WSP 2023) and are maximum of 95th percentile predicted concentrations in the PETBP.

The 2024 remodeling has not resulted in any major water quality concentration changes between the predictions shown in Table 4 and the predictions presented in the 2023 WMP. Some water quality parameter concentrations are modeled to increase or decrease compared to 2023 WMP results, but these revised 2024 predictions do not impact which parameters are considered COCs. Total copper and total selenium remain as COCs, same as discussed in the 2023 WMP, and the same COC mitigation strategies apply as were discussed in the 2023 WMP (discussed in Section 4.7.1 in the 2023 WMP Rev0). Dissolved cadmium is no longer predicted to require treatment, which is supported by monitoring data for dissolved cadmium remaining below permit limit, also as discussed in the 2023 WMP.

3.3 Overall Impact to Water Management

The resulting impact of the water transfer changes at the Mine to the overall water management at the Mine is minor, mainly affecting the quantity of water temporarily retained in the TSF and Wight Pit, with less water stored in the TSF and more water stored in Wight Pit. The transfer changes do not notably impact the predicted quantity of water requiring treatment and discharge from the Mine, nor do they notably impact the predicted water quality experienced at the WTP or the mitigation strategies for COCs. The overall water management plan discussed in the 2023 WMP remains valid, with major water quantity volume differences as discussed in this memorandum.

4.0 CLOSURE

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

We trust the above meets your present requirements. If you have any questions or requirements, please contact the undersigned.

FROM Jesse Maddaloni and Darryl Howard **EMAIL Jesse.Maddaloni@wsp.com; Darryl.Howard@wsp.com**

2023 11678 BAT ASSESSMENT PLAN – MOUNT POLLEY MINE

1.0 INTRODUCTION

This technical memorandum (memo) outlines tasks proposed by WSP Canada Inc. (WSP) to be carried out over 2023 regarding water treatment for the Mount Polley Mine, including progression of the water treatment study program in fulfillment of EMA Permit 11678 Section 2.11.1(a); specifically that the permittee must submit to the director for approval by 31 January of each year a study plan that details bench and pilot scale testing that will be undertaken. Proposed tasks are a continuation of existing work regarding several technologies and topics related to water treatment for the site. A description of previously undertaken water treatment work is not provided, nor is an overview of the overall water management or treatment plan for the site; this memo assumes that the reader is familiar with previous water treatment work carried out.

2.0 WATER TREATMENT INVENTORY AND FRAMEWORK

Mount Polley Mining Corporation (MPMC) has been progressing and evaluating multiple technologies to support the treatment of identified constituents of concern (COCs) and to support potential decentralized water treatment and discharge during closure/post-closure. Various studies have been completed over several years to support these efforts as an important component of treatment technology development. An inventory of treatment technologies and a summary of their development is presented in Table 1, including high-level anticipated timelines for future development.

Good engineering practice typically requires a project to follow a standardized engineering design process for the selection and progressive refinement of the final project concept. A project progresses from a pre-concept phase for the identification of multiple treatment options, through concept, pre-feasibility, and feasibility phases to project execution. Generally, the engineering studies performed for each of these project phases are supported by test work that progresses from proof-of-concept and detailed bench-scale testing to pilot-scale and demonstration scale test work. Some of the treatment technologies tested may not progress to the next stage of development. For example, a treatment technology may be eliminated if its treatment capacity is insufficient to treat the forecasted volumes. This framework takes a staged approach, such that input assumptions, design, and cost for the total system can be refined as each stage is completed and the information that the plan relies on becomes more certain. This allows input assumptions to be less conservative as they become more accurate with accumulated knowledge. The technology development stages presented in Table 1 align with this approach. Additional details regarding this project development framework and how it aligns with the BC Ministry of Environment and Climate Change Strategy's BAT policy is provided in MPMC's 2020 Water Management Plan.

This memo assumes that the reader is familiar with the technologies listed in Table 1. Detailed descriptions of the technologies and associated process flow schematics can be found in MPMC's 202 Water Management Plan.

Table 1: Treatment Technology Inventory and Stage of Development

Technology / Stage of Development	Targeted COCs	Proof-of-Concept Bench-Scale Testing	Detailed Bench-Scale Testing	Pilot-Scale Testing	Demo-Scale Testing	Full-Scale Execution	Work Carried Out to Date
Actiflo	TSS, total copper					→	Bench and full-scale testing.
Lime Treatment	Dissolved copper					→	Already in-use, technology development not applicable.
TMT Treatment	Dissolved copper	→	→	→	2023–24	2024–25	Bench and full-scale testing. Toxicity evaluation.
Pit-Lake Treatment	Selenium, nitrate	→	→	2023–24	2025–26	2027–29	Preliminary concept design and proof-of-concept bench-scale testing. Pilot-scale testing workplan.
Saturated Rock Fill (SRF)	Selenium, nitrate	→	2023–24	2025–26	2027–28	2029–31	Concept design, proof-of-concept bench-scale testing, detailed bench-scale testing workplan, and long-term substrate leach testing. Wight Pit SRF assessments.
Packed Bed Reactor (PBR)	Selenium, nitrate	→	2023–24	2025–26	2027–28	2029–31	Concept design, proof-of-concept bench-scale testing, and detailed bench scale testing workplan (in progress).
Biochemical Reactor (BCR)	Selenium, nitrate	→	→				Concept design and proof-of-concept bench-scale testing.
Submerged Sand Reactor (SSR)	Selenium, nitrate	→					Screening analysis.
Constructed Wetland Treatment (CWT)	Selenium, nitrate	→	→	→	2023–24	2025–27	Concept design, bench-scale testing, and on-site pilot scale testing (by others).

Implemented → Under Consideration → Eliminated/Paused →

Table 1 provides a summary of the development stage of the treatment technologies implemented or being considered for operations, closure, and post-closure. Future work is anticipated for any technology still under consideration that has not achieved full-scale implementation. Permitting to support technology development, although not specifically listed in Table 1, is assumed required before all onsite pilot-scale, demonstration-scale, and full-scale execution phases. The timelines presented in Table 1 are indicative only should not be relied upon for detailed schedule planning.

3.0 PROPOSED 2023 WATER TREATMENT SCOPE

3.1 SRF and PBR Detailed Bench Scale Testing

This task involves progressing Saturated Rock Fill (SRF) and Packed Bed Reactor (PBR) treatment technologies through the detailed bench scale laboratory testing phase for both technologies. The SRF and PBR technologies have already successfully progressed through preliminary bench scale testing to confirm the efficacy of these systems to achieve treatment objectives at that scale. In addition, a long-term bench scale test was performed to determine the impact of substrate leaching in the SRF reactor. The next phase of development is detailed bench scale testing to establish the system parameters for subsequent pilot scale test work. Planning for these detailed bench tests has been undertaken in 2022 with the actual test proposed for 2023.

Assumptions:

- Laboratory work will be carried out in WSP's Langley water treatment laboratory.
- MPMC will need to supply and ship test influent water with target influent water quality characteristics. MPMC will also need to supply suitable SRF and PBR reactor media, verified in the months prior to beginning the tests.
- SRK will provide the results of any geochemical testing undertaken regarding the SRF/PBR media substrate intended for the tests (see Scope Item 2.2), prior to selecting the media for detailed bench scale tests.
- The total test schedule is estimated at 45 weeks for each test, preferably occurring simultaneously.

Deliverable:

- Following lab work completion for each technology, WSP will provide a report for each test that outlines the results of the test and provides recommendations for subsequent pilot scale test work.

3.2 SRF Media Substrate Characterization

This task was begun in 2022 but was not concluded, as it was waiting on completion of the SRF long-term leach test as a key input to the geochemical characterization. The completion report from the long-term leach test is now drafted and under review by MPMC and this substrate characterization task is proposed for execution in 2023.

This task involves both geochemical and geotechnical characterization of the waste rock media that is intended to be used as reactor substrate in future passive treatment systems using the Saturated Rock Fill (SRF) or Packed Bed Reactor (PBR) technologies. Geochemical characterization is understood to be carried out by SRK, MPMC's geochemistry consultant and geotechnical testing will occur in WSP's Burnaby geotechnical laboratory. A technical memorandum will be provided by WSP regarding the geotechnical testing.

Assumptions:

- Geochemical testing and reporting are assumed to be carried out by SRK, following SRK's review of the SRF long-term leach test report.
- MPMC will provide suitable media for testing, pre-screened to 25-80mm, and shipped to WSP or SRK on request or directly to the appropriate laboratory as requested.

Deliverable:

- WSP will provide a brief technical memorandum that summarizes the results of the geotechnical laboratory testing.
- It is assumed that SRK will provide a separate deliverable, available to WSP for inclusion as an appendix to reports.

3.3 Pit-Lake Treatment

Pit-lake treatment is currently assumed as a component of the closure/post-closure treatment system. Pilot-scale pit-lake treatment work was anticipated for Cariboo pit, but recent mine operational changes have resulted in the draining of both Springer and Cariboo pits and pit-lake treatment trials are no longer feasible at these locations. Operational changes have also resulted in Wight pit being filled. The previous pilot-scale study designed for Cariboo pit is proposed to be redesigned for Wight pit if operational conditions in the near future are deemed appropriate, further advancing the development of this treatment technology.

Assumptions:

- It is assumed that conditions in Wight Pit would be suitable for a pit-lake treatment pilot-scale trial and would remain suitable for the required duration of the trial.
- It is assumed that constituents-of-interest would be present in suitable concentrations to allow the pit-lake treatment trial.

Deliverable:

- WSP will provide a revised pilot-scale pit-lake treatment study plan, modified for Wight Pit.

3.4 Flocculant Management Plan

The revised EMA Permit 11678 (revised December 2022) requires that MPMC produce a Flocculant Management Plan (FMP) regarding the use of flocculants and coagulants (settling aids) at their Veolia water treatment plant. The permit requires drafting of the FMP in 2023, with review of the FMP every 5 years thereafter. The FMP is to be submitted with the Annual Report. WSP proposes to prepare the FMP on behalf of MPMC.

The permit details several requirements of the FMP, including describing the planned use of settling aids at the water treatment plant, usage rates, monitoring and inspection expectations, toxicity prevention, and defined procedures for settling aid dosage targets.

Assumptions:

- WSP will produce the FMP according to the requirements stated in the EMA Permit 11678.
- MPMC will provide a timely response to WSP's information request regarding MPMC information required to produce the plan.
- The FMP will include discussion of currently used flocculants and coagulants at the treatment plant and will rely, in part, on information prepared by Golder (now WSP) regarding dosage and toxicity.

Deliverable:

- WSP will provide a Flocculant Management Plan that addresses the permit requirements, based on a plain language, lay person interpretation of the permit requirements.

3.5 Distributed Treatment Comparison

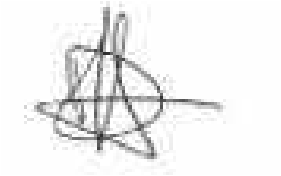
This task involves an options assessment comparing distributed passive/semi-passive water treatment to centralized treatment using Actiflo with potential additional components targeting copper (pit-lake pre-treatment, enhanced settling post treatment, TMT use). These are the two options identified by the BAT assessment for closure. Given the recent proposed modifications to EMA Permit 11678, the direct requirement of investigating passive and semi-passive water treatment technologies for distributed discharge has been removed from the permit. Selenium is modeled to be a parameter of concern during closure, with potential concentrations above permit limits; however, historic observations from site show selenium consistently below permit limits and it is unknown whether treatment systems targeting selenium would be required during closure. Previous work has assumed that selenium may be an issue, based on geochemical predictions (hence development of passive treatment technologies), with investigation into selenium-targeting passive treatment also being a permit requirement.

This assessment would compare anticipated costs of these systems, as well as benefits, drawbacks, uncertainties, and risks. The result of this assessment would provide direction on which water treatment activities should be undertaken to support closure under the revised permit requirements.

Assumptions:

- Conceptual level costing (AACE Class 5) would be used for the assessment.
- Conceptual level sizing for treatment options would be provided to support the costing.
- Centralized and distributed flow rates and water quality would be based on the most recent water balance and water quality modeling carried out for the 2022 Mine Plan and Reclamation Plan Update.

Deliverable:



- A technical memorandum would be produced that summarizes the option comparison and provides recommendations for future treatment investigation to support closure.

4.0 CLOSURE

We trust that the information provided herein is sufficient for your needs at this time. If you have any questions or need additional information, please do not hesitate to contact us.

1 Introduction

1.1 Overview

On December 31, 2020, Mount Polley Mining Corporation (MPMC) received an amendment to Permit 11678 issued by the British Columbia (BC) Ministry of Environment and Climate Change Strategy (ENV) under the BC *Environmental Management Act* (*EMA*). The amendment authorizes, among other things, the discharge of treated effluent from the Mount Polley mine (the "Mine") site runoff and seepage collection water management systems until December 31, 2022 which reflects the operations phase contemplated under the currently authorized mine plan. The following effluent discharge locations were authorized:

- Quesnel Lake via direct pipeline until December 31, 2022.

This 2021 Annual Discharge Plan, required under Section 2.6 of *EMA* Permit 11678 is required to outline, among other items, the expected volume, timing, and quality of effluent released to Quesnel Lake, and plan the discharge in such a manner that avoids "pollution", as defined in *EMA* and as determined by the simple evaluation of parameter concentrations at the edge of the Initial Dilution Zone (IDZ) in Quesnel Lake. Parameter concentrations at the edge of the IDZ will be monitored using a model-based approach as part of a Trigger Response Plan (TRP) designed such that three key priorities (in order) will be met:

1. Protection of human safety (specifically, the safety of Mount Polley Mining Corporation Environmental Department monitors),
2. Protection of the environment and compliance with environmental laws, and
3. Related to bullet 2, the TRP has been designed to reflect the importance for MPMC to be able to effectively manage its site water balance so that it does not accumulate impounded water. The management of site water while minimizing water impoundment has been identified as an important priority not only by MPMC but also by First Nations, Ministry of Energy and Mines, BC ENV and our Independent Expert Review Panel (IERP).

These key priorities helped form the premises for the TRP and subsequent actions. Two major premises have formed the basis of the development of the TRP:

1. The TRP and the actions it contains must be implementable.
2. Modelling of dilution in the Quesnel Lake IDZ can reasonably rely on the near-field dispersion model (CORMIX – Golder) and far-field hydrodynamic model (Tetra Tech EBA) developed for Quesnel Lake.

This model-based TRP approach is in keeping with input from ENV and will help alleviate some of the safety concerns associated with sampling in inclement weather while providing reliable estimates of water quality at the edge of the IDZ.

The Mine's effluent discharge is also regulated by the *Metal and Diamond Mining Effluent Regulations* (*MDMER*) under the Federal *Fisheries Act*. This Plan has been developed for submission to ENV and Environment and Climate Change Canada (ECCC) to satisfy the applicable requirements of both *EMA* Permit 11678 and the *MDMER*.

1.2 EMA Permit 11678 Conditions

This Plan considers EMA Permit 11678 conditions and requirements pertaining to the Plan, as stipulated in *EMA* Permit 11678. Table 1 summarizes MPMC's mitigative and compliance responses to *EMA* Permit 11678 requirements which include:

- An outline of the expected volume, timing, and duration of effluent released to Quesnel Lake;
- Consideration or account of recent hydrology and snowpack information, mine water balance information, Polley Lake discharge control, and background water quality information;
- Demonstrate how the BCWQGs set out in column 2 of Table 1 of the permit will be met at the Edge of the IDZ in Quesnel Lake;
- A maximum turbidity target(s), as measured at the outlet of the treatment plant, which requires immediate reporting to the Director should the turbidity target(s) be exceeded for longer than one hour in duration;
- A trigger and response plan for treatment system shutdown(s), and/or for suspension or reduction of discharge, and for the resumption of the discharge, if the effluent discharge limits at the outlet of the treatment plant cannot be met, or if an objective for the Edge of Quesnel Lake IDZ cannot be met;
- Identification of the sources of mine water and the percent of each source in the total effluent discharge for each day;
- Demonstrate how the discharge will be managed to minimize suspended solids deposition into Quesnel Lake; and,
- Identification of equipment, including calibration and maintenance schedules related to continuous measurements of flow, turbidity, specific conductance and temperature.

Table 1. Requirements and Summary of Compliance and Mitigative Actions.

EMA Permit Requirement	MPMC Mitigative and Compliance Response
An outline of the expected volume, timing, and duration of effluent released to Quesnel Lake	Timing and volume for effluent discharge to Quesnel Lake depends on current climate conditions. Discharge will be managed via the MPMC Tailings Storage Facility (TSF) and the on-site Water Manager. Discharge volume will remain within permit limits.
Consideration or account of hydrology and snowpack information, mine water balance information, Polley Lake discharge control, and background water quality information	See Section 3.1 of this Annual Discharge Plan.
Demonstrate how the objectives set out in column 2 of Table 1 in the permit will be met at the Edge of the IDZ in Quesnel Lake	See Section 4.2 of this Annual Discharge Plan
A maximum turbidity target(s), as measured at the outlet of the treatment plant, which requires immediate reporting to the Director should the turbidity target(s) be exceeded for longer than one hour in duration	See Section 4.3 of this Annual Discharge Plan
A trigger and response plan for treatment system shutdown(s), and/or for suspension or reduction of discharge, and for the resumption of the discharge, if the effluent discharge limits at the outlet of the treatment plant cannot be met, or if an objective for the Edge of Quesnel Lake IDZ cannot be met	See Section 5.1 of this Annual Discharge Plan
Identification of the sources of mine water and the percent of each source in the total effluent discharge for each day	With regard to the source of effluent, this information is outlined in detail in the Technical Assessment Report (TAR) prepared in support of the *EMA* Permit 11678 application for the Long-term Water Management Plan (LTWMP) for the Mine site (the LTWMP being the subject of the April 7, 2017 amendment of *EMA* Permit 11678). A key consideration to this is in Appendix C of the TAR (Derivation of Geochemical Source Terms, SRK 2016). The similarities of the mineralized zones, including their host rocks, indicate that source terms can be appropriately developed on a site-wide basis rather than considering significant differences between the zones.
Demonstrate how the discharge will be managed to minimize suspended solids deposition into Quesnel Lake	See Section 3.4. of this Annual Discharge Plan

EMA Permit Requirement	MPMC Mitigative and Compliance Response
Identification of equipment, including calibration and maintenance related to continuous measurements of flow, turbidity, specific conductance and temperature.	See Section 3.5, Table 3. Summary of equipment, maintenance and calibration for continuous site measurements. of this Annual Discharge Plan

2 Effluent Treatment & Discharge System

2.1 Discharge System Components

Mine contact water is collected in a system of ditches located around the Mine site. The water, primarily rain and snow melt, ultimately reports to the Perimeter Embankment Till Borrow Pond (PETBP) from which it is pumped to the Water Treatment Plant (WTP). Treated contact water leaving the WTP flows by gravity through a buried 24" HDPE pipe to Quesnel Lake. At Quesnel Lake, the water is discharged into the lake through two twin diffusers (4 ports in total) with each of the twin diffusers located at depths of 45 meters and 50 meters.

In summary, the major infrastructure components associated with the collection, treatment, and discharge of mine contact water are:

1. Mine site contact water collection system (site-wide ditch system, sumps and pumps)
2. The PETBP
3. Veolia Actiflo^{TM} water treatment plant
4. 24" pipeline from the Veolia Actiflo^{TM} water treatment plant to Quesnel Lake
5. 2 depth staggered, dual port (4 ports in total), submerged diffusers in Quesnel Lake

The construction of the pipeline from the Veolia Actiflo^{TM} water treatment plant to the outfall of the Quesnel Lake diffusers was completed on November 24, 2017. All other works are as before, and were completed in the fall of 2015.

2.2 Water Treatment Plan (WTP)

As outlined in the LTWMP TAR site contact water, primarily originating as rain and snow melt, is conveyed through a site-wide ditch system to the PETBP (Golder 2016a). Water from the PETBP is pumped to the Veolia Actiflo^{TM} WTP, which is operated by qualified personnel 24/7. The Actiflo system is a flocculation/clarifier system which makes use of sand-ballasted lamellar settling to remove suspended solids present in the contact water. The WTP doses the raw water with coagulant to a tank where a polymer is injected to create floc particles. Microsand is added to ballast the flocculants, which move on to another tank that allows them to swell and mature. The water flows to the next stage, which uses lamella to clarify the water and promote fast settling of the microsand ballasted sludge. The clarified water is discharged and the sludge is separated from the microsand, the microsand being recycled for reuse. An in-line turbidity meter measures the turbidity every ten seconds and estimates the total suspended solids (TSS) using a calibrated algorithm based on a site-specific correlation between turbidity and TSS. If the effluent TSS is above 13 milligrams per liter (mg/L) for 1 minute there is an audible and visible alarm. If the effluent TSS is over 14 mg/L instantaneously, an alarm sounds to alert the operator and the WTP automatically goes into recirculation mode and ceases discharge to the pipeline.

2.3 Discharge System Locations

The diffusers, each of which are fitted with a "Y" splitter to two ports, are located at depth in Quesnel Lake at the following coordinates:

- 5,817,932 N and 601,747 E, and 5,817,935 N and 601,785 E.

3 Discharge Plan

3.1 Hydrology

The Mine area is drained by three main watersheds: Hazeltine Creek at Quesnel Lake, Edney Creek at Quesnel Lake, and Morehead Lake. The Hazeltine Creek watershed includes Polley Lake and the upstream Frypan Lake, and conveys all water from Polley Lake, the east side of the Mine area, and the area surrounding the Mine's TSF.

MPMC maintains a hydrological monitoring station on upper Hazeltine Creek that was originally installed by the Water Survey of Canada (08KH027). In general, the hydrology of Hazeltine Creek (and by extension, the Mine area), can be described as snowmelt-driven, with the majority of annual runoff occurring during freshet. Measured hydrology data for 2016 and early 2017 is included in Table 2, and compared to historic averages for rainfall (Golder 2016b), snowpack (estimated from Golder 2016b), snowmelt (estimated from Golder 2016b) and evaporation (Golder 2016b).

Table 2. Hydrology data including actual data from 2016 and early 2017, rolling average data from 2016 and early 2017, and historic averages for comparison.

mm = millimetres

3.2 Mine Water Balance

Contact water from roads, haul roads, waste rock dumps, and other Mine areas is managed by a series of ditches, sumps and pumps. Currently (June 2020), any contact water that requires storage on site (i.e., when flows exceed those able to be treated and discharged) is pumped to the TSF. Tailings and process water from the Mill report by gravity to the TSF.

The WTP sources water from the PETBP. Treated water from the WTP is discharged by gravity to Quesnel Lake via the installed pipeline (completed November 2017) to the two outfall pipes. Effluent discharge to the Hazeltine Creek channel ceased as of September 30, 2017. A map of the water collection infrastructure is provided in Figure 1.

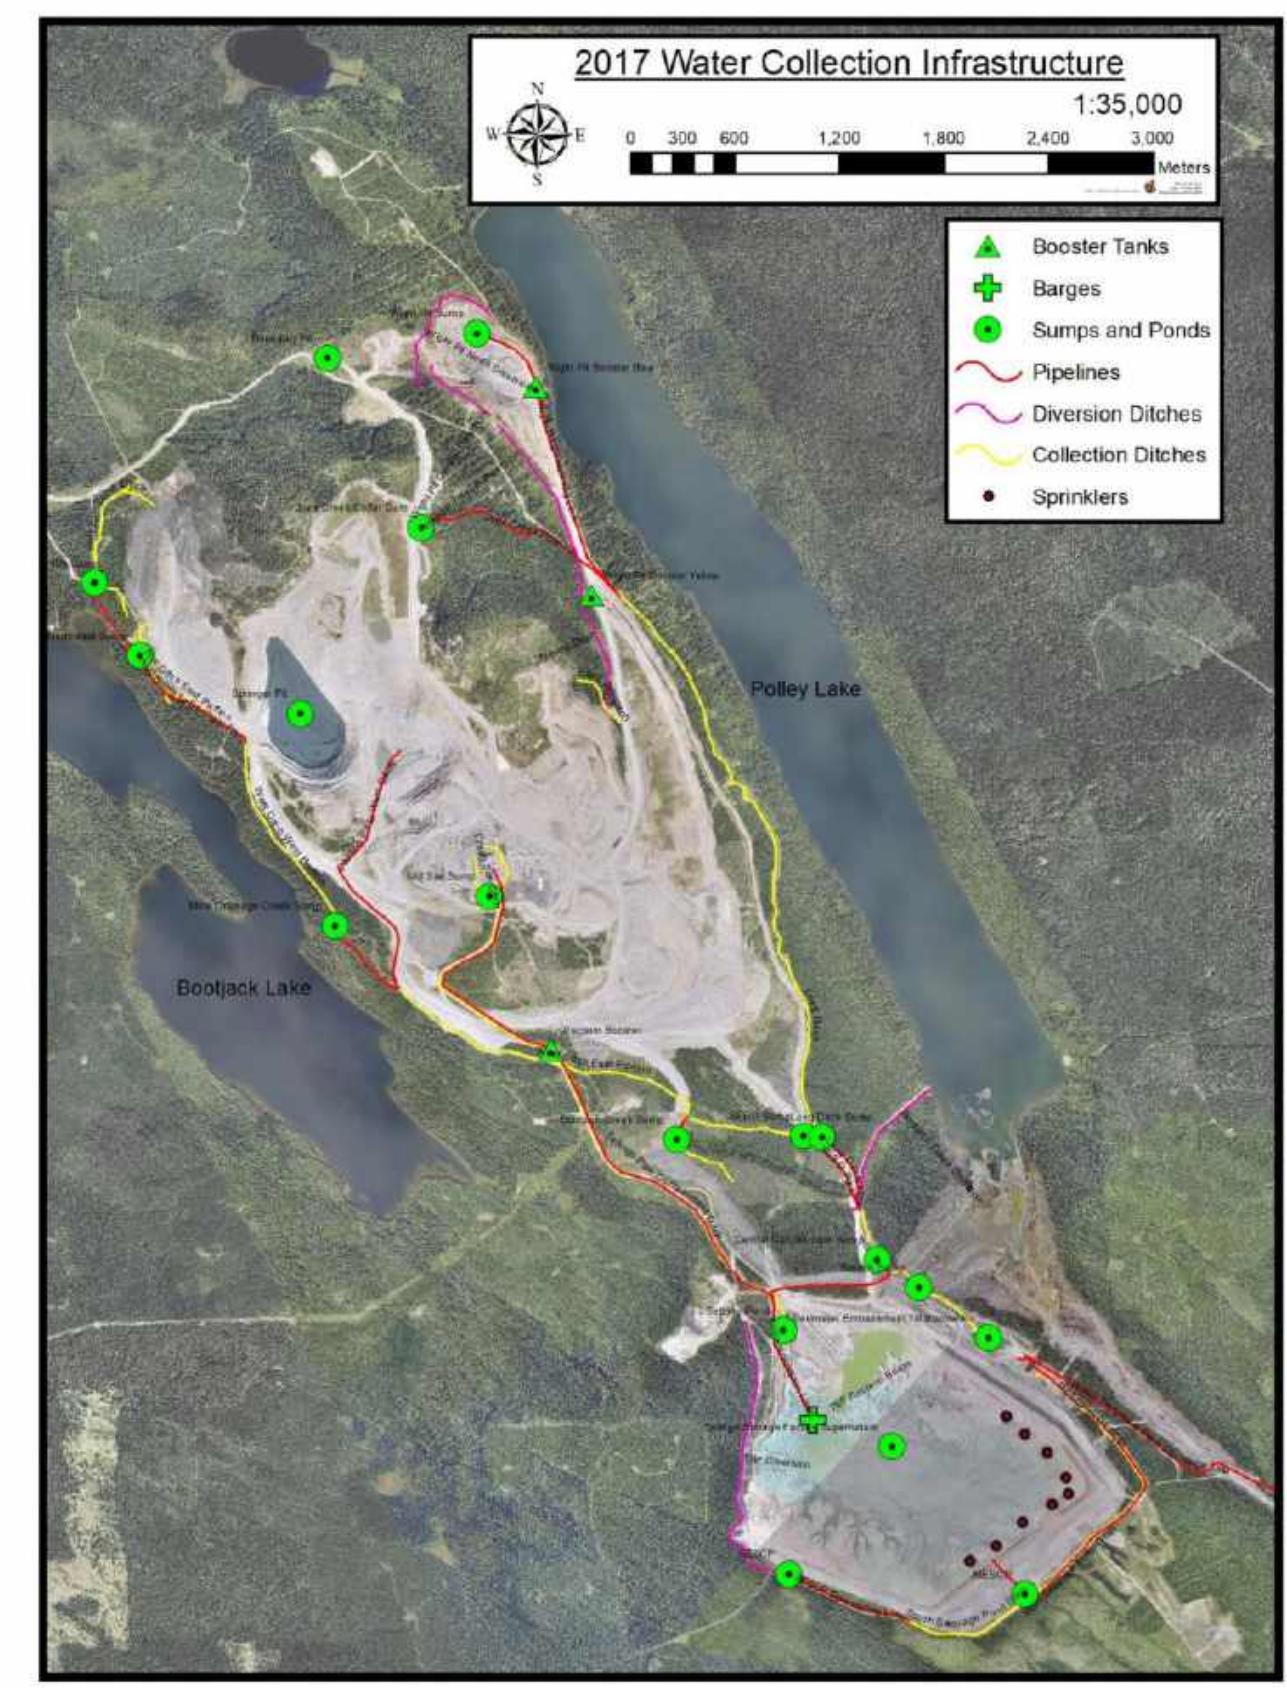

Figure 1. Water management infrastructure at the Mine.

3.3 Expected Volume, Timing, and Duration of Effluent Discharge

MPMC will discharge treated water in 2020 within the confines of *EMA* Permit 11678. Discharge of treated water to Quesnel Lake is limited to a maximum volume of 52,000 m^3/day, with an annual average of 29,000 m^3/day (Sections 1.2.1 and 1.2.2 of *EMA* Permit 11678). Discharge volumes are based on the maximum authorized instantaneous discharge rate of 0.6 m^3/s and maximum authorized annual average discharge rate of 0.33 m^3/s, respectively. The primary water sources for the WTP will be excess water collected and conveyed to the PETBP by the site contact water management systems and any water temporarily detained in the TSF.

With regard to snowpack, water volumes from snowpack and rainfall are aggregated in the maximum permitted discharge volumes, all of which report to Quesnel Lake through the subsurface diffusers and are subject to the flow limits imposed by the permit.

3.4 Management of Suspended Solids

The primary control method to minimize the discharge of suspended solids into Quesnel Lake is the WTP which is an active treatment system designed to remove suspended solids from influent water (Section 2.2).

The secondary method of reducing suspended solids and to reduce the potential for adverse effect on water quality is the utilization of significant engineered erosion control (e.g., armouring) as source control. These Best Management Practices (BMPs) are installed and constructed in the site-wide open flow ditch system. The mine also has an erosion and sediment control management plan for the whole of site.

3.5 Water Treatment

As detailed in Section 2.2, the main component of the treatment system is the Veolia Actiflo™ treatment plant, model ACP-650. The Actiflo™ clarifier system uses sand-ballasted settling to remove suspended solids present in the inflow (influent) water. The quality of influent water and effluent water is monitored within the treatment plant by a number of sensors, meters, and controllers. Table 3Table 3 provides a summary of equipment in the WTP, including calibration and maintenance equipment related to continuous measurements of flow, turbidity, and temperature.

Table 3. Summary of equipment, maintenance and calibration for continuous site measurements.

Equipment Type and Location	**Model Number**	**Calibration and Maintenance Requirements**
Turbidity Meter: Influent Pipe	HACH SS6 Surface Scatter Turbidimeter	Scheduled, periodic maintenance requirements of the SS6 Turbidimeter are minimal. Standardization checks should be performed on a monthly basis. Calibration should be performed at least every four (4) months by one of the methods provided in the Instrument Manual. Operation calibrates and checks weekly.
Electromagnetic Flowmeter: Effluent Pipe	Siemens Sitrans F M MAG 5100 W	The device is maintenance-free, although a periodic inspection must be carried out to check: • Ambient conditions • Seal integrity of the process connections, cable entries, and cover screws • Reliability of power supply, lightning protection, and grounds If required, Siemens will recalibrate the sensor using one of the calibration methods included in the Operating Instruction Manual.
Turbidity Sensor: Clarifier Tank	HACH Solitax® model TS-LINE sc	There are no maintenance requirements for the sensor once installed. Calibration for turbidity uses Formazin or StabCal® standard. Calibration for total suspended solids (TSS) is based on gravimetric TSS analysis with a correction factor. Operation calibrates and checks weekly.

Equipment Type and Location	Model Number	Calibration and Maintenance Requirements
pH Sensor (includes temperature and conductivity): Clarifier Tank	HACH Ryton® Sensor model DPD1R1	Maintenance requirements for the pH Sensor include cleaning the sensor and inspecting the sensor for damage every 90 days. Instructions on how to clean the sensor are in the User Manual. Automatic calibration identifies the buffer table corresponding to the chosen buffer and automatically calibrates the probe after it stabilizes. Alternatively, a manual calibration is performed by placing the pH Sensor in any buffer or sample with a known value and then entering that known value into the controller. Operation calibrates and checks weekly.
Flowmeter Signal Converter: Influent Pipe	Krohne IFC 010 Signal Converter	This is a signal converter and does not require any maintenance or calibration.
Universal Controller: Main Plant Controls	HACH sc200™	This is a signal controller and does not require any maintenance or calibration.

It should be noted that the WTP generates small volumes of sludge (precipitate) during active treatment. This material reports to a holding tank and is then pumped to a pond adjacent to the WTP. Typically, TSS is reduced from approximately 12 mg/L (influent) to approximately 7 mg/L (effluent) so 5 mg/L is considered "waste". This equates to approximately 5 m^3/1,000,000 m^3 of treated water. The sludge requires no further treatment as it is chemically inert.

3.6 Shutdown Criteria

The primary shutdown criterion for the WTP is based on TSS in the effluent. If TSS in the effluent reaches 14 mg/L, discharge to the pipeline is suspended until the level of TSS in the effluent drops to below this value. This is monitored using the automated in-line turbidity sensor and process logic controller, that will put the WTP into a recirculation mode if the limit is exceeded and then water is diverted back into the PETBP.

The secondary shutdown criterion is if laboratory analysis indicates an exceedance of any water quality parameters listed in Section 1.2.4 of *EMA* Permit 11678 at the end-of-pipe (as represented by the discharge from the WTP). Shutdown in that circumstance is operator-induced. In the event that water quality parameters at the edge of the IDZ (mid and near bottom samples) in Quesnel Lake (IDZ) exceed the quantities for those parameters set out in the final column in Table 4, the monitoring, reporting and response procedure will follow the TRP, described in more detail in Section Exceedances: Trigger Response Plan5.1 of this Plan. Sampling at the edge of the IDZ will only take place four times per year for ongoing model verification. It should be noted that the primary fail-safe to avoid any water quality exceedance with the end-of-pipe discharge or criteria listed in Table 4 at the IDZ is shutdown of the WTP, or, for shorter duration events an automated switch-over of the plant to a recirculation mode. Troubleshooting or additional monitoring would occur to identify and mitigate any problems leading to an increase in constituent levels at the end-of-pipe or the IDZ before the WTP would resume operations (Section 5.15).

4 Protection of the Receiving Environment

4.1 Background Water Quality

Background water quality in Quesnel Lake is summarized in Table 4 below.

In the last version of the Annual Discharge Plan (submitted on July 30, 2018 and approved on September 6, 2018), MPMC proposed to change the background water quality reference site from QUL-120a to QUL-2a (Table 4) as it has been shown to be not significantly different from location QUL-120a and poses less of a safety concern for sampling access (Golder 2018b). Location QUL-2a is the closest upgradient site to the discharge and water quality at a depth of 40 m was shown to be a better representation of what would be measured at the IDZ in Quesnel Lake in the absence of a discharge.

As summarized in the technical memo on evaluating background water quality data in Quesnel Lake (Golder, 2018b), all parameters at QUL-2a during 2016, met the Edge of Quesnel Lake IDZ limits established under Section 1.2.4 of *EMA* Permit 11678 with the exception of total copper, which was over the guideline in one sample and total phosphorus which was over the guideline in one sample.

Table 4. 2017 Background water quality information for Quesnel Lake (QUL-2a, 2017 data)

Parameter	Minimum	Average	Maximum	Edge of Quesnel Lake IDZ[1]
pH (in situ) (relative units)	7.83	7.90	7.95	n/a
Temperature (in situ) (Degrees Celsius)	2.70	7.22	17.83	n/a

Dissolved Cadmium (Cd) (mg/L)	0.0000025	0.0000025	0.0000025	0.00013

(1) Edge of Quesnel Lake IDZ limits as established under Section 1.2.4 of EMA Permit 11678

Notes – where value is above the MDL, 0.5x the MDL is used in calculation, where values are all below MDL, then MDL is presented.

– DLs were substituted with 1/2 DL.

4.2 Predicted Water Quality

The TAR (Golder 2016a) included measures to manage the following water conveyances:

- Collection and temporary storage of all site contact water in the TSF
- Springer Pit dewatering
- Discharge of up to 0.6 m^3/s instantaneously and 0.33 m^3/s averaged annually of treated effluent to Quesnel Lake, via direct pipeline and two twin diffusers installed below the thermocline in Quesnel Lake (during the Quesnel Lake Discharge)

As part of the TAR, a water quality model was developed to predict the treated effluent chemistry of site discharge during operations and to evaluate the influence of the effluent discharge on Quesnel Lake (Golder 2016a). The model was developed using the GoldSim Contaminant Transport Module (GoldSim 2010). GoldSim is a graphical, object-oriented mathematical model where all input parameters and functions are defined by the user and are built as individual objects or elements linked together by mathematical expressions. The object-based nature of the model is designed to facilitate understanding of the various factors which control an engineered or natural system and predict the future performance of the system.

In GoldSim, each flow that could influence water quality was itemized and assigned a chemical profile based on site water quality monitoring data. The model was designed to track the volume and the mass load in the effluent discharge based on each water source (e.g., site runoff or pumped Mine flows) contributing to the discharge. Based on the quantity of these two parameters, the discharge water quality was calculated. A treatment efficiency was applied to the predicted discharge water qualities to evaluate the concentration of each parameter in the treated effluent.

The model was run stochastically using a Monte Carlo approach to bracket the range of effluent qualities that could occur. A probability distribution function was assigned to each source that could influence the discharge water quality and the model was run for 1,000 realizations on a monthly timestep, allowing the model to generate 1,000 unique values for each input. At each timestep, median and 95th percentile concentrations were calculated based on the 1,000 simulated values (referred to as "Scenario 1"). To account for potential changes in water chemistry over the long-term, a source-term based model was also used to simulate concentrations using the same water balance model (referred to as "Scenario 2").

The results of the model, accounting for treatment efficiency, were proposed as the effluent limits to be included in the application for amendment of *EMA* Permit 11678 for the Quesnel Lake Discharge. Depending on the water quality constituent, either Scenario 1 or Scenario 2 was used. In either case, the proposed *EMA* Permit 11678 limits were calculated such that treated effluent would not cause an exceedance of BC Water Quality Guidelines (WQGs) at the edge of the IDZ in Quesnel Lake, provided that natural conditions beyond MPMC's control do not cause WQG exceedances. It was assumed that such natural occurrences would be evaluated through monitoring associated with the Response Framework, which is part of the approved 2016 Comprehensive Environmental Monitoring Plan (CEMP) (MPMC 2018).

A Cornell Mixing Zone Expert System (CORMIX) model was developed to evaluate near-field concentrations within the Quesnel Lake IDZ, and a hydrodynamic model was also developed for Quesnel Lake (Tetra Tech 2015) to evaluate the concentrations of modelled parameters beyond the edge of the IDZ. Both models considered seasonality in the inputs with respect to effluent and ambient temperature and total dissolved solids (as they relate to water density) and wind currents (as they affect water currents). Both models predicted a wide range of dilution factors under various weather conditions, and the cautionary value of 40 was adopted for the TAR, reflecting the lower end of the range of predictions. In the TAR, the predicted dilution factor in the mixing zone in Quesnel Lake was applied to the proposed *EMA* Permit 11678 concentration limits to predict the concentrations beyond the edge of the IDZ. The resultant concentrations formed the basis of the impact assessment in the TAR. The outcomes of this assessment indicated the following:

- The predicted effluent was not acutely toxic; and
- The predicted concentrations at the edge of the IDZ in Quesnel Lake would not result in adverse effects to surface water quality.

Based on the information provided above, ENV approved the proposed effluent limits included in the TAR (Section 1.2.4 of *EMA* Permit 11678).

Discharge of treated site contact water from the Mine began on December 1, 2015, in accordance with the amendment of *EMA* Permit 11678 (November 29, 2015). Monitoring of the discharge and surface water quality has validated three of the models used to derive *EMA* Permit 11678 limits (water balance model, water quality model, and dispersion model). Based on this model validation, there is a high level of confidence that the effluent limits proposed in the TAR will not result in concentrations at the edge of the IDZ that are greater than BCWQGs. As part of the 2020 annual water management, it is expected that the BCWQGs will continue to be met at the edge of the IDZ in Quesnel Lake if MPMC continues to operate within the current end-of-pipe *EMA* Permit 11678 limits (Golder 2016b). While the effluent is not expected to result in water at the edge of the IDZ not meeting the BCWQGs, should background waters exceed the BCWQGs as they occasionally do because of, for example, seasonal events in tributary streams, then the water at the edge of the IDZ would reflect such natural lake conditions rather than the effluent discharge. MPMC will continue to sample at QUL-58 in accordance with the CEMP.

MPMC has previously attempted to locate the plume while in the field and, as expected (the model predicts a <3% chance of locating it), could not find a plume signature at the edge of the IDZ. MPMC has consulted with Tetra Tech who provided some additional advice and efforts based on that advice will be made towards plume identification while sampling. The challenges in identifying the plume in the field reflect the dispersion that is occurring.

In addition to being used for establishing the effluent limits included in the TAR, dispersion models will be used as part of the TRP to model dilution in the Quesnel Lake IDZ to determine compliance and to verify that water and effluent management by MPMC remains protective of the environment and compliant with environmental statutes. This model-based approach for the TRP will provide reliable water quality estimates at the IDZ while mitigating the safety risk associated with obtaining samples in the IDZ when it is unsafe to do so. The Quesnel Lake surface sample location at the edge of the IDZ (QUL-58), while appropriate as a monitoring point, is not a suitable compliance point as there are many other influences unrelated to the WTP discharge (especially in winter). An updated model validation shows that modelled dilution factors previously determined for *EMA* Permit 11678 amendment are still suitable for their intended use and that the overall dilution factor achieved by the effluent infrastructure is protective of Quesnel Lake (Golder 2018c).

An analysis of remaining assimilative capacity at the IDZ, taking into account contemporary background conditions and observed effluent has shown that while background concentrations limit some parameters and treated effluent limits others, the combination of background and effluent loading does not suggest exceedances to receiving environment limits set out in the final column of Table 4 (Golder 2018a). The results of the analysis showed that 14 of the 18 constituents remained below the receiving environment limits set out in the final column of Table 4 when viewed in aggregate (and therefore below BCWQGs at the IDZ) and the remaining constituents showed assimilative capacity on all days but one, for total copper, which fell to about 10% due to higher than normal Quesnel Lake background conditions.

Part of the monitoring approach will include ongoing analysis of the assimilative capacity at the IDZ, which demonstrates the relative loading percentages of background concentrations and effluent loading in comparison to the permit limit (Golder 2018a). Assimilative capacity will be monitored for all 18 constituents and reported through the use of a loading chart (Figure 2) in the quarterly report.

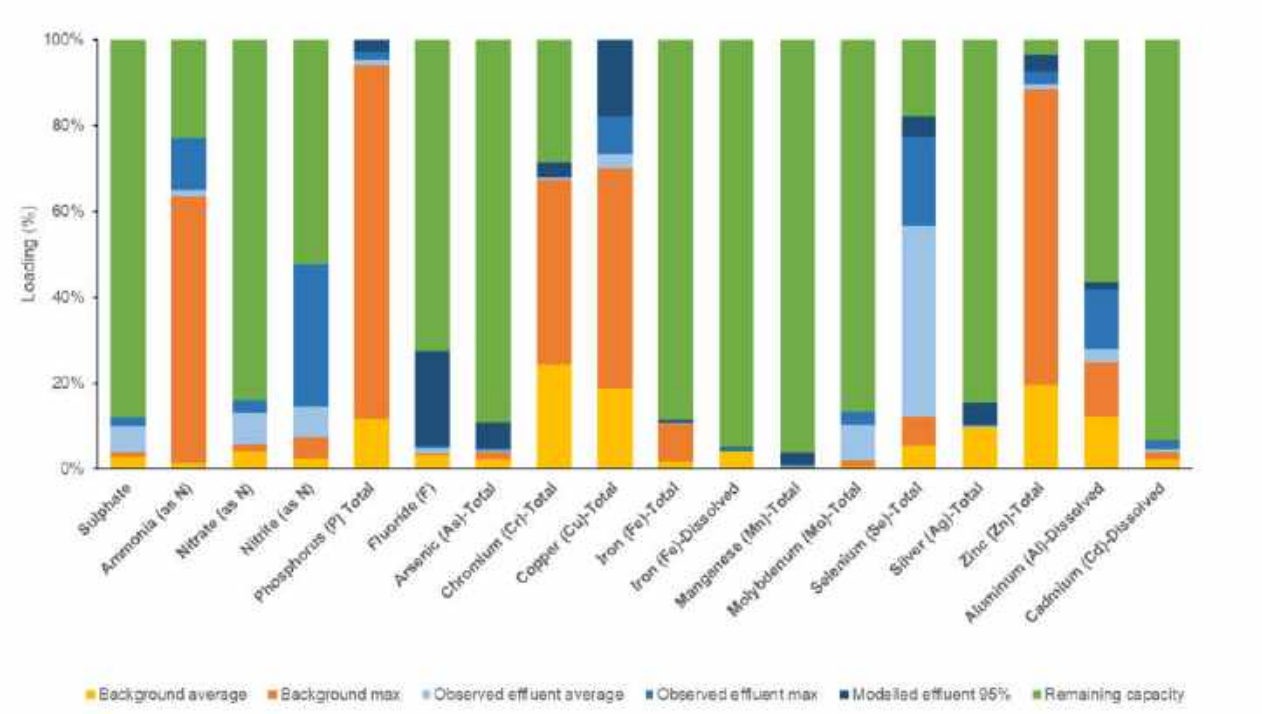

Figure 2. Calculated Assimilative Capacity of Constituents with Permit Limits

Interpretation of the loading chart must take into account that, while background concentrations tend to limit some parameters, treated effluent discharge tends to limit others. As well, when conservatively viewed in aggregate, constituents appear close to the receiving environment limits set out in the final column of Table 4 than when viewing the loading chart across individual days for a particular constituent.

Triggers will apply at the IDZ against the sampling completed four times per year (and subsequent sampling thereafter with respect to actions under the TRP), although it must be acknowledged that the data collected may not be representative of effluent discharge influences due to inputs from other sources (for example Horsefly River) that MPMC has no control over or responsibility for. This is detailed in the TRP in Section 5.1 of this Plan.

4.3 Turbidity Target Levels

MPMC has set target levels for turbidity at the edge of the IDZ in Quesnel Lake based on BCWQGs. Turbidity in Quesnel Lake should not exceed 5 NTU above the background on a 24-hour average basis, or 2 NTU above the background on a 30-day average basis (based on an average of five samples collected in 30 days). The first point of turbidity control remains at source where the water treatment plant monitors turbidity every 10 seconds with cautionary trigger levels programmed into the process logic controller. The system is automated such that if source turbidity is exceeded, the plant goes into recirculation mode (i.e., automatically stops discharging).

Regular monitoring and comparison to these levels is performed by MPMC. Further details of planned monitoring are presented in the CEMP (MPMC 2018).

5 Exceedances and Reporting

5.1 Exceedances: Trigger Response Plan

As detailed in the TAR (Golder 2016a), derivation of the effluent permit limits was based on attainment of Best Achievable Technology (BAT), attainment of the BCWQGs at the edge of the IDZ in Quesnel Lake and absence of acute lethality at the end-of-pipe. As such, compliance will be determined as follows:

- End-of-pipe (HAD-3): compliance with the effluent limits in EMA Permit 11678
- Quesnel Lake IDZ: execution of the Trigger and Response Plan set out in Section Edge of Quesnel Lake Initial Dilution Zone5.1.2 of this Annual Discharge Plan.

The model-based TRP approach helps to address several of the safety concerns associated with sampling in inclement weather while providing reliable but cautionary estimates of water quality at the edge of the IDZ. An updated model validation shows that modelled dilution factors previously determined for *EMA* Permit 11678 amendment continue to provide reasonable, though conservative predictions of water quality at the IDZ and that the overall dilution factor achieved by the effluent infrastructure is protective of Quesnel Lake (Golder 2018c).

Sampling in Quesnel Lake may be impeded if safety is considered to be a concern. If predicted/actual winds exceed 10 kilometres per hour (km/h), forecasted/actual thunderstorms or whitecaps are observed, sampling will not occur due to safety concerns. Strong winds that create greater than usual water currents also have the potential to prevent the collection of representative samples. During winter months, the West Arm of Quesnel Lake is often frozen over, partially frozen, or if it remains unfrozen, other vessels are typically absent. The presence of other mariners on the water is the main first response system that is used by the Canadian Coast Guard as part of vessel safety systems and absence of other mariners therefore increases safety risks (by increasing consequence) when on the water.

Modelling of dilution in the Quesnel Lake IDZ can reasonably rely on the near-field dispersion model (CORMIX – Golder) and far-field hydrodynamic model (Tetra Tech EBA) developed for Quesnel Lake. This provides a suitable means for effluent and receiving environment management that is not predicated on putting staff at risk. Ongoing confirmation of the suitability of this approach is also enabled through periodic monitoring when conditions safely allow.

It is normal for effluent volume and quality to fluctuate based on conditions of mining operations, weather, analytical precision and natural factors. Accordingly, a margin of safety between expected quality and permit limits has been incorporated into the modeling for the TAR and ultimately *EMA* Permit 11678 limits at the end-of-pipe. Considering this, the following TRP is conservatively protective of the environment (i.e., the approach is cautionary).

MPMC maintains a data management system that can be used for data monitoring purposes. All compliance and internal triggers are established in the database and an alert is automatically emailed to the Environmental Superintendent (and other qualified personnel) should an exceedance of a limit occur. As outlined in the CEMP, laboratory analytical data is uploaded to the database as soon as it is made available to the mine (or on the first working day thereafter).

Trigger response will be based on automatic exceedance alerts triggered by end-of-pipe (HAD-3) limit exceedances and on sampling undertaken at QUL-58 four times per year. Sampling at QUL-58 in combination with 5-sample 30-day frequency end-of-pipe (HAD-3) sampling will also be used in model verification.

Whenever safely possible, attempts will be made to sample at reference sites (QUL-2a and QUL-120a) during model verification.

Reference sites for background conditions have previously been QUL-120a and QUL-2a. However, location QUL-2a will be preferentially used due to better accessibility and safety. QUL-120a will be sampled annually.

Error! Reference source not found. provides a diagrammatic representation of the TRP decision-making process for end-of-pipe limits and Figure 4 provides a graphical representation of the TRP decision-making process for the receiving environment IDZ limits.

5.1.1 Effluent Limits (end-of-pipe)

MPMC maintains an end-of-pipe sampling point at the outlet of the WTP referenced as HAD-3 (EMS code E304230). This sample location is monitored at a 5-sample 30-day frequency as outlined in the CEMP (MPMC 2018). Samples are collected and shipped to a certified laboratory as outlined in the most current version of the Quality Assurance Manual, and required by Section 3.8.1 of *EMA* Permit 11678. It should be noted that under Levels 1 and 2, samples collected on the weekend (Friday to Sunday) cannot be shipped to the laboratory until the following Monday.

5.1.1.1 Level 1 Trigger: End-of-Pipe (HAD-3) 80% Early Warning Threshold– Monitoring and Response

Level 1 monitoring and response is undertaken should any parameter listed in Section 1.2.4 of *EMA* Permit 11678 exceed 80% of the discharge limit in the permit (with the exception of pH).

Level 1 monitoring and response is triggered when a database alert (automatically issued) indicates an exceedance of the 80% discharge limit. When this alert is received, the following response plan is initiated (flow chart representation in **Error! Reference source not found.**):

- Step 1: Collect effluent sample at HAD-3 and send for analysis.
- Step 2: Compare HAD-3 sample results to permit limits.
    - If sampling indicates levels less than 80%, proceed to Step 7.
    - If sampling indicates levels remain at or above 80%, proceed to Step 3.
- Step 3: Reduce discharge flows by 20% of the discharge at the time of the increased parameter values.
- Step 4: Review influent (E19) water quality data and compare to historic values.
- Step 5: Notify ENV Director of the Level 1 Alert.
- Step 6: Investigate cause and short term trends of rise in parameter values. Return to Step 1.
- Step 7: Once sampling indicates levels less than 80%, resume normal operations.
- Step 8: Document exceedance of the 80% target and investigation results in monthly report.

Sample(s) at HAD-3 will be collected as soon as reasonably possible. A "Priority" request will be made to the lab on any such additional sample such that turn around time to receive analytical results for the sample is reduced to two or three business days. It should be noted that samples collected on the weekend (Friday to Sunday) cannot be shipped to the laboratory until the following Monday.

5.1.1.2 Level 2: End-of-Pipe (HAD-3) Permit Exceedance – Monitoring and Response

Level 2 monitoring and response is undertaken should any parameter, listed in Section 1.2.4 of *EMA* Permit 11678, exceed the compliance limit.

The Level 2 trigger is initiated by a database alert (automatically issued), or when review of the data indicates an exceedance of a permit limit. When this alert is received, the following response plan is initiated (flow chart representation in Figure 3):

- Step 1: Place WTP in recirculation mode or shut down (following internal communication plan)
- Step 2: Notify ENV Director of exceedance
- Step 3: Collect samples of influent (E19) and effluent (HAD-3) and send for analysis. If weather conditions allow, collect sample at Quesnel Lake IDZ (QUL-58) and send for analysis.
    - Step 3a: If exceedance at QUL-58, proceed to Level 3 Alert (flow chart representation in Figure 4). If no exceedance, take no further action.
    - Step 3b: Compare HAD-3 sample results to permit limits.
        - If sampling indicates levels less than 80%, proceed to Step 5.
        - If sampling indicates levels at or above 80%, proceed to Step 3 of the Level 1 Alert.
        - If sampling indicates levels exceeding the permit limits, proceed to Step 4.
- Step 4: Investigate influent water quality and water treatment plant operations to determine cause of exceedance.
- Step 5: Notify ENV Director, and communicate progress and findings of investigation throughout the process.
- Step 6: Resume normal operation.
- Step 7: Submit exceedance investigation report to ENV Director

Sample(s) at HAD-3 will be collected as soon as reasonably possible. Sample(s) at QUL-58 will be collected as soon as reasonably possible, weather and safety permitting. A "Priority" request will be made to the laboratory on any such additional sample such that turn around time to receive analytical results for the sample is reduced to two or three business days. Since sampling at QUL-58 may not be possible for safety reasons, resumption of the discharge during a Level 2 Alert will be dependent on the effluent (HAD-3) meeting the permit limits in Section 1.2.4. Concurrently, an investigation will be implemented to determine the cause of the exceedance of the permit limit.

Once the monitoring and the investigation has been completed, a report will be submitted to the Director as outlined in *EMA* Permit 11678 Section 4.3. This report will include:

a) All relevant test results related to the exceedance event(s),
b) An explanation of the most probable cause(s) of the exceedance(s), and
c) A plan to prevent similar exceedance(s).

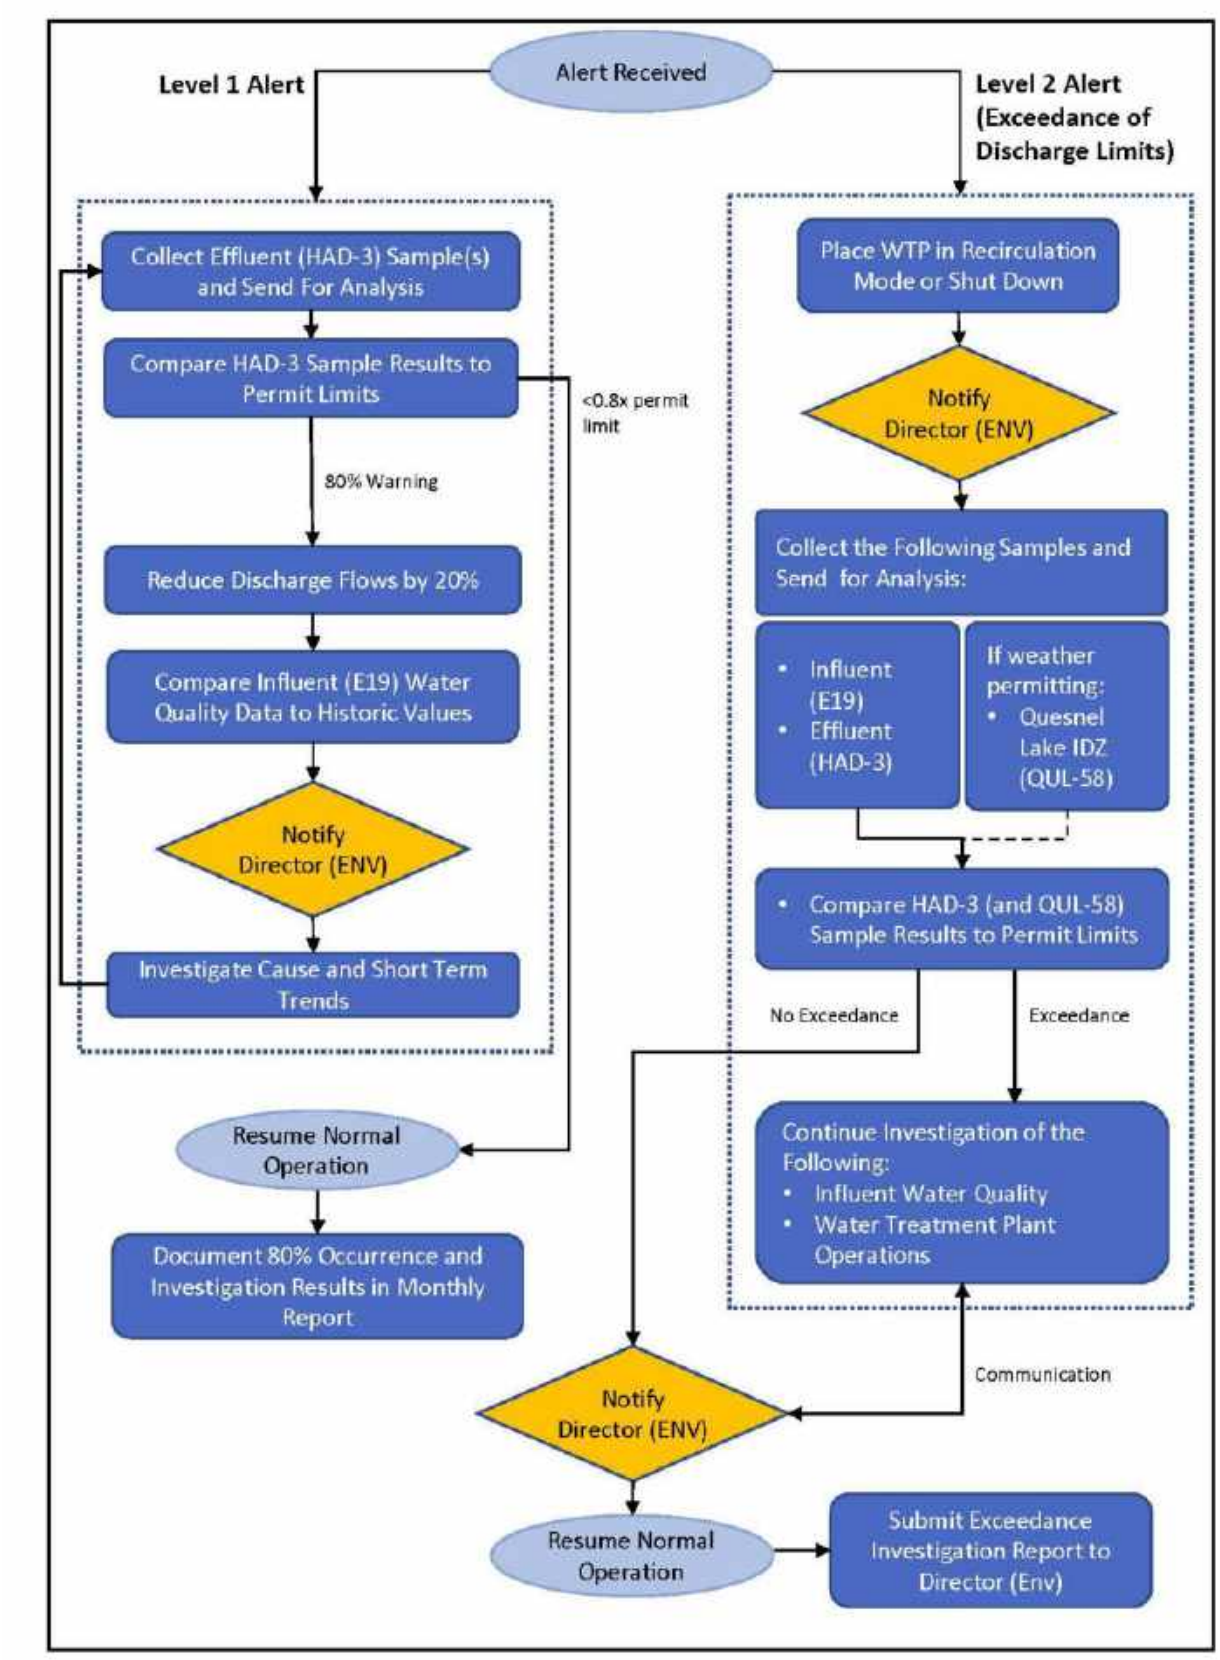

Figure 3. Flow chart representation of the TRP decision-making process for the treated effluent (end-of-pipe)

5.1.2 Edge of Quesnel Lake Initial Dilution Zone

MPMC maintains a sampling point at the edge of the IDZ referenced as QUL-58 (EMS code E304876). This sample location is monitored four times per year, as outlined in the CEMP (MPMC 2018). Samples are collected and shipped to a certified laboratory as outlined in the most current version of the Quality Assurance Manual, which is required by Section 3.8.1 of *EMA* Permit 11678. Ongoing sampling at QUL-58 will serve as a model verification for the near-field dispersion model (CORMIX – Golder).

5.1.2.1 Level 3: Exceedance of Receiving Environment Trigger Levels - Monitoring and Response

Level 3 monitoring and response is undertaken if any parameter listed in Section 1.2.4 of *EMA* Permit 11678 exceeds the receiving environment trigger levels set out in the right-most column of Table 4. Monitoring and response is triggered when a sample taken at QUL-58, either as part of routine sampling or following a Level 2 Alert, indicates an exceedance of these trigger levels. When this alert is received, the following response plan is initiated (flow chart representation in Figure 4):

- Step 1: Place WTP in recirculation mode or shut down (following internal communication plan)
- Step 2: Notify ENV Director of exceedance
- Step 3: Determine if weather conditions allow samples to be taken on Quesnel Lake safely.
    - If yes, sample QUL-58 and QUL-2a and send for analysis.
    - If no, use HAD-3 sample and most recent QUL-2a sample to model water quality at QUL-58.
- Step 4: Compare modelled and measured (if available) QUL-58 results to receiving environment trigger levels.
    - If exceedance, proceed to Step 5.
    - If no exceedance, proceed to Step 8.
- Step 5: Continue investigation of Quesnel Lake water quality by comparing current water quality data to historic data and modelled (TAR) data and dilution modelling.
- Step 6: Use water quality data and dilution modelling to determine discharge rate based on assimilative capacity.
- Step 7: Based on data, and subject to any directions the Director may give:
    - If the data does not support resuming operations, return to Step 5.
    - Resume operation. If discharge rate is less than permitted discharge rate, return to Step 3 and repeat the analysis. Otherwise, proceed to Step 10.
- Step 8: Notify ENV Director.
- Step 9: Resume normal operation.
- Step 10: Submit exceedance investigation report to ENV Director.

Sample(s) at QUL-58 and at QUL-2a (background) will be collected as soon as reasonably possible, weather permitting. A "Priority" request will be made to the lab so that turn around time to receive analytical results for the sample is reduced to two or three business days. It should be noted that samples collected on the weekend (Friday to Sunday) cannot be shipped until the following Monday.

A review and comparison of the re-sample data with parameter concentrations at the reference station QUL-2a (located in the West Arm of Quesnel Lake), which will serve as a reference comparison, shall be made, and the Relative Percent Difference (RPD) shall be calculated.

- If the RPD is ≤ 20%, the sampling results are considered to be analytically indistinguishable from the reference concentrations. The dilution capacity of Quesnel Lake will be assumed to be diminished and discharge will only be resumed as described below.

- If the RPD is > 20%, then a review of the existing monitoring data for the effluent discharge, the edge of the IDZ, and other monitoring points outside the IDZ in the receiving environment (e.g., QUL-2a, Edney Creek, Hazeltine Creek) shall be undertaken. This review shall include an evaluation of the estimated dilution at the edge of the IDZ. The estimated dilution shall be compared with the dilution factors predicted in the TAR.
- If the dilution is less than the minimum dilution predicted in the TAR:
    - An evaluation of the effluent and ambient conditions shall be undertaken to resolve the discrepancy. Depending on the outcome, the evaluation may include an inspection of the outfall pipes and diffuser ports to confirm that they are intact.
    - MPMC shall investigate and present the findings to the ENV Environmental Protection Director identifying the likely cause of the low dilution and its remedy.
    - MPMC shall provide an Interim Discharge Plan to the ENV Environmental Protection Director that outlines interim measures to be undertaken by MPMC to manage the water balance in accordance with EMA Permit 11678 and any requirements under *Mines Act* Permit M-200.
- If the dilution is greater than the minimum dilution predicted in the TAR, it is assumed that background concentrations are elevated and the dilution capacity of Quesnel Lake is diminished. Discharge will be resumed only when resampling the effluent discharge (while in recirculation mode) and resampling at QUL-58 indicate that the receiving environment trigger levels can be met using the minimum dilution predicted in the TAR (i.e., the dilution capacity of Quesnel Lake is no longer predicted to be diminished). The flow rate of the effluent discharge can be managed accordingly depending on the sampling results.

When monitoring and analysis has determined the WTP is effectively treating water to meet the end-of-pipe permit limit, and the dilution model indicates that the IDZ does not exceed the Edge of the IDZ trigger levels in Table 4, the Director will be notified and the WTP effluent will be redirected to the discharge pipeline.

Once the monitoring and the investigation has been completed, a report will be submitted to the Director as outlined in EMA Permit 11678 Section 4.3. This report will include:

- All relevant test results related to the exceedance event(s),
- An explanation of the most probable cause(s) of the exceedance(s), and
- A plan to prevent similar exceedance(s).

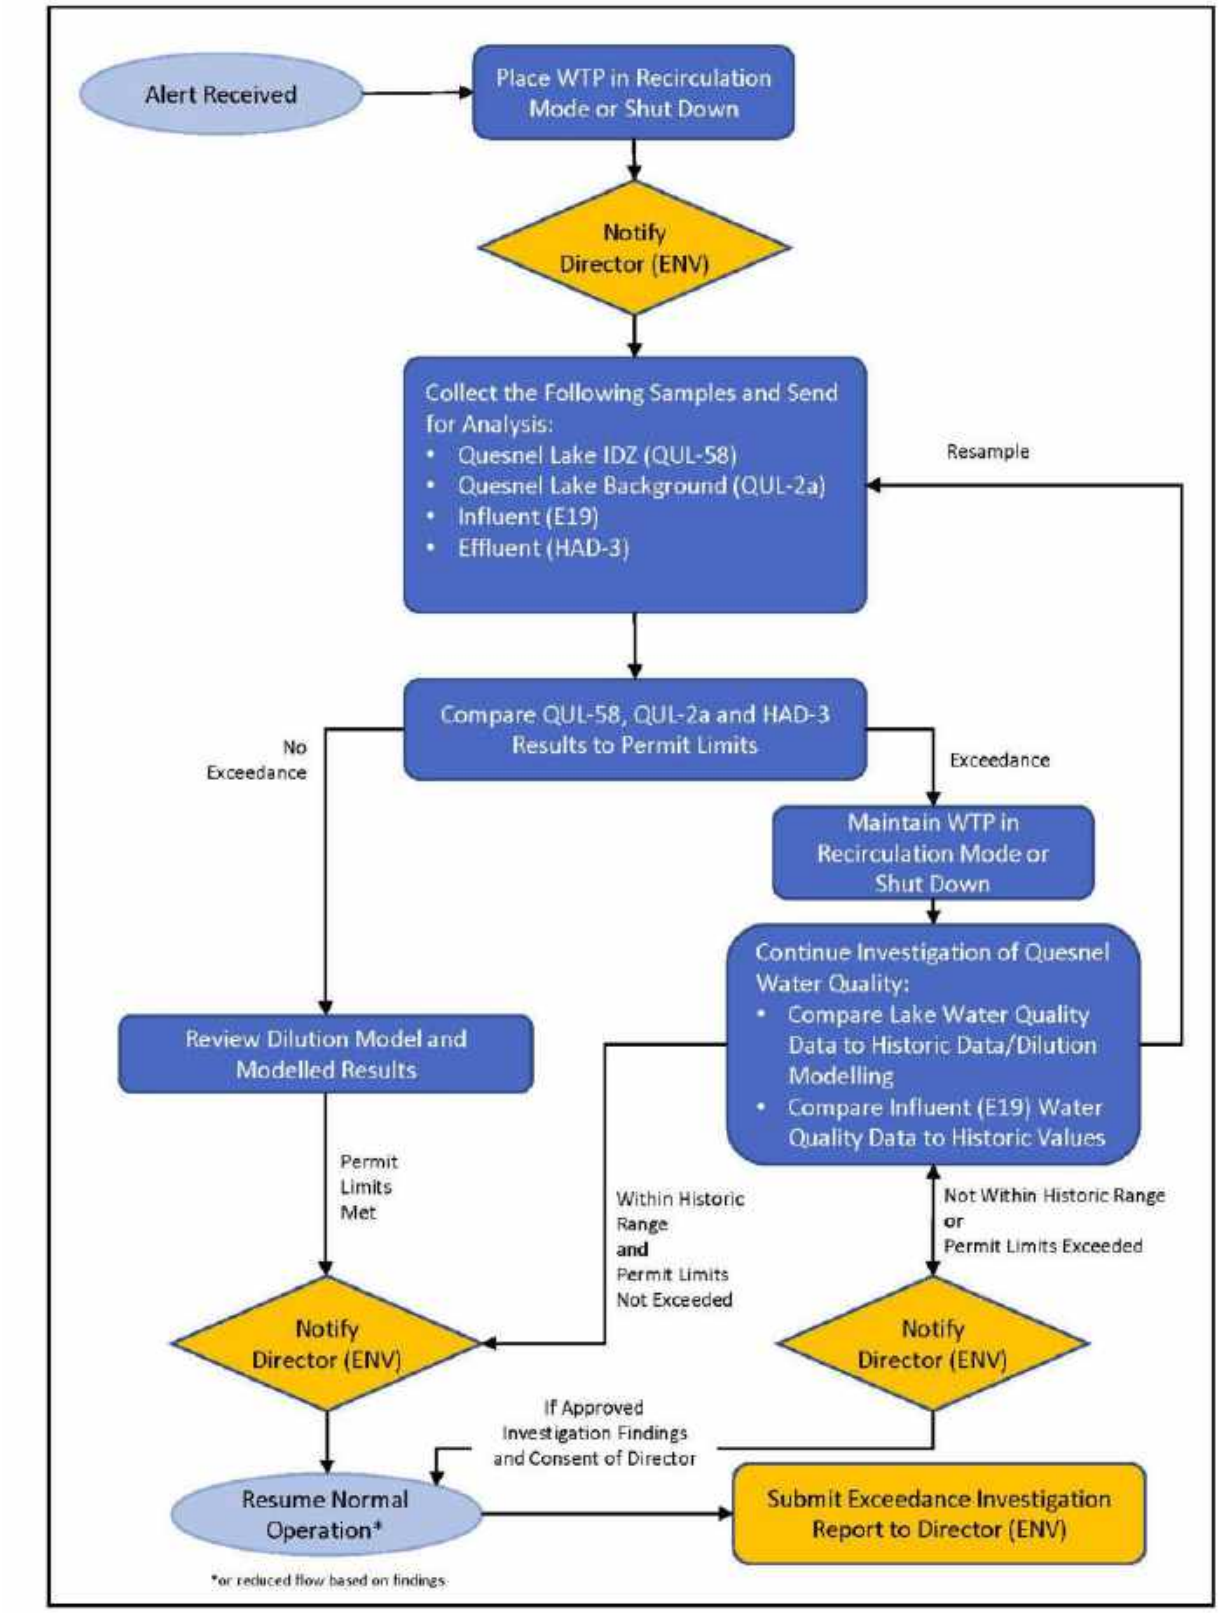

Figure 4. Flow chart representation of the TRP decision-making process for the receiving environment IDZ limits

5.2 Reporting: Ministry of Environment

In accordance with Section 4.0 of *EMA* Permit 11678, MPMC will submit required reports for each month that discharge occurs. Report shall include at a minimum:

- The volume of treated effluent discharged,
- a summary of continuous Turbidity readings of the treated effluent discharged, and
- the most recently available water quality results for the effluent discharged, including toxicity.
- Each monthly report shall be submitted within seven days of the end of previous month via email to EnvAuthorizationsReporting@gov.bc.ca.
- Each monthly report shall also contain and present all data submitted in the previous 2 monthly reports in a manner that would identify potential trends.

Any toxicity test failures, as defined and described in Section 4.4 of *EMA* Permit 11678, shall be reported to the ENV Environmental Protection Director as stipulated below. A sample is considered to have failed the specific toxicity test if:

- **96-hr LC50 Rainbow Trout:** Using 100% effluent concentration, more than 50% of the fish die within a 96 hour test period,
- **48-hr LC50 Daphnia magna:** Using 100% effluent concentration, more than 50% of the organisms die within a 48 hour test period,
- **7-day Ceriodaphnia dubia reproduction**: The water is determine to cause greater than 25% inhibition of survival and reproduction; or
- **7-day ELS toxicity test with a salmonid fish**: The water is determined to cause greater than 25% non-viable embryos.

MPMC will also notify the ENV Director of any non-compliance and take appropriate remedial action. MPMC will provide written confirmation of all non-compliance events within 24 hours of the original notification to the Director, and will follow up with a written report within 30 days, as described in Section 4.3 of *EMA* Permit 11678. In the case of the Edge of Quesnel Lake IDZ limits as outlined in Table 4, MPMC will notify the ENV Director of any exceedance and take appropriate action as outlined under the TRP (Section 5.1.2). MPMC will provide written confirmation of all Edge of Quesnel Lake IDZ limit exceedance events with 24 hours of the original notification to the Director, and will follow up with a written report on the steps taken under the TRP (Section 5.1.2) within 30 days and prior to resuming effluent discharge.

5.3 Reporting: Environment Canada

As required under *MDMER* Section 24 (1-2), the Inspector will be notified if effluent monitoring results show that concentrations exceed those limits for the parameters specified in *MDMER* Schedule 4; if the effluent is outside the pH range of 6.5 to 9.5; or, if the effluent is acutely lethal (greater than 50% mortality at 100% effluent concentration). A written report to the Inspector will follow within 30 days of the tests being completed.

If the effluent is determined to be acutely lethal, the effluent water quality samples will be characterized without delay and additional acute lethality sampling will be conducted as required under *MDMER* Section 15.

If deposits outside of the normal course of events occur, acute lethality testing will be completed as required by *MDMER* Section 14 (1). A written report meeting the requirements outlined in *MDMER* Section 31 will be submitted to the Inspector within 30 days.

5.4 Reporting: Local Communities

Reporting of any actions under this Plan will be in accordance with the Communication Plan developed under Section 2.11 of *EMA* Permit 11678.

1 Introduction

The BC Ministry of Forest, Lands and Natural Resource Operations (as per the British Columbia [BC] Inter-Ministry Invasive Plant Working Group) defines invasive plants as “non-native (alien) plants whose introduction into BC cause, or are likely to cause, economic or environmental damage, or harm to human health” (MFLNRO, 2014). The Invasive Species Council of BC has a similar definition, and notes that invasive plants can establish quickly and easily on both disturbed and un-disturbed sites, causing widespread negative economic, social, and environmental impacts (ISCBC, 2015).

Mining operations result in disturbed areas, which can be susceptible to invasion of invasive plants. Such invasions have the potential to hinder reclamation efforts or interfere with regional invasive plant management programs. To manage this risk, Mount Polley Mining Corporation (MPMC) has developed this Invasive Plant Management Plan (the “Plan”). The purpose of the Plan is to outline procedures for the prevention and, if necessary, control (mitigation) of the establishment of invasive plants or noxious weeds in the Mount Polley Mine (the “Mine”) area throughout the Mine project life, including closure.

1.1 Regulatory Framework

The BC *Weed Control Act* (RSBC, 1996) requires owners or occupiers of crown and private lands in BC (excluding those under federal jurisdiction) to control listed noxious weeds. As such, MPMC is under legal obligation to control these species. At the time of last update of this Plan, the BC Proposed Prohibited Noxious Weeds List (MFLNRO, 2016) was the most up to date applicable listing.

As per the BC *Mines Act* Section 10.7, mine land surfaces must be reclaimed to an approved end land use at closure, excluding lands that are not to be reclaimed, and the average land capability should be equal to or greater than the average land capability present prior to mining. While these requirements do not specifically mention invasive plants, they are inherently included; given the undesirable nature of invasive plants, their associated negative environmental and economic impacts, and the fact that invasive plants are non-native, such species are likely inconsistent with closure revegetation objectives and could result in a mining company not meeting their closure revegetation targets.

In addition, under MPMC’s *Mines Act* Permit M-200, the following additional specific conditions apply to invasive species management at the site:

- The Permittee shall manage and control invasive species that establish on the site and shall take reasonable efforts to ensure that invasive species do not move from the site to adjacent areas.
- The Permittee shall ensure that all seed mixes are certified as weed-free.
- Revegetation species shall be selected based on the principles of ecological succession and traditional use and cultural significance, including all reasonable efforts to use only native species unless short-lived agronomic species are required to temporarily control erosion or prevent ingress of invasive species.

While not associated with regulatory requirements, the Cariboo Chilcotin Coast Invasive Plant Council (CCCIPC) is a non-profit organization that coordinates the invasive plant management efforts of government agencies, individuals, communities and industry sectors, and promotes awareness and education about invasive plants in the region. Each year, the CCCIPC produces an Annual Strategic Plan (http://cccipc.ca/index.php/S=0/resources/regional-strategic-plans/) which incorporates provincial requirements (e.g., noxious weeds listings) and is to be used as a guide for invasive plant management activities and resource allocation in region.

2 Objectives

As described above, the purpose of the Plan is to outline procedures for the prevention and, if necessary, mitigation of the establishment of invasive plants or noxious weeds in the Mount Polley Mine area throughout the Mine project life and closure. The specific objectives are to:

- Control invasive plant establishment on the site, such that reclamation objectives are achieved. Reclamation objectives include establishing self-sustaining vegetative covers on disturbed areas at the Mine site with native vegetation this is appropriate to the target site series and consequently promotes the target end land use(s); and
- Implement invasive plant control measures consistent with the Regional Strategic Plan and the BC Proposed Prohibited Noxious Weeds List.

This Plan applies to the operations footprint of the Mine as well as areas being rehabilitated following the tailings dam embankment breach. However, only the Mine site is regulated under the BC *Mines Act* and associated items (e.g., permit requirements and land capability requirements) do not apply to breach rehabilitation areas. Instead, reclamation revegetation objectives for the breach area will be defined by the Remediation Plan due for submission in the third quarter of 2017.

The Plan follows the Plan, Do, Check, and Act cycle developed by the International Standards Organization guidelines. The cycle is described as follows:

- **PLAN** - identifies potential sources of invasive plant ingress that may challenge achieving the objectives of the program;
- **DO** - documents the prevention and control management practices in place at the Mine;
- **CHECK** - describes the monitoring procedures and methods for evaluating monitoring results against the objectives; and
- **ACT** - describes review of the management program and update of procedures based on monitoring results in order to promote its continuous improvement and mitigate identified deficiencies.

3 Plan: Identification of Potential Sources of Invasive Plant Ingress

Mining activities can facilitate the introduction or spread of invasive plants by removing native vegetation, which decreases competition for weedy plants, and creating exposed soil in disturbed areas. Exposed areas create a soil bed which may allow invasive plants to establish. These areas include:

- Soil stockpiles and areas from which the soil was salvaged;
- Soil applied to reclamation areas;
- Road and powerline construction and maintenance activities; and
- Exposed areas around the Mill site, maintenance areas and other associated infrastructure.

Table 1 provides an overview of potential sources of invasive plant ingress to the site. Each potential source is classified into if control is possible or not. If control is not possible, for example the movement of wildlife or wind transport of seed, only prevention methods (and, if necessary, mitigation measures) are applicable to management.

Table 1 Potential sources of invasive plant ingress and/or spread at the Mount Polley Mine site

Category	Source	Control Method Possible
Animals	Livestock	×
	Wildlife	×
Natural spread	Wind (long-distance)	×
	Rhizome spread or seed drop (short-distance)	✓ (within Mine site only)
Human-mediated spread	People – on-site (e.g., employees, and contractors)	✓
	People – off-site (e.g., tourists and recreationists; spread to areas immediately adjacent to site)	×
	Vehicles and equipment – on-site	✓

4 Do: Prevention and Control Measures

4.1 Preventative Measures

The primary goal involved in managing invasive plant infestations in the project area is to carry out mining activities in a manner that prevents the introduction or spread of invasive plants and supports the ability to establish desired species during site reclamation activities.

MPMC is to implement the following best management practices for preventing invasive plant establishment on disturbed areas at the Mine, which are to minimize disturbance during all phases of the mining operation in order to limit the availability of exposed, un-vegetated ground to invasive plant seed deposition; and establish a vegetative cover as soon as possible after ground disturbance. Specifics for establishing ground cover vegetation are as follows:

- Seed ground disturbed due to construction or mining activity with a rapidly establishing seed mix for erosion protection and invasive plant control if reclamation of the area is not imminent. Active areas (e.g., open pits or areas without appropriate substrates for vegetation growth) at the Mine do not require invasive plant control as vegetation does not have a chance to become established;
- Seed soil stockpiles; water management features such as ditches and sediment pond berms; borrow pits; road edges; powerline access roads and power pole installation sites; inactive sections of mill site areas, storage and equipment yards; and generally any disturbed ground where invasive plant establishment is possible;
- Use only high quality grade seed in the reclamation and interim invasive plant control seed mixtures. Low quality grade seed may contain a higher portion of weed seed in the seed lot. At minimum, ensure that the seed used for revegetation is of the grade Common #1 Forage Mixture or Canada No. 1 Ground Cover Mixture.
- Assess soil amendments that may contain invasive plant seeds or propagules. This is currently only applicable to biosolids, and MPMC's supplier (Metro Vancouver) tests the material to verify that invasive plant seeds are not present.

MPMC typically conducts a seeding program annually in the spring and/or fall, and any disturbed areas (as described above) or areas that were previously seeded but lack appropriate native vegetative cover, should be added to the list of areas to be seeded.

4.2 Control Measures

If monitoring results (Section 5) show areas of invasive species infestation that are not consistent with the objectives of this Plan (Section 2), available control or mitigation options for managing established invasive plants include mechanical, biological, and chemical methods.

Mechanical methods include:

- Hand weeding or pulling (if plants are hand-pulled, propagules are to be removed from the site and disposed of in a way that does not allow the spread of seeds. i.e., burned, not composted);
- Mowing or cutting; and
- Burning.

Biological control agents are natural organisms that are another option for reducing invasive species populations. Typically, they are insects, nematodes, fungi or viruses that infect or invade the invasive plants and weaken the target species by decreasing seed production and reducing density. Biological control is only an option for select invasive species

Chemical control through application of herbicides will be the method of last resort because applications are limited by proximity to watercourses and can potentially have detrimental effects on native vegetation.

In addition to these mitigation methods, contingency control programs that could be reviewed for feasibility and implemented are:

- Inspection and/or cleaning of vehicles or equipment coming from offsite or moving from an infested area to an uninfested area within the site;
- Refraining from driving through areas infested with invasive plants;
- Limiting road maintenance to the road surface to retain vegetation along the roadsides;
- Keeping equipment yards and vehicle storage facilities free of invasive plants; and
- Training personnel on preventing invasive plant spread by checking and removing seeds from clothing and equipment.

It is important to note that majority of the invasive plants observed at the Mine are designated in the CCCIPC Regional Strategic Plans as “established” or are designated as non-native species (not invasive species), and management options are not implemented regionally because control of these species is not currently feasible. As such, MPMC does not actively manage these species, unless they are directly impeding reclamation efforts. These aforementioned control measures are listed as options for future use, as required, and are currently not a routine component of MPMC’s invasive plant management activities, as the Plan objectives are being met without their use.

Mitigation measures will focus on the “new invaders” and “containment” categories, as well as any “established” species if they are directly impeding reclamation efforts. Consistent with the Regional Strategic Plan, the treatment goal for “new invaders” is eradication (elimination of all individuals and their propagules), while the treatment objective for species listed for “containment” is prevention of invasive

plants from spreading to uninfested areas. For species that are impeding reclamation revegetation, but are regionally listed under “containment” or “established” categories, the primary option will be suppression (reduction in plant population size and abundance). These control measures generally follow the following process, based on the level of infestation:

1. Prevent new infestations from becoming established;
2. Eradicate small or isolated “satellite” infestations;
3. Contain the perimeter of large “core” infestations; and
4. Suppress the interior of large “core” infestations.

If control measures area applied in the future, any sites that have treatments applied will be monitored through the established methods (described in Section 5) in subsequent years to assess if treatment measures have been successful.

5 Check: Monitoring Program

The MPMC invasive plant monitoring program includes visual surveys conducted in combination with routine assessments of progressive reclamation sites and annual soil stockpiles inspections; invasive plant species present and their percent cover are documented and compiled with revegetation results.

In addition, more formal invasive plant inventories are to be conducted routinely at the Mine site. These inventories should encompass disturbed areas, including any that are undergoing reclamation, as well as adjacent undisturbed areas from which invasive plants could ingress. Inventories may be conducted by MPMC Environmental Department staff with sufficient expertise or an external consultant. Each inventory should include the following items, with the results presented in a report:

- Surveying and mapping of infestation locations, with a focus on reclamation areas and soil stockpiles;
- Identification of invasive plant species present;
- Assessment of the degree of invasive plant growth, distribution, and density present at infestation sites;
- Assessment of success of any prevention and control measures that were previously implemented;
- Recommendations for any prevention and control measures that should be implemented; and
- Recommendations for when the next inventory should be conducted.

Where possible, all assessments and inventories should take place in the late spring/early summer so that eradication measures can be undertaken prior to seed dispersal in late summer/early fall. Alternatively, assessments and inventories can be conducted in mid to late summer, when plants are readily identifiable, with interpretation of results to take place over winter and management applications to be implemented early the following growing season.

6 Act: Program Review and Continuous Improvement

Each year, the results of invasive species monitoring should be reviewed with respect to the objectives outlined in Section 2, and the Plan and associated site invasive plant management activities should be updated accordingly. Specific items that should be reviewed and associated actions are listed in Table 2. When the Plan is updated, it is to be submitted to the Ministry of Energy and Mine with the Annual Environmental and Reclamation Report. In addition, an update on invasive plant monitoring, prevention

and control activities at the Mine (including any pertinent results from progressive reclamation and soil stockpile inspections, and site invasive plant inventory reports) is to be included in the Annual Environmental and Reclamation Report each year.

Table 2 Invasive plant management program review process

Item to Review	Associated Actions
Verify that all seed mixes used were certified weed-free (i.e., comply with Canadian Food Inspection Agency standards).	If seed utilized is not certified weed-free (or invasive plants were suspected to be present in the seed mixtures used): • Change seed suppliers and/or seed mixtures.
Verify that all soil amendments (where appropriate) were tested to confirm they did not contain invasive plant propagules or seeds.	If soil amendments were not tested: • Conduct post-application assessments for any soil amendments not tested; • Discontinue use of any soil amendments not tested until appropriate testing has been completed; and • Plan appropriately to test all amendments prior to use in the future.
Verify that no invasive plants identified in monitoring are on provincial noxious weed lists.	If any noxious weeds are identified: • Implement appropriate control measures (Section 4.2), with the objective of eradication; and • Ensure that measures taken are monitored as per the program in Section 5.
Verify that all invasive plants identified in monitoring are being managed according to the most recent CCCIPC Annual Strategic Plan.	If invasive plant management is inconsistent with the Regional Strategic Plan: • Implement prevention and/or control actions (Section 4) until management actions are consistent with the Regional Strategic Plan; and • Ensure that measures taken are monitored as per the program in Section 5.
Verify that results from reclamation revegetation assessments are consistent with closure objectives (with respect to species composition and/or functional groups). If results are not consistent, verify that invasive plants are not a constraining factor. The prioritization matrix in Figure 1 can be used to aid in separating innocuous from disruptive species in reclamation areas and prioritize management actions accordingly.	If invasive plants are identified as a constraint to meeting revegetation objectives: • Delineate the specific species and areas of concern; • Implement prevention and/or control actions (Section 4) appropriate for the level of infestation, the life history of the identified invasive plants, and available control options; and • Ensure that measures taken and target native reclamation species are monitored in the identified reclamation areas as per the program in Section 5.

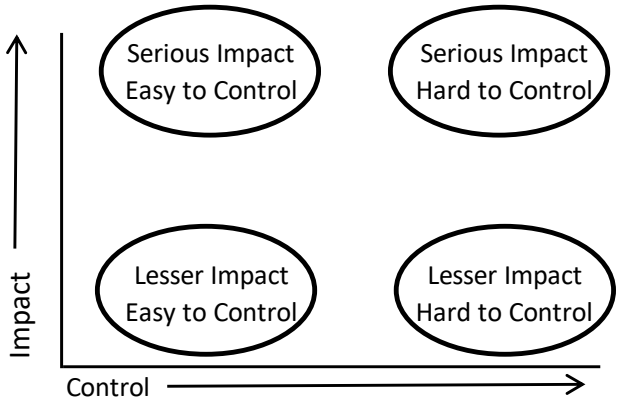

Figure 1 Invasive plant management prioritization matrix (adapted from USFWS, 2009)

7 Responsibilities

Responsible individuals for implementing this Plan are described below.

Environmental Superintendent or designate (e.g., Environmental Supervisor):

- Be knowledgeable of, adhere to, and coordinate implementation of all aspects of this Plan;
- Ensure all other responsible individuals have reviewed the most up to date version of this Plan;
- Ensure this Plan and monitoring data are reviewed annually and updated accordingly, with updates submitted in the Annual Environmental and Reclamation Report and appropriate management actions implemented;
- Be aware of high level mine planning to ensure that seeding of disturbed areas can be done in a timely manner and transport of soil is appropriately managed;
- Review updates to the MPMC *Mines Act* Permit 11678, BC *Mines* Act, CCCIPC Regional Strategic Plan and provincial noxious weed lists and regulations;
- Schedule and assign staff or external contractors to carry out all requirements of this Plan, including monitoring programs and reporting;
- Plan and budget for necessary invasive plant control measures;
- Obtain and permits or authorizations required for control measures that are implemented; and
- Ensure that individuals conducting monitoring, data interpretation, reporting, and planning and implantation of prevention and control measures have appropriate training.

Qualified individual conducting monitoring and reporting (e.g., Environmental Technician, contractor):

- Be knowledgeable of and adhere to all aspects of this Plan;
- Conduct assigned activities, such that all requirements of this Plan (at minimum) are met; and
- Have appropriate training and expertise for assigned components of this Plan.

Staff or contractors conducting control measures

- Have appropriate training and expertise for prevention and control actions they are implementing.

Mine Planning Engineer and General Foreman:

- Notify the Environmental Superintendent or designate of planned disturbances and any transport of soil materials;
- Where possible, minimize the disturbance of vegetated areas; and
- Transmit relevant information related to the aforementioned points to the Mine Operations Supervisors.

Mine Operations Supervisors:

- Supervise operators such that new disturbances and soil handling are conducted as planned.

1 INTRODUCTION

The Wildlife Management Plan (the Plan) was developed for the Mount Polley Mining Corporation (MPMC) for all operational activities of the Mount Polley Mine (the Facility). The Facility is located approximately 100 km northeast of the city of Williams Lake, British Columbia (BC), near the town of Likely, BC. For the purposes of this Plan, the term 'wildlife' will collectively refer to mammals, birds, amphibians, reptiles, and fish unless otherwise specified.

The objectives of the Plan are to:

- Meet the requirements of permits approved under the *Environmental Management Act* and *Mines Act*, in addition to all relevant provincial and federal wildlife regulations,
- Develop guidelines for minimizing the potential for mine-related impacts to wildlife at the Facility and its surrounding areas, with emphasis on protecting wildlife that have been designated as a *Species at Risk*,
- Describe concrete measures for how mine personnel can help minimize wildlife impacts through implementing best management practices, following protocols for specific types of wildlife encounters, and documenting and reporting observations,
- Ensure wildlife management is incorporated into the long-term goals of the Facility through comprehensive monitoring programs and reporting plans, recommendations for reclamation and closure planning, stakeholder consultation, and incorporation of adaptive management.

The Plan is a living document that may be periodically updated as new information becomes available or as authorizations and regulations change.

1.1 PERMIT REQUIREMENTS

The Plan is a component of the Comprehensive Environmental Management Plan (CEMP) which is a requirement of Permit 11678 issued under the provision of the *Environmental Management Act* (SBC 2003, c. 53.) by the BC Ministry of Environment and Climate Change Strategy (ECCCS, 2020). The implementation of wildlife monitoring programs that track the progress of wildlife and wildlife habitat impacted by mine-related activities is one of the objectives of the CEMP and is addressed in Section 5.4 of the Plan.

The Plan also addresses conditions outlined in the M-200 Permit issued under the provision of the *Mines Act* (RSBC 1996, c. 293) by the BC Ministry of Energy, Mines and Low Carbon Innovation, formerly known as the Ministry of Energy, Mines and Petroleum Resources (MEMPR, 2020). Conditions under the M-200 Permit include restrictions and requirements that protect wildlife and personnel (Section 5.3.1) and ensure wildlife habitat is incorporated into long-term land use goals during reclamation and closure planning (Section 5.5).

1.2 PROVINCIAL AND FEDERAL REGULATIONS

All phases of the Facility, including construction, operation, decommissioning, and reclamation, are regulated under the BC *Environmental Management Act* (EMA), BC *Mines Act*, as well as other legislation implemented by the BC Ministry of Forests, Lands, Natural Resource Operations and Rural Development (MFLNRORD) as outlined in MPMC (2019). The following provincial and federal *Acts* are additional legislation specifically relevant to wildlife and wildlife habitat:

- BC *Wildlife Act,*
- BC *Forest and Range Practices Act,*
- BC *Water Sustainability Act,*
- Canada's *Migratory Birds Convention Act,* and
- Canada's *Species at Risk Act.*

Not all the relevant *Acts* will be applicable for every activity carried out by MPMC. For further information on how the *Acts* relate to the management of specific wildlife and activities, refer to Section 3.0.

2 FACILITY DESCRIPTION

The Facility represents the permitted areas of the mine where most mine-related activities occur, as shown in Figure 1 of MEMPR (2020). The Facility generally includes:

- The tailings storage facility (TSF),
- The crusher and mill processing site, and,
- Operations areas (open pits, waste rock dumps, stockpiles, roads, etc.).

The Facility has been in a temporary Care and Maintenance phase since May 31, 2019. Care and Maintenance operations are focused primarily on general site maintenance to ensure that all pumps, sumps and water management systems are functioning as intended. Eleven full time employees work in four shifts, including day and night shifts. Environmental monitoring and sampling activities continue to be followed during the Care and Maintenance phase, as required by all permits. For further details regarding Facility operations, refer to the CEMP (MPMC, 2019).

2.1 TAILINGS STORAGE FACILITY (TSF)

The TSF at the Facility consists of tailings material and a single embankment made up of three dams, including the Main Embankment, Perimeter Embankment, and the South Embankment. During the TSF embankment failure that occurred on August 4, 2014, water (both supernatant and interstitial) was released from the TSF, resulting in much of the tailings within the TSF being exposed to the elements (i.e., no longer submerged).

The embankment failure of the Mount Polley TSF resulted in the deposition of tailings between Polley Lake and Hazeltine Creek (known as the Polley Flats); for the purpose of this Plan, the impacted areas between Polley Lake and Hazeltine Creek are also referred to as the Surrounding Areas (see Section 2.4).

2.2 CRUSHER AND MILL PROCESSING SITE

The crusher and mill processing site are comprised of the crusher and mill building, the coarse ore pile, tertiary pile, fine ore (mill feed) pile, and pebble pile. No crushing operations are conducted during the Care and Maintenance period.

2.3 PITS

Open pits at the Facility include the Cariboo and Springer Pits, while the waste rock dumps include the Temporary Northwest Potential Acid-Generating (PAG) Stockpile, North East Zone (NEZ) Rock Dump and the South East Rock Dump (SERD). Mineral extraction activities are not occurring during the Care and Maintenance period.

2.4 SURROUNDING AREAS

Surrounding Areas are defined as the areas outside the Facility (i.e., permitted mine area) that were impacted by the TSF embankment failure (Section 2.1), including Polley Flats and the Hazeltine Creek Corridor, which are now subject to ongoing remedial works and monitoring (Golder, 2017; MPMC, 2019). For the purpose of this Plan, the Surrounding Area will also refer to the primary road networks that connect to the Facility, such as the Morehead-Bootjack Forest Service Road (FSR), Gavin Lake Road, and Mitchell Bay Road.

The Surrounding Area is characterized by Interior Cedar Hemlock (ICH) biogeoclimatic (BEC) zone vegetation, which consists of Western red cedar, Douglas-fir, hybrid spruce, and subalpine fir, with a lesser presence of trembling aspen, black cottonwood, and paper birch (MPMC, 2019). Much of the area has previously been harvested in commercial logging operations and is currently used for cattle grazing (MPMC, 2019).

2.4.1 Polley Flats

Polley Flats is located south of Polley Lake and east of the TSF embankment failure (Section 2.1). Prior to the TSF embankment failure, Polley Flats was an established wetland with a riparian vegetation community that encompassed approximately 900 m of the upstream portion of Hazeltine Creek, where it immediately drained from Polley Lake. The wetland, Hazeltine Creek corridor, and their associated riparian vegetation were significantly impacted by the release of water and tailings during the TSF embankment failure. The release deposited large volumes of mine-related materials into the Polley Flats wetland area and Hazeltine Creek corridor, stripping the riparian vegetation and native soil (Golder, 2017). Since the TSF embankment failure, MPMC has been conducting ongoing remediation of Polley Flats, including removal of tailings, wetland reconstruction, earth mounding, soil placement, planting native seeds, shrubs, and trees, and installing coarse woody debris (CWD; Golder, 2017; MPMC, 2019). Multiple avian nest boxes were also installed to increase nesting sites for secondary cavity-nesting species, such as Tree Swallows and Mountain Bluebirds.

2.4.2 Hazeltine Creek Corridor

Hazeltine Creek (WSC: 160-585700) commences from the southern point of Polley Lake (WSC: 160-585700) and subsequently drains southeast for 8.5 km before terminating at Quesnel Lake (WSC: 160). Edney Creek (WSC: 160-5857-038) and Bootjack Creek (WSC: 160-5857-487) are tributaries of Hazeltine

Creek and are located approximately 1 km and 8.5 km upstream of the confluence of Hazeltine Creek and Quesnel Lake (Pedersen, 1998; Province of BC, 2021).

Hazeltine Creek provided extensive spawning habitat for Sockeye Salmon and Rainbow Trout prior to the TSF embankment failure (Pedersen, 1998). Following the TSF embankment failure, Hazeltine and Edney Creek were re-channelized and armoured, and engineered log structures were installed to improve fish rearing habitat (Golder, 2017). Passive wetland (sediment settling) ponds were constructed near the Quesnel Lake confluence to improve water quality and increase wildlife forage (Golder, 2017). Rehabilitation of the riparian habitat was initiated by planting native trees, shrubs, and seeds, and by using landscape techniques to improve site growing conditions, such as mounding soil, spreading CWD, and adding mulch (Golder, 2017).

3 WILDLIFE REGULATION OVERVIEW

The following provincial and federal regulations are the most relevant legislation applicable to wildlife and wildlife habitat during the life of the mine and, along with the applicable permit conditions, are the foundation for the guiding principles in this document. Not all provincial and federal legislation will be applicable for every operational activity at the Facility. If there are any concerns regarding whether a specific activity will contravene one of the following regulations in this section, personnel should consult with the Operations Supervisor or Accountable Facility Representative for further clarification and guidance.

3.1.1 BC *Wildlife Act*

The BC *Wildlife Act* protects almost all vertebrate species from direct harm, except from activities that are authorized under regulation. The *Wildlife Act* includes provisions for wildlife prohibitions and authorizations, where applicable, such as:

- Hunting and trapping,
- Angling,
- Beaver dam removal,
- Attracting dangerous wildlife,
- Wildlife capture,
- Birds, nests and eggs,
- Transportation of wildlife,
- Accidental killing of wildlife,
- Destruction of animals,
- Endangered wildlife (Species at Risk), and
- Fines and penalties.

Section 34 of the BC *Wildlife Act* also provides specific instructions for the protection of birds, nests, and eggs, including for bird species not adopted under Canada's *Migratory Bird Convention Act* (MBCA). Under this section, it is an offence to possess, take, injure, molest, or destroy a bird, its egg, and its nest when occupied (*Wildlife Act*, RSBC 1996, c. 488., s. 34). Nests belonging to an eagle, peregrine falcon, gyrfalcon,

osprey, heron, or burrowing owl are also protected year-round regardless of occupancy (*Wildlife Act*, RSBC 1996, c. 488., s. 34).

Prior to initiating any activity that may be in contravention of the BC *Wildlife Act*, authorization under a provincial permit would be required. A permit associated with the listed activities under the *Act* are typically only authorized if the activity does not contravene a federal act (e.g., *MBCA*).

The Minister responsible for the BC *Wildlife Act* may designate a wildlife species as a *Species at Risk* subject to additional protection under the *Act*. Most species that have been designated as a *Species at Risk* in BC by the responsible Minister have been designated through Provincial Order under the BC *Forest and Range Practices Act* (FRPA) to enable conditions that will protect these species during forest and range activities on Crown land (see Section 3.1.2). However, only four species to date have been designated as a *Species at Risk* under the BC *Wildlife Act*. Refer to Table 1 in Section 4.0 for a list of the designated *Species at Risk* under the *Act* which have been previously documented in the Cariboo Region.

Mine activities that have the potential to impact wildlife should occur within the applicable timing windows, where possible, to avoid contravention of the BC *Wildlife Act* (see Section 5.1).

3.1.2 BC *Forest and Range Practices Act* (FRPA)

The Minister responsible for the BC *Wildlife Act* has the authority to issue a Provincial Order that identifies wildlife species that may require management and protection during activities that occur on Crown Land (Section 3.1.1). To date, most of these Orders have been established under Sections 11 and 13 of the *Government Actions Regulations* (BC Reg. 582/2004) of FRPA (SBC 2002, c. 69.). Wildlife species protected under FRPA through Provincial Order fall into one of two categories, including *Species at Risk* and Ungulates. Species in one of these two categories are subject to additional protection under FRPA during forest and range activities on Crown land through management of habitat areas, ungulate winter ranges, and implementation of general wildlife measures associated with the target species. A third category for *Regionally Important Wildlife* is still under consideration by the Minister.

The Order for the Ungulate category currently includes elk (*Cervus canadensis*), moose (*Alces americanus*), and three populations of Caribou (*Rangifer tarandus*), including the boreal, southern mountain, and northern mountain populations. For a summary of wildlife species that have been designated as a *Species at Risk* under FRPA in the Cariboo Region, refer to Table 1 in Section 4.0.

Activities governed by FRPA generally include timber harvesting, road construction, road maintenance, road use, road deactivation, silviculture treatments, collection of botanical forest products, fire use, control and suppression, or activities carried out under the BC *Forest Act*, a special use permit, or a road use permit (*Forest and Range Practices Act*, SBC 2002, c. 69.). Not all mining activity is expected to fall into the prescribed categories governed by FRPA; however, should any activity undertaken by the mine fall under FRPA's mandate, additional protection measures for the species identified by the Orders may apply.

3.1.3 BC *Water Sustainability Act* (WSA)

The BC *Water Sustainability Act* (WSA) provides protection for aquatic systems and fish habitat and includes mechanisms for authorizations to conduct work activities in and around streams (*Water Sustainability Act*, SBC 2014, c. 15.). Additional provisions for protecting and reducing risk to sensitive streams that contain fish are outlined in Sections 18 – 20 of the *Water Sustainability Regulation* (BC Reg. 36/2016). Work activities occurring in, or around, streams should target the appropriate Fisheries Timing Window to reduce the risk to aquatic organisms (see Section 5.1). Consultation with a Qualified Environmental Professional (QEP) may be required if additional instream mitigation is requested as part of the authorization to conduct the works.

3.1.4 Canada's *Species at Risk Act* (SARA)

Additional prohibitions may apply for species that have been designated as extirpated, endangered, or threatened under Schedule 1 of Canada's *Species at Risk Act* (SARA). It is prohibited to kill, harm, harass, capture, take, possess, collect, buy, sell, or trade any species listed under Schedule 1 of the *Act* (*Species at Risk Act*, SC 2002, c. 29., s. 32.). In addition, the damage or destruction of the residence (e.g., den, nest, etc.), or any part of the critical habitat of a listed species, is prohibited for endangered or threatened species, or for extirpated species that have a recovery strategy that recommends its reintroduction into the wild (*Species at Risk Act*, SC 2002, c. 29., s. 33., s. 58.). Critical habitat is defined as, "the habitat that is necessary for the survival or recovery of a listed wildlife species and that is identified as the species' critical habitat in the recovery strategy or in an action plan for the species" (*Species at Risk Act*, SC 2002, c. 29., s. 2(1).).

Except for listed aquatic species and listed bird species also protected under Canada's MBCA, prohibitions under SARA apply on federal lands only. However, a Federal Order can be issued to the Province by the Governor in Council requesting further intervention for a SARA-listed species on non-federal lands. Therefore, most terrestrial species that are listed under Schedule 1 of SARA, including their associated residence and critical habitat, fall within the jurisdiction of the Province and will be subject to protection measures that will vary depending on the recovery strategy for that species, scope of works, habitat present, and whether the species is part of a Federal Order that requires the Province to adopt the prohibitions of SARA on non-federal lands.

For a summary of wildlife species adopted under Schedule 1 of SARA that have been documented in the Cariboo Region, refer to Table 1 in Section 4.0.

3.1.5 Canada's *Migratory Bird Convention Act* (MBCA)

The MBCA protects most birds in Canada (including non-migratory species) through provisions outlined in the *Migratory Birds Regulations* (MBR) which stipulate that an individual must not (CRC, c. 1035., s. 5(1)):

- Capture, kill, take, injure or harass a migratory bird (i.e., a bird listed under the *Act*),
- Destroy, take or disturb an egg; or,
- Damage, destroy, remove or disturb a nest, nest shelter, eider duck shelter or duck box.

Permits authorizing some of the actions listed in Section 5(1) of the MBR is possible to obtain for certain activities, such as scientific research. However, there is no permitting process to undertake an activity that

may incidentally result in one of the actions outlined in Section 5(1) of the MBR, such as vegetation clearing. Therefore, incidental disturbance to breeding birds protected under the MBCA, including their eggs, young, and nests, constitutes a non-compliance under the MBCA. The best method of avoiding a non-compliance under the MBCA is to avoid work activities in an area where birds are actively breeding (see Section 5.1.2). When this option is not feasible, there are risk-management strategies that may be utilized as outlined in Section 5.2.1.

4 SPECIES AT RISK

In BC*, Species at Risk* are collectively managed under the BC *Wildlife Act*, the BC *FRPA*, and Canada's *SARA.* Wildlife that are designated as a *Species at Risk* may fall under one or more of these *Acts*. Prohibitions that may apply for species protected under these *Acts* are summarized in Section 3.0.

A list of *Species at Risk* adopted under provincial and/or federal legislation were narrowed down to highlight species that have the potential to occur at the Facility and in the Surrounding Areas, or within the Cariboo Region (BC CDC, 2021). However, *Species at Risk* that were determined to be primarily habitat specialists based on elevation or vegetation requirements (e.g., Bunchgrass BEC zone) in the Cariboo Region were excluded from the final list. Refer to Table 1 for the list of *Species at Risk* that were determined to have the highest potential of occurring at the Facility or in the Surrounding Areas.

Most species in Table 1 are not anticipated to be encountered on the grounds of the Facility. Instead, species in Table 1 are more likely to be encountered in transit to the mine, or in the Surrounding Areas. The exception may include barn swallows or *Myotis* (bat) species attempting to utilize anthropogenic structures for nesting and hibernacula. Refer to Section 5.2 for guidelines regarding wildlife encounters that have a higher potential of occurring at the Facility.

A number of wildlife species have been identified by the BC Conservation Data Centre as vulnerable (i.e., Blue or Red-listed) but have not yet been legally adopted under any statute. For a list of these species, refer to Appendix A.

Table 1. *Species at Risk* adopted under the BC *Wildlife Act*, BC *Forest and Range Practices Act* (FRPA), and/or Schedule 1 of Canada's *Species at Risk Act* (SARA)[1]

Wildlife Species			Adopted under Act? (YES / no)			Conservation Status	
English Name	Scientific Name	Category	FRPA	Wildlife Act	SARA	BC List[2]	SARA[3]
American Badger	*Taxidea taxus*	Mammal	YES	no	YES	Red	E (2018)
American White Pelican	*Pelecanus erythrorhynchos*	Bird	YES	YES	no	Red	no status
Barn Swallow	*Hirundo rustica*	Bird	no	no	YES	Blue	T (2017)
Black Swift	*Cypseloides niger*	Bird	no	no	YES	Blue	E (2019)
Bobolink[4]	*Dolichonyx oryzivorus*	Bird	no	no	YES	Blue	T (2017)
Bull Trout	*Salvelinus confluentus*	Fish	YES	no	no	Blue	no status
Caribou (Southern Mountain Pop.)	*Rangifer tarandus pop. 1*	Mammal	YES	no	YES	Red	T (2003)
Common Nighthawk	*Chordeiles minor*	Bird	no	no	YES	Yellow	T (2010)
Evening Grosbeak	*Coccothraustes vespertinus*	Bird	no	no	YES	Yellow	SC (2019)
Fisher	*Pekania pennanti*	Mammal	YES	no	no	no status	no status
Flammulated Owl[4]	*Psiloscops flammeolus*	Bird	YES	no	YES	Blue	SC (2003)
Great Blue Heron, *herodias* subspecies	*Ardea herodias herodias*	Bird	YES	no	no	Blue	no status
Grizzly Bear	*Ursus arctos*	Mammal	YES	no	YES	Blue	SC (2018)
Lewis's Woodpecker	*Melanerpes lewis*	Bird	YES	no	YES	Blue	T (2012)
Little Brown Myotis	*Myotis lucifugus*	Mammal	no	no	YES	Yellow	E (2014)
Long-billed Curlew	*Numenius americanus*	Bird	YES	no	YES	Blue	SC (2005)
Northern Myotis	*Myotis septentrionalis*	Mammal	no	no	YES	Blue	E (2014)
Olive-sided Flycatcher	*Contopus cooperi*	Bird	no	no	YES	Blue	T (2010)
Painted Turtle - Intermountain - Rocky Mountain Population	*Chrysemys picta pop. 2*	Reptile	no	no	YES	Blue	SC (2007)
Red-necked Phalarope	*Phalaropus lobatus*	Bird	no	no	YES	Blue	SC (2019)
Rusty Blackbird	*Euphagus carolinus*	Bird	no	no	YES	Blue	SC (2009)
Sharp-tailed Grouse, *columbianus* subspecies	*Tympanuchus phasianellus columbianus*	Bird	YES	no	no	Blue	no status
Short-eared Owl	*Asio flammeus*	Bird	YES	no	YES	Blue	SC (2012)
Western Grebe	*Aechmophorus occidentalis*	Bird	no	no	YES	Red	SC (2017)
Western Toad	*Anaxyrus boreas*	Amphibian	no	no	YES	Yellow	SC (2018)
Wolverine	*Gulo gulo*	Mammal	no	no	YES	no status	SC (2018)
Yellow-breasted Chat[4]	*Icteria virens*	Bird	YES	no	YES	Red	E (2003)

[1] BC CDC Search criteria: Vertebrates AND SARA Schedule 1 Status: True OR Identified Wildlife Status: True AND Area of Interest: User Defined Polygon. The exported BC CDC list was further filtered by comparing the results to the CDC mapped locations, COSEWIC distribution maps, and Habitat Wizard wildlife observation points.

[2] Based on Status designated by BC Conservation Data Centre – Yellow = Least Risk, Blue = Special Concern, Red = Endangered/Threatened.

[3] Based on Status designated under SARA – SC = Special Concern, T = Threatened, E = Endangered. The year the status was adopted is in brackets.

[4] These species are at the northern extent of their range but may occur periodically in the region as vagrants.

5 WILDLIFE MANAGEMENT

5.1 TIMING WINDOWS

Reduced Risk Timing Windows for fish and wildlife are intended to provide specific timing windows to target during operational planning to lower the potential for impacts to fish and wildlife. Least risk timing windows typically coincide with the breeding period for a given species, although they may also encompass other life history activities, such as juvenile dispersal and migration events. These timing windows do not guarantee that there will be zero risk to fish and wildlife during these periods, and do not authorize anyone to conduct or participate in activities that are contrary to any statute.

5.1.1 Fisheries Timing Window

To reduce the risk of contravening the WSA (see Section 3.1.3), all work activities that occur instream should utilize the appropriate fisheries timing window for the region. Fisheries timing windows (also referred to as in-stream work windows) apply to all fish-bearing streams and watercourses that have direct connectivity to fish-bearing waters downstream. Within the Central Cariboo District, all streams located at elevations less than 1325 m have a reduced risk timing window of **July 22 – August 15** to account for the presence of both spring and fall spawning fish species occupying the system (Province of BC, 2004). However, this timing window does not necessarily protect anadromous salmonids in freshwater systems; therefore, the regional Department of Fisheries and Oceans (DFO) should be consulted prior to working in any streams where salmon may be present to determine whether adjustments to the reduced risk timing window is required.

If instream works must occur outside the fisheries timing window, a Change Approval authorization may be required through MFLNRORD. In addition, the implementation of risk-management strategies under the direction of a QEP may be a condition of authorization.

5.1.2 Bird Nesting Window

To reduce the risk of contravening the BC *Wildlife Act* (see Section 3.1.1) and MBCA (see Section 3.1.5), any activity that may impact breeding birds, including their eggs and nests, should be conducted outside of the peak breeding period for birds in the region; for example, vegetation clearing or removal of buildings that birds are actively nesting on. The least-risk period for nesting birds in the region is from **August 12 – April 14,** which is the period when less than 5% of the majority of actively breeding birds in forest and wetland habitat are expected to be present within the region (ECCCS, 2018). In addition, any nest belonging to an eagle, peregrine falcon, gyrfalcon, osprey, heron, or burrowing owl is protected year-round regardless of whether the nest is active (*Wildlife Act*, RSBC 1996, c. 488., s. 34). Should an **inactive** nest belonging to one of these species require removal, authorization through MFLNRORD would be required.

If the peak nesting period cannot be avoided, additional risk-management strategies may be required under the direction of a QEP (see Section 5.2.1).

5.1.3 Amphibian and Reptile Window

An amphibian and reptile timing window has not been formally developed for the Cariboo Region. However, to avoid contravention of the BC *Wildlife Act* (see Section 4.1.1), operational activities should avoid areas where amphibian and reptile species have been confirmed hibernating, breeding or migrating. All amphibian species native to the Cariboo region require different habitat types (both aquatic and terrestrial) at different times of the year. Adult amphibians breed and lay eggs in freshwater, where they hatch into aquatic larvae, that grow and metamorphose into semiterrestrial juveniles. Highest risk periods for amphibians are typically related to movement of individuals between different habitat types, including migration of adults between aquatic breeding habitat and upland foraging or overwinter sites, or dispersal of juvenile amphibians from aquatic breeding sites to nearby terrestrial habitats. Although reptiles in the region, such as the Western Painted Turtle, Common Garter Snake, and Wandering Garter Snake, do not breed aquatically, their life history is also characterized by seasonal movements between different habitats. Due to both groups' heavy reliance on, and association with, freshwater habitats, any work in and around wetlands, streams, or small water bodies (including water-filled ditches), may also pose a risk of harm to individuals or damage to habitat. The highest risk period for amphibians and reptiles occurs between April 1 and September 30, when individuals of these species are expected to be active on the landscape (i.e., not hibernating) (BC MOE, 2017). Therefore, the reduced risk timing window for amphibians and reptiles is estimated to be **October 1 – March 31** for the Cariboo Region.

If amphibians or reptiles have the potential to be impacted by an activity, such as a clearing and grubbing, the completion of a survey under the direction of a QEP may be required to determine if amphibians, reptiles, or their habitats, are present, and/or at risk. If amphibians or reptiles cannot be avoided, a salvage that has been authorized by MFLNRORD through a General Wildlife Permit may be required so that amphibians or reptiles can be safely translocated from the site to nearby suitable habitat.

5.2 WILDLIFE ENCOUNTERS

To avoid contravention of the relevant wildlife legislation outlined in Section 3.0, wildlife-specific strategies may be required during human-wildlife encounters at the Facility, or within the Surrounding Areas. In most circumstances, allowing the animal to leave the area and reporting the incident to the Operations Supervisor or Accountable Facility Representative, will be the best course of action. In certain situations, further mitigation may be required based on the time of year, status of the species, and nature of the anticipated work activity. Individuals should consult with the Operations Supervisor or Accountable Facility Representative if they have any questions regarding protocols for a particular situation that involves a wildlife encounter. Additional in-house training may be required for some personnel to ensure they have the skills to safely handle human-wildlife conflicts, such as bear encounters, and identify sensitive wildlife features.

5.2.1 Birds

The majority of birds in BC are collectively protected under the BC *Wildlife Act*, Canada *MBCA*, and/or Canada's SARA, which generally acknowledge that birds are most vulnerable during the breeding period when adults are caring for nests, eggs, and young (see Sections 3.1.1 and 3.1.5). The following mitigation measures will be implemented if actively breeding birds are encountered at the Facility or in the Surrounding Areas:

- The destruction or disruption of migratory birds, nests, and eggs, is prohibited, including during travel to and from work sites. If destruction or disruption occurs in the form of incidental harm (i.e., unintentional), the incident will be immediately reported to the Operations Supervisor or Accountable Facility Representative.
- To reduce the risk of encountering and disturbing breeding birds, any activity that has the potential to disturb and harm birds, nests, eggs, or young, should be completed outside of the peak avian breeding period for the region (see Section 5.1.2). Vegetation clearing would be a common example of this.
- Report any active bird nests, or repeat observations of breeding pairs, to the Operations Supervisor or Accountable Facility Representative. Birds that are observed at the same location on consecutive days, hover in close proximity to humans, or display agitated behaviour such as persistent alarm-calling or dive-bombing (i.e., swooping down close, before veering away) are evidence that a breeding pair and nest may be present.
- If an active nest or established breeding pair continue to occupy an area of the Facility where the presence of personnel is only periodic and work activity is not constantly occurring (e.g., water sampling), the Accountable Facility Representative may recommend the installation of a buffer around the nest site to signal to other crew members to avoid the area to reduce disturbance. Only the periphery of the buffer should be marked and never the nest or nest tree, itself. Common buffer sizes used according to different avian groups, include (MFLNRO, 2013; MFLNRO, 2014):
    - Songbirds – 30 m radius,
    - Waterfowl – 100 m radius,
    - Swallow colonies – 50 m radius, and
    - Raptors: 100 – 500 m radius (species dependent)
- If an active nest or established breeding pair continue to occupy an area of the Facility where personnel will be regularly present for mine activities that occur for an extended period of time (e.g., geotechnical drilling), or the species is determined to be a designated *Species at Risk* from Table 1, the Accountable Facility Representative may consult with a QEP to determine the most suitable mitigation measures appropriate for the species, habitat, and magnitude of the anticipated disturbance.
- Report the presence of any stick nests to the Operations Supervisor or Accountable Facility Representative since some stick nests are protected year-round regardless of occupancy (see Section 3.1.1).
- Any birds nesting on anthropogenic structures (e.g., barn swallows and cliff swallows) must be allowed to finish nesting once nesting has commenced. If a building with intact barn swallow nests has been scheduled for demolition or removal outside the peak breeding period, consultation with MFLNRORD will be required since barn swallows (and their nests) are protected under Schedule 1 of SARA (see Section 3.1.4).

5.2.2 Mammals

Small and large mammals are regularly documented at the Facility, including black bears, coyotes, lynx, moose, and mule deer. Although the presence of some mammal species on the mine is to be expected due to the remote location of the Facility, the objective is to minimize interactions and, thereby, risks to personnel and animals. The following measures will be implemented if mammals are encountered at the Facility or in the Surrounding Areas:

- Reduce driving speeds to avoid a potential collision with mammal species, especially during hours at dawn and dusk when wildlife activity is heightened, and along known wildlife migration corridors; refer to Section 5.3.2 for further guidelines to prevent wildlife-vehicle collisions.
- Avoid approaching or feeding any mammal species. Food and waste should be securely stored in buildings, approved waste receptacles, or vehicles at all times; Refer to Section 5.3.3 for further guidelines on how to manage for wildlife attractants.
- If a mammal is a designated *Species at Risk* (e.g., caribou), as listed in Table 1 (Section 4.0), disturbance should be reduced to a minimum until the animal has left the area. If driving, temporarily stop the vehicle or pull over if it is safe to do so. If the animal has occupied a work area where mine activities are occurring, temporarily suspend works until the animal has moved out of the work area. All sightings of *Species at Risk* at the Facility should be reported to the Operations Supervisor or Accountable Facility Representative as soon as possible. If repeated observations of a *Species at Risk* occur at a specific location at the Facility, or in the Surrounding Areas, consultation with a QEP may be required to determine the appropriate course of action for that species.
- If a suspected residence (e.g., den or borrow) of a mammal species is encountered, a GPS coordinate will be collected (if possible) and the location will be immediately reported to the Operations Supervisor or Accountable Facility Representative. If there is evidence the suspected residence of a large mammal species is active due to the presence of recent scat, hair, and/or tracks, the crew will immediately leave the area of the residence until further instructions can be provided by the Accountable Facility Representative.
- If a kill site (e.g., carcass locations that will attract wildlife) or mineral lick (e.g., an area where ungulates regularly congregate to obtain mineral nutrients) is discovered, immediately report the location to the Operations Supervisor or Accountable Facility Representative.
- If conflict wildlife, such as habituated bears or cougars, are observed at the Facility or in the Surrounding Areas, the observation should be reported to the Operations Supervisor or Accountable Facility Representative so that the regional Conservation Officer Service can be notified. Personnel should never attempt to engage with conflict wildlife.
- Mine personnel and visitors whose job responsibilities may place them in a situation where a bear encounter is possible must have bear safety awareness training and be trained on how to safely carry and deploy bear deterrents, such as bear spray.

5.2.3 Bats

Fourteen species of bat have the potential to occur within the Cariboo region, including the Northern Myotis and Little Brown Myotis which are both designated as Endangered under Schedule 1 of Canada's *SARA* (Section 4.0). Both the Northern Myotis and Little Brown Myotis have the potential to occur at the Facility or within the Surrounding Areas. Summer roost sites and winter hibernation sites (i.e., hibernacula) are critical for most bats to carry out their sensitive life stages (BC MOE, 2016), and therefore, preservation of these sites is important for the conservation of these species. Roosts may be found in the cavities or loose bark of trees, rock crevices, caves, cliffs, and anthropogenic structures, such as buildings and bridges (BC MOE, 2016).

The following measures will be implemented if bat presence is suspected or confirmed at the Facility or in the Surrounding Areas:

- If the presence of a bat roost or hibernacula is suspected at the Facility or in the Surrounding Areas, a GPS coordinate will be collected (if possible) and the location will be reported to the Operations Supervisor or Accountable Facility Representative.
- If the presence of a bat roost or hibernacula is suspected in an area scheduled for vegetation removal, further instruction will be required from the Accountable Facility Representative. A survey by a QEP may be necessary prior to initiating the works.
- If a natural cave feature is identified, a GPS coordinate will be collected (if possible) and the location will be reported to the Operations Supervisor or Accountable Facility Representative. No personnel shall attempt to enter a natural cave feature that has been identified.
- If bats are observed utilizing an anthropogenic structure at the Facility, the location will be reported to the Operations Supervisor or Accountable Facility Representative. Further recommendation for mitigation may be provided by the Accountable Facility Representative if there is concern bats and personnel will be in close proximity during work activities.
- Prior to removal of any buildings or structures at the Facility, a survey may be required by a QEP to ensure the building or structure is not being utilized by a designated *Species at Risk*, such as the Little Brown Myotis, which are known to use anthropogenic structures for roosting and overwintering.

5.2.4 Amphibians and Reptiles

Amphibians and reptiles rely on aquatic and terrestrial habitat to carry out their necessary biological functions. However, Western Toads and Painted Turtles are particularly vulnerable to road mortality due to the distance the two species will travel between breeding and overwintering grounds in the spring and fall (PWTWG, 2014; BC MOE, 2017); both are a designated *Species at Risk* in Table 1 (Section 4.0). Large congregations of Western Toads adults or juveniles crossing roadways can be a common phenomenon where roads bisect crucial aquatic (breeding) habitat and suitable upland (overwintering) habitat (PWTWG, 2014). In contrast, Painted Turtles rely on suitable aquatic habitat for overwintering and move to terrestrial habitats in the spring to breed (BC MOE, 2017). Painted Turtles exist in significantly lower numbers in the Cariboo Region compared to other amphibian and reptile species and should be reported if observed (BC MOE, 2017). The Common and Wandering garter snake have the potential to occur at the Facility and in the Surrounding Areas, and both species den communally in hibernacula.

Aquatic habitat, particularly riparian and wetland, are present in the Surrounding Areas around the Facility and, therefore, personnel should be aware that amphibians and reptiles have the potential to be present on commute roads. The following measures will be implemented to reduce the risk to amphibians and reptiles:

- Mine activities will consider the reduced-risk window for amphibians and reptiles during project planning, as outlined in Section 5.1.3. Activities that occur outside the reduced-risk window should determine the level of risk to amphibians and reptiles at the project location prior to commencing.
- If mine activities are occurring outside the reduced risk window in an area that has been determined to be high-risk for the presence of amphibians and reptiles, the Accountable Facility Representative may request that additional mitigation is implemented at the site, such as temporary installation of exclusion fencing to keep amphibians and reptiles out of the area of disturbance.
- If amphibians and reptiles are occurring inside the boundaries of the work site, an amphibian and reptile salvage may be required by a QEP under the authorization of a Wildlife Permit through MFLNRORD. Handling of amphibians and reptiles by unauthorized personnel is prohibited due to the potential to transfer disease between individuals and incidentally cause harm.
- Observations of large aggregations of amphibians, including migrations across roadways, will be immediately reported to the Operations Supervisor or Accountable Facility Representative so that further mitigation can be implemented, as necessary. Mitigation may include ensuring all personnel are aware to avoid that location, posting signage, installing temporary exclusion fencing, or having a QEP conduct an authorized salvage. The same procedures apply for a single observation of a Painted Turtle, which occur in lower numbers. Aggregations of snakes may indicate the presence of a hibernacula, which should also be similarly reported.
- Mine activities must not disturb any wetlands, streams or water features, including small, ephemeral (temporary) pools and water-filled ditches, as such habitats can provide important breeding, foraging, and hydration sites for amphibians.
- Any activities near aquatic habitats should protect shallow water areas and their vegetation from trampling and other disturbance; these areas serve as breeding habitat and cover for many amphibians.

5.3 General Best Management Practices

5.3.1 General Restrictions

To ensure compliance with Section D-12 of the M-200 permit, the following provisions and restrictions apply:

- No hunting or shooting shall occur within any area encompassed by the mine permit,
- No fishing or hunting shall occur while on company business, or while commuting to and from the mine for all MPMC personnel and contractors,

- Any exclusion fencing (e.g., electric fencing) that is installed shall be regularly maintained to ensure it is effectively functioning at all times that people are present on site.

To ensure compliance with all relevant wildlife regulations (Section 3.0), the following general provisions and restrictions apply:

- Feeding wildlife is strictly prohibited and is a direct violation of the BC *Wildlife Act* (Section 3.1.1). Feeding wildlife may result in wildlife becoming attracted to human foods and habituated to human presence, which can result in the creation of 'conflict wildlife' and have serious consequences for the animal and other people.
- Cooking outside and using outdoor cooking appliances is prohibited.
- Littering is prohibited. All garbage, including organic wastes (e.g., banana peels, pear cores, etc.), should be stored in wildlife-proof temporary containers and removed and appropriately disposed of off-site (see Section 5.3.3).
- Harassment of wildlife is strictly prohibited and is also a direct violation of the BC *Wildlife Act*. Harassment of wildlife can lead to the abandonment of habitat or the disruption of critical activities (e.g., nesting), and may result in injury to wildlife and/or humans.
- All potentially sensitive wildlife features, including bird nests, dens, roosts, hibernacula, kill sites (e.g., carcass locations that will attract wildlife), and mineral licks (e.g., an area where ungulates regularly congregate to obtain mineral nutrients) will be reported to the Operations Supervisor or Accountable Facility Representative. The Accountable Facility Representative may implement measures to avoid or reduce adverse effects to known wildlife features from mine-related activities, which could include restricting the knowledge of the feature location to reduce traffic at the site and prevent vandalism.

5.3.2 Equipment and Vehicles

To reduce incidents of wildlife-vehicle collisions and near-misses at the Facility, the following general provisions and restrictions apply:

- The Accountable Facility Representative will be familiar with the BC Wildlife Collision Prevention Program (http://www.wildlifecollisions.ca/Default.aspx) and will be responsible for ensuring all mine personnel and visitors are orientated on best management practices for preventing wildlife collisions.
- When travelling to and from the mine, Facility personnel and visitors are required to report incidental wildlife observations. This information will be valuable in identifying areas where potential wildlife-vehicle collisions have a higher chance of occurring.
- Road signage that informs mine personnel (and other road users) to be attentive for wildlife will be established, as necessary. Signage will be placed where potential collisions are predicted (e.g., at known wildlife crossings, blind hills, blind corners, etc.) or have already occurred. All Facility personnel and visitors must obey traffics signs.
- On public gravel or forest service roads, the maximum speed limit is 60 km/hour or per posted signage. During poor road conditions when visibility and traction are reduced, personnel are encouraged to slow down and drive safely to the conditions.

- The maximum speed limit on the mine property is 40 km/hour in ideal driving conditions.
- Wildlife has the right-of-way, except in select circumstances when it is unsafe to apply the brake or come to a complete stop. When wildlife is present on a road, slow down or stop and allow the animal(s) to depart the roadway.
- Limit access to deactivated trails, seasonally or permanently, using signage and high visibility barricades.
- Report wildlife remains observed along access roads at the Facility, and in the Surrounding Areas, to the Operations Supervisor or Accountable Facility Representative. Wildlife carcasses have the potential to lure other wildlife onto the roadway, which may result in an increased likelihood of wildlife-vehicle collisions. MPMC will relay reports of wildlife remains along highways to the regional Conservation Officer Service.
- Wildlife-vehicle collisions that cause injury or death to wildlife must be reported immediately. If an animal is killed as a result of a vehicle collision, the Accountable Facility Representative will notify the regional Conservation Officer Service so the remains can be removed from the road in a timely fashion, suitably disposed of, and documented in an Incident Report. The RCMP must be notified if damage is greater than $1,000 or if there are human injuries. If an animal is injured as a result of a vehicle collision, the Accountable Facility Representative will contact the regional Conservation Officer Service to determine the best course of action (e.g., animal destruction). Some injured animals may present a safety hazard (e.g., bears, moose, deer, etc.); consequently, personnel should not approach injured animals.
- A near-miss animal-vehicle collision will be reported as an “incident” as this information will be important for determining high-risk collision areas that may require warning signage.

5.3.3 Waste Management

Garbage and food waste are wildlife attractants which may lure and create conflict wildlife, such as bears, foxes, and coyotes. In addition, wildlife attractants may include vegetation growing along the roadside (e.g., grasses), chemicals (e.g., gasoline), waste containers (e.g., empty fuel cannisters), and wildlife remains. Conflict wildlife can create unsafe working conditions for personnel and result in damage to facility structures and equipment.

The following waste management measures will be followed to reduce wildlife conflicts related to food waste and garbage:

- Adhere to the guidelines outlined in the General Restrictions (Section 5.3.1).
- Food waste, sewage, and mechanical maintenance waste (e.g., motor oil) will be handled and disposed of appropriately under the direction of the Accountable Facility Representative.
- Temporary recycling and garbage containers shall not be placed or stored outside.
- Wildlife incidents related to garbage or human food attractants will be promptly reported to the Accountable Facility Representative.
- Waste disposed of incorrectly will be reported promptly to the Accountable Facility Representative. The Accountable Facility Representative will affirm that any inappropriately disposed of waste, within and around the Facility, is correctly disposed of.

- Regular site inspections will be conducted of waste transfer areas to ensure site cleanliness, adequate bear-proofing features, and to document improper garbage storage.
- When seeding along road corridors is required at the Facility, the Accountable Facility Representative will select seed mixes that do not contain wildlife attractants (e.g., clover), as these can result in an increase in animal-vehicle collisions.

5.3.4 Reporting Wildlife Observations and Incidents

Observations of wildlife or wildlife incidents by mine personnel and visitors must be documented and reported to the Accountable Facility Representative. An observation is defined as physical observations of wildlife or identification of signs that wildlife may be present in the area (e.g., nests, scat, tracks, dens, etc.). An incident may include animal-vehicle collisions, strange behavior (e.g., the animal behaving aggressively or losing its fear of humans), close encounters on foot or within a vehicle, or witnessing deceased or wounded animals.

Reports of wildlife observations and incidents provide information that can help determine:

- Hazardous circumstances requiring intervention (e.g., conflict wildlife).
- Whether notification to the regional Conservation Officer Service is required (e.g., roadkill).
- If there are deficiencies in the conflict wildlife mitigation and waste management measures.
- Areas along roadways that are potential hotspots for animal-vehicle collisions and, thus, require warning signs.

5.3.4.1 Wildlife Observations

Observations of wildlife and wildlife habitat features (e.g., nests, dens, wildlife trees, cavities, etc.), provide important data on wildlife habitat usage and behavior patterns at the Facility and in the Surrounding Areas. Wildlife observations will be collected and documented by the Operations Supervisor who will forward the information to the Accountable Facility Representative. All observations will be reviewed to assess the potential for conflict wildlife and to ensure current guidelines are sufficient in protecting personnel and wildlife. Wildlife observations will be included in MPMC's annual reporting.

Most wildlife and wildlife habitat observations will be discussed at health and safety meetings. However, the location of sensitive wildlife habitat features (e.g., mineral licks) may be disclosed to a restricted number of mine personnel at the discretion of the Accountable Facility Representative.

5.3.4.2 Wildlife Incidents

Mine personnel and visitors are required to promptly notify wildlife incidents to the Operations Supervisor or Accountable Facility Representative, who may request the completion of an Incident Report. Incident Reports regarding wildlife will be reviewed for any evidence of conflict wildlife development, to ensure current guidelines are sufficient in protecting personnel and wildlife, and for annual reporting purposes.

5.4 WILDLIFE MONITORING

In accordance with the permit requirements outlined in Section 1.1, monitoring programs will be developed to evaluate the effects of mining-related activities on wildlife and wildlife habitat at the Facility and in the Surrounding Areas. Wildlife monitoring will also help determine the success of remediation works completed at Polley Flats and the Hazeltine Creek Corridor, as well as the success of any future remediation that is implemented to achieve long-term reclamation and closure objectives. All monitoring programs will incorporate adaptive management to optimize procedures and outcomes as new information becomes available. The design and development of specialized projects may be done in consultation with QEPs, as required.

An Ecological Risk Assessment was conducted for Polley Flats and the Hazeltine Creek Corridor in 2017 to determine the potential impact of heavy metals on biological receptors and to determine the direction of future remediation and monitoring efforts (Golder, 2016). The assessment determined that the risk of metal uptake was low in aquatic and terrestrial systems and was less likely to cause adverse impacts to wildlife than the effects of the physical disruption to functional habitat (Golder, 2016). For further details regarding wildlife monitoring requirements, refer to the CEMP (MPMC, 2019).

5.5 RECLAMATION PLANNING

MPMC has identified wildlife habitat as one of the primary land-use objectives during reclamation and closure planning, which will fulfill the requirements outlined in Section E-2 of the M-200 permit. Reclamation initiatives will utilize a variety of different strategies to achieve self-sustaining ecosystems that will create long-term habitat for wildlife, including soil amendments to improve soil conditions, revegetation of native species, enhanced landscape features that attract wildlife, and construction of habitat systems that provide ecosystem functions for many species. For further details on how wildlife habitat will be incorporated into long-term reclamation and closure planning, refer to the *Reclamation and Closure Plan Update* by MPMC (2017).

5.6 REPORTING REQUIREMENTS

A summary of the effectiveness of the Plan will be included in the annual reclamation report. In addition, summary reports of wildlife-related mitigation measures, incidents, and observations will be generated annually and will form the basis of adaptive management strategies to address compliance issues and conflict wildlife. These summary reports will be provided to MFLNRORD, First Nations, and community stakeholders upon request (Section 7.0).

6 RESPONSIBILITIES

The following sections summarize the responsibilities held by each of the employment levels at the Facility as they pertain to this Plan.

6.1 SENIOR MANAGEMENT REPRESENTATIVE: MINE MANAGER

The Senior Management Representative, or designate, is responsible for:

- Ensuring the required resources are in place to execute the Plan,
- Submitting the results of the Plan to all relevant Provincial agencies and First Nations groups.

6.2 ACCOUNTABLE FACILITY REPRESENTATIVE: ACTING GENERAL MANAGER

The Accountable Facility Representative, or designate, is responsible for:

- Reviewing the effectiveness of the current wildlife management measures at the Facility,
- Scheduling and coordinating the implementation of measures outlined in the Plan, and,
- Training site personnel and contractors on the Plan and ensuring best management practices are implemented,
- Ensuring additional in-house training is provided regarding protocols for wildlife encounters and sensitive wildlife features for personnel and contractors who may require it,
- Consolidating and reviewing all documentation and data regarding incidental wildlife observations, wildlife encounters, conflict-wildlife, sensitive wildlife features, and the presence of *Species at Risk* on site; this information will be reported to the Mine Manager,
- Communication of additional wildlife mitigation strategies that may be required prior to the initiation or continuation of mine activities.

6.3 OPERATIONS SUPERVISOR: GENERAL FOREMAN

The Operations Supervisor, or designate, is responsible for:

- Reviewing the effectiveness of the current Plan,
- Collecting all documentation and data from personnel regarding incidental wildlife observations, wildlife encounters, conflict-wildlife, sensitive wildlife features, and the presence of *Species at Risk*; this information will be forwarded to the Accountable Facility Representative,
- Implementation of additional wildlife mitigation strategies that may be required prior to the initiation or continuation of mine activities.

6.4 FACILITY PERSONNEL AND CONTRACTORS

All Facility Personnel and Contractors are responsible for:

- Following all the measures and guidelines outlined in this Plan and addressing any questions or concerns with the Operations Supervisor,
- Reporting all wildlife observations to the Operations Supervisor,
- Submitting a wildlife incident report in the event of a wildlife-collision or encounter with conflict-wildlife.

6.5 TECHNICAL SERVICES SUPERINTENDENT

The Technical Services Superintendent is responsible for:

- Providing feedback on the effectiveness of the current Plan at the Facility,
- Conducting internal audits of the guidelines and measures outlined in the Plan at the Facility,
- Coordinating external audits of the Plan at the Facility,
- Coordinating the wildlife monitoring programs, and,
- Reporting the results of the audits and monitoring programs to the regulatory authorities.

7 STAKEHOLDER CONSULTATION

In accordance with the MPMC Communication Plan as a condition of Permit 11678, environmental data will be shared with the Xatśūll First Nation, Williams Lake First Nation, Cariboo Regional District, and the Community of Likely. First Nation and community stakeholders will be provided avenues for discussing and communicating concerns regarding the Plan, including the implementation and results of the wildlife monitoring programs. For further details regarding First Nation and community stakeholder participation, refer to the *Communication Plan* by MPMC (2016).

8 ADAPTIVE MANAGEMENT

The Plan will be continually adapted based on the results of ongoing wildlife monitoring programs, reclamation planning, incident and summary reports, and employee education programs. The adaptive management framework recognizes that new information obtained from those sources of information should be used to inform future planning, decision-making, mitigation, and program design to help MPMC maintain compliance. An annual review of the Plan to determine the potential need for revisions will also be required to ensure adaptive management strategies can be successfully identified and integrated.

Appendix A

Table of Wildlife Species with a Conservation Status in the BC Cariboo Region not legally Adopted under any Statute

Wildlife species documented in the BC Cariboo Region that have been given a conservation status by the BC Conservation Data Centre and/or the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) but have not been legally adopted under any statute[1]

Wildlife Species			Conservation Status	
English Name	**Scientific Name**	**Category**	**BC List[2]**	**COSEWIC[3]**
American Avocet	*Recurvirostra americana*	Bird	Blue	no status
American Bittern	*Botaurus lentiginosus*	Bird	Blue	no status
American Golden-Plover[4]	*Pluvialis dominica*	Bird	Blue	no status
Black-crowned Night-heron[4]	*Nycticorax nycticorax*	Bird	Blue	no status
Broad-winged Hawk[4]	*Buteo platypterus*	Bird	Blue	no status
California Gull[4]	*Larus californicus*	Bird	Blue	no status
Caspian Tern[4]	*Hydroprogne caspia*	Bird	Blue	NAR (1999)
Double-crested Cormorant[4]	Phalacrocorax auritus	Bird	Blue	NAR (1978)
Eared Grebe	*Podiceps nigricollis*	Bird	Blue	no status
Green Heron[4]	*Butorides virescens*	Bird	Blue	no status
Gyrfalcon[4]	*Falco rusticolus*	Bird	Blue	NAR (1987)
Horned Lark, *merrilli* subspecies[4]	*Eremophila alpestris merrilli*	Bird	Blue	no status
Northern Goshawk, *atricapillus* subspecies	*Accipiter gentilis atricapillus*	Bird	Blue	NAR (1995)
Rough-legged Hawk	*Buteo lagopus*	Bird	Blue	NAR (1995)
Short-billed Dowitcher[4]	*Limnodromus griseus*	Bird	Blue	no status
Surf Scoter[4]	*Melanitta perspicillata*	Bird	Blue	no status
Swainson's Hawk	*Buteo swainsoni*	Bird	Red	no status
Townsend's Big-eared Bat[4]	*Corynorhinus townsendii*	Mammal	Blue	no status
Tundra Swan	*Cygnus columbianus*	Bird	Blue	no status
Upland Sandpiper[4]	*Bartramia longicauda*	Bird	Red	no status
White-throated Swift[4]	*Aeronautes saxatalis*	Bird	Blue	no status

[1] BC CDC Search criteria: Vertebrates AND BC Conservation Status: Red (Extirpation, Endangered, or Threatened) OR Blue (Special Concern) AND Area of Interest: User Defined Polygon. The exported BC CDC list was further filtered by comparing the results to the CDC mapped locations, distribution maps, and Habitat Wizard wildlife observation points.

[2] Based on Status designated by the BC Conservation Data Centre: Blue = Special Concern, Red = Endangered/Threatened.

[3] Based on Status designated by the Committee on the Status of Endangered Wildlife in Canada: NAR = Not at Risk. The year the status was adopted is in brackets.

[4] These species are either at the northern extent of their range and occur infrequently in the region, or are more likely to occur while on migration or as vagrants.

STUDY LIMITATIONS

WSP Canada Inc. (WSP) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by WSP for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents WSP's professional judgement based on the knowledge and information available at the time of completion. WSP is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to WSP by MPMC, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by WSP are considered its professional work product and shall remain the copyright property of WSP. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

Archaeology Branch Found Human Remains Policy

APPENDIX C
Archaeological Chance Find Documentation Form

1.0 INTRODUCTION

This document provides guidance and a communication plan in the event that Mount Polley Mining Corporation (Mount Polley) project activities inadvertently disturb or uncover archaeological deposits, human remains, or objects of historical importance.

Legislative protection for British Columbia's archaeological and heritage resources is provided by the *Heritage Conservation Act* (HCA) (R.S.B.C. 1996, Chapter 187). Under the HCA, a permit is required to search for or alter heritage sites or objects that represent physical evidence of human habitation or use before 1846. Certain site types, including burial places and rock art that have heritage value, are protected regardless of age, and heritage wrecks are protected if two or more years have passed from the date that the vessel or aircraft sank, was washed ashore or crashed. Sites that post-date 1846 are not automatically protected but may be afforded protection by an Order-In-Council, based on the site's heritage value to British Columbia, a community, or an aboriginal people.

Mount Polley engages in a variety of activities that require ground disturbance. Activities that may result in disturbance to a known heritage site require an Alteration Permit pursuant to Section 12.4 of the HCA. The permit will outline procedures for archaeological work during Project activities, if required. Such permits currently take approximately 32 weeks to procure and therefore planning for the management of such sites should take place well in advance of the commencement of disturbance. In most cases, disturbance would result from ground altering activities, but above-ground works could impact heritage sites such as structures, rock cairns, culturally modified trees, or other features.

Mount Polley projects also have the potential to disturb currently unrecorded heritage sites. The following step-by-step procedure is intended to guide Mount Polley in case heritage resources are unexpectedly encountered during project activities. The procedure includes basic archaeological site recognition criteria and reporting procedures. If archaeological assessment or monitoring is required as the result of a chance find, a Heritage Inspection Permit will be required under Section 12.2 of the HCA. A Heritage Inspection Permit will be obtained for the Mount Polley to facilitate chance find responses without delay.

2.0 DEFINITIONS

The following definitions apply to the content of this management plan:

Table 1: Definition of Terms

Term	Definition
Archaeology	The science concerned with the discovery and interpretation of the human past through the study of physical remains.
Archaeological Site	Any place where physical evidence of past human activity is found.
Artifact	Any object that has been modified or manufactured by humans. Artifacts can include tools, weapons, ornaments, utensils, and sculptures.
Cache Pit	Circular depressions, usually less than 3 metres in diameter, used for storing goods or food.
Chance Find	Heritage material that is unexpectedly encountered, typically during project-related activities.
Culturally Modified Tree	A tree that has been intentionally altered by Indigenous people through their traditional use of forest resources (for food, manufacture, or medicinal purposes) or in order to mark a trail
Heritage Site	Land, including land covered by water, that has heritage value to British Columbia, a community or an aboriginal people.
Heritage Value	The historical, cultural, aesthetic, scientific or educational worth or usefulness of a site or object.
Historical	Refers to a time period during which there are written records. This period of time is also referred to as post-contact. “Post Contact” refers to the time after the arrival of Europeans.
Petroglyph	An image that has been carved, incised, engraved, pecked, or ground into the surface of a rock.
Pictograph	An image that has been painted on a rock using organic and mineral pigments.
Rock cairn	A deliberately constructed pile of stones forming a mound, often marking a burial place.

3.0 SITE RECOGNITION CRITERIA

The following lists some criteria that may signal the presence of an archaeological or burial site. The list is not exhaustive, but it includes site indicators that may be expected within the Mount Polley mine site area. The Basic Archaeological Site Identification Guide (Appendix A) provides more detailed descriptions and photographs.

Archaeological Site Indicators

- Artifacts such as stone, bone, or antler tools. Artifacts may be formed implements, such as arrowheads or spear points (also known as projectile points), or simply scatters of chipped/flaked stone. Be aware of concentrations of chipped stone materials that are not otherwise present in the project area (e.g., dacite, tourmalinite, argillite, chert, chalcedony, obsidian).
- Rock art, specifically pictographs (paintings on stone) or petroglyphs (images pecked in stone).
- Small circular depressions (about 1 m to 4 m across) representing pit ovens, cache pits etc. – particularly if associated with trails, or if found in clusters.
- Large circular or oval depressions, representing house-pits.
- Buried or exposed hearths, represented by localized dense concentrations of charcoal and/or ash sometimes associated with fire broken rock, burnt bone, or soil.
- Caves or rock overhangs.
- Trails of possible heritage significance.
- Culturally modified trees, such as blazes and bark removal scars.

Burial Places

- Human remains.
- Stone cairns.
- Earthen mounds.
- Shallow depressions or low mounds at the base of talus slopes.
- Rectangular or oval depressions.

4.0 CHANCE FIND PROCEDURES FOR HERITAGE RESOURCES

4.1 Archaeological Sites or Objects

Step 1: If known or suspected archaeological deposits or objects are encountered, stop work immediately. Secure the find location.

Step 2: Contact the Chief Compliance Officer and the Environmental Coordinator. The Environmental Coordinator will contact a professional archaeologist for further guidance (see Sections 5.0 and 6.0). Do not move or otherwise disturb the artifacts or site deposits. Do not resume work until directed by the Environmental Coordinator. Be prepared to transmit detailed location information and images of the find/location (see form in Appendix C).

Step 3: The archaeologist will advise on further action.

Initial Action

Depending on the nature of the situation, one of the following responses is likely:

- Based on information provided by the on-site representative, it may be decided that there are no further concerns, allowing project activities to continue as planned.
- A field visit by an archaeologist may be recommended. If the find is confirmed to be of archaeological concern, the archaeologist will provide direction about the interim management of impacts at the location, including the staking or flagging off the affected location.
- The archaeologist will notify the Archaeology Branch and the appropriate Indigenous communities of the find. The Archaeology Branch will recommend follow-up actions, primarily through discussions with Mount Polley, Indigenous communities, and the archaeologist. The archaeologist will advise the Environmental Coordinator regarding the resumption of project activities at the location.

Follow-up Action

- The archaeologist will implement any follow-up actions recommended by the Archaeology Branch, including but not limited to, the filing of a British Columbia Archaeological Site Registration Form for entry to the Provincial Heritage Register and archaeological investigations or monitoring.
- Findings or incidents involving heritage resources will be reported to the Environmental Coordinator and documented in Mount Polley's Environmental Management System.

4.2 Human Remains

Should suspected human remains be identified during project activities, the following responses are required. See Appendix B for Archaeology Branch Found Human Remains Policy.

Step 1: If known or suspected human remains are encountered, **stop work immediately**. Immediately notify the Environmental Coordinator and the Chief Compliance Officer. Do not move or otherwise disturb the remains or artifacts present. Take notes of the incident and be prepared to transmit detailed information and a description of the find.

Step 2: Secure the site. If the site is in a busy location or has high public visibility, assign an employee to stand watch until the local policing authority or archaeologist arrives to prevent additional disturbance or removal of evidence. Ensure that the remains are treated with dignity and respect by all those at the scene, including limiting photography to that required by the local policing authority and the archaeologist. Cover any exposed remains with plastic sheeting, plain paper, or other clean and appropriate covering to protect them. Do not backfill.

Step 3: The Environmental Coordinator will contact the Project Archaeologist (see Sections 5.0 and 6.0). Do not move or otherwise disturb the remains or associated artifacts or sediments. Do not resume work until directed by the Project Archaeologist. If some remains may have been placed in a spoil pile, do not move the pile or continue to use it. If material thought to contain remains has been removed from site, try to isolate the spoil at its new location and discontinue further disturbance of the spoil until it can be more thoroughly examined by an archaeologist or forensic specialist. The archaeologist will contact the local policing authority, if necessary, as described below.

Step 4: A qualified archaeologist will advise on further action if the remains are archaeological in nature.

Initial Action

Depending on the nature of the situation, one of the following responses is likely:

- Based on a telephone description of the encounter and review of available images, it may be determined that the remains are not human, and project activities may continue as planned.
- Based on a telephone description of the encounter and review of available images, it may be determined that the remains are likely human, and the archaeologist will contact the local policing authority and the Coroner's Office. The Coroner will determine whether the remains are human, and, if human, whether they are of forensic concern.
- If forensic, the local policing authority will assume management of the scene and liaise directly with the Environmental Coordinator and Chief Compliance Officer.

If archaeological, the archaeologist will notify the Environmental Coordinator and the Chief Compliance Officer, the Archaeology Branch, and all Indigenous communities with an interest in the area. Consultations will follow to establish an appropriate procedure for handling the remains according to cultural protocols. The Archaeology Branch Policy for Found Human Remains (Appendix A) may be used to guide the discussions.

- If the remains are not of Indigenous ancestry, the archaeologist will notify cultural groups identified by the Archaeology Branch and will attempt to identify and contact an organization representing that cultural group.
- The Archaeology Branch, in consultation with the Environmental Coordinator, the Indigenous community or other cultural group (if applicable) and the archaeologist, will determine follow-up procedures, including:
  - Interim management of project impacts and activities at the location, including the staking or flagging-off of the affected location.
  - The need for complete documentation of the burial site.
  - Appropriate treatment of the human remains.
  - Management of future project activities.

Follow-up Action

- Report findings or incidents involving heritage resources to Mount Polley's Environmental Management System.
- The archaeologist will implement any follow-up actions recommended by the Archaeology Branch, including but not limited to, the filing of a British Columbia Archaeological Site Registration Form for entry to the Provincial Heritage Register.

5.0 COMMUNICATIONS PROTOCOL

- All communications should be made using email or telephone and should be documented, with written follow-up to concerned parties.
- All face-to-face meetings are to be documented, with minutes prepared for review and finalization by all parties.
- The proceedings of all meetings are confidential among the parties to the meeting and are not to be distributed.
- All media queries will be directed to the Environmental Coordinator who will notify the Company spokesman.
- All queries from Indigenous community members with an identified interest at the site will be directed to their Chief and Council or other designated organization. All other queries from Indigenous community members will be directed to the Environmental Coordinator.
- Site safety and security is the responsibility of Mount Polley; when implementing safety or security measures, input from the Archaeology Branch and the Project Archaeologist should be sought to help ensure additional impacts to the burial place do not inadvertently occur.

6.0 CONTACT NAMES AND NUMBERS

Table 2: Contact Name and Numbers – Current October 2023

7.0 LIMITATIONS AND USE OF CHANCE FIND MANAGEMENT PLAN

This document was prepared by WSP Canada Inc. for the exclusive use of Mount Polley and their contractors. Consistent with the intent of the *Heritage Conservation Act*, Mount Polley is advised that if unanticipated cultural materials or features are encountered during construction, all work in the immediate area should cease, and the guidelines for archaeological chance find management, as presented above, should be implemented.

Any use, reliance, or decisions made by third parties on the basis of this report are the sole responsibility of such third parties. WSP Canada Inc. accepts no responsibility for damages, if any, suffered by any third party as a result of decisions or actions based on this report.

8.0 CLOSURE

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this report.

We trust that the information contained in this report meets your present requirements. Please contact us if you have any questions or concerns regarding the above.

APPENDIX A

Basic Archaeological Site Identification

BASIC ARCHAEOLOGICAL SITE IDENTIFICATION GUIDE

Common criteria that may signal the presence of an archaeological site are noted below. The examples are not exhaustive but includes common site indicators that may be encountered within the Mount Polley Mining Corporation area of operations.

Artifact or Artifact Scatter

Portable object(s) manufactured or modified by human beings. These items may include chipped or ground stone objects or implements made from bone or antler (Photos 1 to 6).

Look for: Obviously formed stone objects or pieces of stone that have been chipped and/or ground in a non-natural way. Bone and antler artifacts will exhibit obvious modification (i.e., cutting, shaping, incision, etc.).

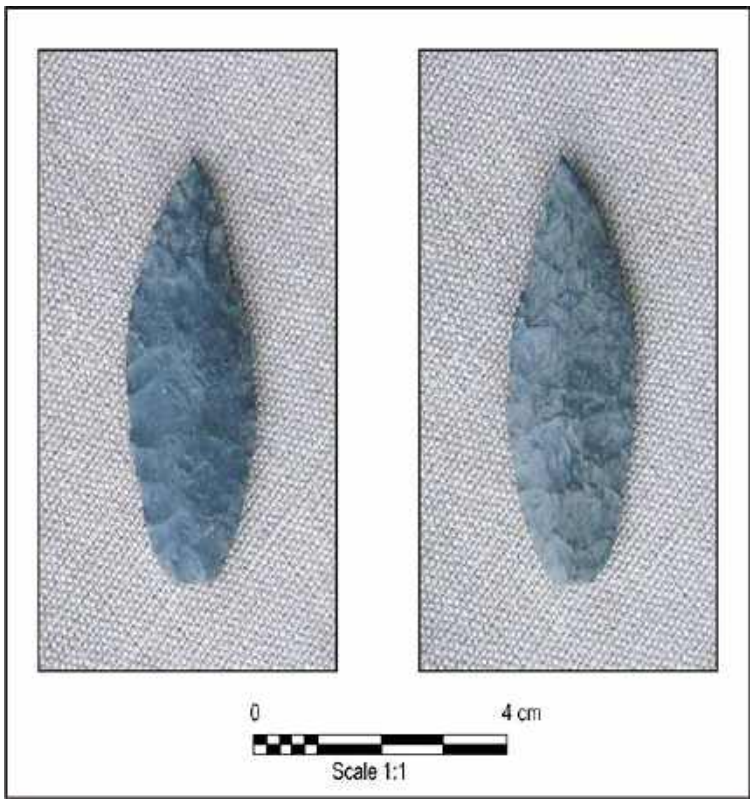

Photo 1: Projectile Point (© WSP Canada Inc.)

Photo 2: Scraper, Projectile Point, Key-shaped Drill (© WSP Canada Inc.)

Photo 3: Obsidian Knife. Obsidian is Volcanic Glass and is Extremely Sharp (© WSP Canada Inc.)

Photo 4: Bone and Antler Artifacts (© WSP Canada Inc.)

Photo 5: Pecked Stone Hand Maul (hammer) (© WSP Canada Inc.)

Photo 6: Chipped Stone Artifacts (flakes) (© WSP Canada Inc.)

Rock Art

Pictographs are paintings on rock and are the most common form of rock art in the region. The paint is often a mixture of ochre and rendered animal fat and is applied using a finger or stylus (Photo 7).

Photo 7: Pictograph (© WSP Canada Inc.)

Cultural Depressions

Cultural depressions range in size and function and may include: small circular depressions (about 1 m to 4 m across) representing pit ovens or food caches – particularly if associated with trails, or if found in clusters; and, large circular depressions (about 5 m to 20 m across) representing house-pits (Photos 8 to 10).

Photo 8: House-pit Depression (© WSP Canada Inc.)

Photo 9: Roasting or Cache Pit (© WSP Canada Inc.)

Photo 10: Roasting Pit in Profile (© Adam Gray)

Fire Cracked Rock (FCR) and Hearth Features

Fire cracked rock (FCR) is heat fractured stone resulting from rapid or alternate heating and cooling in campfires, or when using heated rocks to boil water in boiling pits. FCR is often associated with resource processing and/or food preparation (Photo 11). Hearth features are the remains of camp fires, indicates by dark stained soil, often with charcoal and ash (Photo 12).

Look for: concentrations of fractured rock, either in a hearth formation or dispersed with signs of being burnt in a fire, such as heavily oxidized surfaces sometimes reddish in color.

Photo 11: Fire Cracked Rock (© Andrew Mason)

Photo 12: Buried Fire Hearth (© WSP Canada Inc.)

Aboriginal Trails

Trails are often located in creek valleys and over saddles and ridges. Trails are often in association with other heritage sites such as campsites containing stone or bone artifacts, FCR, hearth features or cache pits (Photo 13).

Photo 13: Aboriginal Trail (© WSP Canada Inc.)

Burial Places

Burials take numerous forms which may include rock cairns, mound burials, and rectangular or oval depressions; however, many burial sites have no surface expression (Photos 14 and 15).

Photo 14: Burial Mounds (© WSP Canada Inc.)

Photo 15: Burial Cairn (© Andrew Mason)

APPENDIX B

Archaeology Branch Found Human Remains Policy

FOUND HUMAN REMAINS

Issued: September 22, 1999

Purpose

The purpose of this directive on found human remains is to provide guidelines to Archaeology Branch staff, archaeologists, other agencies and the public as to branch procedures for handling human remains that may be protected under the *Heritage Conservation Act* (1996, RSBC, Chap. 187), and to facilitate the respectful treatment of these remains.

Mandate

Pursuant to section 13(2)(b) of the *Heritage Conservation Act* (HCA), a permit is required under section 12 or 14 before a person can undertake any actions affecting a burial place of historical or archaeological value, human remains or associated heritage objects.

Authority

The Director of the Archaeology Branch and the Manager, Permitting and Assessment Section, have been authorized to exercise the powers of the Minister to issue permits under sections 12(2) and 14(2), as well as ministerial orders under section 14(4) where necessary for emergency conservation purposes.

Policy Statement

Upon notification of the discovery of human remains that are not of forensic concern, the Archaeology Branch will take steps to facilitate the respectful handling and disposition of those remains within the limits of existing funds and program priorities.

Procedures

The following procedures will normally apply in cases where human remains are discovered fortuitously through various land altering activities such as house renovations, road construction or natural erosion; or during archaeological studies conducted under an *HCA* permit:

1) Fortuitous Discoveries

In cases where the branch has been notified that human remains have been discovered by chance, the following procedures should normally apply:

- The Coroner's Office and local policing authority should be notified as soon as possible.
- The Coroner's Office should determine whether the matter is of contemporary forensic concern. The branch may provide information and advice that may assist in this determination.
- If the Coroner's Office determines the reported remains are not of forensic concern, the branch will attempt to facilitate disposition of the remain.
- If a cultural affiliation for the remains can be reasonably determined, the branch will attempt to contact an organization representing that cultural group.
- If remains are determined to be of aboriginal ancestry, the branch will attempt to contact the relevant First Nation(s).
- Generally, if remains are still interred and are under no immediate threat of further disturbance, they will not be excavated or removed.
- If the remains have been partially or completely removed, the branch will facilitate disposition.
- If removal of the remains is determined to be appropriate, they will be removed under authority of a permit issued pursuant to section 12 or 14, or an order under section 14 of the *HCA*, respecting the expressed wishes of the cultural group(s) represented to the extent this may be known or feasible.
- If circumstances warrant, the branch may arrange for a qualified physical anthropologist or an archaeologist with training in human osteology to provide an assessment of the reported remains in order to implement appropriate conservation measures.
- Analysis should be limited to basic recording and in-field observations until consultation between the branch and appropriate cultural group(s) has been concluded.

2) Permitted Archaeological Projects

In cases where human remains are encountered in the course of a permitted project, the Archaeology Branch should be contacted as soon as possible.

- The remains are to be handled in accordance with the methods specified in the permit, respecting the expressed wishes of the cultural group(s) represented, to the extent that these may be known or feasible.
- If the permit does not specify how remains are to be handled and if the cultural affiliation of the remains can be reasonably determined, the field director or permit-holder should attempt to contact an organization representing that group. The permit-holder or field director should advise the branch of the organization contacted, and any wishes expressed by that organization.
- The branch, in consultation with the appropriate cultural group(s), will determine disposition of the remains.
- Analysis should be limited to basic recording and in-field observations, until consultation between the branch and appropriate cultural group(s) has been concluded.

1 OVERVIEW

1.1 Scope

Being prepared for a mine site emergency is critical in order to effectively respond and control any unexpected occurrence.

The following Mine Emergency Response Plan has been designed and developed for Mount Polley mine to coordinate and effectively respond to any and all mine emergencies.

This is a requirement of the Health, Safety and Reclamation Code for Mines in British Columbia (HSRC) 3.7.1

1.2 Definition of an Emergency

A current or imminent situation that requires prompt coordination of actions of trained personnel to protect health, safety, or welfare of people and to limit damage to property and to the environment.

1.3 Goals

- To identify and ensure adequate resources are available on site and off site in order to facilitate effective emergency response.
- To introduce and train management in the roles of the "Control Group"
- To introduce and train workers in the relevance of the Mine Emergency Response Plan.
- To ensure and maintain a high standard of emergency response training for mine personnel.

1.4 Training

For the ERP Training Program to be successful, with adequate revision of this Plan, it is necessary to establish a Drill Program. The Health and Safety, Environmental and any other operational areas will take part in the drills.

All personnel assigned specific duties within this plan shall review pertinent sections of the plan

All personnel in positions of leadership shall be trained in the Incident Command System

Emergency Response Drill Schedule

- LEVEL 1 Once every 6 months - Area specific evacuation practice
- LEVEL 2 Once every year / Mine Site wide Involving the Mine Rescue Team (ERT)
- LEVEL 3 Once every two years / Involving the ERT and Activating the Emergency Operation Centre

2 EMERGENCY RESPONSE PLAN MANAGEMENT

Mount Polley Mining Corporation shall designate an Emergency Response Plan Coordinator and Emergency Response Planning Committee who shall oversee the development, review and implementation of the Emergency Response Plan.

2.1 Emergency Response Plan Coordinator

The Emergency Response Plan Coordinator shall normally be the Senior Safety Coordinator or his designate.

2.2 Plan Audits and Revisions

The emergency response planning group will be comprised of the Mount Polley Occupational Health, Safety and Environment Committee members.

The ERP Planning Committee shall review the emergency response plan annually. The Emergency Response Plan shall also be reviewed following any incident, to determine if the planned response procedures were adequate or require revision. The planning committee shall be chaired by the Emergency Response Plan Coordinator.

Date	Rev.#	Revision	Originator
July 2019	#0	N/A	M Dyment
July 2020	#1		M Dyment
Aug 2020	#2		M Dyment
Dec 2020	#3	E2 Propane plan	M Dyment
Aug 2021	#4	Contact info	M Dyment

2.3 Emergency Response Plan Distribution

The Emergency Response Plan will be maintained as a secure document with limited printed copies. Digital copies will be stored on the Mount Polley Microsoft Teams network at General\Emergency Response Plans\Surface. Printed copies will be maintained in the following locations:

Copy	**Location**
1	Emergency Operations Center – 2nd Floor Boardroom
2	On-call Binder – Reception Desk
3	Mine Manager

3 COMMUNICATIONS

3.1 Level of Emergency

Mount Polley Mine Incident Reporting Policy requires that all levels of emergencies be reported immediately. Based on the level of emergency the Incident Commander and Safety Representative shall be notified as required.

EMERGENCY RESPONSE LEVELS
Level 1 "Low": Green
A "Low Level" emergency can be controlled by area personnel from the affected area.
Level 2 "Medium": Yellow
A "Medium Level" emergency cannot be handled by the personnel of the affected area. The Mine Rescue Team is required. It does not exceed the resources of the site. The Emergency Operations Group should be activated.
Level 3 "High": Red
A "High Level" incident is one which exceeds the resources available at the site and outside help, such as government, industry and or corporate, is required.

The highest severity rating for any individual risk factor determines the overall severity rating of the emergency.

3.2 Emergency Communications

EMERGENCY COMMUNICATION / INCIDENT NOTIFICATION

EMPLOYEE / BYSTANDER

Emergency Communications

1. By Radio on area radio frequency EMERGENCY – EMERGENCY –EMERGENCY - I have an Emergency
2. Report significant details of the incident

Provide the following information:

1. Your name, area and company
2. Location of the Emergency
3. Description of the Emergency
4. Number of injured persons if any and their health condition
5. Telephone number or radio frequency you will be monitoring
6. **Notify your Supervisor immediately**
    - DO NOT CALL the local media to report the emergency
    - DO NOT CALL the family or friends of the persons involved in the emergency (Management will take charge of making such calls)
    - DO NOT CALL the government agencies (Management will take charge of making such calls)

SUPERVISOR

On Scene Commander (OSC), Senior Area Supervisor present at the scene:

1. Confirms/Determines the Level or Emergency: Level 1 GREEN / 2 YELLOW / 3 RED
2. Informs Safety of the resources needed at the scene
3. Directs the on-scene activities
4. Initiates the dispatch of site based resources for the appropriate response:
    - Site Mine Rescue Personnel
    - First Aid
    - The on-call Health and Safety representative.
5. Contacts the Mine Manager or designate senior on call or the next higher level to report the Level of Emergency and response needs.

MANAGER

Manager
Incident Commander (IC), Mine Manager or Designate:

1. Confirms or Determines the Level of Emergency & assumes command at pre-designated Emergency Operations Center (2nd floor Boardroom).
2. Responsible for the overall management of an emergency.
3. Evaluates the emergency and determines the required level of response.
4. Confirms or initiates the dispatch of the resources for the appropriate response:
    - Site Mine Rescue personnel
    - First Aid
    - Ministry of Energy, Mines and Low Carbon Innovation
        - Senior Inspector of Mines, Health and Safety
    - RCMP - 911
    - BC Ambulance - 911
    - Forestry Fire Service etc.- 1-800-663-5555
    - Emergency Management BC – 1-800-663-3456
    - Williams Lake First Nation, Xatśūll First Nation

INITIAL RADIO AND TASK PROCEDURES WHEN AN EMERGENCY IS DECLARED
When an Emergency is called:
• **Radio Silence -** All non-essential radio communication are immediately ceased. Radio silence will remain in effect until lifted by the Incident Commander
• **Pit Operations 1 – Channel 5 -** is reserved for Emergency Incident Reporting, Management & High Priority Communications only
• **All Employees Monitor Pit Ops 1** to stay informed of the incident and listen for updates & instructions. Maintain radio silence unless you have a Priority Message
• **Cease High Risk Activities** in the initial stages of any reported emergency until a status can be determined by Management
• **Wait For Instruction -** Communications may be done with briefness on regular assigned channels to ask or receive instructions from your immediate Supervisor &/or Management
• **Prolonged Work Interruptions** will be at the discretion of the Incident Commander or his designate
• **Evacuation Ordered -** Proceed to designated Muster Points and report to your supervisor

3.3 Mount Polley Mine Radio Frequencies

Mount Polley Radio Communications

Highland Helicopters Ltd	Williams Lake Base Quesnel Base	250-398-7142 250-249-9660

3.6 Media and Public Relations

During an emergency it is critical that all media and public communication be managed so that only accurate and required information is communicated to outside groups. All media and public communications will be handled by the Mine Manager or Designate. All requests for information shall be directed to Mine Manager or Designate. In the event of an emergency involving personal injury, specific focus should be given to notification of family members prior to public release.

The Shut Down of site external communications shall be determined by Mine Manager or Designate

4 PERSONNEL DUTIES AND RESPONSIBILITIES

4.1 General Responsibilities of Personnel

Anyone first finding or recognizing an emergency situation that would be cause for evacuation shall;

- Immediately report the emergency, pull the fire alarm and evacuate the building.
- Notify the supervisor of the emergency situation.
- Provide help until the appropriate response personnel arrive.
- Never place yourself or others in danger, especially during fires, electrical or chemical emergencies.
- If an alarm is sounded or you are instructed to do so, evacuate the area to designated assembly points and stay there until the "**All Clear**" signal is given.
- If an evacuation takes place, make sure you and any visitors you are responsible for are accounted for.
- If safe to do so, ensure that shutdown procedures for your area are completed prior to evacuation.

General Procedure G50 Evacuation Procedure shall be followed.

4.2 First aid Attendant

In the event of an emergency, the first aid attendant shall take over primary care of any injured workers. If Mine Rescue trained personnel are in command of an incident scene, the first aid attendant will take over care of the injured workers once the Mine Rescue personnel confirms the area is safe to approach.

4.3 Mine Rescue

4.3.1 Emergency Response Coordinator

The Emergency Response Coordinator or his designate must be contactable at all times, both during office hours and after hours. During office hours, the coordinator must be in close proximity to a radio or telephone.

The Emergency Response Coordinator will liaise with Incident Commander, Mine Rescue Personnel and Coordinate assistance for the incident and disseminates warnings and information as required.

Upon notification of an emergency The Emergency Response Coordinator will:

- Immediately report to the Emergency Operations Center
- Proceed to the mine rescue station and organize the emergency response personnel

- Coordinate the gathering of all required equipment and vehicles
- Ensure all required personal protective equipment is identified and utilized
- Brief the Mine Rescue personnel regarding the nature of the emergency and assigned duties
- Ensure that proper communication is established and maintained with all active Mine Rescue personnel throughout operation
- Ensure that a complete record is kept regarding assignments, communications and de-briefing

The Mine Rescue Personnel will seek the Emergency Response Coordinators approval prior to commencing any interventions that could endanger either Mine Rescue Team Members or other personnel.

4.3.2 Mine Rescue Team Captain

The Mine Rescue Team Captain reports directly to the Emergency Response Coordinator in an emergency. The Mine Rescue Team Captain directs the actions of the mine rescue team to rescue trapped or injured workers, protect the mine property from further damage, and rehab the affected area and equipment. The Captain has the right to refuse any task he considers an unacceptable risk to the team. The Mine Rescue Team Captain will be responsible for:

- knowing the Mine Recue Team Members available on site;
- knowing the locations and status of rescue vehicles;
- the direction and safety of team members during emergency situations.

4.3.3 Mine Rescue Personnel

In the event of an emergency all Mine Rescue Team Members report directly to the Mine Rescue Team Captain in the mine rescue training center for briefing. Once assessment of the incident has been completed by the Team Captain any team members not required will be returned to their duties and shall remain on call until needed or the incident has been controlled.

> **3.7.5 HSRC** The manager of an open pit mine employing more than 25 persons per shift shall ensure that
> (1) there is one fully trained and equipped mine rescue team, and
> (2) on every shift where more than 10 persons are working, there are four persons trained in mine rescue procedures.

4.3.4 Mine Rescue Equipment

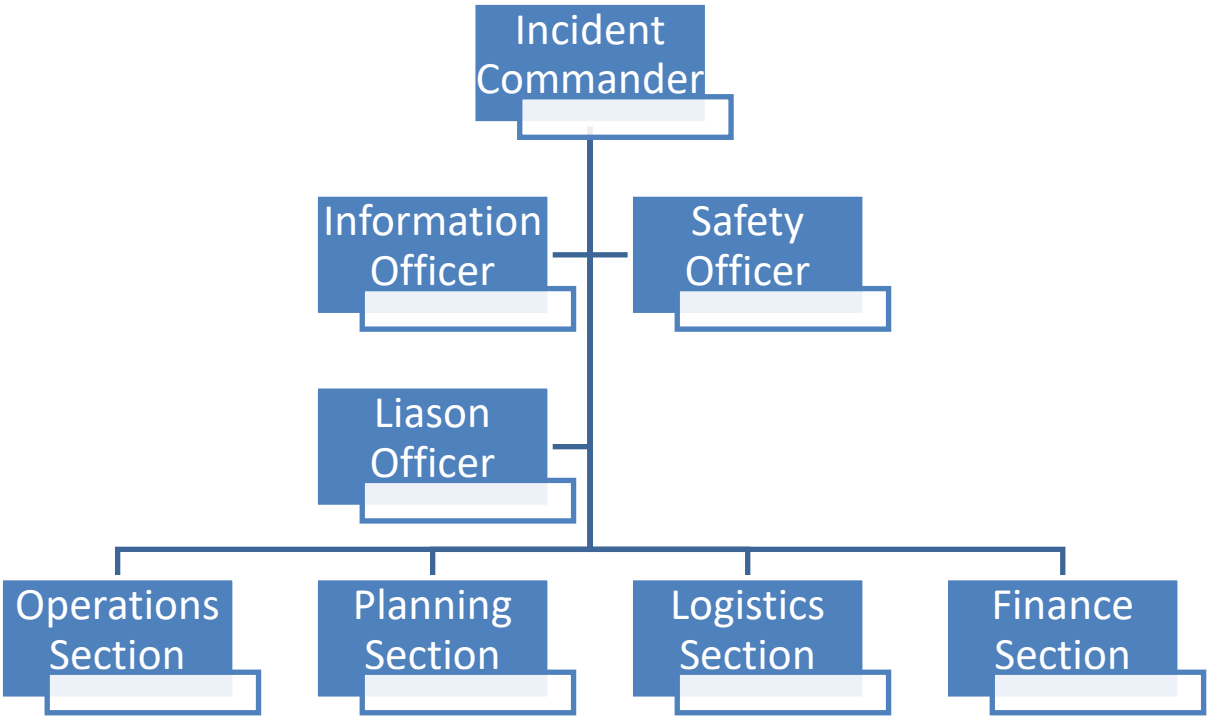
An updated copy of the mine rescue equipment inventory shall be maintained in the mine rescue training center and on the mine rescue truck. These mine rescue inventories shall be inspected on a monthly basis with any changes to the inventory list being completed as soon as discrepancies are found. The Safety Officer will maintain these lists.

4.3.5 Mutual Aid

Mount Polley Mining Corporation does not currently have a Mutual Aid agreement.

All costs pertaining to rendering assistance from other mines or jurisdictions are the responsibility of the mine seeking assistance.

5 EMERGENCY INCIDENT COMMAND



5.1 Incident Command Roles "Control Group"

Incident Command System (ICS)

- In charge of all aspects of emergency management
- Performing command activities, such as establishing commander and the Incident Command Post
- Protecting life and property
- Setting objectives, strategies and incident action plan
- Controlling and accounting for personnel and equipment resources
- Establishing and maintaining an effective liaison with outside agencies and organizations

With the exception of the Incident Commander (IC), who shall always be designated, the following positions may be implemented by the Incident Commander based on the scope and requirements of the emergency. In smaller incidents the roles may be performed by the IC, but larger incidents may require the IC to establish Sections whose activities are to support the IC.

5.2 ICS - Chain of Command Flow Chart

The Incident Commander will assign personnel to these positions.

6 EMERGENCY IDENTIFICATION, PREVENTION AND PROTECTION

6.1 General Evacuation

When an emergency occurs that is significant enough to affect the health and safety of employees in any work area, an evacuation of all areas may be required.

6.1.1 Responsibilities of Personnel

- Know the location of all the emergency exits in your work area, particularly the nearest one to you.
- When the alarm for the evacuation of your area is sounded and/or the notification is given by your supervisor, immediately stop what you are doing and go, in an orderly manner, directly to the areas designated Muster Point.
- When you leave your work site, CLOSE ALL DOORS AND WINDOWS. If you have enough time, close valves, shut off equipment, computers, office equipment and lights; safeguard confidential information by locking desks and file cabinets.
- If you are the last person to leave the area, check that all work areas are emptied of personnel, provided that circumstances and time allow you to do so.
- Personnel that work in critical areas of the process must perform the emergency shutdown procedures established for these areas.
- **WALK, DON'T RUN**. In an emergency, move fast but don't run. Remain in control, do not panic.
- Avoid smoke-filled environments. If a space that is full of smoke is the only exit route, crawl, escape through a window or if safe to do so remain in position and notify your supervisor of your location.
- Go to the muster Point assigned to your **work area**. Make sure that you establish contact with your supervisor (or the designated person) as soon as possible.
- Those people who know of lost personnel should immediately inform their supervisor.
- Do not re-enter the evacuated area or return to the scene of emergency to offer aid, unless the Incident Commander specifically requests your presence.

6.1.2 Muster Points

The Muster Points are designed to be used by personnel during an evacuation due to an emergency. Accommodations will be made to avoid exposure of the evacuees to the inclemency of the weather.

The following areas are designated Muster Points in the event of an emergency:

- **Outside Mine Rescue Training Center**
  All workers assigned to duties in the mill building, warehouse, admin
  Back-up Location: Employee parking lot
- **Outside the Crusher Maintenance shop**
  All workers assigned to duties in the Crusher building, Crusher Maintenance shop
  Back-up Location: Employee parking lot
- **South East Rock Dump (SERD)**
  All workers assigned to duties in the Pit and around the Tailings Storage Facility including The Water Treatment Plant
  Back-up Location: In-Pit Washrooms

In the event that an identified muster point cannot be used due to safety concerns the Incident Commander will designate alternate locations.
Generally a Muster Point is defined as an area that is:

- A minimum of 15 meters distance from the affected facility
- Located against the wind and uphill

6.1.3 Accounting for Personnel

All personnel working onsite shall sign in and out at the Mine Access Gate House.

The supervisor or most senior employee will be responsible for accounting for the personnel under their charge. This is done by performing the following steps:

- Ensuring that all the personnel leave their work area during the evacuation.
- When they have reached the designated Muster Point, perform a headcount of all personnel (employees, contractors, visitors, etc.) who were within the work area at the time of the emergency.
- The Daily Sign-In Sheet will be used for accounting of personnel during emergency situations. Once the head count has been completed, the supervisor must report any discrepancies in personnel, including any missing personnel and/or any individuals that normally work elsewhere.
- In turn, each supervisor will report to their next level of management until personnel information reaches the senior management person for each department at the assembly area.
- The senior management person for each department will account for all departmental personnel. This accounting should include all employees, contractors, delivery personnel, temporaries, and visitors under their supervision.

- Once all personnel have been accounted for the senior department representative shall communicate this information with Incident Command and Emergency Response Coordinator
- Departmental management at each assembly area should communicate with each other to determine the location of any missing personnel.
- If personnel are deemed to be missing, the Incident Commander and Emergency Response Coordinator should be contacted immediately.
- All supervisors shall keep their groups together at their respective assembly areas until the Incident Commander gives further instructions.

6.1.4 Search and Rescue

If a building has been evacuated, personnel shall not re-enter the building until the all clear signal is given, or directed to do so by the Incident Commander.

Mine Rescue trained personnel are permitted to enter an area that has been evacuated to perform search and rescue before the all-clear signal is given. Search and rescue is the responsibilities of the Mine Rescue personnel and will be conducted in accordance with their standard operating guidelines. The Mine Rescue Team Captain may enlist support from the Area Supervisor or their designate for knowledge of the area.

Note: There will be no search and rescue undertaken unless an adequate backup personnel are ready and standing by.

6.1.5 Pit Evacuation

Notification to evacuate the pit will be made through radios and may only be authorized by the supervisor. Instructions will be given for the operations personnel in charge of vehicles to move to the Assembly Points that have been determined to pose no danger.

The personnel who do not have any vehicle or do not have access to one (such as operators of drills, blasting equipment, etc.) will be picked up by light vehicles. It is very important that these workers wait at the designated Muster Point safely outside the emergency area.

6.1.6 Site Evacuation

The decision to conduct a full site evacuation will be made by the Incident Commander. The Incident Command Team will be responsible for arranging transportation off of the property.

- The Incident Commander must determine the final location of the evacuees.
- Transportation for the personnel must be coordinated.
- The headcount should be confirmed to ensure all personnel are accounted for.

Access and Egress to the Mine site

In the event that mine access road prevents any entry or egress of the mine site, the Incident Commander will refer to Appendix A – Site Evacuation Routes for alternate site evacuation routes. If all of these routes are compromised then other options, such as helicopter evacuation shall be considered.

6.1.7 End of the Emergency and Return to Work

The evacuated area must be left free of dangers. The Mine Rescue trained personnel will conduct a thorough inspection of the evacuated facilities. If there was a fire or if damage is found in the structures, the area must be inspected by Maintenance and Health and Safety personnel to determine if the area is safe to be occupied.

Once the area has been declared to be safe, the On Scene Commander will notify the Incident Commander of this circumstance so that he proceeds to stop the emergency signal. The Incident Commander will transmit the order to stop the emergency signal through all channels. Transmission will include a description of the evacuated areas with the key phrase:

"All clear"/you can return to the area".

This message must be repeated three consecutive times.

The employees may return to their work once the transmission of the end of the emergency has concluded.

A debriefing will be completed at the end of all emergencies. The debriefing session will be documented to address what was completed correctly and what improvements are needed. The Emergency Response Plan will be reviewed and, if necessary, revision made.

6.2 Medical Emergencies

6.2.1 Responsibilities

First on Scene Persons Duties

- Prior to accessing the scene ensure the area is safe. If unsafe to approach, immediate contact the supervisor to report the conditions.
- Quickly assess the situation determining the number of injured persons, the severity of injuries and what resources may be required to deal with the emergency situation.
- Immediately inform the area supervisor of the incident, including required resources.
- Give the supervisor the following information:
  - Your name
  - The location of the accident
  - The number of injured persons
  - The nature of the injuries
  - The best route to be used to approach the accident location
- The supervisor will contact the Incident Commander in order to dispatch the Mine Rescue Team.
- Do not move the injured unless they are in imminent danger.

- Restrict access to the scene by any unauthorized individuals and ensure security of any evidence.

On-Scene Commanders Duties

- At all times ensure the safety of personnel and emergency responders.
- Assess the accident scene.
- Contact the Incident Commander to apprise them of the situation, notify them of what additional resources may be required, and update the information whenever the situation changes or additional information becomes available.
- Have someone present assist you with the communications and recording of information & times. (Assign a Log Keeper)
- Control access to and preserve the emergency scene

- Note and record all details of the incident as soon as possible
- Prepare a report of the incident
- Get the names of eyewitnesses and others who may have relevant information.

Emergency Response Team Duties

- Respond to the scene as directed by the on scene or Incident Commander
- Apply appropriate care following protocols outline in training
- Initiate the request for any off-site resources as required (BC Ambulance, Fire Department)
- The Emergency Response Team Captain or Medic will keep the Emergency Response Coordinator or Incident Commander informed of any required resources
- Provide medical assistance and/or evacuate the patients(s) safely and quickly
- Preserve evidence and scene security

6.2.2 Transportation

MPMC procedure G03 Medical Evacuation shall be followed when any injured worker requires medical evacuation, either to meet BC Ambulance Service or to a medical facility.

6.2.3 Fatality

Personal injuries that result in fatalities require special action due to local law and conditions. If the injured party is clearly and definitely deceased, the remains are not to be moved until authorization is received from the RCMP, or the Coroner. Mount Polley Mine Manager or Designate is responsible for notifying the RCMP, Coroner and Ministry of Energy, Mines and Low Carbon Innovation (EMLI).

Due to the nature of fatalities, special emphasis shall be placed on securing the incident scene and all evidence. This shall be done to support investigating the accident, determining the causes and taking the necessary steps to prevent any reoccurrence.

All fatalities will be investigated by a Special Investigation Team made up of:

- The General Manager or his designate.
- The Superintendent of the Area Affected.
- The Senior Safety Coordinator
- The employee's supervisor
- JOHSEC Co-Chairs (Joint Occupation, Health, Safety and Environment Committee)
- Others, as determined by the General Manager / Health & Safety and as circumstances require, e.g. technical advisors

Work Related Fatality – Supervisors Duties

- The Supervisor ensures the barricading of the area surrounding the accident scene to guarantee evidence is preserved.
- The Supervisor ensures that the Health & Safety personnel are notified immediately.
- The Supervisor shall notify promptly the following people:
  - His immediate Supervisor
  - The Area Superintendent
  - Incident Commander
- The supervisor will confine the information to the facts of the accident, having made positive identification of the deceased. Radio discussions of the accident will be minimized and names will not be broadcast.
- The supervisor will preserve the accident scene and all physical information until relieved of this responsibility by the Health & Safety Representative, or employee he designated, or the Area Superintendent. Accident site visits will be limited to only necessary emergency response personnel, managers, and regulatory officials as required.
- The supervisor is responsible for completing a preliminary report of the accident. The Investigation Team will complete and distribute the final report as appropriate.

Work Related Fatality- Health and Safety Duties

- Ensure that the scene is properly preserved, documented and evidence collected.
- Health & Safety will initiate legal reporting, to all agencies that have authorization in the case. The Senior Safety Coordinator or his designate will follow up to ensure that appropriate notifications have taken place.
- The Senior Safety Coordinator will inform Mount Polley Mining Corporation's Senior Management.
- The Senior Safety Coordinator and other necessary management personnel will conduct a briefing session, if possible, with representatives from the local authorities prior to their inspection of the accident scene.
- The Senior Safety Coordinator will serve as a member of the Special Investigation Team.

- After all investigations have been completed, the Senior Safety Coordinator will prepare a final report of the accident in writing to the General Manager, and area Superintendents. He will also include copies to be sent to the local authorities after approval.
- No information will be given to any other source or agency without authorization from the General Manager.

Work Related Fatality – Department Superintendent Duties

- Ensure that the scene of the accident is secured and that no evidence can be tampered with
- Advise promptly the facts of the fatality to the Incident Commander.
- Stand ready to act as required or directed by the Incident Commander.
- Serve as a member of the Special Investigation Team.

Work Related Fatality – General Manager Duties

- Inform Mount Polley senior management and executive team of the occurrence.
- Ensure notification of the appropriate authorities is underway:
    - RCMP
    - Coroner
    - Ministry of Energy, Mines and Low Carbon Innovation
        - Local Inspector
        - Chief Inspector
    - Local JOHSEC (Joint Occupation, Health, Safety and Environment Committee)
- Ensure notification of next of kin occurs as soon as authorities allow
- Once the emergency is under control, the General Manager or his designate will visit the accident scene to assist in the investigation.
- The Incident Commander will return the accident site to its operational condition as soon as possible, being consistent with the requirements of Health, Safety and Reclamation Code.

6.3 Fire Emergencies

At all times be familiar with the evacuation routes of your work area. The best way to protect yourself is to be able to quickly evacuate a work area in the event of a fire or other emergency. Prior to fighting any fire, ensure that it is within the scope of your training and that you maintain a suitable exit route at all times. Large fire will be managed by the site Mine Rescue/Emergency Response Teams.

6.3.1 Fire Prevention

Automatic Fire Alarm: Site buildings are monitored through a fire alarm system. This system will activate and signal through audible bells and sirens for area evacuation.

Monthly fire suppression systems and handheld fire extinguisher inspections are essential to ensure the integrity of all systems.

Scheduled maintenance and repairs are imperative in order to maintain the integrity of fire suppression systems. Particular attention to housekeeping and observing the National Fire Code will ensure that fire protection remains effective at all times.
Combustibles shall not be stored inside buildings unless they are part of a work process.
Flammable materials such as paints and aerosols shall be stored in approved and appropriate storage cabinets.
Fire Extinguisher training: personnel shall be trained and familiar with safe use and application of Hand Held Fire Extinguishers.

6.3.2 Reporting and Extinguishing Small Fires

The site is equipped with hand-held fire extinguishers and fire hydrants for occupant first-response use on small fires. The initial response should be as follows:

- Warn occupants in the immediate fire area.
- Activate a fire alarm if one is nearby
- Activate any fire suppression systems that may be available.
- Attempt to extinguish the fire with a handheld fire extinguisher or fire hydrant if safe to do so.
- Notify the area supervisor via the appropriate radio channel.

Other Actions

- Relevant Supervisor is responsible for making sure that their area is evacuated.
- Regardless of the size of the fire, building occupants must assemble immediately at a designated Muster Point.
- All supervisors shall keep their groups together at their respective assembly areas until the Incident Commander gives further instructions.

6.3.3 Uncontrolled Fires

The following procedures apply to small fires that cannot be extinguished or fires that pose danger to human life/property or production.

- Warn occupants in the immediate fire area.
- Activate a fire alarm if one is nearby
- Activate any fire suppression systems that may be available.
- Notify area supervisor.
- Notify Mine Rescue trained personnel of the location and extent of the fire.

Mine Rescue Team (ERT)

- Responds to the emergency with the relevant equipment.
- Isolate the area and evacuate as many people as possible.
- Ensure rescue of trapped or injured workers.
- Provide firefighter measures within scope of training and request outside resources if required.

Isolating Utilities

The Incident Commander shall instruct the Mill Maintenance and Electrical department to Shut off and isolate power and other utilities to the fire area that could hinder emergency response.

Water Sources

- One of the most important factors to consider when fighting fire shall be maintaining an adequate supply of water and ensuring that alternate sources are readily available.

6.3.4 Wild Land Fires

Any range fire on mine property should be immediately reported to the area Supervisor. The area supervisor shall be responsible for summoning the help needed to extinguish the fire if necessary.

All responses to the fire will be coordinated by the Area Supervisor & Incident Commander. Response should be limited to extinguishing a small fire in its early stages. If the fire cannot be contained with the resources of the mine, response will be limited to protection of mine property.

The Site Manager should be notified of any major fire, or a fire that threatens life or mine property.

The main aim in responding to a Rangeland Fire is to:

- Report it to the area supervisor and Incident Command
- Evaluate the danger to personnel and infrastructure.
- Continual monitoring of the fire for direction, speed, size, smoke, etc.
- Allocation of resources as needed.
- Evacuate to a safe place accounting for all persons on site.
- Help with fire in area as situation warrants and as directed by Incident Command

BC Wildfire Service (BCFS) Wildfire Management Branch

The Wildfire Management Branch has the resources and personnel that are specially training to deal with wildfires. If required, the Incident Commander should initiate contact with the BC Wildfire Service as soon as possible during a wildfire event.

BC Wildfire Service contact line - 1-800-663-5555 or *5555 from a cellular phone

6.4 Hazardous Materials and Chemicals

6.4.1 Spill

For detailed information on Hazardous Materials and Chemical spills see the Spill Response Manual Appendix D

6.4.2 Training

Personnel assigned spill clean up duties must be trained in Hazardous Materials Spill Cleanup

6.4.3 Main Response Elements

Any reportable leak, spill, or release outside containment areas must be reported to the Environmental Department immediately. All external notification and reporting shall be conducted by the Environmental Superintendent or their designate. Containment and cleanup activities shall only be performed as directed by Environmental personnel.

6.4.4 Find and identify

- Mitigate the source of the spill
- Establish communications system
- Collect information
- Isolate the Emergency Scene

6.4.5 Notify

Hazardous Materials spills must be reported to the Environmental Department immediately.

6.4.6 Spill Assessment

See; Spill Response Manual 2019 Appendix D

6.5 Vehicle Incidents

There is a potential for vehicle accidents involving multiple casualties on the Mine-Access road. There would be a reasonably high risk of multiple casualties taking into consideration the volume of traffic and the mode of transportation, that being buses and multi-passenger vehicles.

Access control

One of the early priorities would be to prevent access to the scene by assigning 2 persons as guards, one at each end of the mine access road.
Travel into and out of the mine can then be restricted to essential and key personnel.

Emergency Response Personnel

If indeed there are multiple casualties it may be necessary for additional outside medical help. It would take a minimum of 1 hour for help to arrive from Williams Lake and if available, 30 minutes response from Likely; therefore, it is of the utmost importance that a “Triage station” be established so that casualties can be transported in the order of emergency medical importance.

Transportation

Consideration must be given to the situation where there are multiple casualties needing transportation to medical facilities in Williams Lake. If this is the case it may be necessary to facilitate the use of crew cabs or other multi-passenger vehicles as long as they can provide the necessary comfort for the casualties
The Designated First Aid Attendant is to respond to Medical Emergencies.
Where injuries require Medical Treatment follow procedure G03 Medical Evacuation
Where there are multiple casualties it may be necessary to establish a "Triage station" so that casualties can be transported in the order of emergency medical importance.

6.6 Land Movement

6.6.1 Prevention of Burial

Either a shift boss or a qualified person will examine dumps or stockpiles prior to any work being performed. Dumps, Stockpiles and Pit Walls will be monitored at intervals not to exceed four hours while in use.

The conditions noted shall be recorded in the daily logbook. Items of concern include:

6.6.1.1 Dumps and Stockpiles:

- Cracks appearing on the dump floor or face.
- Subsidence of the dump floor.
- Material hanging up on the face of the dump.
- Water flows or pooling

6.6.1.2 Pit Walls:

- Cracks developing along or near the edge.
- Cracks in the face.
- Overhangs developing on the bench face.
- Water flowing into the rock

If any of the above items are observed contact the Shift boss who will inspect the site and determine what actions are to be taken. In the event that the area appears unsafe do not enter and contact the Shift boss immediately for direction.

If cracks are observed on the rock dump floor the area shall be blocked off and monitored to determine if additional movement is occurring. Dumping in the area shall not recommence until the Shift Boss gives approval.

Overburden and soils piles will slough and compact as they are being built. Dumping shall take place back from the edge and dozed over. If bulging of the face or curved cracks are observed dumping shall cease in the area and the area shall be monitored for additional movement. Dumping in the area shall not recommence until the Shift Boss gives approval.

6.7 Tailings Storage Facility

6.7.1 Potential Emergencies

For detailed information on potential Tailings Storage Facility Emergencies see: MOUNT POLLEY MINE TAILINGS STORAGE FACILITY EMERGENCY PREPAREDNESS AND RESPONSE PLAN.

Located at the Mount Polley Microsoft Teams network at General \ Emergency Response Plans \ Tailings Storage Facility

6.8 Weather Related Emergencies and Natural Disasters

In severe weather, seismic, or other natural disaster situations personnel will keep away from high risk areas created by the condition.

Examples are:

- High winds or earth movement/permafrost subsidence - Stay away from power lines, high walls, and embankments that may be affected.
- Extreme precipitation (heavy snow or rain fall) - Keep personnel and equipment out of possible voids & high drift zones or flood areas in the case of heavy rain
- Heavy snow - Maintain accessibility for personnel and emergency equipment
- Lightning - Keep personnel out of non-protected elevated areas and other high-risk situations.

In the event of any severe weather conditions or other natural disaster situations the Mine Manager or Designate shall be notified.

6.9 Unplanned Explosions

Unscheduled Explosion – First on Scene Duties

- Call the relevant supervisor, report the situation, and follow their instructions.
- Assess the situation. Evacuate the affected area. Move to a safe vantage position. Do not endanger yourself or other rescuers.
- Stop all operations in the area until it is safe to resume.
- If there is anyone injured, follow the procedures herein for Injuries / Medical Accidents.
- If there is anyone in need of rescue, identify the need for the Mine Rescue team.
- Remain at the safe vantage position until relieved by the Supervisor and authorized to leave.
- Ensure that the Department Manager is informed of the emergency via radio or telephone.

Unscheduled Explosion - Supervisors Duties

- In the event of an unplanned detonation, ensure that the area is evacuated and secured. DO NOT ENTER the area except to rescue an injured person and then only if safe to re-enter (If possible, efforts should be made to get the Mine Rescue Team to the scene.)

- Proceed to a safe vantage position. Confirm the assessment of the situation with the First on Scene Person.
- Co-ordinate the immediate emergency response from the safe vantage position.
- Together with the Area Manager, decide on the Level of Emergency (LOE) warranted by the situation. Be prepared to change this if the situation escalates or diminishes in severity.
- Establish controls on all roads leading to the area.
- Prepare access to the scene for emergency services vehicles when it is safe for them to enter the area, and direct them to the scene.
- Ensure that the following personnel have been notified: Mine Operations Manager, Mine Operations Assistant Superintendent, Senior Safety Coordinator.
- See that the Mine Rescue Team is supported in their immediate response requirements.
- With the On Scene Commander, decide if additional off-site emergency services are required.
- When the situation is stabilized, assist the Manager with the investigation of the emergency.
- Ensure the area is secured.

Unscheduled Explosion – Area Superintendent Responsibilities

- Proceed to the scene of the emergency, if it is safe to do so, for an initial assessment.
- Consider secondary explosions, toxic gases, and structural collapses.
- Co-ordinate the response of various on-site specialists such as medical, fire, environmental, Mine Rescue Team, etc.
- Advise the Emergency Operations Group with details of the emergency, the immediate response taken, and if any risks remain.
- When the situation has stabilized, conduct an investigation of the causes, effects and response to the explosion, and prepare a written report.
- Security shall be assigned to control access to the affected area.

6.10 Bomb Threat

6.10.1 Bomb Threat - General Guidelines Procedures

Threat recipient:

- Make every effort to remain calm and relaxed.
- Record the call, if recording equipment is available.
- If a recording cannot be made, try to transfer the caller to the emergency number where a recording can be made.
- If unsuccessful, follow the guidelines in the Bomb/Threatening Call Record sheet to obtain as much information as possible from the person making the threat. **Attached at Appendix A**
- If the threat is in written form, put the letter and envelope in a plastic cover and refrain from unnecessary handling.

- Inform the Senior Safety Coordinator and Area Manager immediately after receiving the threat and wait for further instructions.
- If the caller indicates that the bomb is in the building that you are occupying, immediately start the evacuation process, taking the notes made during the threat call with you.

Observer of item suspected as a Bomb:

- Do not touch the device.
- Inform the Area manager as well as the Senior Safety Coordinator
- Start the orderly evacuation of the immediate area.

6.10.2 Responsibilities

On-Scene Commander's Duties

- Notify Internal Security and consider advice from the RCMP.
- Assess the situation and decide the following:
  - If a full or partial evacuation, or none at all, is warranted.
  - If a search is warranted and can be safely done.
  - When it is safe to reoccupy the site or office.
- Make sure everyone is accounted for at the designated assembly point for that area.

Mine Rescue Team Duties

- The Mine Rescue Team will respond with an ambulance, (if available) and appropriate rescue and firefighting equipment. These units will stand-by at the Incident Staging area where the On-Scene Commander (OSC) is located, at least 300 meters from the suspect device or location of threat.
- In the event of a detonation, when deemed safe to do so, normal Emergency Response procedures will be carried out.
- The Mine Rescue Team will provide the required fire/rescue/medical/search and recovery services and any other services as needed.
- The Mine Rescue Team does not participate in securing the bomb.

7 MINE WATER SUPPLY SYSTEM

- Mine site tap water is untreated and is not considered drinkable, bottled drinking water is provided and all sink tap locations are signed with “DO NOT DRINK TAP WATER”.
- Bottled Drinking water provided to site by Cool Clear Water, Williams Lake.
- All Mount Polley’s water samples are tested by ALS CANADA LTD.
- When maintenance tasks are required and unable to be completed by onsite personnel, then resources will be drawn from outside contractors.
- Interior health can be contacted in any emergency scenario to help with health risk assessments.

7.1 Potential Emergencies

7.1.1 Mechanical / Electrical water system failure

- Contact the General Manager or his designate (On Call Manager)
- Limit water usage on mine site
- Arrange for potable water to be trucked to site until the water well supply system is returned to operational condition
- Arrange for Sanitary stations
- Affect repairs

7.1.2 Water sampling test results outside acceptable parameters.

- Shut down water supply system
- Contact the General Manager or his designate (On Call Manager)
- Arrange for potable water to be trucked to site until the water well supply system is returned to operational condition
- Arrange for Sanitary stations
- Identify source of contamination
- Disinfect well system if applicable

8 MINE SITE ACCESS CONTROL DURING EMERGENCY OPERATIONS

During an emergency, access to the mine site shall be limited to persons and equipment necessary for support of the management of the incident. In order to facilitate site access control a guard will be positioned at a location on the Bootjack FSR that allows for traffic control. This position will normally be at KM 8 of the Bootjack FSR.

The following materials will be needed when deploying site access control:

- A log book to record all personnel being granted access to the site. This log shall record date, check-in/out time, name and company name
- Reliable communication with mine site
- Lighting for night operation
- Traffic control devices, reflective cones, flagging tape and/or barricades
- Warning signage for vehicle operators

Appendix C Protocol for Corporate Reporting 104

Appendix D Preliminary Incident Report 106

Appendix E Reportable Levels 108

Mount Polley Mining Corporation
EMERGENCY RESPONSE PLAN

EFFECTIVE DATE: February 2005

REVISION DATE: March 2013, April 2014, March 2016, July 2019 , Aug 2020

1. Overview

1.1. Policy:

To ensure preparedness and to maximize valuable time in case of an emergency.

To confirm Mount Polley Mining Corporation commitment to operating its business at the highest standards to protect the health and safety of workers, the public, and the environment.

1.2. Definition of an Emergency

A current or imminent situation that requires prompt coordination of actions of trained persons to protect health, safety, or welfare of people and to limit damage to property and to the environment.

1.3. Definition of a Reportable Spill

- A release or discharge into the environment, not authorized under the BC *Environmental Management Act* of a substance in an amount equal to or greater than the amount listed in Appendix E.
- A release of mine influenced water of any volume (outside of permitted effluent discharge volumes) is reportable.
- A release or deposit any deleterious substance in any water.

1.4. Legal Definition:

A spill means any polluting substance whether gaseous, liquid or solid that, in the opinion of the minister, is capable of causing pollution if it were to:

- Escape into the air
- Be spilled onto any land or into any body of water, or
- Escape onto any land or into any body of water.

1.5. Objectives:

1. Ensure compliance with B.C. Environmental Management Act: Part 7
2. Ensure compliance with the Federal Metal Mining Effluent Regulation.
3. Ensure compliance with the Federal Transportation of Dangerous Goods Act.
4. Ensure compliance with the Federal Fisheries Act.
5. Outlines response strategies to spills of potentially hazardous substances at or near the mine-site.
6. Facilitate the rapid deployment of trained personnel to deal with spills so that the environmental impact and risk are minimized.
7. Provides Guidelines for Communicating environmental incidents and issues to corporate management
8. Ensure that responsible personnel are:

- Familiar with the Emergency Spill Response Contingency Plan.
- Aware and are trained in the potential hazards associated with the Plan.
- Understand and are trained in the responsibilities of Team Members.
- Locations of spill containment materials.
- Action Plan for respective substances.
- Reporting procedures.

1.6. Plan Audits and Revisions:

The Environmental Superintendent is responsible for conducting an annual review of this plan and revising it when necessary.

1.7. Training:

It is the responsibility of the Mine Manger or Designate, with the assistance of the Safety Department, to organize, coordinate and conduct training sessions of the mine-site Emergency Response Team Members.

2. Contact Numbers

2.1. Critical Personnel Contact Phone Numbers

For Critical Personnel Contact Phone Numbers see Critical Personnel Contact Phone Numbers Section 3.4 Mount Polley Mining Corporation Emergency Response Plan

2.2. Agency Critical Contact Phone Numbers

2.3. Regulatory Reporting Numbers

The Emergency Contingency Plan Control Officer/Designate must contact Emergency Management BC.

1-800-663-3456

This is a 24-hour toll free number.

The Emergency Management BC Program staff will notify all concerned agencies, including the following, as appropriate:

BC Ministry of Environment	EnvironmentalCompliance@gov.bc.ca
Ministry of Health.	1-800-663-7867
Environment Canada (24hEmergency – report to BC Ministry of Justice)	1-800-663-3456
Environment Canada (Vancouver Office)	1-604-664-9100
Soda Creek Indian Band	1-250-989-2323
Williams Lake Indian Band	1-250-296-3507
BC Mines Inspector	1778-220-5852

3. Spills

3.1. Potential Spill Materials:

1. Gasoline
2. Diesel Fuel
3. Waste Oil
4. Coolant
5. Hydraulic Fluid
6. Mill Tailings
7. Propane
8. Lime
9. Mill Reagent NaHS
10. Acids
11. MIBC (W22)
12. Concentrate
13. Mine Influenced Water
14. Till/mud/soil/rock
15. IPAC

3.2. Potential Spill Types:

1. Minor spills from equipment due to leaks.
2. Minor spills from containers being damaged or knocked over.
3. Minor/Major spills from fueling stations.
4. Major spills from storage tanks outside the Mill.
5. Major spills from storage tanks inside the Mill.
6. Major spills form transportation and delivery vehicles.
7. Spills from slurry tailings line.
8. Releases of mine influenced water from water collection or transportation facilities.

3.3. Potential Spill Locations:

1. General Mine-site grounds.
2. Mill Building and surrounding areas.
3. Fueling station.
4. Access road to mine site.
5. Access road around mine site.
6. Open Pits.
7. Ditches and pipeline routes.
8. Water storage sumps and ponds.
9. Creeks, lakes and surface water bodies in and around the mine site, including the Hazeltine Creek effluent discharge site.

3.4. Spill Response Materials Locations

1. Light vehicle fuel island (Warehouse).
2. Fuel Island (beside the Crusher).
3. Maintenance areas (Pit Shop, Finning/Shovel Crew Laydown)
4. Springer Pit.(MDG)
5. Warehouse (Entrance and in yard, with spare materials in stock).
6. Lower Hazeltine
7. Reach 3 Creek Construction
8. Cold-Water Pump location (Weir)
9. 9K Sump
10. Mine Drainage Sump
11. CCS Sump
12. South Seepage Sump

3.5. Spill Assessment Potential

Transportation:

The area of greatest vulnerability for spills is transport related incidents resulting from road conditions, and mechanical failures. Contingency plans are filed by the Shipper of the transport company with Transport Canada and drivers are required to be in possession of these files in order to address these types of incidents.
Ensure that Shipping Paper is carried in the cabin of the transport vehicle.

The Company:

Undertakes to provide information to the Shipper on avoidance of poor road conditions and rescheduling of deliveries, if necessary.
Ensures to maintain the mine road conditions in as favourable condition as possible.
Provides the manpower and equipment required to control and minimize the effects on the environment.

Fuels:
Standard procedures are in effect for the safe unloading of fuels to storage tanks and safety berms are provided to contain spills at the storage facilities.
Emergency Contingency Plans for effective response to spills are addressed in this document.

Lime:
Unloading of granular quicklime from bulk tank trucks can result in spillage. These spillages, if any, will be cleaned up with a front-end loader and disposed of.

Explosives:
Transport, handling and transfer of explosives are addressed within the Emergency Contingency plan of this document. Explosive materials storage is in separate containers and conform to the Ministry of Mines and Transport Canada standards.

Tailings:
The tailings lines are protected by against vehicle collision. The pipeline is also contained in a ditch along the access road to the tailings pond.

Mine Influenced Water:
Site water collection sumps, ponds, and ditches, water transport pipes, and the Hazeltine Creek Discharge System, all have the potential to release water into the environment, possibly entering surface water bodies. Breaches may occur due extreme runoff events, physical damage to pipes or other facilities, or pump failure.

Hazeltine Creek Effluent Discharge System

The installation of continuous monitoring for conductivity, temperature, and flow provides employees with immediate notification of changes in the discharge. As well, the emergency “shut down” system will prevent the discharge of water which exceeds the set limits for continuous monitoring as defined by Mount Polley Mining Corp. the Metal Mines Effluent Permit, and Ministry of Environment PE-11678.

Pump failure triggers emergency "shut down" and all storage tanks are designed to overflow into existing effluent storage facilities.

Other Consumables:
All consumables are contained within their original shipment containers prior to transfer to end user containers. End user spillage Emergency Contingency Plans are addressed in this document.

4. Response

4.1. Contact Group

Spills of chemicals, fuels and other substances may occur as isolated events or they may occur with other emergencies such as fire, explosion, natural causes or accident.

A number of response personnel may be involved to protect mine property and the health and safety of mine personnel and the public.

The key persons involved during a spill occurrence would be as follows:

- The person discovering the spill, and his/her Supervisor.
- The General Manager or his designate (who may be the On-Call Supervisor if the General Manger cannot be reached outside of regular hours).
- The Area Superintendent.
- The Safety Department.
- Mine Rescue trained personnel
- The clean-up crews.

The responsibilities of key personnel are outlined in the Personnel Responsibilities section.

Applicable telephone numbers are kept current and posted at the mine-site.

4.2. First-On-The-Scene Personnel Responsibilities

4.2.1. Person discovering the spill:

- Assess the hazard to one's own health and safety and to others in the vicinity.

- If the risk of gas poisoning exists ensure to conduct atmospheric testing with the appropriate equipment prior to entry.

- If fire or explosion hazards are perceived immediately retreat to safe distance.

4.2.2. In both these situations:

- Barricade/Flag the area.
- Place physical guards at a safe distance.
- Warn others in the immediate vicinity of the situation.
- Notify the Area Supervisor IMMEDIATELY following initial response action.
- Arrange for appropriate operating equipment to be shut down, if applicable, to minimize the extent of the spill.
- If warranted, notify designated First Aid Attendant for first aid.
- Firefighting response will be trained site personnel backed up by Mine Rescue trained personnel.
- The Supervisor or the person discovering the spill with the following information must contact the General Manager or his designate IMMEDIATELY following initial response action:

  - Name of person discovering the spill.
  - The time of the spill.
  - The location of the spill.
  - The type of substance spilled.
  - The quantity of material been spilled.
  - The cause of the spill.
  - The weather conditions.
  - Perceived potential for hazard, and any injury to aquatic systems, wildlife or people.
  - Actions already taken.
  - Whether a fire or explosion hazard is deemed to exist.
  - Personnel already notified.
  - If the spill is contained.
  - Any environmental effects that have or could occur.
  - Any injuries.

Note:

Ensure every remedial action is taken safely and efficiently to stop and/or minimize the extent of the spill.

The Supervisor must remain in place to direct personnel and equipment upon instructions from the Command Post.

4.3. Levels of Emergency

Level 1- A spill that is **below the external reportable quantity** or an emergency where the **potential health and safety risks are low** (no employees are injured). Incidents that can be cleaned up or resolved with little impact on the mine and or environment. No command post is necessary in such an incident.

Level 2- A spill that is **above the external reportable quantity** or an emergency whereby the **health and safety of staff member(s) may be jeopardized**. It is a spill that requires the initiation of the emergency measures. No external help is needed in this situation but a command post may need to be established.

Level 3- A spill that is **above the external reportable quantity** or an emergency where there is **great potential health and safety risks**. There may be casualties. This type of emergency requires internal and (may require) external intervention. A command post may be set up both onsite and offsite.

	Is the spill above external report quantity?	**Potential Health and Safety Risk**	**Emergency Operations Center**	**External Support**
Level 1	**No**	**Low**	**No**	**No**
Level 2	**Yes**	**Maybe**	**Maybe**	**No**
Level 3	**Yes**	**Yes**	**Yes**	**Maybe / yes**

4.4. Main Response Elements

Find and Identify

Mitigate the source of the spill
Establish Communication System
Collect Information
Isolate the Emergency Scene

Notify

Site supervisors, managers, and employees (according to procedures outlined in this document)
Regulatory bodies and agencies as required (Ministry of Environment, Environment Canada, Provincial Emergency Program), if required.
Soda Creek Indian Band and Williams Lake Indian Band, if required.
Notification to public and media, if required.

Ensure Public Health and Safety Protection

Work with appropriate first responders
- Mine Rescue Team and site First Aid attendants
- Ambulance
- Fire Department
- Police
- Search and Rescue

Environmental Protection

Establish Spill Plan
Manage spill response equipment and resources
Conduct spill material clean up

Terminate the Incident

Complete an incident report

4.5. Personnel Responsibilities

General Manager/Designate:

Deploy response crews and equipment operators to undertake the actual clean-up and supervise their work. Notifies Corporate, Emergency Management BC, First Nations groups, and Media.

Maintain responsibility for the activities at the site of the spill.

Maintain contact with and co-ordinate work with the Environmental Superintendent, Terminates the Incident, conducts brief**.**

- Notifies Government Agencies.
- Monitors Environmental Impact.
- Establishes decontamination measures with safety coordinator.
- Update the Spill Contingency Plan as required, for all potentially hazardous materials, accurate names of personnel and phone numbers.
- Plan and co-ordinate required skills.
- Be responsible for assessing new spill hazards as they develop and take preventative actions, whether covered in the manual or not.
- Check and maintain the operating status of required response equipment, which may be required at a spill.
- Train emergency response personnel with respect to their duties, or work with the Safety Department to do so.

Superintendent of Affected Area:

- Has authority to direct response operations.
- Needs to clear incident action plan with the General Manager (or designate).
- Determines level of Incident.
- Assigns Command Post if necessary.
- Executes the incident action plan.
- Enforces worker safety and environmental protection.
- Briefs team on specific assignment.

Communications

Responsible for the communication and emergency assistance

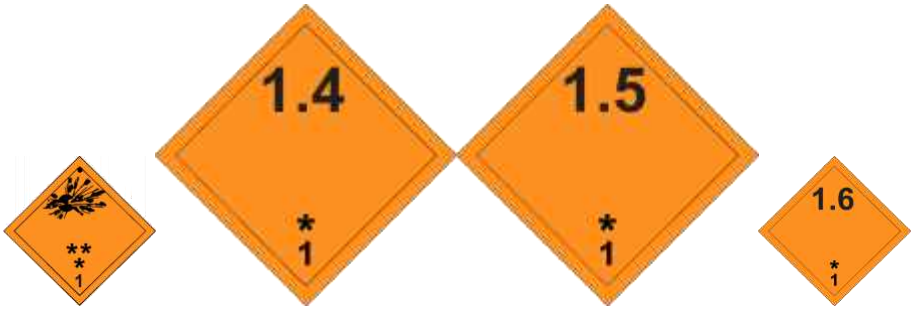
Notifies emergency response personnel by telephone or radio in the event of an emergency

- Assigns scribe
- Records incident details and subsequent developments as they occur.
- Responsible for establishing communication and emergency assistance.
- Establishes external support system (if required)
- Assisting Safety Supervisor.
- Maintains communication contact with the work parties via walkie-talkies, signal horns, or other means

Health and Safety:

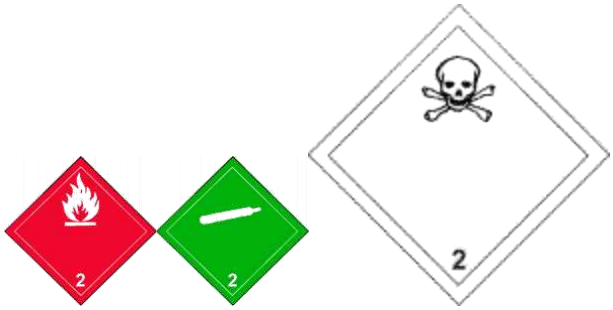
- Advises the incident commander on all aspects of health and safety on the site.
- Recommends stopping the work if any of the work operations threaten worker or public safety.
- Ensure proper PPE is used and maintained.
- Controls entry and exit at the access control points.
- Monitors onsite hazards and conditions.
- Enforces the Buddy system.
- Control the decontamination of all equipment, personnel and samples from the contaminated areas.
- Assist In the disposal of contaminated clothing and materials.
- Advise medical personnel of potential exposures and consequences.

4.6. Emergency Response Team Members:



- Consult the Mine Emergency Response Plan to review the site plan relative to building location of the spilled material and specific location of the material within the building/site.
- Consult the appropriate ACTION PLAN contained in this document, to review the properties of the spilled material and recommended response actions.
- If further information is required, contact one of the resource services listed in Heading 2 of this document.
- Assess the spill requirements for manpower, equipment, materials, tools and protective gear to contain the spill, in consideration of the resources available.
- Mobilize these resources and take responsibility for implementation of the response actions in the spill site.
- If the spill is too large or complex to be handled entirely by the Company's resources, call an appropriate group or agency listed on page 3 of this document.
- Contact the Area Superintendent to determine what, if any, sampling should be done and to discuss the spill and any environmental implications.

- Once the initial response action is underway, contact the General Manager or designate to review the situation and strategy.



Appendix A

Federal and provincial legislation provide for the regulation of an extensive list of products, substances or organisms classified as dangerous. The products fall into one of nine classes:

- Class 1 explosives

- Class 2 gases

- Class 3 flammable liquids

- Class 4 flammable solids, spontaneously combustibles and substances that, on contact with water, emit flammable gases

- Class 5 oxidizing substances and organic peroxides

- Class 6 poisonous (toxic) and infectious substances

- Class 7 radioactive materials

- Class 8 corrosives

- Class 9 miscellaneous products or substances
  - miscellaneous identified dangerous goods
  - certain specified goods considered dangerous to the environment
  - dangerous

Appendix B

Hazardous Material Response Plan

H**azardous Material Response Plan**

Hazardous Materials Checklist

1. Isolate the Area and Deny Entry
   - ❑ Determine the Hazard Area Involved
   - ❑ Establish Control of the Hazard Area
   - ❑ Determine Incident Control Zones (Hot, Warm, Cold)
   - ❑ Advise All Units of Area to be Isolated

2. Identify and Verify the Materials Involved
   - ❑ Obtain Shipping Papers or Facility Documents (*only if safely possible*)
   - ❑ Write Down All Information Obtained
   - ❑ Verify the Source and Accuracy of all Information

3. Hazard and Risk Assessment
   - ❑ Evaluate the Following Concerns

     Health Physical Properties

     Flammability Chemical Properties

     Reactivity

   - ❑ Assess Container Integrity (Stress, Breach, Release, etc.)
   - ❑ Determine all Exposures
   - ❑ Estimate Likely Harm Without Intervention

4. Evaluate Protective Clothing and Equipment
    - ❑ Determine Proper Type and Level of Protective Clothing Required

Note: Structural Fire-Fighting Clothing Will Not Provide Protection

5. Coordinate Information and Resources

- ❑ Coordinate Information Between All Branches/Divisions/Groups
- ❑ Conduct Briefing of All Division/Group Officers to Develop Tactical Options
- ❑ Advise Incident Commander of Tactical Options and Recommendations

6. Control, Containment and Confinement

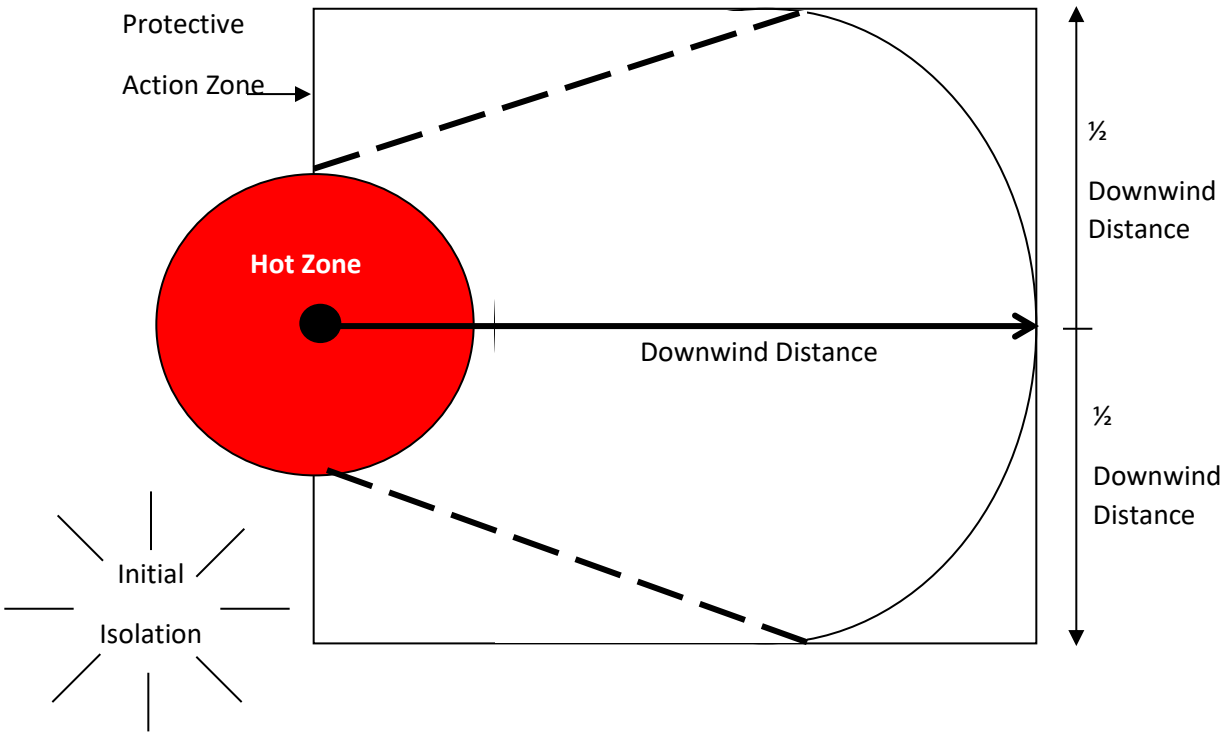
- ❑ Review Tactical Options With Entry Personnel
- ❑ Coordinated All Operations With the Safety Officer
    - ❑ Will Decontamination be Required After Entry Operations?
        - ❑ Yes Implement **Decontamination Procedures Prior to Entry**
        - ❑ No Continue

7. Decontamination Procedures
    - ❑ Decontamination Procedures Determined and Verified
    - ❑ Decon Area In Place and Fully Staffed

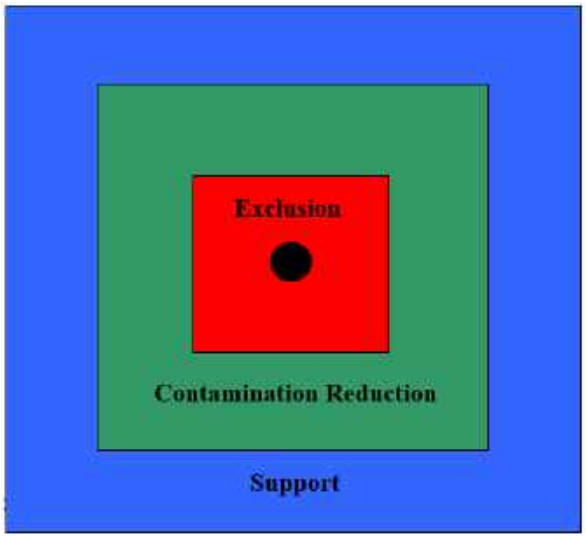
8. Entry Team Procedures

    (SOP's of the department supplying the hazardous materials technicians shall be used for all entries)

9. Termination Procedures



- ❑ Ensure All Personnel Are Briefed as Necessary
- ❑ Signs and Symptoms of Exposure Provided
- ❑ Personnel Exposures Documented

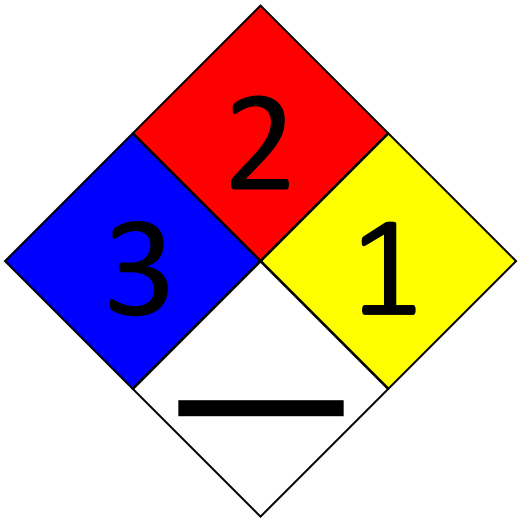


Initial Isolation/Protective Action

Hot- Exclusion Zone. Entry Team only

Warm- Decontamination, Properly trained & equipped personnel only

Cold- Staging & Operations



NFPA 704 HazMat*

Classification

Health Hazard
4-Deadlly
3-Extreme danger
2-Hazardous
1-Slightly hazardous
0-Normal material

Flammability
0-4

Fire Hazard
Flash Points
4-Below 73 F
3-Below 100 F
2-Below 200 F
1-Above 200 F
0-Will not burn

Health
0-4

Reactivity
0-4

(*Not intended to identify non-emergency health hazards)

Specific Hazard

Oxidizer	OXY
Acid	ACID
Alkali	ALK
Corrosive	COR
Simple Asphyxiant	SA
Use NO WATER	W
Radiation Hazard	

Reactivity
4-May detonate
3-Shock and heat
may detonate
2-Violent Chemical change
1-Unstable if heated
0-Stable

Mount Polley Mining Corporation
EMERGENCY RESPONSE PLAN

Hazardous Materials Response Plan

Response Guide by TDG Hazardous Classification

Environmental Canada's Transportation of Dangerous Goods Act divides hazardous materials into nine major hazard classes. A hazard class is a group of materials that share a common major hazardous property, i.e., radioactivity, flammability, etc. These hazard classes include:

Class 1-Explosives

Class 2-Compressed Gases

Class 3-Flammable Liquids

Class 4-Flammable Solids

Class 5-Oxidizers

Class 6-Poisonous and Infectious Substances

Class 7-Radioactive Materials

Class 8-Corrosives

Class 9-Miscellaneous Hazardous Materials

Notes:

- In some emergency response procedures for TDG hazard classes, a distinction is made between bulk or package quantities. Packing Groups indicate the degree of danger of a product or substance, and are always shown in Roman Numerals: **I great danger, II moderate danger, III minor danger**

- Class 9, "Miscellaneous Hazardous Materials," refers to those materials that are hazardous but do not meet criteria for inclusion in the aforementioned classes.

Note: The material presented in this Response Guide has been written in accordance with industry standards. However, this guide cannot anticipate all possible emergency events or situations and emergency responses and therefore cannot be used without the competent review of the emergency response team and plant management. Conditions may develop in operations where standard methods will not suffice and nothing in this guide shall be interpreted as an obstacle to the experience, initiative, and ingenuity of the responders in overcoming the complexities that exist under actual emergency conditions. Responders should use all available resources to determine the appropriate strategies and tactics.

Class 1: Explosives

Definition

An explosive is any chemical compound, mixture, or device, the primary or common purpose of which is to function by explosion, e.g., with a substantial instantaneous release of gas and heat.

General Emergency Response Procedures

1. Identify the material involved.
2. Keep non-essential people away (includes non-essential emergency service personnel).
3. Establish control zones (isolate area and deny entry).
4. Extinguish all sources of ignition in the vicinity. Do not allow vehicles or other sources of ignition in the area.
5. Wear positive pressure SCBA and full protective clothing.
6. Avoid exposure to smoke, fumes, vapors, dust, or direct contact. The combustion products of some propellant explosives are poisonous.

7. Do not allow personnel to touch or move explosives. Explosives should be moved only under the advice and supervision of trained explosive personnel.

8. Contact local police or military bomb units.

9. When a hazmat team is requested to respond to a bomb threat involving hazardous materials, under no circumstances will the hazmat team conduct building or area searches even when hazardous materials are involved. The hazmat team will stage in a safe area, but not less than 200 meters feet from the incident scene.

10. The hazmat team will act as a technical resource for the bomb unit. This may involve the loaning of chemical protective clothing to bomb unit personnel, assistance in dressing, researching chemical data, etc.

Emergency Response Procedures-Fire

1. Do not fight fire in cargo or storage area containing explosives. Withdraw from the area and let the fire burn.

2. If a fire is near explosives, efforts should be taken to prevent the fire from reaching the explosives. For fires involving the motor, cab, or tires of vehicles transporting explosives, flood the area with water.

3. The application of water to burning Class A or B explosives may cause an explosion.

4. Evacuate the area:

    - Class A Explosives – 800 m in all directions.
    - Class B Explosives – 800 m in all directions.
    - Class C Explosives – 450 m in all directions.
    - Blasting Agents- 800 m in all directions.

5. Do not overhaul areas where explosives have burned or exploded.

6. Explosives that have been exposed to heat may be very shock sensitive. Keep all personnel away and do not move these containers.

7. When explosives are involved in fire or serious accidents on the roadways, Canutec (613) 996-6666 should be notified.

Class 2: Flammable Compressed Gases

Definition

A flammable material or mixture having a vapor pressure exceeding 40 psi absolute at 100° F.

General Emergency Response Procedures

1. Identify the material involved.
2. Keep non-essential people away (includes non-essential emergency service personnel.)
3. Establish control zones (isolate area and deny entry).
4. Stay upwind and keep out of low areas.
5. Ventilate confined areas before entering.
6. Wear positive pressure SCBA and full protective clothing. This is a minimum level of protective clothing and will not provide adequate protection for all incidents. In some cases, chemical protective clothing carried by the hazmat team will be required for the safe handling of the incident.
7. Avoid exposure to gas.
8. Since the application of water to pools of liquefied gas will increase the vaporization rate, this is not usually a recommended practice.
9. If a tank truck or tank car is involved in fire, isolate 800 m in all directions.
10. Determine and implement appropriate decontamination procedures for personnel and equipment.
11. Consult CANUTEC (1-613-996-6666) for product information and assistance.

Emergency Response Procedures-Fire

1. Do not extinguish the fire unless the flow of gas can be stopped. The recommended means of extinguishing is to stop the flow.

2. If a leaking tank is involved in fire, cooling the tank with water may reduce the internal pressure and the rate of leakage. If sufficient water is available, use water spray to cool the tanks and adjacent combustibles affected by the heat of the fire. For massive fires, use unmanned monitors. If this is not possible, withdraw from the area and let the fire burn.

3. Un-insulated pressure tanks may rupture violently if there is flame impingement on the vapor space at the top of the tank. If it can be done safely, remove all vehicles or containers not already burning.

4. Let tank, car, tank truck or storage tanks burn unless leak can be stopped.

5. Stay away from the ends of the tank exposed to heat or flame impingement.

6. Observe tanks for evidence of bulging or red hot spots in the metal, and listen for a rising sound from venting safety devices. These indicate that the tank may fail.

Emergency Response Procedures-Spill or Leak

1. Extinguish all sources of ignition in the vicinity (vehicles, traffic light control boxes, machinery, tar pots, etc.).

2. Flammable gases may be heavier or lighter than air. Determine the vapor density of the material from reference sources and use combustible gas detectors to determine the boundary of the gases. Survey the area where the gases are likely to accumulate. Common lighter-than-air flammable gases include:

    - Hydrogen
    - Acetylene
    - Hydrogen cyanide
    - Ammonia

- Methane
- Natural Gas
- Carbon Monoxide
- Ethylene (ethane)
- Propane is heaver and will tend to migrate to low laying areas. (Density 1.5)

3. Flammable gases may ignite and flash back to the opening from which the gas originated.

4. Do not allow vehicles or other sources of ignition in the area as long as the combustible gas detector indicates the presence of flammable gases.

5. Do not enter the gas cloud. Be aware that the flammable gases extend beyond any visible cloud.

6. Water spray can be used to absorb water miscible gases, and water spray or explosion proof fans can be used to disperse gas clouds. Do not get water inside containers. Runoff must be contained for later analysis and possible disposal. Do not permit the runoff to enter storm, sewer, or water systems.

7. If it can be done safely, locate all leaks and close valves or otherwise reduce the amount of leakage.

8. If it can be done safely, move undamaged containers to a safe area, being careful to avoid sparks or friction.

9. Post guards and keep spectators at least 800 m away from leaks from tank cars, tank trucks, or large storage tanks containing compressed gas, liquefied gas, and cryogenics.

10. Wrecking operations or transfer of product should not begin until all the gas is dispersed. Confirmation of gas dispersal should be done with a combustible gas detector.

11. To prevent the build-up of static electricity, bond and ground the containers and equipment before product transfer.

12. Cutting torches or spark generating saws must not be used on the shell of empty or loaded cars or containers.

13. Empty tanks or tanks containing residue should be regarded as containing an ignitable gas-air mixture.

Class 3: Flammable Liquids

Definition

A liquid having a flash point below 140° F.

General Emergency Response Procedures

1. Identify the materials involved.

2. Keep non-essential people away (this includes non-essential emergency service personnel).

3. Establish control zones (isolate area and deny entry).

4. Stay upwind and keep out of low areas.

5. Eliminate ignition sources.

6. Ventilate confined areas before entering.

7. Wear positive pressure SCBA and full protective clothing. This is a minimum level of protective clothing and will not provide adequate protection for all flammable liquid incidents. In some cases, chemical protective clothing carried by the hazmat team will be required for the safe handling of the incident.
8. Avoid exposure to smoke, fumes, vapors, or direct contact.

9. If spilled material has entered storm, sewer, or water systems, notify the proper authority.

    - Maps should be used to determine the direction of flow and destination (outflow) of the system. Consideration should be given to dyking the storm, sewer, or water system ahead of the flow.

    - It may be appropriate to apply foam not only at the spill site, but also into the storm, sewer, or water system.

- To lessen the chances of ignition, it may be advisable to apply foam ahead of the flowing spill, either into storm drains or manholes down flow from the spill or down flow on the surface of open storm, sewer, or water systems.

10. If a tank truck or tank car is involved in fire, isolate 800 m in all directions.

11. Most flammable liquids float on water. Therefore, the application of water to a spill area may enable the flammable liquid to spread beyond the boundaries of the original incident.

12. The vapors of all flammable liquids are heavier than air. Therefore, in addition to eliminating ignition sources in the immediate spill area, the downwind area and adjacent low areas should be checked for sources of ignition and accumulations of flammable vapors.

13. Consider the need for additional resources and equipment (dyking material, absorbents, foam, over pack, containers, transfer equipment, private cleanup contractors, etc.).

14. Request sufficient foam supplies.

15. Determine and implement appropriate decontamination procedures for personnel and equipment.

16. Consult CANUTEC (1-613 996-6666) for product information and assistance.

Emergency Response Procedures-Fire

1. For small fires, use dry chemical, CO2, the appropriate foam or water spray.

2. For large fires use the appropriate foam or water spray. Water may be ineffective on low flash point flammable liquids.

3. If sufficient water is available, use water spray to cool tanks and adjacent combustibles affected by the heat of the fire. For massive fire, use unmanned monitors. If this is not possible, withdraw from the area and let the fire burn.

4. If it can be done safely, remove any vehicles or containers not already burning.

5. Dig trenches or build dikes in the path of the burning liquids to confine the fire and protect exposures.

6. If vapors are burning at the valves, do not extinguish the fire unless re-ignition can be prevented.

7. Observe tanks for evidence of bulging or red hot spots in the metal. Listen for pinging sounds or loud noises from the tank that increases in intensity. Withdraw immediately in case or rising sound from venting safety device or discoloration of tank. These indicate that the tank may fail.

8. Do not puncture or rupture the shell of a transport vehicle involved in a fire as this may liberate more flammable liquid and extend the fire.

9. If safety relief valves are obstructed, try to reposition the tank to allow the valves to function properly, but only if this can be done safely.

Emergency Response Procedures-Spill or Leak

1. Extinguish or eliminate all sources of ignition in the vicinity (traffic light control boxes, machinery, vehicles, tar pots, etc.). Use combustible gas detectors to determine the boundaries of the vapors.

2. Do not allow vehicles or other sources of ignition in the area as long as the combustible gas detector indicated the presence or flammable vapors.

3. Keep oxidizing materials away from spilled flammable liquids.

4. Post guards and keep spectators at least 800 m away for leaks from tank cars, tank trucks or large storage containers.

5. Dig trenches or build dikes ahead of the flow to confine the spill for later disposal or recovery.

6. Do not allow flammable liquids to enter storm, sewer, or water systems.

7. Cover flammable liquids with appropriate foam to blanket the surface and reduce the rate of evaporation. When ambient temperatures are less than 100° F, combustible liquids will usually

not require blanketing to reduce vapors. Do not permit the runoff to enter storm, sewer, or water systems.

8. Water spray can be used to absorb water miscible vapors, and water spray or explosion-proof fans can be used to disperse vapors. Do not get water inside containers. Runoff must be contained for later analysis and possible disposal. Do not permit the runoff to enter storm, sewer, or water systems.

9. If it can be done safely, attempt to close valves or otherwise reduce the amount of leakage.

10. Since most flammable liquids float, for leaks near the bottom of the tank, water may be added to the tank to float the flammable liquid if the leak cannot be controlled or stopped. The water flow can be adjusted so that only water leaks out and the flammable liquid does not overflow the tank. This will provide time to offload the remaining flammable liquid.

11. Wrecking operations or transfer of product should not begin until the area is determined safe. A combustible gas detector should be used to check the area continually during the entire operation.

12. To prevent the buildup of static electricity, bond and ground containers and equipment before product transfer.

13. Empty tanks and tanks containing residue should be regarded as containing an ignitable vapor-air mixture.

14. Cutting torches or spark generating saws must not be used on the shell of empty or loaded cars or containers.

15. If it can be done safely, move undamaged containers to a safe area, being careful to avoid sparks or friction.

16. Do not separate tractor units from their trailer, as the support gear on the trailer may fail.

Class 4: Flammable Solids

Definition

Any solid material, other an explosive, which under conditions normally incident to transportation is likely to cause fires through friction or retained heat from manufacturing or processing, or which can be ignited readily and when ignited burns so vigorously and persistently it creates a serious transportation hazard.

Included in this class are spontaneously combustible and water reactive materials. Two materials shipped in bulk that can cause major problems for responders are phosphorous and sodium.

General Emergency Response Procedures

1. Identify the materials involved.

2. Keep non-essential people away (this includes non-essential emergency service personnel).

3. Establish control zones (isolate area and deny entry).

4. Stay upwind and keep out of low areas.

5. Wear positive pressure SCBA and full protective clothing. This is a minimum level of protective clothing and will not provide adequate protection for all incidents. In some cases, chemical protective clothing carried by the hazmat team will be required for the safe handling of the incident.

6. Avoid exposure to smoke, fumes, vapors, or direct contact. Toxic products may be produced from contact with water, heat, and other substances.

7. Consider the need for additional resources and equipment (dyking material, absorbents, foam, over pack containers, transfer equipment, private cleanup contractors, etc.).

8. If spilled material has entered storm or sewer systems, notify the proper authority.

9. Determine and implement appropriate decontamination procedures for personnel and equipment.

10. Consult CANUTEC (1-613 996-6666) for product information and assistance.

Emergency Response Procedures-Fire

1. Do not use water or foam on water-reactive materials.

2. If it can be done safely, remove containers from fire area.

3. Chemical reference sources will indicate appropriate extinguishing agents. Agents such as dry chemical, soda ash, lime, or sand may be appropriate for use on water-reactive materials, but they must be moisture-free.

4. Water may be used to cool containers exposed to fire, but if the water contacts water-reactive materials, the incident could escalate rapidly.

Emergency Response Procedures-Spill or Leak

1. Keep ignition sources away.

2. Extinguish all sources of ignition in the vicinity. Do not allow vehicles or other sources of ignition in the area.

3. If it can be done safely, attempt to close valves, plug, reposition containers, or otherwise reduce the amount of leakage.

4. Keep water-reactive materials dry and do not get water inside containers containing water-reactive materials.

5. Keep material out of storm, sewer, and water systems.

6. Dig trenches or build dikes around spills of water-reactive or environmentally damaging materials to prevent water from reaching them.

7. Powder spills can be covered with a plastic sheet or tarp to minimize spreading and prevent water/moisture contact.
   Warning: If the sun is shining directly on the plastic sheeting, moisture may collect on the underside of the sheeting, producing a reaction with water reactive materials.

Class 5: Oxidizers and Organic Peroxides

Definition

An oxidizer is a substance that yields oxygen readily to stimulate the combustion of other material.

Organic peroxide is an organic derivative of the inorganic compound hydrogen peroxide where organic radicals have replaced one or more of the hydrogen atoms. Organic peroxides readily release oxygen to stimulate the combustion of other materials.

General Emergency Response Procedures

1. Identify the materials involved.

2. Keep non-essential people away (this includes non-essential emergency service personnel).

3. Establish control zones (isolate area and deny entry).

4. Stay upwind and keep out of low areas.

5. Wear positive pressure SCBA and full protective clothing. This is a minimum level of protective clothing and will not provide adequate protection for all incidents. In some cases, chemical protective clothing carried by the hazmat team will be required for the safe handling of the incident.

6. Ventilate confined areas before entering.

7. Avoid exposure to smoke, fumes, dust, vapors, or direct contact. Burning oxidizers frequently produces toxic products.

8. Caution should be exercised when water is used on oxidizers, as most oxidizers are water-soluble and will produce solutions that can impregnate wood and other organic combustibles. Upon drying, these materials can spontaneously ignite and burn vigorously.

9. In accidents involving chlorates and other oxidizing materials, care is necessary to prevent ignition by friction or contact with acids.

10. When chlorates are mixed with organic matter, or even dust, a flammable mixture is formed.

11. Chlorates mixed with finely divided combustible material may burn with explosive violence.

12. Leaking of nitric acid, perchloric acid, or hydrogen peroxide may cause fire. These materials are also corrosive.

13. Organic peroxides generally have the special property that if they are heated beyond their transportation temperatures; they are likely to detonate.

14. Consider the need for additional resources and equipment (dyking materials, absorbents, foam, over pack containers, transfer equipment, private cleanup contractors, etc.)

15. If spilled material has entered storm or sewer systems, notify the proper authority.

16. Determine and implement appropriate decontamination procedures for personnel and equipment.

17. Consult CANUTEC (1-613-996-6666) for product information and assistance.

Emergency Response Procedures-Fire

1. If it can be done safely, remove any containers not already burning.

2. Cool affected containers with flooding quantities of water. For massive fires, use unmanned monitors. If this is not possible, withdraw and let the fire burn. Runoff water must be contained for later analysis and proper disposal.

Emergency Response Procedures-Spill or Leak

1. Keep flammables, combustibles and organic materials away from spilled material.
2. Avoid contact with spilled material.

3. Extinguish all sources of ignition in the vicinity. Do not allow vehicles or other sources of ignition in the area.

4. If it can be done safely, attempt to close valves, plug, or otherwise reduce the amount of leakage.

5. Water spray can be used to absorb water miscible vapors, and water spray or explosion-proof fans can be used to disperse vapors. Do not get water inside containers. Runoff must be contained for later analysis and possible disposal. Do not permit the runoff to enter storm, sewer, or water systems.

6. Keep material out of storm, sewer, and water systems.

7. Dig trenches or build dikes ahead of the flow to contain the spill for later disposal.

8. Powder spills can be covered with a plastic sheet or tarp to minimize spreading.

Class 6: Pesticides and Poisons

Definition

Pesticides are chemical agents used to destroy pests.

Poisons are substances that, through chemical action, usually kill, injure, or impair an organism.

General Emergency Response Procedures

1. Identify the materials involved.

2. Keep non-essential people away (this includes non-essential emergency personnel).

3. Establish control zones (isolate area and deny entry).

4. Wear positive pressure SCBA and full protective clothing. This is a minimum level of protective clothing and will not provide adequate protection for all incidents.

- Due to the construction and materials used for firefighter turnout clothing, the clothing may actually absorb and hold the pesticide or poison if contact with the smoke, fumes, dust, vapors, or material occurs. The firefighter would be re-exposed each time the clothing were worn if proper decontamination operations were not performed.

- In most incidents involving pesticides or poisons, the chemical protective clothing carried on the hazmat team will be required for safe handling of the incident.

5. Stay upwind and keep out of low area. If you can smell pesticide, you are too close and not sufficiently protected.

6. Avoid exposure to smoke, fumes, vapors, dust or direct contact.

7. Determine signs and symptoms of exposure and advise all personnel operating at the site. Some symptoms may not become present for up to 48 hours following exposure.

8. Ventilate confined areas before entering. It is not advisable for fire personnel to enter tanks or other confined spaces that contain or have contained pesticides and/or poisons.

9. If spilled material has entered storm, sewer, or water systems, notify the proper authority. Maps should be used to determine the direction of flow and destination (outflow) of the system. Consideration should be given to dyking ahead of the flow.

10. Determine and implement appropriate decontamination procedures for personnel and equipment.

11. Flush any contacted material from skin or clothing immediately.

12. Remove and isolate any contaminated clothing at the site and avoid spreading contamination to non-contaminated areas.

13. Consult CANUTEC (1-416-996-6666) for product information and assistance.

Emergency Response Procedures-Fire

1. Consider protecting exposures and allow the fire to burn. This may create less of a hazard to people and the environment, especially if runoff cannot be confined.

2. For small fires, use dry chemical, CO2, water spray or the appropriate foam.

3. For large fires use the appropriate foam or water spray.

4. Do not extinguish fire unless the flow can be stopped.

5. If sufficient water is available, use water spray to cool containers exposed to the fire.

6. Dike fire control water for later analysis and/or disposal.

Emergency Response Procedures-Spill or Leak

1. For a liquid pesticide spill, extinguish or eliminate all sources of ignition in the vicinity as many pesticides have flammable liquids as the carrier of the poison. Use combustible gas detectors to determine the boundary of the vapors if the pesticide is a flammable.
2. Do not allow vehicles or other sources of ignition in the area as long as the combustible gas detector indicates the presence of flammable vapors.

3. If it can be done safely, attempt to close valves, plug, or otherwise reduce the amount of leakage.

4. Water spray can be used to absorb water miscible vapors, and water spray or explosion-proof fans can be used to disperse vapors. Do not get water inside containers. Runoff must be contained for later analysis and possible disposal. Do not permit the runoff to enter storm, sewer or water systems.

5. Keep material out of storm, sewer, and water systems.

6. Dig trenches or build dikes ahead of the flow to confine the spill for later disposal or recovery.

7. Powder spills can be covered with a plastic sheet or tarp to minimize spreading.

Class 6: Infectious Substances

Definition

Substances or materials hosting or contaminated by communicable pathogens. Examples include medical waste, laboratory samples, etc.

General Emergency Response Procedures

1. Identify the materials involved. Infectious substances include the red infectious waste bags and "sharps" containers from hospitals (sharps containers are used for the disposal of needles and other sharp instruments). Caution should be used if these containers are encountered.

2. Keep non-essential people away (this includes non-essential emergency service personnel).

3. Establish control zones (isolate area and deny entry).

4. Wear positive pressure SCBA and chemical protective clothing. Firefighter protective clothing will not provide adequate protection for all incidents involving infectious substances. The chemical protective clothing carried on the hazmat team may be required for safe handling of the incident.

5. Stay upwind and keep out of low areas.

6. Avoid exposure to smoke, fumes, vapors, or dust. Do not contact damaged containers or spilled material. Virus and disease-bearing substances are often present.

7. If leakage is discovered in transit, the vehicle must not be moved and the area must be isolated.

8. If spilled material has entered storm or sewer systems, notify the proper authority.

9. Implement appropriate decontamination procedures. A freshly mixed 10% or stronger bleach/water solution is an effective decontamination solution for most infectious substance exposures.

Emergency Response Procedures-Fire

1. If it can be done safely, remove containers from the fire area. Do not touch or move damaged containers.

2. Use dry chemical, soda ash, or lime for small fires.

Emergency Response Procedures-Spill or Leak

1. Cover damaged containers or spill area with dampened towel or rag, and keep wet with liquid bleach.

    - To decontaminate the area and equipment, a garden sprayer with a 10% bleach/water solution can used to spray exposed surfaces.

    - Recently mixed bleach/water solutions should be used, as premixed solutions lose their strength after a few days.

2. Dike spills for later disposal.

3. Keep material out of storm, sewer and water systems.

Class 7: Radioactive Materials

Definition

Radioactive materials contain charged particles (ions) and have a specific gravity greater than 0.002 microcuries per gram. These charged particles may cause damage to molecules, cells, or tissues. Atoms that emit ionizing radiation are said to be radioactive; radioactivity is the process whereby atomic changes, known as decay or disintegration, occur through the emission of ionizing radiation.

General Emergency Response Procedures

1. Identify the materials involved. Radioactive materials are often shipped in lead containers.

2. Keep people as far away as practical, at least 50 m upwind.

3. Establish control zones (isolate area and deny entry). Use radiation-monitoring devices to determine control zones and assess areas for contamination.

4. Wear positive pressure SCBA and full protective clothing. This is a minimum level of protective clothing and will not provide adequate protection for radioactive incidents.

5. Avoid exposure to smoke, fumes, vapors, dusts or direct contact.

6. All personnel should utilize dosimeters. Zero dosimeters prior to use.

7. Entry should not be made until appropriate radiological personnel are on scene and the degree of radiation is known.

8. Enter Exclusion Zone only to save a life, and limit entry into the Exclusion Zone to the shortest possible time.

9. If spilled material has entered storm, sewer, or water systems, notify the proper authority.

10. Implement appropriate decontamination procedures for personnel and equipment.

11. Delay clean up until arrival or instructions of qualified radiation personnel.

12. Equipment used in the Exclusion Zone shall not be removed until appropriate decontamination procedures have been performed and the equipment has been monitored and declared clean.

13. Contact a radiological team for assistance and equipment.

14. Consult CANUTEC (1-613-996-6666) for product information and assistance.

Emergency Response Procedures-Fire

1. Do not move-damaged containers, but undamaged containers should be moved to a safe area if it can be done safely.

2. Assume the fire involves radioactive materials.

3. Avoid exposure to smoke, fumes, or dust. Airborne contamination is a great cause of concern for emergency responders. Stay upwind from the fire area.

4. Evacuate downwind area.
5. The fire should be extinguished as quickly as possible, with a minimum amount of water. Try not to disturb the radioactive containers.

6. Fight fire from a maximum distance. Do not allow personnel into the area after fire knockdown.

7. For massive fires, use unmanned monitors.

8. Dig trenches or build dikes ahead of the flow to contain the spill for later disposal.

9. The fire area should not be overhead.

Emergency Response Procedures-Spill or Leak

1. Do not touch damaged containers or contact the spilled material.

2. Prevent spread of spilled material and keep it out of water systems and sewers. Dike far ahead of large spills to confine the material for later disposal.

Class 8: Corrosives

Definition

Any liquid or solid, including powders, that can destroy tissue, or a liquid that has a severe corrosion rate on steel or aluminum.

General Emergency Response Procedures

1. Identify the materials involved.

2. Keep non-essential people away (this includes non-essential emergency service personnel).

3. Establish control zones (isolate area and deny entry).

4. Wear positive pressure SCBA and chemical protective clothing. This is a minimum level of protective clothing and will not provide adequate protection for corrosive incidents. The chemical protective clothing carried by the hazmat team may be required for the safe handling of most incidents involving corrosives.

5. Stay upwind and keep out of low areas.

6. Avoid exposure to smoke, fumes, vapors, dusts, or direct contact. Highly toxic fumes are often present.

7. Ventilate confined areas before entering.
8. Consider the need for additional resources and equipment (dyking material, absorbents, over pack containers, transfer equipment, private cleanup contractors, etc.).

9. If spilled material has entered storm or sewer systems, notify the proper authority.

10. Determine and implement appropriate decontamination procedures for personnel and equipment.

11. Consult CANUTEC (1-613-996-6666) for product information and assistance.

Emergency Response Procedures-Fire

1. Many corrosive chemicals react violently with water, liberating heat and toxic gases.

2. If it can be done safely, remove undamaged containers from the fire area.

3. Do not get water inside the container.

4. Use water to cool containers that are exposed to flame until well after the fire is out. Do not allow water to get inside container.

Emergency Response Procedures-Spill or Leak

1. Avoid contact with spilled material.

2. Extinguish all sources of ignition in the vicinity. Do not allow vehicles or other sources of ignition into the area.

3. Do not apply water unless directed to do so. Contact with water may cause the generation of large quantities of vapors and heat.

4. Do not get water inside the container.

5. Water spray can be used to absorb water miscible vapors, and water spray or explosion-proof fans can be used to disperse vapors. Do not get water inside containers and do not put water on leak or spill area. Runoff must be contained for later analysis and possible disposal. Do not permit the runoff to enter storm, sewer, or water systems.

6. Keep combustibles (wood, paper, oil, etc.) away from spilled material.

7. If it can be done safely, attempt to close valves, plug, or otherwise reduce the amount of leakage.

8. Dig trenches or build dikes ahead of the flow to contain the spill for later disposal or recovery.

9. Powder spills can be covered with a plastic sheet or tarp to minimize spreading.

10. Keep material out of storm, sewer, or water systems.

11. Do not attempt neutralization. Neutralization may cause the production of vapors and heat, creating additional problems.

12. Do not attempt dilution. The quantity of water required to dilute one gallon of concentrated acid to a neutral pH of 7 is in the hundreds of thousands of gallons.

Specific Action Plan

Propane (UN1978)

Regulated by Environment and Climate Change Canada (ECCC) for the E2 regulations.

Uses

Fuel source for heating mine buildings such as mill, pit shop, warehouse and water treatment plant. Also used as fuel for forklift trucks

Location

Main Storage tank on east side of Mill building (Max storage capacity is 110,000 litres)

Water Treatment Plant Tank (Max storage capacity is 60,000 litres)

Properties

EXTREMELY FLAMMABLE.

Will be easily ignited by heat, sparks or flames.

Will form explosive mixtures with air.

Vapors from Propane are initially heavier than air and spread along ground.

Vapors may travel to source of ignition and flash back.

GASES UNDER PRESSURE- COMPRESSED GAS

Cylinders exposed to fire may vent and release flammable gas through pressure relief devices.

Containers may explode when heated.

Ruptured cylinders may rocket.

HEALTH

Vapors may cause dizziness or asphyxiation without warning.

Some may be irritating if inhaled at high concentrations.

Contact with gas or liquefied gas may cause burns, severe injury and/or frostbite.

Fire may produce irritating and/or toxic gases.

SAFETY

Keep away from heat, sparks, open flames, and hot surfaces.

No smoking.

Stay upwind, uphill and/or upstream.

Propane gas is heavier than air and will spread along the ground and collect in low or confined areas

DO NOT EXTINGUISH A LEAKING GAS FIRE UNLESS LEAK CAN BE STOPPED.

PROTECTIVE CLOTHING

Wear positive pressure self-contained breathing apparatus (SCBA).

Structural firefighters' protective clothing provides limited thermal protection.

Always wear thermal protective clothing when handling refrigerated/cryogenic liquids.

EVACUATION

Small Spill

Spill or leak- Evacuate area for at least 100 meters (330 feet) in all directions.

Large Spill

Consider initial downwind evacuation for at least 800 meters (1/2 mile).

Evacuation map – Propane

FIRE

If tank or tank truck is involved in a fire, consider initial evacuation for 1600 meters in all directions.

ALWAYS stay away from tanks engulfed in fire.

SMALL FIRE

Dry chemical or CO2.

LARGE FIRE

For massive fire Evacuate from area and let fire burn.

Fight fire from maximum distance.

Water spray or fog.

If it can be done safely, move undamaged containers away from the area around the fire.

Cool containers with flooding quantities of water until well after fire is out.

Do not direct water at source of leak or safety devices; icing may occur.

Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank.

BLEVE (BOILING LIQUID EXPANDING VAPOR EXPLOSION)

A BLEVE occurs when a fire impinged or damaged tank fails to contain its internal pressure and explodes with a sudden product release.

The main hazards from a BLEVE are:

Fire: If the released substance is ignited, there is an immediate fireball.

Thermal radiation: At a distance of about 4 times the radius of a fireball, the heat radiated from a fireball is enough to burn exposed skin in 2 seconds. Wearing protective clothing limits the thermal radiation dose.

Blast: A concussive force caused by the sudden release of the pressurized substance. For a BLEVE occurring out in the open, the blast strength at a distance of 4 times the radius of a fireball can break window glass and may cause minor damage to buildings.

Projectiles: Tank failure can throw metal fragments over large distances. These fragments can and have been deadly.

The danger decreases as you move away from the BLEVE centre. The furthest-reaching hazard is projectiles

For additional information on Propane Hazards refer to Transport Canada Emergency Response Guidebook and Propane Safety Data Sheet (SDS)

Consult CANUTEC (1-613-996-6666) for product information and assistance.

SPILL OR LEAK

ELIMINATE all ignition sources (no smoking, flares, sparks or flames) from immediate area.

All equipment used when handling the product must be grounded.

Do not touch or walk through spilled material.

Stop leak if you can do it without risk.

If possible, turn leaking containers so that gas escapes rather than liquid.

Use water spray to reduce vapors or divert vapor cloud drift. Avoid allowing water runoff to contact spilled material.

Do not direct water at spill or source of leak.

Prevent spreading of vapors through sewers, ventilation systems and confined areas.

Isolate area until gas has dispersed.

FIRST AID

Call 911 or emergency medical service.

Ensure that medical personnel are aware of the material(s) involved and take precautions to protect themselves.

Move victim to fresh air if it can be done safely.

Give artificial respiration if victim is not breathing.

Administer oxygen if breathing is difficult.

Remove and isolate contaminated clothing and shoes.

Clothing frozen to the skin should be thawed before being removed.

In case of contact with liquefied gas, thaw frosted parts with lukewarm water.

In case of burns, immediately cool affected skin for as long as possible with cold water. Do not remove clothing if adhering to skin.

Keep victim calm and warm.

Specific Action Plan

LIME

PROPERTIES:

White powder to granular.

Very alkaline; very corrosive to eye surfaces.

Effects of acute exposure - corrosive.

Effects of chronic exposure are burns, ulceration, and blindness.

ACTION STEPS:

Report spill.

Stop source if possible.

Contain spill materials.

Protect area.

Remove material.

Reclaim area.

Complete spill report.

NOTIFICATION:

Immediately notify the Area Supervisor.

INITIAL SPILL RESPONSE:

Stop spill at source, if possible.

Avoid dusting.

Keep spilled lime dry.

Prevent from entering watercourses.

If mixed with water, dyke and contain the milk of lime.

HAZARDS and ENVIRONMENTAL THREATS:

Heat generated when mixed with water.

Strong alkaline - protect self from exposure, especially eyes.

No environmental hazard.

ACTION FOR FIRE:

Shovel and contain dry material in containers.

Dyke and contain milk of lime and pump into proper mill circuit.

DISPOSAL:

Dispose of recovered solids by recycling material through the crushing circuit to the mill process.

Specific Action Plan

TAILINGS OR CONCENTRATES

PROPERTIES:

Maybe toxic when ingested and or the fumes, if any, are inhaled from residual milling components.

HAZARDS and ENVIRONMENTAL THREATS:

Will cover and kill vegetation.

May exhibit ARD properties overtime.

ACTION STEPS:

Report spill.

Stop source, if possible.

Contain spill, if possible.

Protect area.

NOTIFICATION:

Immediately notify your Area Supervisor.

INITIAL SPILL RESPONSE:

Stop the flow, if possible.

Prevent spills from entering watercourses

Contain spilled liquid using sand, straw, or commercial absorbents.

If raining cover with tarps

ACTION FOR FIRE:

Slightly flammable

RECOVERY:

Pump or scoop up material.

If necessary, contaminated soil should be excavated.

DISPOSAL:

Recovered spilled materials and contaminated soils should be disposed of in the tailing storage facility

Specific Action Plan

MINE INFLUENCED WATER
(NOT RELATED TO HAZELTINE CREEK DISCHARGE SYSTEM)

PROPERTIES:

Water that has been affected by mining or mineral processing and may contain elevated levels of metals, suspended solids, reagents, and other parameters, or a pH outside of the natural range.

HAZARDS and ENVIRONMENTAL THREATS:

May have a detrimental effect on aquatic or terrestrial environments and organisms. May cause erosion and deposition of sediment (on land or in creeks).

ACTION STEPS:

Report spill.

Stop source, if possible.

Contain spill, if possible.

Protect area.

NOTIFICATION:

Immediately notify your Area Superintendent.

INITIAL SPILL RESPONSE:

Stop the release using water diversions or pumps, or contain water using berms or sumps.

Prevent spills from entering watercourses.

If watercourses are affected, conduct full suite and in situ sampling upstream and downstream of the release point.

Use sediment and erosion control methods including, but not limited to, straw, sediment fence, and geotextiles and retention ponds to minimize erosion and limit sediment transport by water.

RECOVERY:

Pump any water out of emergency sumps or water storage facilities.

Re-vegetate any eroded areas.

Review root causes of the release, and implement changes to prevent a re-occurrence.

Specific Action Plan

MINE INFLUENCED WATER
(RELATED TO WTP Discharge System)

PROPERTIES:

Water that has been affected by mining or mineral processing and may contain elevated levels of metals, suspended solids, reagents, and other parameters, or a pH outside of the natural range.

HAZARDS and ENVIRONMENTAL THREATS:

May have a detrimental effect on aquatic or terrestrial environments and organisms. May cause erosion and deposition of sediment in the creek and alter creek morphology.

SYSTEM SPILL PREVENTION MECHANISMS:

In the event that trigger thresholds for conductivity, temperature or flow are exceeded in continuous monitoring of the discharge effluent, a warning will be issued to the Mill Control Room immediately through the Man Machine Interface. These trigger levels (set below permitted allowable levels) allow for the discharge system to be shut off or discharge rates reduced before any guidelines are exceeded.

Pump failure triggers an automatic “shut off”, and water storage tanks have automatic (and manual) overflow systems that drain water into existing effluent storage facilities.

NOTIFICATION:

Immediately notify the Area Superintendent.

In addition to regulatory notifications required for releases of mine influenced water, the Ministry of Environment must be notified of discharge guideline exceedances and Environment Canada must be notified (as outlined in Mount Polley Mining Corp.’s *Annual Discharge Plan,* PE-11678, and the Metal Mining Effluent Regulations).

INITIAL SPILL RESPONSE:

Immediately stop effluent discharge using the manual shut off valves (and tank drains if necessary).

If the release is due to physical damage to the discharge line, if possible, stop the release using water diversions, berms, sumps or pumps to prevent water from entering watercourses, and use sediment and erosion control materials and methods, such as straw, sediment fence, geotextiles, and retention ponds to minimize erosion and limit sediment transport by water.

If watercourses are affected, conduct full suite and in situ sampling upstream and downstream of the release point.

RECOVERY:

Pump any water out of emergency sumps or water storage facilities.

Re-vegetate any eroded areas.

Review root causes of the release, and implement changes to prevent a re-occurrence.

Specific Action Plan

RELEASE OF TILL/MUD/SOIL/ROCK

PROPERTIES:

Any form of rock, soil, or till, including mud and suspended till.

HAZARDS and ENVIRONMENTAL THREATS:

May cause deposition or morphological changes to watercourses and increase turbidity. May disturb vegetated areas and promote erosion. May have a detrimental effect on terrestrial or aquatic environments and organisms. Large transfers of material may be hazardous for humans.

ACTION STEPS:

Report incident.

Stop source, if possible and if area is safe.

Contain material, if possible and if area is safe.

Protect area.

NOTIFICATION:

Immediately notify your Area Superintendent.

INITIAL RESPONSE:

Stop the release using methods including berms or containment sumps.

Take action to protect any infrastructure or prevent further incidents (example: shut off water in dewatering pipelines that may be affected).

Prevent material from entering watercourses.

If watercourses are affected, conduct full suite and in situ sampling upstream and downstream of the release point.

Use sediment and erosion control methods including, but not limited to, straw, sediment fence, and geotextiles and retention ponds to minimize erosion and limit sediment transport by water.

RECOVERY:

Move material, as possible and as required (example: away from infrastructure).

Install long-term sediment and erosion control works, including re-vegetation of any eroded areas.

Restore aquatic habitats, as required.

Review root causes of the release, and implement changes to prevent a re-occurrence

Appendix C Protocol for Corporate Reporting of an Environmental Incident

A) Protocol for Corporate Reporting of an Environmental Incident:

1) Corporate reporting of an "environmental incident" is required when:

(a) Any environmental incident occurs that:

- Poses a serious or imminent threat to human health or to the environment.
- Precipitates an immediate, external reporting requirement to regulatory authorities.
- Requires a minimum expenditure of $Cdn25, 000 in materials and/or offsite technical or legal support.
- Is subject of an inquiry from the media.

(b) Any environmental event occurs when:

- An administrative or judicial enforcement action is taken.
- A notice of a citizen suit or other significant complaint from the public is received.
- A private lawsuit premised on personal injury or property damage is filed.
- A civil or criminal action is taken against any Mount Polley Mining Corp. employee, manager, officer or Director.

2) Protocol for Report

(a) The Area Superintendent will immediately notify the General Manager (or his designate).

(b) The general manager will notify the Company President. (CP)

(c) Consultation with the general manager will determine the extent of legal counsel involvement.

(d) The Area Superintendent will prepare a " Preliminary Draft Incident Report for the General Manager to authorize and fax as soon as possible to the CP. The "Final Incident Report" will be submitted once the investigation of the incident is complete.

B) Protocol for Communicating Environmental Issue

1) Corporate communication of an "environmental issue" is required when:

(a) A situation arises or an event occurs that has, in the opinion of the Area Superintendent, the potential to become an Environmental Incident as defined above.

2) Protocol for Communicating and Environmental Issue.

(a) When an issue becomes apparent, the Area Superintendent will inform the General Manager.

(b) Actions plans to mitigate a possible incident will be developed and approved by the General Manager.

(c) The General Manager will keep the CP informed of any issues with the potential to become " Incidents".

Appendix E Reportable Levels for Certain Substances

Item	Column 1	Column 2
	Substance spilled	**Specified amount**
1 **Ammonium Nitrate**	Class 1, Explosives as defined in section 2.9 of the Federal Regulations	Any quantity that could pose a danger to public safety or 50 kg
2	PCB Wastes as defined in section 1 of the Hazardous Waste Regulation	10 kg
4 **Propane**	Class 2.1, Flammable Gases, other than natural gas, as defined in section 2.14 (a) of the Federal Regulations	10 kg
3	Class 2.2 Non-Flammable and Non-Toxic Gases as defined in section 2.14 (b) of the Federal Regulations	10 kg
4	Class 2.3, Toxic Gases as defined in section 2.14 (c) of the Federal Regulations	5 kg
5 **Gasoline, MIBC, Diesel**	Class 3, Flammable Liquids as defined in section 2.18 of the Federal Regulations	100 L
6	Class 4, Flammable Solids as defined in section 2.20 of the Federal Regulations	25 kg
7 **NaHS**	Class 5.1, Oxidizing Substances as defined in section 2.24 (a) of the Federal Regulations	50 kg or 50 L
8	Class 5.2, Organic Peroxides as defined in section 2.24 (b) of the Federal Regulations	1 kg or 1 L
9	Class 6.1, Toxic Substances as defined in section 2.27 (a) of the Federal Regulations	5 kg or 5 L
10	Class 6.2, Infectious Substances as defined in section 2.27 (b) of the Federal Regulations	1 kg or 1 L, or less if the waste poses a danger to public safety or the environment

11	Class 7, Radioactive Materials as defined in section 2.37 of the Federal Regulations	Any quantity that could pose a danger to public safety and an emission level greater than the emission level established in section 20 of the "Packaging and Transport of Nuclear Substances Regulations"
12 **Acids**	Class 8, Corrosives as defined in section 2.40 of the Federal Regulations	5 kg or 5 L
13	Class 9, Miscellaneous Products, Substances or Organisms as defined in section 2.43 of the Federal Regulations	25 kg or 25 L
14	waste containing dioxin as defined in section 1 of the Hazardous Waste Regulation	1 kg or 1 L, or less if the waste poses a danger to public safety or the environment
15	leachable toxic waste as defined in section 1 of the Hazardous Waste Regulation	25 kg or 25 L
16	waste containing polycyclic aromatic hydrocarbons as defined in section 1 of the hazardous Waste Regulation	5 kg or 5 L
17	waste asbestos as defined in section 1 of the Hazardous Waste Regulation	50 kg
18 **Waste Oil**	waste oil as defined in section 1 of the Hazardous Waste Regulation	100 L
19	waste containing a pest control product as defined in section 1 of the Hazardous Waste Regulation	5 kg or 5 L
20	PCB Wastes as defined in section 1 of the Hazardous Waste Regulation	25 kg or 25 L
21	waste containing tetrachloroethylene as defined in section 1 of the Hazardous Waste Regulation	50 kg or 50 L
22	biomedical waste as defined in section 1 of the Hazardous Waste Regulation	1 kg or 1 L, or less if the waste poses a danger to public safety or the environment
23 **Concentrate, Tailings, Lime**	A hazardous waste as defined in section 1 of the Hazardous Waste Regulation and not covered under items 1 – 22	25 kg or 25 L

24	A substance, not covered by items 1 to 23, that can cause pollution	200 kg or 200 L
25	Natural gas	10 kg, if there is a breakage in a pipeline or fitting operated above 100 psi that results in a sudden and uncontrolled release of natural gas
